**Warning:** When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the ‘id’ grain which is verified through the minion's key/cert.

#### Map Mode

The `it-admins` configuration below returns the Pillar `it-admins` by:

- filtering for: members of the group `it-admins` objects with `objectclass=user`
- returning the data of users, where each user is a dictionary containing the configured string or list attributes.

#### Configuration

```yaml
salt-users:
  server: ldap.company.tld
  port: 389
  tls: true
  dn: 'dc=company,dc=tld'
  binddn: 'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw: bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn: 'ou=users,dc=company,dc=tld'
  filter: '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'
```

(continues on next page)
**attrs:**
- cn
- displayName
- givenName
- sn

**lists:**
- memberOf

**search_order:**
- salt-users

Result

```
{
  'salt-users': [
    {
      'cn': 'cn=johndoe,ou=users,dc=company,dc=tld',
      'displayName': 'John Doe',
      'givenName': 'John',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team01,ou=groups,dc=company'
      ]
    },
    {
      'cn': 'cn=janedoe,ou=users,dc=company,dc=tld',
      'displayName': 'Jane Doe',
      'givenName': 'Jane',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team02,ou=groups,dc=company'
      ]
    }
  ]
}
```

`salt.pillar.pillar_ldap.ext_pillar(minion_id, pillar, config_file)`

Execute LDAP searches and return the aggregated data

### 23.12.32 salt.pillar.postgres

Retrieve Pillar data by doing a postgres query

New in version 2017.7.0.

- **maturity** new
- **depends** psycopg2
- **platform** all
Complete Example

```
postgres:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - postgres:
      query: 'SELECT col1,col2,col3,col4,col5,col6,col7
              FROM some_random_table
              WHERE minion_pattern LIKE %%s'
      depth: 5
      as_list: True
      with_lists: [1,3]
```

class salt.pillar.postgres.POSTGRESExtPillar
This class receives and processes the database rows from POSTGRES.

```
exct_queries(args, kwargs)
  This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.
```

```
salt.pillar.postgres.ext_pillar(minion_id, pillar, *args, **kwargs)
  Execute queries against POSTGRES, merge and return as a dict
```

23.12.33 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data.

```
salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
  Execute an unmodified puppet_node_classifier and read the output as YAML
```

23.12.34 salt.pillar.reclass_adapter

Use the "reclass" database as a Pillar source

This ext_pillar plugin provides access to the reclass database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the ext_pillar list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass

If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.

```python
salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)
```

Obtain the Pillar data from reclass for the given minion_id.

### 23.12.35 salt.pillar.redismod

Read pillar data from a Redis backend

New in version 2014.7.0.

```python
depends
  - redis Python module (on master)
```

**Salt Master Redis Configuration**

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- `redis.db` - The Redis database to use. Defaults to 0.
- `redis.host` - The Redis host to connect to. Defaults to 'salt'.
- `redis.port` - The port that the Redis database is listening on. Defaults to 6379.
- `redis.password` - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

**Configuring the Redis ext_pillar**

```python
ext_pillar:
  - redis: {function: key_value}
```

```python
salt.pillar.redismod.ext_pillar(minion_id, pillar, function, **kwargs)
```

Grabs external pillar data based on configured function

```python
salt.pillar.redismod.key_json(minion_id, pillar, pillar_key=None)
```

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if pillar_key is not set.

- `pillar_key` - Pillar key to return data into
salt.pillar.redismod.key_value(minion_id, pillar, pillar_key='redis_pillar')

Looks for key in redis matching minion_id, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.
pillar_key Pillar key to return data into

23.12.36 salt.pillar.rethinkdb_pillar

Provide external pillar data from RethinkDB

New in version 2018.3.0.

depends rethinkdb (on the salt-master)

salt master rethinkdb configuration

These variables must be configured in your master configuration file.

- rethinkdb.host - The RethinkDB server. Defaults to 'salt'
- rethinkdb.port - The port the RethinkDB server listens on. Defaults to '28015'
- rethinkdb.database - The database to connect to. Defaults to 'salt'
- rethinkdb.username - The username for connecting to RethinkDB. Defaults to '
- rethinkdb.password - The password for connecting to RethinkDB. Defaults to ''

salt-master ext_pillar configuration

The ext_pillar function arguments are given in single line dictionary notation.

```python
ext_pillar:
    rethinkdb: {table: ext_pillar, id_field: minion_id, field: pillar_root, pillar_key: external_pillar}
```

In the example above the following happens.

- The salt-master will look for external pillars in the 'ext_pillar' table on the RethinkDB host
- The minion id will be matched against the 'minion_id' field
- Pillars will be retrieved from the nested field 'pillar_root'
- Found pillars will be merged inside a key called 'external_pillar'

Module Documentation

salt.pillar.rethinkdb_pillar.ext_pillar(minion_id, pillar, table='pillar', id_field=None, field=None, pillar_key=None)

Collect minion external pillars from a RethinkDB database

Arguments:

- table: The RethinkDB table containing external pillar information. Defaults to 'pillar'
- id_field: Field in document containing the minion id. If blank then we assume the table index matches minion ids
- field: Specific field in the document used for pillar data, if blank then the entire document will be used
- pillar_key: The salt-master will nest found external pillars under this key before merging into the minion pillars. If blank, external pillars will be merged at top level
23.12.37 salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options

```yaml
ext_pillar:
  - s3:
      bucket: my.fancy.pillar.bucket
      keyid: KASKFJWAKJASJKDAJKSD
      key: ksldafDLKDALSFKSD93q032sdDasdfasdfsadksdf
      multiple_env: False
      environment: base
      prefix: somewhere/overthere
      verify_ssl: True
      service_url: s3.amazonaws.com
      kms_keyid: 01234567-89ab-cdef-0123-4567890abcde
      s3_cache_expire: 30
      s3_sync_on_update: True
      path_style: False
      https_enable: True
```

The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to 'base'. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if `multiple_env` is True.

The `prefix` defaults to ".". It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when `multiple_env` is True or False. Essentially it tells `ext_pillar` to look for your pillar data in a 'subdirectory' of your S3 bucket.

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. *NOTE* If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to 's3.amazonaws.com'. It specifies the base url to use for accessing S3.

The `kms_keyid` parameter is optional. It specifies the ID of the Key Management Service (KMS) master key that was used to encrypt the object.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than jit.

The `path_style` parameter defaults to False. It specifies whether to use path style requests or dns style requests.

The `https_enable` parameter defaults to True. It specifies whether to use https protocol or http protocol.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket. Single environment mode must have this bucket structure:

```bash
s3://<bucket name>/<prefix>/files
```
Multiple environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<environment>/<files>
```

If you wish to define your pillar data entirely within S3 it's recommended that you use the `prefix=` parameter and specify one entry in `ext_pillar` for each environment rather than specifying `multiple_env`. This is due to issue #22471

```https://github.com/saltstack/salt/issues/22471```

**Class** `salt.pillar.s3.S3Credentials`

```key, keyid, bucket, service_url, verify_ssl=True, kms_keyid=None, location=None, path_style=False, https_enable=True, kms_keyid=None, location=None, path_style=False, https_enable=True)```

**Function** `salt.pillar.s3.ext_pillar`

```minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='', service_url=None, kms_keyid=None, s3_cache_expire=30, s3_sync_on_update=True, path_style=False, https_enable=True)```

Execute a command and read the output as YAML

### 23.12.38 salt.pillar.saltclass

SaltClass Pillar Module

```ext_pillar:
- saltclass:
  - path: /srv/saltclass```

For additional configuration instructions, see the `saltclass` module

```salt.pillar.saltclass.ext_pillar(minion_id, pillar, *args, **kwargs)```

Compile pillar data

### 23.12.39 salt.pillar.sql_base

Retrieve Pillar data by doing a SQL query

This module is not meant to be used directly as an `ext_pillar`. It is a place to put code common to PEP 249 compliant SQL database adapters. It exposes a python ABC that can be subclassed for new database providers.

```maturity new```

```platform all```

**Theory of sql_base ext_pillar**

Ok, here's the theory for how this works...

- First, any non-keyword args are processed in order.
- Then, remaining keywords are processed.

We do this so that it's backward compatible with older configs. Keyword arguments are sorted before being appended, so that they're predictable, but they will always be applied last so overall it's moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.
- A list has the first entry used as the query, the second as the pillar depth.
A mapping uses the keys "query" and "depth" as the tuple.

You can retrieve as many fields as you like, how they get used depends on the exact settings.

Configuring a sql_base ext_pillar

The sql_base ext_pillar cannot be used directly, but shares query configuration with its implementations. These examples use a fake 'sql_base' adapter, which should be replaced with the name of the adapter you are using.

A list of queries can be passed in

```
ext_pillar:
  - sql_base:
    - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    - "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

Or you can pass in a mapping

```
ext_pillar:
  - sql_base:
    main: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    extras: "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

The query can be provided as a string as we have just shown, but they can be provided as lists

```
ext_pillar:
  - sql_base:
    - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    2
```

Or as a mapping

```
ext_pillar:
  - sql_base:
    query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    depth: 2
```

The depth defines how the dicts are constructed. Essentially if you query for fields a,b,c,d for each row you'll get:

- With depth 1: {a: {b: b, "c": c, "d": d}}
- With depth 2: {a: {b: {c: c, "d": d}}}
- With depth 3: {a: {b: {c: d}}}

Depth greater than 3 wouldn't be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

Then they are merged in a similar way to plain pillar data, in the order returned by the SQL database.

Thus subsequent results overwrite previous ones when they collide.

The ignore_null option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

```
ext_pillar:
  - sql_base:
    query: "SELECT pillar,value FROM pillars WHERE minion_id = 'default' and minion_id != %s"
    depth: 2
```

(continues on next page)
If you specify `as_list: True` in the mapping expression it will convert collisions to lists.

If you specify `with_lists: '...'` in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string '1,3' will result in:

```
a,b,c,d,e,1 # field 1 same, field 3 differs
a,b,c,f,g,2 # ^^^^  
```

These columns define list grouping

```
{a:
 {c:
  {e: 1},
  {g: 2}
 },
 {h:
  {j: 3, k: 4 }
 }
}
```

The range for `with_lists` is 1 to `number_of_fields`, inclusive. Numbers outside this range are ignored.

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your `minion_id` is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

Configuration of the connection depends on the adapter in use.

More complete example for MySQL (to also show configuration)

```
mysql:
 user: 'salt'
pass: 'super_secret_password'
db: 'salt_db'

ext_pillar:
 - mysql:
   fromdb:
    query: 'SELECT col1,col2,col3,col4,col5,col6,col7 FROM some_random_table WHERE minion_pattern LIKE %s'
    depth: 5
    as_list: True
    with_lists: [1,3]
```
class salt.pillar.sql_base.SqlBaseExtPillar
This class receives and processes the database rows in a database agnostic way.

    as_list = False
    depth = 0
    enter_root(root)
        Set self.focus for kwarg queries
    extract_queries(args, kwargs)
        This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.
    fetch(minion_id, pillar, *args, **kwargs)
        Execute queries, merge and return as a dict.

field_names = None
focus = None
ignore_null = False
num_fields = 0
process_fields(field_names, depth)
    The primary purpose of this function is to store the sql field list and the depth to which we process.
process_results(rows)
    This function takes a list of database results and iterates over, merging them into a dict form.

result = None
with_lists = None

23.12.40 salt.pillar.sqlcipher

Retrieve Pillar data by running a SQLCipher query

New in version 2016.3.0.

Python SQLCipher support is provided by the pysqlcipher Python package. You need this module installed to query Pillar data from a SQLCipher database.

This module is a concrete implementation of the sql_base ext_pillar for SQLCipher.

    maturity new
    depends pysqlcipher (for py2) or pysqlcipher3 (for py3)
    platform all
Configuring the sqlcipher ext_pillar

Use the 'sqlcipher' key under ext_pillar for configuration of queries.

SQLCipher database connection configuration requires the following values configured in the master config:

- `sqlcipher.database` - The SQLCipher database to connect to. Defaults to '/var/lib/salt/pillar-sqlcipher.db'.
- `sqlcipher.pass` - The SQLCipher database decryption password.
- `sqlcipher.timeout` - The connection timeout in seconds.

Example configuration

```yaml
sqlcipher:
  database: /var/lib/salt/pillar-sqlcipher.db
  pass: strong_pass_phrase
  timeout: 5.0
```

Complete Example

```yaml
sqlcipher:
  database: '/var/lib/salt/pillar-sqlcipher.db'
  pass: strong_pass_phrase
  timeout: 5.0

ext_pillar:
  - sqlcipher:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
        FROM some_random_table
        WHERE minion_pattern LIKE ?'
        depth: 5
        as_list: True
        with_lists: [1,3]
```

class `salt.pillar.sqlcipher.SQLCipherExtPillar`

This class receives and processes the database rows from SQLCipher.

`salt.pillar.sqlcipher.ext_pillar(minion_id, pillar, *args, **kwargs)`

Execute queries against SQLCipher, merge and return as a dict

23.12.41 salt.pillar.sqlite3

Retrieve Pillar data by doing a SQLite3 query

New in version 2015.8.0.

sqlite3 is included in the stdlib since Python 2.5.

This module is a concrete implementation of the sql_base ext_pillar for SQLite3.

```python
platform all
```
Configuring the sqlite3 ext_pillar

Use the ‘sqlite3’ key under ext_pillar for configuration of queries.

SQLite3 database connection configuration requires the following values configured in the master config:

Note, timeout is in seconds.

| sqlite3.database: /var/lib/salt/pillar.db |
| sqlite3.timeout: 5.0 |

Complete Example

```yaml
sqlite3:
    database: '/var/lib/salt/pillar.db'
    timeout: 5.0

ext_pillar:
- sqlite3:
    fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                FROM some_random_table
                WHERE minion_pattern LIKE ?'
        depth: 5
        as_list: True
        with_lists: [1,3]
```

class salt.pillar.sqlite3.SQLite3ExtPillar

This class receives and processes the database rows from SQLite3.

salt.pillar.sqlite3.ext_pillar(minion_id, pillar, *args, **kwargs)

Execute queries against SQLite3, merge and return as a dict

23.12.42 salt.pillar.stack

Simple and flexible YAML ext_pillar which can read pillar from within pillar.

New in version 2016.3.0.

PillarStack is a custom saltstack ext_pillar which was inspired by varstack but is heavily based on Jinja2 for maximum flexibility.

Any issue should be reported to the upstream project at: https://github.com/bbinet/pillarstack/issues

It supports the following features:

- multiple config files that are jinja2 templates with support for pillar, __grains__, __salt__, __opts__ objects
- a config file renders as an ordered list of files (paths of these files are relative to the current config file)
- this list of files are read in ordered as jinja2 templates with support for stack, pillar, __grains__, __salt__, __opts__ objects
- all these rendered files are then parsed as yaml
- then all yaml dicts are merged in order with support for the following merging strategies: merge-first, merge-last, remove, and overwrite
stack config files can be matched based on pillar, grains, or opts values, which make it possible to support kind of self-contained environments

Installation

PillarStack is already bundled with Salt since 2016.3.0 version so there is nothing to install from version 2016.3.0. If you use an older Salt version or you want to override PillarStack with a more recent one, follow the installation procedure below.

Installing the PillarStack ext_pillar is as simple as dropping the stack.py file in the <extension_modules>/pillar directory (no external python module required), given that extension_modules is set in your salt-master configuration, see: http://docs.saltstack.com/en/latest/ref/configuration/master.html#extension-modules

Configuration in Salt

Like any other external pillar, its configuration takes place through the ext_pillar key in the master config file. However, you can configure PillarStack in 3 different ways:

Single config file

This is the simplest option, you just need to set the path to your single PillarStack config file like below:

```
ext_pillar:
  - stack: /path/to/stack.cfg
```

List of config files

You can also provide a list of config files:

```
ext_pillar:
  - stack:
    - /path/to/stack1.cfg
    - /path/to/stack2.cfg
```

Select config files through grains|pillar|opts matching

You can also opt for a much more flexible configuration: PillarStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:

```
ext_pillar:
  - stack:
    pillar:environment:
      dev: /path/to/dev/stack.cfg
      prod: /path/to/prod/stack.cfg
    grains:custom:grain:
    value:
```

(continues on next page)
PillarStack configuration files

The config files that are referenced in the above `ext_pillar` configuration are jinja2 templates which must render as a simple ordered list of `yaml` files that will then be merged to build pillar data.

The path of these `yaml` files must be relative to the directory of the PillarStack config file. These paths support unix style pathname pattern expansion through the `Python glob module <https://docs.python.org/2/library/glob.html>`.

The following variables are available in jinja2 templating of PillarStack configuration files:

- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-)  
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don't have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your list of `yaml` files that will be merged in pillar data.

For example, you could have a PillarStack config file which looks like:

```bash
$ cat /path/to/stack/config.cfg
core.yml
common/*.yml
osarchs/{{ __grains__['osarch'] }}.yml
oscodenames/{{ __grains__['oscodename'] }}.yml
{% for role in pillar.get('roles', []) %}
    roles/{{ role }}.yml
{% endfor %}
minions/{{ minion_id }}.yml
```

And the whole directory structure could look like:

```bash
$ tree /path/to/stack/
/path/to/stack/
    config.cfg
    core.yml
    common/
    ├── xxx.yml
    │   └── yyy.yml
    └── osarchs/
        └── amd64.yml
          └── armhf.yml
    oscodenames/
        └── wheezy.yml
          └── jessie.yml
    roles/
```

(continues on next page)
Overall process

In the above PillarStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and
which pillar roles is ["db"], the following yaml files would be merged in order:

• core.yml
• common/xxx.yml
• common/yyy.yml
• osarchs/amd64.yml
• oscodenames/jessie.yml
• roles/db.yml
• minions/test-1-dev.yml

Before merging, every files above will be preprocessed as Jinja2 templates. The following variables are available in
Jinja2 templating of yaml files:

• stack: the PillarStack pillar data object that has currently been merged (data from previous yaml files in
PillarStack configuration)
• pillar: the pillar data (as passed by Salt to our ext_pillar function)
• minion_id: the minion id ;-)  
• __opts__: a dictionary of mostly Salt configuration options
• __grains__: a dictionary of the grains of the minion making this pillar call
• __salt__: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your pillar data, and even use other pillar values that has already been
merged by PillarStack (from previous yaml files in PillarStack configuration) through the stack variable.

Once a yaml file has been preprocessed by Jinja2, we obtain a Python dict - let’s call it yaml_data - then, PillarStack will merge this yaml_data dict in the main stack dict (which contains already merged PillarStack pillar data). By default, PillarStack will deeply merge yaml_data in stack (similarly to the recurse salt pillar_source_merging_strategy), but 3 merging strategies are currently available for you to choose (see next section).

Once every yaml files have been processed, the stack dict will contain your whole own pillar data, merged in
order by PillarStack. So PillarStack ext_pillar returns the stack dict, the contents of which Salt takes care to
merge in with all of the other pillars and finally return the whole pillar to the minion.
Merging strategies

The way the data from a new `yaml_data` dict is merged with the existing `stack` data can be controlled by specifying a merging strategy. Right now this strategy can either be `merge-last` (the default), `merge-first`, `remove`, or `overwrite`.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the `overwrite` strategy (other strategies don't make sense in that case).

The merging strategy can be set by including a dict in the form of:

```
_: <merging strategy>
```

as the first item of the dict or list. This allows fine grained control over the merging process.

.merge-last (default) strategy

If the `merge-last` strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the `recurse` salt `pillar_source_merging_strategy`). This allows for extending previously defined data.

.merge-first strategy

If the `merge-first` strategy is selected, then the content of dict or list variables are swapped between the `yaml_data` and `stack` objects before being merged recursively with the `merge-last` previous strategy.

.remove strategy

If the `remove` strategy is selected, then content of dict or list variables in `stack` are removed only if the corresponding item is present in the `yaml_data` dict. This allows for removing items from previously defined data.

.overwrite strategy

If the `overwrite` strategy is selected, then the content of dict or list variables in `stack` is overwritten by the content of `yaml_data` dict. So this allows one to overwrite variables from previous definitions.

Merging examples

Let's go through small examples that should clarify what's going on when a `yaml_data` dict is merged in the `stack` dict.

When you don't specify any strategy, the default `merge-last` strategy is selected:
Then you can select a custom merging strategy using the `__` key in a dict:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td>users:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tom:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>users:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>tom:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uid: 1000</td>
<td></td>
</tr>
<tr>
<td></td>
<td>roles:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- developer</td>
<td></td>
</tr>
<tr>
<td></td>
<td>mat:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uid: 1001</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>users:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>tom:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uid: 1000</td>
<td></td>
</tr>
<tr>
<td></td>
<td>roles:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- sysadmin</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- developer</td>
<td></td>
</tr>
<tr>
<td></td>
<td>mat:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uid: 1001</td>
<td></td>
</tr>
<tr>
<td></td>
<td>root:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>uid: 0</td>
<td></td>
</tr>
</tbody>
</table>
You can also select a custom merging strategy using a `__` object in a list:
### Stack Differences

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>

- __: overwrite  
- mat | **users:**  
- mat |

```python
salt.pillar.stack.ext_pillar(minion_id, pillar, *args, **kwargs)
```

#### 23.12.43 salt.pillar.svn_pillar

Clone a remote SVN repository and use the filesystem as a Pillar source.

This external Pillar source can be configured in the master config file like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (`master`), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```yaml
base:
  '*':
    - foo
```

To use other environments from the same SVN repo as `svn_pillar` sources, just add additional lines, like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo
  - svn: dev svn://svnserver/repo
```

In this case, the `dev` branch would need its own `top.sls` with a `dev` section in it, like this:
**class** salt.pillar.svn_pillar.SvnPillar(*branch*, *repo_location*, *root*, *opts*)

Deal with the remote SVN repository for Pillar

**pillar_dir()**

Returns the directory of the pillars (repo cache + branch + root)

**update()**

salt.pillar.svn_pillar.ext_pillar(*minion_id*, *pillar*, *repo_string*)

Execute a command and read the output as YAML

---

23.12.44 salt.pillar.varstack_pillar

Use Varstack data as a Pillar source

**Configuring Varstack**

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:

```
ext_pillar:
  - varstack: /etc/varstack.yaml
```

Varstack will then use /etc/varstack.yaml to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.

salt.pillar.varstack_pillar.ext_pillar(*minion_id*, *pillar*, *conf*)

Parse varstack data and return the result

---

23.12.45 salt.pillar.vault

Vault Pillar Module

**maintainer** SaltStack

**maturity** New

**platform** all

New in version 2016.11.0.

This module allows pillar data to be stored in Hashicorp Vault.

Base configuration instructions are documented in the execution module docs. Below are noted extra configuration required for the pillar module, but the base configuration must also be completed.

After the base Vault configuration is created, add the configuration below to the ext_pillar section in the Salt master configuration.

```
ext_pillar:
  - vault: path=secret/salt
```

---

23.12. pillar modules 3259
Each key needs to have all the key-value pairs with the names you require. Avoid naming every key 'password' as you they will collide:

If you want to nest results under a nesting_key name use the following format:

```
ext_pillar:
    • vault: conf: path=secret/salt nesting_key: vault_key_name
```

```
$ vault write secret/salt auth=my_password master=127.0.0.1
```

The above will result in two pillars being available, auth and master.

You can then use normal pillar requests to get each key pair directly from pillar root. Example:

```
$ salt-ssh '*' pillar.get auth
```

Multiple Vault sources may also be used:

```
ext_pillar:
  - vault: path=secret/salt
  - vault: path=secret/root
  - vault: path=secret/minions/{minion}/pass
```

You can also use nesting here as well. Identical nesting keys will get merged.

```
ext_pillar:
  - vault:
      conf: path=secret/salt
      nesting_key: keyname1
  - vault:
      conf: path=secret/root
      nesting_key: keyname1
  - vault:
      conf: path=secret/minions/{minion}/pass
      nesting_key: keyname2
```

The difference between the return with and without the nesting key is shown below. This example takes the key value pairs returned from vault as follows:

- path=secret/salt
Key Value --- ----- salt-passwd badpasswd1
- path=secret/root
Key Value --- ----- root-passwd rootbadpasswd1
- path=secret/minions/{minion}/pass
Key Value --- ----- minion-passwd minionbadpasswd1

```
#Nesting Key not defined

local:
  ----------
  salt-passwd:
      badpasswd1
  root-passwd:
      rootbadpasswd1
  minion-passwd:
```

(continues on next page)
salt.pillar.vault.ext_pillar(minion_id, pillar, conf, nesting_key=None)
Get pillar data from Vault for the configuration conf.

23.12.46 salt.pillar.venafi

Venafi Pillar Certificates

This module will only return pillar data if the venafi runner module has already been used to create certificates.

To configure this module, set venafi to True in the ext_pillar section of your master configuration file:

```
ext_pillar:
  - venafi: True
```

salt.pillar.venafi.ext_pillar(minion_id, pillar, conf)
Return an existing set of certificates

23.12.47 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)
Accept the key for the VM on the hyper, if authorized.

23.12.48 salt.pillar.vmware_pillar

Pillar data from vCenter or an ESXi host

New in version 2017.7.0.

depends
  - pyVmomi

This external pillar can pull attributes from objects in vCenter or an ESXi host and provide those attributes as pillar data to minions. This can allow for pillar based targeting of minions on ESXi host, Datastore, VM configuration, etc. This setup requires only the salt master have access to the vCenter server/ESXi hosts.

The pillar will return an empty dict if the 'os' or 'virtual' grain are not 'VMWare', 'ESXi', or 'VMWare ESXi'.
Defaults

- The external pillar will search for Virtual Machines with the VM name matching the minion id.
- Data will be returned into the 'vmware' pillar key.
- The external pillar has a default set of properties to return for both VirtualMachine and HostSystem types.

Configuring the VMWare pillar

The required minimal configuration in the salt master ext_pillar setup:

```
ext_pillar:
  - vmware:
    host: <vcenter/esx host>
    username: <user to connect with>
    password: <password>
```

Optionally, the following keyword arguments can be passed to the ext_pillar for customized configuration:

- **pillar_key** Optionally set the pillar key to return the data into. Default is *vmware*.
- **protocol** Optionally set to alternate protocol if the vCenter server or ESX/ESXi host is not using the default protocol. Default protocol is *https*.
- **port** Optionally set to alternate port if the vCenter server or ESX/ESXi host is not using the default port. Default port is 443.
- **property_name** Property name to match the minion id against. Defaults to *name*.
- **property_types** Optionally specify a list of pyVmomi vim types to search for the minion id in 'property_name'. Default is ['VirtualMachine'].

For example, to search both vim.VirtualMachine and vim.HostSystem object types:

```
ext_pillar:
  - vmware:
    host: myesx
    username: root
    password: complex_password
    property_types:
      - VirtualMachine
      - HostSystem
```

Additionally, the list of property types can be dicts, the item of the dict being a list specifying the attribute to return for that vim object type.

The pillar will attempt to recurse the attribute and return all child attributes.

To explicitly specify deeper attributes without attempting to recurse an attribute, convert the list item to a dict with the item of the dict being the child attributes to return. Follow this pattern to return attributes as deep within the object as necessary.

**Note**: Be careful when specifying custom attributes! Many attributes have objects as attributes which have the parent object as an attribute and which will cause the pillar to fail due to the attempt to convert all sub-objects recursively (i.e. infinite attribute loops). Specifying only the sub-attributes you would like returned will keep the infinite recursion from occurring.

A maximum recursion exception will occur in this case and the pillar will not return as desired.
The above ext_pillar example would return a pillar like the following for a VirtualMachine object that's name matched the minion id:

```yaml
vmware:
  config:
    bootOptions:
      bootDelay: 1000
      bootRetryDelay: 1000
```

If you were to retrieve these virtual machine attributes via pyVmomi directly, this would be the same as

```python
vmObject.config.bootOptions.bootDelay
vmObject.config.bootOptionis.bootRetryDelay
```

The above ext_pillar example would return a pillar like the following for a HostSystem object that's name matched the minion id:

```yaml
vmware:
  datastore:
    - name: Datastore1
    - name: Datastore2
```

The ‘datastore’ property of a HostSystem object is a list of datastores, thus a list is returned.

replace_default_attributes If custom attributes are specified by the property_types parameter, replace_default_attributes determines if those will be added to default attributes (False) or replace the default attributes completely (True). The default setting is 'False'.

Note: vCenter "Custom Attributes" (i.e. Annotations) will always be returned if it exists on the object as part of the pillar regardless of this setting.
## 23.13 proxy modules

23.13.1 salt.proxy.arista_pyeapi

Arista pyeapi

New in version 2019.2.0.
Proxy module for managing Arista switches via the eAPI using the pyeapi library.

- **codeauthor**: Mircea Ulinic <ping@mirceaulinic.net>
- **maturity**: new
- **depends**: pyeapi
- **platform**: unix

Note: To understand how to correctly enable the eAPI on your switch, please check https://eos.arista.com/arista-eapi-101/.

Dependencies

The pyeapi Proxy module requires pyeapi to be installed: `pip install pyeapi`.

Pillar

The pyeapi proxy configuration requires the following parameters in order to connect to the network device:

- **transport**: `https` Specifies the type of connection transport to use. Valid values for the connection are `socket`, `http_local`, `http`, and `https`.
- **host**: `localhost` The IP address or DNS host name of the connection device.
- **username**: `admin` The username to pass to the device to authenticate the eAPI connection.
- **password** The password to pass to the device to authenticate the eAPI connection.
- **port** The TCP port of the endpoint for the eAPI connection. If this keyword is not specified, the default value is automatically determined by the transport type (80 for `http`, or 443 for `https`).
- **enablepwd** The enable mode password if required by the destination node.

All the arguments may be optional, depending on your setup.

Proxy Pillar Example

```yaml
proxy:
  proxytype: pyeapi
  host: router1.example.com
  username: example
  password: example

salt.proxy.arista_pyeapi.call(method, *args, **kwargs)
  Calls an arbitrary pyeapi method.

salt.proxy.arista_pyeapi.conn()
  Return the connection object.
```
salt.proxy.arista_pyeapi.init(opts)
Open the connection to the Arista switch over the eAPI.
salt.proxy.arista_pyeapi.initialized()
Connection finished initializing?
salt.proxy.arista_pyeapi.ping()
Connection open successfully?
salt.proxy.arista_pyeapi.shutdown(opts)
Closes connection with the device.

23.13.2 salt.proxy.chronos

Chronos
Proxy minion for managing a Chronos cluster.

Dependencies

- chronos execution module (salt.modules.chronos)

Pillar

The chronos proxy configuration requires a 'base_url' property that points to the chronos endpoint:

```
proxy:
    proxytype: chronos
    base_url: http://my-chronos-master.mydomain.com:4400
```

New in version 2015.8.2.

salt.proxy.chronos.init(opts)
Perform any needed setup.
salt.proxy.chronos.ping()
Is the chronos api responding?
salt.proxy.chronos.shutdown(opts)
For this proxy shutdown is a no-op

23.13.3 salt.proxy.cimc

Proxy Minion interface module for managing Cisco Integrated Management Controller devices

New in version 2018.3.0.

codeauthor Spencer Ervin <spencer ervin@hotmail.com>
maturity new
depends none
platform unix
This proxy minion enables Cisco Integrated Management Controller devices (hereafter referred to as simply 'cimc' devices to be treated individually like a Salt Minion.

The cimc proxy leverages the XML API functionality on the Cisco Integrated Management Controller. The Salt proxy must have access to the cimc on HTTPS (tcp/443).

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt’s documentation.

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID.

```yaml
proxy:
  proxytype: cimc
  host: <ip or dns name of cimc host>
  username: <cimc username>
  password: <cimc password>
  verify_ssl: True
```

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this cimc Proxy Module, set this to `cimc`.

**host**

The location, or ip/dns, of the cimc host. Required.

**username**

The username used to login to the cimc host. Required.

**password**

The password used to login to the cimc host. Required.

```python
salt.proxy.cimc.get_config_resolver_class(cid=None, hierarchical=False)
```

The configResolverClass method returns requested managed object in a given class.

```python
salt.proxy.cimc.grains()
```

Get the grains from the proxied device

```python
salt.proxy.cimc.grains_refresh()
```

Refresh the grains from the proxied device
salt.proxy.cimc.init(opts)
   This function gets called when the proxy starts up.

salt.proxy.cimc.initialized()
   Since grains are loaded in many different places and some of those places occur before the proxy can be
   initialized, return whether our init() function has been called

salt.proxy.cimc.logon()
   Logs into the cimc device and returns the session cookie.

salt.proxy.cimc.logout(cookie=None)
   Closes the session with the device.

salt.proxy.cimc.ping()
   Returns true if the device is reachable, else false.

salt.proxy.cimc.prepare_return(x)
   Converts the etree to dict

salt.proxy.cimc.set_config_modify(dn=None, inconfig=None, hierarchical=False)
   The configConfMo method configures the specified managed object in a single subtree (for example, DN).

salt.proxy.cimc.shutdown()
   Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

23.13.4 salt.proxy.cisconso

Proxy Minion interface module for managing (practically) any network device with Cisco Network Services Orches-
trator (Cisco NSO). Cisco NSO uses a series of remote polling agents, APIs and SSH commands to fetch network
configuration and represent it in a data model. PyNSO, the Python module used by this proxy minion does the task
of converting native Python dictionaries into NETCONF/YANG syntax that the REST API for Cisco NSO can then
use to set the configuration of the target network device.

Supported devices:
   • A10 AX Series
   • Arista 7150 Series
   • Ciena 3000, 5000, ESM
   • H3c S5800 Series
   • Overture 1400, 2200, 5000, 5100, 6000
   • Accedian MetroNID
   • Avaya ERS 4000, SR8000, VSP 9000
   • Cisco: APIC-DC, ASA, IOS, IOS XE, IOS XR, er, ME-4600, NX OS, Prime Network Registrar, Quan-
tum, StarOS, UCS ManagWSA
   • Huawei: NE40E, quidway series, Enterprise Network Simulation Framework
   • PaloAlto PA-2000, PA-3000, Virtualized Firewalls
   • Adtran 900 Series
   • Brocade ADX, MLX, Netiron, Vyatta
   • Dell Force 10 Networking S-Series
   • Infinera DTN-X Multi-Terabit Packet Optical Network Platform
   • Pulsecom SuperG
- Adva 150CC Series
- CableLabs Converged Cable Access Platform
- Ericsson EFN324 Series, SE family
- Juniper: Contrail, EX, M, MX, QFX, SRX, Virtual SRX
- Quagga Routing Software
- Affirmed Networks
- Citrix Netscaler
- F5 BIG-IP
- NEC iPasolink
- Riverbed Steelhead Series
- Alcatel-Lucent 7XXX, SAM
- Clavister
- Fortinet
- Nominum DCS
- Sonus SBC 5000 Series
- Allied Telesys
- Open vSwitch

New in version 2016.11.0.

**codeauthor** Anthony Shaw <anthony.shaw@dimensiondata.com>

This proxy minion enables a consistent interface to fetch, control and maintain the configuration of network devices via a NETCONF-compliant control plane. Cisco Network Services Orchestrator.

More in-depth conceptual reading on Proxy Minions can be found in the *Proxy Minion* section of Salt’s documentation.

**Dependencies**

- pynso Python module

**PyNSO**

PyNSO can be installed via pip:

```
pip install pynso
```
**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the NSO host, the pillar should look like this:

```yaml
proxy:
    proxytype: cisconso
    host: <ip or dns name of host>
    port: 8080
    use_ssl: false
    username: <username>
    password: password
```

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this Cisco NSO Proxy Module, set this to `cisconso`.

**host**

The location, or IP/dns, of the Cisco NSO API host. Required.

**username**

The username used to login to the Cisco NSO host, such as `admin`. Required.

**password**

The password for the given user. Required.

**use_ssl**

Whether to use HTTPS messaging to speak to the API.
port

The port that the Cisco NSO API is running on, 8080 by default

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the Cisco NSO host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the cisconso host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the Cisco NSO host to make sure it is responding:

```
salt <id> test.ping
```

```
salt.proxy.cisconso.apply_rollback(datastore, name)
```

Apply a system rollback

- **datastore** (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
- **name** (str) -- an ID of the rollback to restore

```
salt.proxy.cisconso.get_data(datastore, path)
```

Get the configuration of the device tree at the given path

- **datastore** (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
- **path** (list of str OR tuple) -- The device path, a list of element names in order, comma separated

```
salt.proxy.cisconso.get_rollback(name)
```

Get the backup of stored a configuration rollback

- **name** (str) -- Typically an ID of the backup
Return type \texttt{str}  
Returns the contents of the rollback snapshot

\begin{verbatim}
salt.proxy.cisconso.get_rollbacks()
get a list of stored configuration rollbacks
\end{verbatim}

\begin{verbatim}
salt.proxy.cisconso.grains()
get the grains from the proxy device.
\end{verbatim}

\begin{verbatim}
salt.proxy.cisconso.init(opts)
\end{verbatim}

\begin{verbatim}
salt.proxy.cisconso.ping()
check to see if the host is responding. Returns False if the host didn't respond, True otherwise.
\end{verbatim}

\begin{verbatim}
salt.proxy.cisconso.set_data_value(datastore, path, data)
get a data entry in a datastore
\end{verbatim}

\textbf{Parameters}
\begin{itemize}
  \item \texttt{datastore} (DatastoreType (str enum). -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
  \item \texttt{path} (list of str OR tuple) -- The device path to set the value at, a list of element names in order, comma separated
  \item \texttt{data} (dict) -- The new value at the given path
\end{itemize}

\begin{verbatim}
Return type \texttt{bool}
Returns True if successful, otherwise error.
\end{verbatim}

\begin{verbatim}
salt.proxy.cisconso.shutdown()
shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.
\end{verbatim}

\subsection{23.13.5 \texttt{salt.proxy.docker}}

Docker Proxy Minion

New in version 2019.2.0.

\texttt{depends} docker

This proxy minion is just a shim to the docker executor, which will use the \texttt{docker.call} for everything except state runs.

To configure the proxy minion:

\begin{verbatim}
proxy:
  proxitype: docker
  name: festive_leakey
\end{verbatim}

It is also possible to just name the proxy minion the same name as the container, and use grains to configure the proxy minion:

\begin{verbatim}
proxy:
  proxitype: docker
  name: {{grains['id']}}
\end{verbatim}

name
  Name of the docker container
salt.proxy.docker.init(opts)
    Always initialize

salt.proxy.docker.initialized()
    This should always be initialized

salt.proxy.docker.module_executors()
    List of module executors to use for this Proxy Minion

salt.proxy.docker.shutdown(opts)
    Nothing needs to be done to shutdown

### 23.13.6 salt.proxy.dummy

This is the a dummy proxy-minion designed for testing the proxy minion subsystem.

salt.proxy.dummy.fns()
    Method called by grains module.

salt.proxy.dummy.grains()
    Make up some grains

salt.proxy.dummy.grains_refresh()
    Refresh the grains

salt.proxy.dummy.init(opts)
    Required. Can be used to initialize the server connection.

salt.proxy.dummy.initialized()
    Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.dummy.package_install(name, **kwargs)
    Install a "package" on the REST server

salt.proxy.dummy.package_list()
    List "packages" installed on the REST server

salt.proxy.dummy.package_remove(name)
    Remove a "package" on the REST server

salt.proxy.dummy.package_status(name)
    Check the installation status of a package on the REST server

salt.proxy.dummy.ping()
    Degenerate ping

salt.proxy.dummy.service_list()
    List "services" on the REST server

salt.proxy.dummy.service_restart(name)
    Restart a "service" on the REST server

salt.proxy.dummy.service_start(name)
    Start a "service" on the dummy server

salt.proxy.dummy.service_status(name)
    Check if a service is running on the REST server

salt.proxy.dummy.service_stop(name)
    Stop a "service" on the dummy server

23.13. proxy modules
salt.proxy.dummy.shutdown(<opts>)
    For this proxy shutdown is a no-op

salt.proxy.dummy.test_from_state()
    Test function so we have something to call from a state :return:

salt.proxy.dummy.upgrade()
    "Upgrade" packages

salt.proxy.dummy.uptodate()
    Call the REST endpoint to see if the packages on the "server" are up to date.

23.13.7 salt.proxy.esxcluster

Proxy Minion interface module for managing VMWare ESXi clusters.

Dependencies

- pyVmomi
- jsonschema

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. This can now happen from the proxy’s configuration file.

Example pillars:

userpass mechanism:

```
proxy:
    proxytype: esxcluster
    cluster: <cluster name>
    datacenter: <datacenter name>
    vcenter: <ip or dns name of parent vcenter>
    mechanism: userpass
    username: <vCenter username>
    passwords: (required if userpass is used)
        - first_password
        - second_password
        - third_password
```

sspi mechanism:

```
proxy:
    proxytype: esxcluster
    cluster: <cluster name>
    datacenter: <datacenter name>
    vcenter: <ip or dns name of parent vcenter>
    mechanism: sspi
```
domain: <user domain>
principal: <host kerberos principal>

**proxytype**

To use this Proxy Module, set this to **esxdatacenter**.

**cluster**

Name of the managed cluster. Required.

**datacenter**

Name of the datacenter the managed cluster is in. Required.

**vcenter**

The location of the VMware vCenter server (host of ip) where the datacenter should be managed. Required.

**mechanism**

The mechanism used to connect to the vCenter server. Supported values are **userpass** and **sspi**. Required.

*Note: Connections are attempted using all (username, password) combinations on proxy startup.*

**username**

The username used to login to the host, such as root. Required if mechanism is **userpass**.

**passwords**

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is **userpass**. When the proxy comes up, it will try the passwords listed in order.
domain

User domain. Required if mechanism is sspi.

principal

Kerberos principal. Required if mechanism is sspi.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity <id>:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is /etc/salt/proxy. If in a different location, the <configuration_folder> has to be specified when running the proxy: file with at least the following in it:

```
salt-proxy --proxyid <proxy_id> -c <configuration_folder>
```

Commands

Once the proxy is running it will connect back to the specified master and individual commands can be runs against it:

```
# Master - minion communication
salt <cluster_name> test.ping

# Test vcenter connection
salt <cluster_name> vsphere.test_vcenter_connection
```
States

Associated states are documented in `salt.states.esxcluster`. Look there to find an example structure for Pillar as well as an example `.sls` file for configuring an ESX cluster from scratch.

```python
cycle.proxy.esxcluster.find_credentials()
    Cycle through all the possible credentials and return the first one that works.

cycle.proxy.esxcluster.get_details()
    Function that returns the cached details

cycle.proxy.esxcluster.init(opts)
    This function gets called when the proxy starts up. For login the protocol and port are cached.

cycle.proxy.esxcluster.ping()
    Returns True.
    CLI Example:
    ```
    salt esx-cluster test.ping
```

cycle.proxy.esxcluster.shutdown()
    Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

23.13.8 cycle.proxy.esxdatacenter

Proxy Minion interface module for managing VMWare ESXi clusters.

Dependencies

- pyVmomi
- jsonschema

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. This can now happen from the proxy’s configuration file.

Example pillars:

```
userpass mechanism:

proxy:
    proxitype: esxdatacenter
datacenter: <datacenter name>
vcenter: <ip or dns name of parent vcenter>
mechanism: userpass
username: <vCenter username>
passwords: (required if userpass is used)
    - first_password
```
sspi mechanism:

```
proxy:
  proxytype: esxdatacenter
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: sspi
  domain: <user domain>
  principal: <host kerberos principal>
```

**proxytype**

To use this Proxy Module, set this to `esxdatacenter`.

**datacenter**

Name of the managed datacenter. Required.

**vcenter**

The location of the VMware vCenter server (host of ip) where the datacenter should be managed. Required.

**mechanism**

The mechanism used to connect to the vCenter server. Supported values are `userpass` and `sspi`. Required.

---

**Note:** Connections are attempted using all `(username, password)` combinations on proxy startup.

**username**

The username used to login to the host, such as `root`. Required if mechanism is `userpass`.

**passwords**

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is `userpass`. When the proxy comes up, it will try the passwords listed in order.
domain

User domain. Required if mechanism is sspi.

principal

Kerberos principal. Required if mechanism is sspi.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity <id>:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is /etc/salt/proxy. If in a different location, the <configuration_folder> has to be specified when running the proxy: file with at least the following in it:

```
salt-proxy --proxyid <proxy_id> -c <configuration_folder>
```

Commands

Once the proxy is running it will connect back to the specified master and individual commands can be runs against it:

```
# Master - minion communication
salt <datacenter_name> test.ping

# Test vcenter connection
salt <datacenter_name> vsphere.test_vcenter_connection
```
States

Associated states are documented in `salt.states.esxdatacenter`. Look there to find an example structure for Pillar as well as an example `.sls` file for configuring an ESX datacenter from scratch.

```python
salt.proxy.esxdatacenter.find_credentials()
```
Cycle through all the possible credentials and return the first one that works.

```python
salt.proxy.esxdatacenter.get_details()
```
Function that returns the cached details.

```python
salt.proxy.esxdatacenter.init(opts)
```
This function gets called when the proxy starts up. All login details are cached.

```python
salt.proxy.esxdatacenter.ping()
```
Returns True.

```bash
salt dc_id test.ping
```

```python
salt.proxy.esxdatacenter.shutdown()
```
Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

### 23.13.9 salt.proxy.esxi

Proxy Minion interface module for managing VMware ESXi hosts.

New in version 2015.8.4.

**Special Note:** SaltStack thanks Adobe Corporation for their support in creating this Proxy Minion integration.

This proxy minion enables VMware ESXi (hereafter referred to as simply 'ESXi') hosts to be treated individually like a Salt Minion.

Since the ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can't run a Salt Minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the Salt Master. The master does not know nor care that the target is not a "real" Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the [Proxy Minion section of Salt's documentation](#).

**Dependencies**

- pyVmomi Python Module
- ESXCLI
**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```yaml
proxy:
  proxtotype: esxi
  host: <ip or dns name of esxi host>
  username: <ESXi username>
  passwords:
    - first_password
    - second_password
```

(continues on next page)
proxytype

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to `esxi`.

host

The location, or ip/dns, of the ESXi host. Required.

username

The username used to login to the ESXi host, such as `root`. Required.

passwords

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

This also allows you to use any number of potential fallback passwords.

---

**Note:** When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi's login system. We have to wait for the first attempt to fail before trying the next password on the list.

This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a `True` result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.
protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

credstore

If the ESXi host is using an untrusted SSL certificate, set this value to the file path where the credential store is located. This file is passed to esxcli. Default is <HOME>/vmware/credstore/vicecredentials.xml on Linux and <APPDATA>/VMware/credstore/vicecredentials.xml on Windows.

Note: HOME variable is sometimes not set for processes running as system services. If you want to rely on the default credential store location, make sure HOME is set for the proxy process.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the ESXi host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```plaintext
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```plaintext
salt-proxy --proxyid <id you want to give the host>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```plaintext
salt-key -a <id you gave the esxi host>
```

You can confirm that the pillar data is in place for the proxy:

```plaintext
salt <id> pillar.items
```

And now you should be able to ping the ESXi host to make sure it is responding:

```plaintext
salt <id> test.ping
```

At this point you can execute one-off commands against the host. For example, you can get the ESXi host’s system information:

```plaintext
salt <id> esxi.cmd system_info
```
Note that you don’t need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It’s important to understand how this particular proxy works. Salt.modules.vsphere is a standard Salt execution module. If you pull up the docs for it you’ll see that almost every function in the module takes credentials and a target host. When credentials and a host aren’t passed, Salt runs commands through pyVmomi against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of pyVmomi is installed, and that host would reach out over the network and communicate with the ESXi host.

esxi.cmd acts as a “shim” between the execution module and the proxy. Its first parameter is always the function from salt.modules.vsphere. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for this Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you’ll want to look in salt.modules.vsphere instead of salt.modules.esxi.

States

Associated states are thoroughly documented in salt.states.esxi. Look there to find an example structure for Pillar as well as an example .sls file for standing up an ESXi host from scratch.

```
salt.proxy.esxi.ch_config(cmd, *args, **kwargs)

This function is called by the salt.modules.esxi.cmd shim. It then calls whatever is passed in cmd inside the salt.modules.vsphere module. Passes the return through from the vsphere module.

cmd  The command to call inside salt.modules.vsphere
args  Arguments that need to be passed to that command.
kwargs  Keyword arguments that need to be passed to that command.
```

```
salt.proxy.esxi.find_credentials(host)

Cycle through all the possible credentials and return the first one that works.
```

```
salt.proxy.esxi.get_details()

Return the proxy details
```

```
salt.proxy.esxi.grains()

Get the grains from the proxy device.
```

```
salt.proxy.esxi.grains_refresh()

Refresh the grains from the proxy device.
```

```
salt.proxy.esxi.init(opts)

This function gets called when the proxy starts up. For ESXi devices, the host, login credentials, and, if configured, the protocol and port are cached.
```

```
salt.proxy.esxi.is_connected_via_vcenter()

Returns True if connection is to be done via a vCenter (no connection is attempted). Check to see if the host is responding when connecting directly via an ESXi host.

CLI Example:

salt esxi-host test.ping
```

```
salt.proxy.esxi.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.
```
23.13.10 salt.proxy.esxvm

Proxy Minion interface module for managing VMWare ESXi virtual machines.

Dependencies

- pyVmomi
- jsonschema

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. This can now happen from the proxy’s configuration file.

Example pillars:

userpass mechanism:

```yaml
proxy:
  proxycityte: esxvm
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: userpass
  username: <vCenter username>
  passwords: (required if userpass is used)
    - first_password
    - second_password
    - third_password
```

sspi mechanism:

```yaml
proxy:
  proxycityte: esxvm
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: sspi
  domain: <user domain>
  principal: <host kerberos principal>
```

proxytype

To use this Proxy Module, set this to esxvm.
datacenter

Name of the datacenter where the virtual machine should be deployed. Required.

vcenter

The location of the VMware vCenter server (host or IP) where the virtual machine should be managed. Required.

mechanism

The mechanism used to connect to the vCenter server. Supported values are userpass and sspi. Required.

Note: Connections are attempted using all (username, password) combinations on proxy startup.

username

The username used to login to the host, such as root. Required if mechanism is userpass.

passwords

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is userpass. When the proxy comes up, it will try the passwords listed in order.

domain

User realm domain. Required if mechanism is sspi.

principal

Kerberos principal. Required if mechanism is sspi.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.
**port**

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

**Salt Proxy**

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity <id>:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is /etc/salt/proxy. If in a different location, the <configuration_folder> has to be specified when running the proxy: file with at least the following in it:

```
salt-proxy --proxyid <proxy_id> -c <configuration_folder>
```

**Commands**

Once the proxy is running it will connect back to the specified master and individual commands can be runs against it:

```
# Master - minion communication
salt <proxy_id> test.ping

# Test vcenter connection
salt <proxy_id> vsphere.test_vcenter_connection
```

**States**

Associated states are documented in `salt.states.esxvm`. Look there to find an example structure for Pillar as well as an example .sls file for configuring an ESX virtual machine from scratch.

`salt.proxy.esxvm.find_credentials()`  
Cycle through all the possible credentials and return the first one that works.

`salt.proxy.esxvm.get_details()`  
Function that returns the cached details

`salt.proxy.esxvm.init(opts)`  
This function gets called when the proxy starts up. For login the protocol and port are cached.

`salt.proxy.esxvm.ping()`  
Returns True.  
CLI Example:

```
salt esx-vm test.ping
```

`salt.proxy.esxvm.shutdown()`  
Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.
23.13.11 salt.proxy.fx2

Dell FX2 chassis

New in version 2015.8.2.

Proxy minion interface module for managing Dell FX2 chassis (Dell Chassis Management Controller version 1.2 and above, iDRAC8 version 2.00 and above)

Dependencies

- iDRAC Remote execution module (salt.modules.dracr)
- Chassis command shim (salt.modules.chassis)
- Dell Chassis States (salt.states.dellchassis)
- Dell's `racadm` command line interface to CMC and iDRAC devices.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this proxy minion integration.

This proxy minion enables Dell FX2 and FX2s (hereafter referred to as simply "chassis", "CMC", or "FX2") chassis to be treated individually like a salt-minion.

Since the CMC embedded in the chassis does not run an OS capable of hosting a Python stack, the chassis can't run a minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the salt-master. The master does not know nor care that the target is not a real minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

To configure this integration, follow these steps:

**Pillar**

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar, and a reference in the Pillar topfile that matches the ID. At a minimum for communication with the chassis the pillar should look like this:

```
proxy:
    host: <ip or dns name of chassis controller>
    admin_username: <iDRAC username for the CMC, usually 'root'>
    fallback_admin_username: <username to try if the first fails>
    passwords:
        - first_password
        - second_password
        - third-password
    proxytype: fx2
```

The `proxytype` line above is critical, it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the salt-master (if you have created your own proxy module, for example).

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password, a potential fallback password, and the third password can be the one you intend to change the chassis to use. This way, after it is changed, you should not need to restart the proxy minion--it should just pick up the third password in the list. You can then change pillar at will to move that password to the front and retire the unused ones.
Beware, many Dell CMC and iDRAC units are configured to lockout IP addresses or users after too many failed password attempts. This can generate user panic in the form of "I no longer know what the password is‼!". To mitigate panic try the web interface from a different IP, or setup a emergency administrator user in the CMC before doing a wholesale password rotation.

The automatic lockout can be disabled via Salt with the following:

```
salt <cmc> chassis.cmd set_general cfgRacTuning cfgRacTuneIpBlkEnable 0
```

and then verified with

```
salt <cmc> chassis.cmd get_general cfgRacTuning cfgRacTuneIpBlkEnable
```

### salt-proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your salt-master and to the chassis in question. SaltStack recommends that this machine also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can start the proxy with

```
salt-proxy --proxyid <id you want to give the chassis>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you want to give the chassis>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the chassis to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the chassis. For example, you can get the chassis inventory:

```
salt <id> chassis.cmd inventory
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. `Salt.modules.dracr` is a standard Salt execution module. If you pull up the docs for it you'll see that almost every function in the module takes credentials and a target host. When credentials and a host aren't passed, Salt runs `racadm` against the local machine. If you wanted you could run functions from this module on any host where an appropriate version of `racadm` is installed, and that host would reach out over the network and communicate with the chassis.
Chassis.cmd acts as a "shim" between the execution module and the proxy. Its first parameter is always the function from salt.modules.dracr to execute. If the function takes more positional or keyword arguments you can append them to the call. It's this shim that speaks to the chassis through the proxy, arranging for the credentials and hostname to be pulled from the pillar section for this proxy minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the chassis, you'll want to look in salt.modules.dracr instead of salt.modules.chassis.

States

Associated states are thoroughly documented in salt.states.dellchassis. Look there to find an example structure for pillar as well as an example .sls file for standing up a Dell Chassis from scratch.

salt.proxy.fx2.admin_password()

Return the admin_password in the DETAILS dictionary, or 'calvin' (the Dell default) if there is none present

salt.proxy.fx2.admin_username()

Return the admin_username in the DETAILS dictionary, or root if there is none present

salt.proxy.fx2.chconfig(cmd, *args, **kwargs)

This function is called by the salt.modules.chassis.cmd shim. It then calls whatever is passed in cmd inside the salt.modules.dracr module.

Parameters

• cmd -- The command to call inside salt.modules.dracr
• args -- Arguments that need to be passed to that command
• kwargs -- Keyword arguments that need to be passed to that command

Returns

Passthrough the return from the dracr module.

salt.proxy.fx2.find_credentials()

Cycle through all the possible credentials and return the first one that works

salt.proxy.fx2.grains()

Get the grains from the proxied device

salt.proxy.fx2.grains_refresh()

Refresh the grains from the proxied device

salt.proxy.fx2.host()

salt.proxy.fx2.init(opts)

This function gets called when the proxy starts up. We check opts to see if a fallback user and password are supplied. If they are present, and the primary credentials don't work, then we try the backup before failing.

Whichever set of credentials works is placed in the persistent DETAILS dictionary and will be used for further communication with the chassis.

salt.proxy.fx2.ping()

Is the chassis responding?

Returns

Returns False if the chassis didn't respond, True otherwise.

salt.proxy.fx2.shutdown(opts)

Shutdown the connection to the proxied device. For this proxy shutdown is a no-op.
23.13.12  `salt.proxy.junos`

Interface with a Junos device via proxy-minion. To connect to a junos device via junos proxy, specify the host information in the pillar in `'/srv/pillar/details.sls'`

```yaml
proxy:
  proxytype: junos
  host: <ip or dns name of host>
  username: <username>
  port: 830
  password: <secret>
```

In `'/srv/pillar/top.sls'` map the device details with the proxy name.

```yaml
base:
  'vmx':
    - details
```

After storing the device information in the pillar, configure the proxy in `'/etc/salt/proxy'`

```yaml
master: <ip or hostname of salt-master>
```

Run the salt proxy via the following command:

```
salt-proxy --proxyid=vmx
```

class  `salt.proxy.junos.RebootActive(**kwargs)`

Class to get static variable, to indicate when a reboot/shutdown is being processed and the keep_alive should not probe the connection since it interferes with the shutdown process.

```python
reboot_shutdown = False
```

class  `salt.proxy.junos.alive(opts)`

Validate and return the connection status with the remote device.

New in version 2018.3.0.

class  `salt.proxy.junos.conn()`

class  `salt.proxy.junos.get_reboot_active()`

class  `salt.proxy.junos.get_serialized_facts()`

class  `salt.proxy.junos.init(opts)`

Open the connection to the Junos device, login, and bind to the Resource class

class  `salt.proxy.junos.initialized()`

class  `salt.proxy.junos.ping()`

Ping? Pong!

class  `salt.proxy.junos.proxytype()`

Returns the name of this proxy

class  `salt.proxy.junos.reboot_active()`

class  `salt.proxy.junos.reboot_clear()`

class  `salt.proxy.junos.shutdown(opts)`

This is called when the proxy-minion is exiting to make sure the connection to the device is closed cleanly.
23.13.13 salt.proxy.marathon

Marathon

Proxy minion for managing a Marathon cluster.

Dependencies

- marathon execution module (salt.modules.marathon)

Pillar

The marathon proxy configuration requires a 'base_url' property that points to the marathon endpoint:

```yaml
proxy:
  proxysqltype: marathon
  base_url: http://my-marathon-master.mydomain.com:8080
```

New in version 2015.8.2.

salt.proxy.marathon.init(opts)
  Perform any needed setup.

salt.proxy.marathon.ping()
  Is the marathon api responding?

salt.proxy.marathon.shutdown(opts)
  For this proxy shutdown is a no-op

23.13.14 salt.proxy.napalm

NAPALM: Network Automation and Programmability Abstraction Layer with Multivendor support

New in version 2016.11.0.

Proxy minion for managing network devices via NAPALM library.

codeauthor Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>
maturity new
depends napalm
platform unix
Dependencies

The `napalm` proxy module requires `NAPALM` library to be installed: `pip install napalm`. Please check `Installation` for complete details.

Note: Beginning with Salt release 2017.7.3, it is recommended to use `napalm >= 2.0.0`. The library has been unified into a monolithic package, as in opposite to separate packages per driver. For more details you can check this document. While it will still work with the old packages, bear in mind that the NAPALM core team will maintain only the main `napalm` package.

Moreover, for additional capabilities, the users can always define a library that extends NAPALM's base capabilities and configure the `provider` option (see below).

Pillar

The `napalm` proxy configuration requires the following parameters in order to connect to the network device:

- **driver** Specifies the network device operating system. For a complete list of the supported operating systems please refer to the NAPALM Read the Docs page.
- **host** The IP Address or FQDN to use when connecting to the device. Alternatively, the following field names can be used instead: `hostname`, `fqdn`, `ip`.
- **username** The username to be used when connecting to the device.
- **passwd** The password needed to establish the connection.

Note: This field may not be mandatory when working with SSH-based drivers, and the username has a SSH key properly configured on the device targeted to be managed.

- **optional_args** Dictionary with the optional arguments. Check the complete list of supported optional arguments.
  - **always_alive**: `True` In certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In that case, the user can select to initialize the connection only when needed, by specifying this field to `false`. Default: `true` (maintains the connection with the remote network device).
    
    New in version 2017.7.0.
  - **provider**: `napalm_base` The library that provides the `get_network_device` function. This option is useful when the user has more specific needs and requires to extend the NAPALM capabilities using a private library implementation. The only constraint is that the alternative library needs to have the `get_network_device` function available.
    
    New in version 2017.7.1.
  - **multiprocessing**: `False` Overrides the `multiprocessing` option, per proxy minion. The `multiprocessing` option must be turned off for SSH-based proxies. However, some NAPALM drivers (e.g. Arista, NX-OS) are not SSH-based. As multiple proxy minions may share the same configuration file, this option permits the configuration of the `multiprocessing` option more specifically, for some proxy minions.
    
    New in version 2017.7.2.

Proxy pillar file example:
proxy:
  proxytype: napalm
  driver: junos
  host: core05.nrt02
  username: my_username
  passwd: my_password
  optional_args:
    port: 12201

Example using a user-specific library, extending NAPALM's capabilities, e.g. `custom_napalm_base`:

proxy:
  proxytype: napalm
  driver: ios
  fqdn: cr1.th2.par.as1234.net
  username: salt
  password: ''
  provider: custom_napalm_base

See also:

- **NAPALM grains**: select network devices based on their characteristics
- **NET module**: network basic features
- **Network config state**: Manage the configuration using arbitrary templates
- **NAPALM YANG state**: Manage the configuration according to the YANG models (OpenConfig/IETF)
- **Network ACL module**: Generate and load ACL (firewall) configuration
- **Network ACL state**: Manage the firewall configuration
- **NTP operational and configuration management module**
- **BGP operational and configuration management module**
- **Routes details**
- **SNMP configuration module**
- **Users configuration management**

Note: Beginning with release codename 2019.2.0, any NAPALM command executed when running under a NAPALM Proxy Minion supports the `force_reconnect` magic argument.

Proxy Minions generally establish a connection with the remote network device at the time of the Minion startup and that connection is going to be used forever.

If one would need execute a command on the device but connecting using different parameters (due to various causes, e.g., unable to authenticate the user specified in the Pillar as the authentication system - say TACACS+ is not available, or the DNS resolver is currently down and would like to temporarily use the IP address instead, etc.), it implies updating the Pillar data and restarting the Proxy Minion process restart. In particular cases like that, you can pass the `force_reconnect=True` keyword argument, together with the alternative connection details, to enforce the command to be executed over a separate connection.

For example, if the usual command is `salt '*' net.arp`, you can use the following to connect using a different username instead: `salt '*' net.arp username=my-alt-usr force_reconnect=True`. 

---

[3294 Chapter 23. Salt Module Reference]
salt.proxy.napalm.alive(opts)
    Return the connection status with the remote device.

    New in version 2017.7.0.

salt.proxy.napalm.call(method, *args, **kwargs)
    Calls a specific method from the network driver instance. Please check the readthedocs page for the updated list of getters.

    Parameters
    • method -- specifies the name of the method to be called
    • params -- contains the mapping between the name and the values of the parameters needed to call the method

    Returns A dictionary with three keys:
    • result (True/False): if the operation succeeded
    • out (object): returns the object as-is from the call
    • comment (string): provides more details in case the call failed
    • traceback (string): complete traceback in case of exception. Please submit an issue including this traceback on the correct driver repo and make sure to read the FAQ

    Example:

```python
__proxy__["napalm.call"]("cli"
**{
    'commands': [
        'show version',
        'show chassis fan'
    ]
})
```

salt.proxy.napalm.fns()
    Method called by NAPALM grains module.

salt.proxy.napalm.get_device()
    Returns the network device object.

salt.proxy.napalm.get_grains()
    Retrieve facts from the network device.

salt.proxy.napalm.grains_refresh()
    Refresh the grains.

salt.proxy.napalm.init(opts)
    Opens the connection with the network device.

salt.proxy.napalm.initialized()
    Connection finished initializing?

salt.proxy.napalm.ping()
    Connection open successfully?

salt.proxy.napalm.shutdown(opts)
    Closes connection with the device.
Salt Documentation, Release 3003.1

23.13.15 salt.proxy.netmiko_px

Netmiko

New in version 2019.2.0.
Proxy module for managing network devices via Netmiko.

codeauthor Mircea Ulinic <ping@mirceaulinic.net> & Kirk Byers <ktbyers@twb-tech.com>
maturity new
depends netmiko
platform unix

Dependencies

The netmiko proxy modules requires Netmiko to be installed: pip install netmiko.

Pillar

The netmiko proxy configuration requires the following parameters in order to connect to the network device:

- device_type - Class selection based on device type. Supported options:
  - a10: A10 Networks
  - accedian: Accedian Networks
  - alcatel_aos: Alcatel AOS
  - alcatel_sros: Alcatel SROS
  - apresia_aeos: Apresia AEOS
  - arista_eos: Arista EOS
  - aruba_os: Aruba
  - avaya_ers: Avaya ERS
  - avaya_vsp: Avaya VSP
  - brocade_fastiron: Brocade Fastiron
  - brocade_netiron: Brocade Netiron
  - brocade_nos: Brocade NOS
  - brocade_vdx: Brocade NOS
  - brocade_vyos: VyOS
  - checkpoint_gaia: Check Point GAIA
  - calix_b6: Calix B6
  - ciena_saos: Ciena SAOS
  - cisco_asa: Cisco SA
  - cisco_ios: Cisco IOS
  - cisco_nxos: Cisco NX-os
- cisco_s300: Cisco S300
- cisco_tp: Cisco TpTcCe
- cisco_wlc: Cisco WLC
- cisco_xe: Cisco IOS
- cisco_xr: Cisco XR
- coriant: Coriant
- dell_force10: Dell Force10
- dell_os10: Dell OS10
- dell_powerconnect: Dell PowerConnect
- eltex: Eltex
- enterasys: Enterasys
- extreme: Extreme
- extreme_wing: Extreme Wing
- f5_ltm: F5 LTM
- fortinet: Fortinet
- generic_termserver: TerminalServer
- hp_comware: HP Comware
- hp_procurve: HP Procurve
- huawei: Huawei
- huawei_vrpv8: Huawei VRPV8
- juniper: Juniper Junos
- juniper_junos: Juniper Junos
- linux: Linux
- mellanox: Mellanox
- mrv_optiswitch: MrvOptiswitch
- netapp_cdot: NetAppcDot
- netscaler: Netscaler
- ovs_linux: OvsLinux
- paloalto_panos: Palo Alto Panos
- pluribus: Pluribus
- quanta_mesh: Quanta Mesh
- ruckus_fastiron: Ruckus Fastiron
- ubiquiti_edge: Ubiquiti Edge
- ubiquiti_edgeswitch: Ubiquiti Edge
- vyatta_vyos: VyOS
- vyos: VyOS
- brocade_fastiron_telnet: Brocade Fastiron over Telnet
- brocade_netiron_telnet: Brocade Netiron over Telnet
- cisco_ios_telnet: Cisco IOS over Telnet
- apresia_aeos_telnet: Apresia AEOS over Telnet
- arista_eos_telnet: Arista EOS over Telnet
- hp_procurve_telnet: HP Procurve over Telnet
- hp_comware_telnet: HP Comware over Telnet
- juniper_junos_telnet: Juniper Junos over Telnet
- calix_b6_telnet: Calix B6 over Telnet
- dell_powerconnect_telnet: Dell PowerConnect over Telnet
- generic_termserver_telnet: TerminalServer over Telnet
- extreme_telnet: Extreme Networks over Telnet
- ruckus_fastiron_telnet: Ruckus Fastiron over Telnet
- cisco_ios_serial: Cisco IOS over serial port

- `ip` - IP address of target device (not required if `host` is provided)
- `host` - Hostname of target device (not required if `ip` is provided)
- `username` - Username to authenticate against target device, if required
- `password` - Password to authenticate against target device, if required
- `secret` - The enable password if target device requires one
- `port` - The destination port used to connect to the target device
- `global_delay_factor` - Multiplication factor affecting Netmiko delays (default: 1)
- `use_keys` - Connect to target device using SSH keys (default: False)
- `key_file` - Filename path of the SSH key file to use
- `allow_agent` - Enable use of SSH key-agent
- `ssh_strict` - Automatically reject unknown SSH host keys (default: False, which means unknown SSH host keys will be accepted)
- `system_host_keys` - Load host keys from the user's "known_hosts" file (default: False)
- `alt_host_keys` - If True, host keys will be loaded from the file specified in `alt_key_file` (default: False)
- `alt_key_file` - SSH host key file to use (if `alt_host_keys=True`)
- `ssh_config_file` - File name of OpenSSH configuration file
- `timeout` - Connection timeout, in seconds (default: 90)
- `session_timeout` - Set a timeout for parallel requests, in seconds (default: 60)
- `keepalive` - Send SSH keepalive packets at a specific interval, in seconds. Currently defaults to 0, for backwards compatibility (it will not attempt to keep the connection alive using the KEEPALIVE packets).
- `default_enter` - Character(s) to send to correspond to enter key (default: \n)
- `response_return` - Character(s) to use in normalized return data to represent enter key (default: \n)
- **always_alive** - In certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In that case, the user can select to initialize the connection only when needed, by setting this option to `False`. By default this option is set to `True` (maintains the connection with the remote network device)

- **multiprocessing** - Overrides the `multiprocessing` option, per proxy minion, as the Netmiko communication channel is mainly SSH (default: `False`)

- **connection_timeout** - The number of seconds to attempt to connect to the device in seconds. (default: 300)

**Proxy Pillar Example**

```yaml
proxy:
  proxytype: netmiko
  device_type: juniper_junos
  host: router1.example.com
  username: example
  password: example

proxy:
  proxytype: netmiko
  device_type: cisco_ios
  ip: 1.2.3.4
  username: test
  use_keys: true
  secret: w3@k
```

```python
salt.proxy.netmiko_px.alive(opts)
    Return the connection status with the network device.

call
salt.proxy.netmiko_px.args()  
    Return the Netmiko device args.

salt.proxy.netmiko_px.call(method, *args, **kwargs)
    Calls an arbitrary netmiko method.

call
salt.proxy.netmiko_px.conn()  
    Return the connection object.

salt.proxy.netmiko_px.connection(connection_timeout=300)

salt.proxy.netmiko_px.init(opts)
    Open the connection to the network device managed through netmiko.

salt.proxy.netmiko_px.initialized()
    Connection finished initializing?

salt.proxy.netmiko_px.make_con(connection_timeout=300)

salt.proxy.netmiko_px.ping()  
    Connection open successfully?

salt.proxy.netmiko_px.shutdown(opts)
    Closes connection with the device.
```
23.13.16 salt.proxy.nxos

Proxy Minion for Cisco NX-OS Switches

New in version 2016.11.0.

The Cisco NX-OS Proxy Minion is supported on NX-OS devices for the following connection types: 1) Connection Type SSH 2) Connection Type NX-API (If Supported By The Device and Image Version).

- maturity: new
- platform: nxos

SSH uses the built in SSHConnection module in salt.utils.vt_helper

To configure the proxy minion for ssh:

```
proxy:
    proxytype: nxos
    connection: ssh
    host: 192.168.187.100
    username: admin
    password: admin
    prompt_name: nxos-switch
    ssh_args: '-o PubkeyAuthentication=no'
    key_accept: True
```

To configure the proxy minion for nxapi:

```
proxy:
    proxytype: nxos
    connection: nxapi
    host: 192.168.187.100
    username: admin
    password: admin
    transport: http
    port: 80
    verify: False
    save_config: False
```

proxytype: (REQUIRED) Use this proxy minion nxos

connection: (REQUIRED) connection transport type. Choices: ssh, nxapi Default: ssh

host: (REQUIRED) login ip address or dns hostname.

username: (REQUIRED) login username.

password: (REQUIRED) login password.

save_config: If True, 'copy running-config starting-config' is issues for every configuration command. If False, running config is not saved to startup config Default: True

The recommended approach is to use the save_running_config function instead of this option to improve performance. The default behavior controlled by this option is preserved for backwards compatibility.

Connection SSH Args:

- prompt_name: (REQUIRED when connection is ssh) (REQUIRED, this or prompt_regex below, but not both) The name in the prompt on the switch. Recommended to use your device's hostname.

- prompt_regex: (REQUIRED when connection is ssh) (REQUIRED, this or prompt_name above, but not both) A regular expression that matches the prompt on the switch and any other possible prompt
at which you need the proxy minion to continue sending input. This feature was specifically developed for situations where the switch may ask for confirmation. `prompt_name` above would not match these, and so the session would timeout.

Example:

```
xos-switch#.*|\(y\|n\)\)?.*
```

This should match

```
xos-switch#
```

or

```
Flash complete. Reboot this switch (y/n)? [n]
```

If neither `prompt_name` nor `prompt_regex` is specified the prompt will be defaulted to

```
.+#$
```

which should match any number of characters followed by a # at the end of the line. This may be far too liberal for most installations.

**ssl_args:** Extra optional arguments used for connecting to switch.

**key_accept:** Whether or not to accept the host key of the switch on initial login. Default: `False`

Connection NXAPI Args:

**transport:** (REQUIRED) when `connection` is `nxapi`. Choices: `http`, `https` Default: `https`

**port:** (REQUIRED) when `connection` is `nxapi`. Default: `80`

**verify:** (REQUIRED) when `connection` is `nxapi`. Either a boolean, in which case it controls whether we verify the NX-API TLS certificate, or a string, in which case it must be a path to a CA bundle to use. Default: `True`

When there is no certificate configuration on the device and this option is set as `True` (default), the commands will fail with the following error: `SSLError: [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed (_ssl.c:581)`. In this case, you either need to configure a proper certificate on the device (recommended), or bypass the checks setting this argument as `False` with all the security risks considered.

The functions from the proxy minion can be run from the salt commandline using the `salt.modules.nxos` execution module.

**salt.proxy.nxos.grains()**

Helper function for nxos execution module functions that need to retrieve nxos grains using the proxy minion.

**salt.proxy.nxos.grains_refresh()**

Helper function for nxos execution module functions that need to refresh nxos grains using the proxy minion.

**salt.proxy.nxos.init(opts=None)**

Required. Initialize device connection using ssh or nxapi connection type.
salt.proxy.nxos.initialized()  
Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether the init() function has been called.

salt.proxy.nxos.ping()  
Helper function for nxos execution module functions that need to ping the nxos device using the proxy minion.

salt.proxy.nxos.proxy_config(commands, save_config=None)  
Helper function for nxos execution module functions that need to configure an nxos device using the proxy minion.

salt.proxy.nxos.sendline(commands, method='cli_show_ascii', **kwargs)  
Helper function for nxos execution module functions that need to send commands to an nxos device using the proxy minion.

salt.proxy.nxos.shutdown()  
Not supported. Only used as a place holder to satisfy shutdown function requirement.

23.13.17 salt.proxy.nxos_api  
Proxy Minion to manage Cisco Nexus Switches (NX-OS) over the NX-API  
New in version 2019.2.0.

Proxy module for managing Cisco Nexus switches via the NX-API.

codeauthor Mircea Ulinic <ping@mirceaulinic.net>
maturity new
platform any

Usage

Note: To be able to use this module you need to enable to NX-API on your switch, by executing feature nxapi in configuration mode.

Configuration example:

```
switch# conf t
switch(config)# feature nxapi
```

To check that NX-API is properly enabled, execute show nxapi.

Output example:

```
switch# show nxapi
nxapi enabled
HTTPS Listen on port 443
```

Note: NX-API requires modern NXOS distributions, typically at least 7.0 depending on the hardware. Due to reliability reasons it is recommended to run the most recent version.
Pillar

The `nxos_api` proxy configuration requires the following parameters in order to connect to the network switch:

- **transport**: `https` Specifies the type of connection transport to use. Valid values for the connection are `http` and `https`.
- **host**: `localhost` The IP address or DNS host name of the connection device.
- **username**: `admin` The username to pass to the device to authenticate the NX-API connection.
- **password** The password to pass to the device to authenticate the NX-API connection.
- **port** The TCP port of the endpoint for the NX-API connection. If this keyword is not specified, the default value is automatically determined by the transport type (`80` for `http`, or `443` for `https`).
- **timeout**: `60` Time in seconds to wait for the device to respond. Default: 60 seconds.
- **verify**: `True` Either a boolean, in which case it controls whether we verify the NX-API TLS certificate, or a string, in which case it must be a path to a CA bundle to use. Defaults to `True`.

When there is no certificate configuration on the device and this option is set as `True` (default), the commands will fail with the following error: `SSLError: [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed (_ssl.c:581)`. In this case, you either need to configure a proper certificate on the device (`recommended`), or bypass the checks setting this argument as `False` with all the security risks considered.

All the arguments may be optional, depending on your setup.

## Proxy Pillar Example

```yaml
proxy:
  proxytype: nxos_api
  host: switch1.example.com
  username: example
  password: example
```

- `salt.proxy.nxos_api.get_conn_args()`
  - Returns the connection arguments of the Proxy Minion.

- `salt.proxy.nxos_api.init(opts)`
  - Open the connection to the Nexus switch over the NX-API.

    As the communication is HTTP based, there is no connection to maintain, however, in order to test the connectivity and make sure we are able to bring up this Minion, we are executing a very simple command (`show clock`) which doesn't come with much overhead and it's sufficient to confirm we are indeed able to connect to the NX-API endpoint as configured.

- `salt.proxy.nxos_api.initialized()`
  - Connection finished initializing?
salt.proxy.nxos_api.ping()
  Connection open successfully?
salt.proxy.nxos_api.rpc(commands, method='cli', **kwargs)
  Executes an RPC request over the NX-API.
salt.proxy.nxos_api.shutdown(opts)
  Closes connection with the device.

23.13.18 salt.proxy.panos

Proxy Minion interface module for managing Palo Alto firewall devices

New in version 2018.3.0.

  codeauthor Spencer Ervin <spencer_ervin@hotmail.com>
  maturity new
  depends none
  platform unix

This proxy minion enables Palo Alto firewalls (hereafter referred to as simply `panos`) to be treated individually like a Salt Minion.

The panos proxy leverages the XML API functionality on the Palo Alto firewall. The Salt proxy must have access to the Palo Alto firewall on HTTPS (`tcp/443`).

More in-depth conceptual reading on Proxy Minions can be found in the `Proxy Minion` section of Salt's documentation.

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. There are four connection options available for the panos proxy module.

  - Direct Device (Password)
  - Direct Device (API Key)
  - Panorama Pass-Through (Password)
  - Panorama Pass-Through (API Key)
Direct Device (Password)

The direct device configuration configures the proxy to connect directly to the device with username and password.

```yaml
proxy:
  proxytype: panos
  host: <ip or dns name of panos host>
  username: <panos username>
  password: <panos password>
  verify_ssl: True
```

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.

**host**

The location, or ip/dns, of the panos host. Required.

**username**

The username used to login to the panos host. Required.

**password**

The password used to login to the panos host. Required.

Direct Device (API Key)

Palo Alto devices allow for access to the XML API with a generated ‘API key’ instead of username and password.

```yaml
proxy:
  proxytype: panos
  host: <ip or dns name of panos host>
  apikey: <panos generated api key>
```

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.
host

The location, or ip/dns, of the panos host. Required.

apikey

The generated XML API key for the panos host. Required.

Panorama Pass-Through (Password)

The Panorama pass-through method sends all connections through the Panorama management system. It passes the connections to the appropriate device using the serial number of the Palo Alto firewall.

This option will reduce the number of connections that must be present for the proxy server. It will only require a connection to the Panorama server.

The username and password will be for authentication to the Panorama server, not the panos device.

```
proxy:
  proxytype: panos
  serial: <serial number of panos host>
  host: <ip or dns name of the panorama server>
  username: <panorama server username>
  password: <panorama server password>
```

proxytype

The proxytype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt’s install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to panos.

serial

The serial number of the panos host. Required.

host

The location, or ip/dns, of the Panorama server. Required.

username

The username used to login to the Panorama server. Required.
password

The password used to login to the Panorama server. Required.

Panorama Pass-Through (API Key)

The Panorama server can also utilize a generated 'API key' for authentication.

<table>
<thead>
<tr>
<th>proxy:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>proxotype</strong>: panos</td>
</tr>
<tr>
<td><strong>serial</strong>: &lt;serial number of panos host&gt;</td>
</tr>
<tr>
<td><strong>host</strong>: &lt;ip or dns name of the panorama server&gt;</td>
</tr>
<tr>
<td><strong>apikey</strong>: &lt;panos generated api key&gt;</td>
</tr>
</tbody>
</table>

proxytype

The `proxotype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.

serial

The serial number of the panos host. Required.

host

The location, or ip/dns, of the Panorama server. Required.

apikey

The generated XML API key for the Panorama server. Required.

```python
call(payload=None)
```

This function captures the query string and sends it to the Palo Alto device.

```python
grains()
```

Get the grains from the proxied device

```python
grains_refresh()
```

Refresh the grains from the proxied device

```python
init(opts)
```

This function gets called when the proxy starts up. For panos devices, a determination is made on the connection type and the appropriate connection details that must be cached.

```python
initialized()
```

Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

```python
is_required_version(required_version='0.0.0')
```

Because different versions of Palo Alto support different command sets, this function will return true if the current version of Palo Alto supports the required command.
salt.proxy.panos.ping()
   Returns true if the device is reachable, else false.
salt.proxy.panos.shutdown()
   Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

23.13.19 salt.proxy.philips_hue

Philips HUE lamps module for proxy.
New in version 2015.8.3.
First create a new user on the Hue bridge by following the Meet hue instructions.
To configure the proxy minion:

```
proxy:
   proxytype: philips_hue
   host: [hostname or ip]
   user: [username]
```

class salt.proxy.philips_hue.Const
   Constants for the lamp operations.
   COLOR_BLUE = {'hue': 46920, 'sat': 254}
   COLOR_DAYLIGHT = {'xy': [0.3806, 0.3576]}
   COLOR_GREEN = {'hue': 25500, 'sat': 254}
   COLOR_ORANGE = {'hue': 12000, 'sat': 254}
   COLOR_PINK = {'xy': [0.3688, 0.2095]}
   COLOR_PURPLE = {'xy': [0.3787, 0.1724]}
   COLOR_RED = {'hue': 0, 'sat': 254}
   COLOR_WHITE = {'xy': [0.3227, 0.329]}
   COLOR_YELLOW = {'xy': [0.4432, 0.5154]}
   LAMP_OFF = {'on': False, 'transitiontime': 0}
   LAMP_ON = {'on': True, 'transitiontime': 0}
salt.proxy.philips_hue.call_alert(*args, **kwargs)
   Lamp alert
   Options:
   • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
   • on: Turns on or off an alert. Default is True.
   CLI Example:
   ```
salt '*' hue.alert
salt '*' hue.alert id=1
salt '*' hue.alert id=1,2,3 on=false
```
salt.proxy.philips_hue.call_blink(*args, **kwargs)
   Blink a lamp. If lamp is ON, then blink ON-OFF-ON, otherwise OFF-ON-OFF.
   Options:
   • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
• \texttt{pause}: Time in seconds. Can be less than 1, i.e. 0.7, 0.5 sec.

CLI Example:

```
salt '*' hue.blink id=1
salt '*' hue.blink id=1,2,3
```

\texttt{salt.proxy.philips_hue.call_brightness(*args,**kwargs)}

Set an effect to the lamp.

Arguments:
• \texttt{value}: 0–255 brightness of the lamp.

Options:
• \texttt{id}: Specifies a device ID. Can be a comma-separated values. All, if omitted.
• \texttt{transition}: Transition 0–200. Default 0.

CLI Example:

```
salt '*' hue.brightness value=100
salt '*' hue.brightness id=1 value=150
salt '*' hue.brightness id=1,2,3 value=255
```

\texttt{salt.proxy.philips_hue.call_color(*args,**kwargs)}

Set a color to the lamp.

Options:
• \texttt{id}: Specifies a device ID. Can be a comma-separated values. All, if omitted.
• \texttt{color}: Fixed color. Values are: \texttt{red}, \texttt{green}, \texttt{blue}, \texttt{orange}, \texttt{pink}, \texttt{white}, \texttt{yellow}, \texttt{daylight}, \texttt{purple}. Default \texttt{white}.
• \texttt{transition}: Transition 0–200.

Advanced:
• \texttt{gamut}: XY coordinates. Use gamut according to the Philips HUE devices documentation. More: \url{http://www.developers.meethue.com/documentation/hue-xy-values}

CLI Example:

```
salt '*' hue.color
salt '*' hue.color id=1
salt '*' hue.color id=1,2,3 color=red transition=30
salt '*' hue.color id=1 gamut=0.3,0.5
```

\texttt{salt.proxy.philips_hue.call_effect(*args,**kwargs)}

Set an effect to the lamp.

Options:
• \texttt{id}: Specifies a device ID. Can be a comma-separated values. All, if omitted.
• \texttt{type}: Type of the effect. Possible values are "none" or "colorloop". Default "none".

CLI Example:

```
salt '*' hue.effect
salt '*' hue.effect id=1
salt '*' hue.effect id=1,2,3 type=colorloop
```

\texttt{salt.proxy.philips_hue.call_lights(*args,**kwargs)}

Get info about all available lamps.

Options:
• \texttt{id}: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
salt '::*' hue.lights
salt '::*' hue.lights id=1
salt '::*' hue.lights id=1,2,3

salt.proxy.philips_hue.call_ping('args', '**kwargs')
    Ping the lamps by issuing a short inversion blink to all available devices.
    CLI Example:
    salt '::*' hue.ping

salt.proxy.philips_hue.call_rename('args', '**kwargs')
    Rename a device.
    Options:
    • id: Specifies a device ID. Only one device at a time.
    • title: Title of the device.
    CLI Example:
    salt '::*' hue.rename id=1 title='WC for cats'

salt.proxy.philips_hue.call_status('args', '**kwargs')
    Return the status of the lamps.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    CLI Example:
    salt '::*' hue.status
    salt '::*' hue.status id=1
    salt '::*' hue.status id=1,2,3

salt.proxy.philips_hue.call_switch('args', '**kwargs')
    Switch lamp ON/OFF.
    If no particular state is passed, then lamp will be switched to the opposite state.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    • on: True or False. Inverted current, if omitted
    CLI Example:
    salt '::*' hue.switch
    salt '::*' hue.switch id=1
    salt '::*' hue.switch id=1,2,3 on=True

salt.proxy.philips_hue.call_temperature('args', '**kwargs')
    Set the mired color temperature. More: http://en.wikipedia.org/wiki/Mired
    Arguments:
    • value: 150–500.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    CLI Example:
    salt '::*' hue.temperature value=150
    salt '::*' hue.temperature value=150 id=1
    salt '::*' hue.temperature value=150 id=1,2,3
salt.proxy.philips_hue.init(cnf)
Initialize the module.
salt.proxy.philips_hue.ping(*args, **kw)
Ping the lamps.
salt.proxy.philips_hue.shutdown(opts, *args, **kw)
Shuts down the service.

23.13.20 salt.proxy.rest_sample

This is a simple proxy-minion designed to connect to and communicate with the bottle-based web service contained in https://github.com/saltstack/salt-contrib/tree/master/proxyminion_rest_example

salt.proxy.rest_sample.alive(opts)
salt.proxy.rest_sample.fix_outage()
salt.proxy.rest_sample.fns()
salt.proxy.rest_sample.grains()
Get the grains from the proxied device
salt.proxy.rest_sample.grains_refresh()
Refresh the grains from the proxied device
salt.proxy.rest_sample.id(opts)
Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion
salt.proxy.rest_sample.init(opts)
salt.proxy.rest_sample.initialized()
Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called
salt.proxy.rest_sample.package_install(name, **kwargs)
Install a "package" on the REST server
salt.proxy.rest_sample.package_list()
List "packages" installed on the REST server
salt.proxy.rest_sample.package_remove(name)
Remove a "package" on the REST server
salt.proxy.rest_sample.package_status(name)
Check the installation status of a package on the REST server
salt.proxy.rest_sample.ping()
Is the REST server up?
salt.proxy.rest_sample.service_list()
List "services" on the REST server
salt.proxy.rest_sample.service_restart(name)
Restart a "service" on the REST server
salt.proxy.rest_sample.service_start(name)
Start a "service" on the REST server
salt.proxy.rest_sample.service_status(name)
Check if a service is running on the REST server

23.13. proxy modules
salt.proxy.rest_sample.service_stop(name)
   Stop a "service" on the REST server

salt.proxy.rest_sample.shutdown(opts)
   For this proxy shutdown is a no-op

salt.proxy.rest_sample.test_from_state()
   Test function so we have something to call from a state :return:

salt.proxy.rest_sample.uptodate(name)
   Call the REST endpoint to see if the packages on the "server" are up to date.

23.13.21 salt.proxy.ssh_sample

This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH. This can be used as an option when the device does not provide an api over HTTP and doesn't have the python stack to run a minion.

salt.proxy.ssh_sample.fns()
   Method called by grains module.

salt.proxy.ssh_sample.grains()
   Get the grains from the proxied device

salt.proxy.ssh_sample.grains_refresh()
   Refresh the grains from the proxied device

salt.proxy.ssh_sample.init(opts)
   Required. Can be used to initialize the server connection.

salt.proxy.ssh_sample.initialized()
   Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.ssh_sample.package_install(name, "**kwargs")
   Install a "package" on the ssh server

salt.proxy.ssh_sample.package_list()
   List "packages" by executing a command via ssh This function is called in response to the salt command

   salt target_minion pkg.list_pkgs

salt.proxy.ssh_sample.package_remove(name)
   Remove a "package" on the ssh server

salt.proxy.ssh_sample.parse(out)
   Extract json from out.
   Parameter out: Type string. The data returned by the ssh command.

salt.proxy.ssh_sample.ping()
   Required. Ping the device on the other end of the connection

salt.proxy.ssh_sample.service_list()
   Start a "service" on the ssh server
   New in version 2015.8.2.

salt.proxy.ssh_sample.service_restart(name)
   Restart a "service" on the ssh server
   New in version 2015.8.2.
**salt.proxy.ssh_sample.service_start(name)**
Start a "service" on the ssh server
New in version 2015.8.2.

**salt.proxy.ssh_sample.service_stop(name)**
Stop a "service" on the ssh server
New in version 2015.8.2.

**salt.proxy.ssh_sample.shutdown(opts)**
Disconnect

---

### 23.13.22 salt.proxy.vcenter

Proxy Minion interface module for managing VMWare vCenters.

- **codeauthor** Rod McKenzie (roderick.mckenzie@morganstanley.com)
- **codeauthor** Alexandru Bleotu (alexdandru.bleotu@morganstanley.com)

**Dependencies**

- pyVmomi Python Module

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See [Issue #29537](https://github.com/saltstack/salt/issues/29537) for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**Configuration**

To use this proxy module, please use one of the following configurations:

```yaml
proxy:
  proxitype: vcenter
  vcenter: <ip or dns name of parent vcenter>
  username: <vCenter username>
  mechanism: userpass
  passwords:
```

(continues on next page)
proxy:

proxytype: vcenter
vcenter: <ip or dns name of parent vcenter>
username: <vCenter username>
domain: <user domain>
mechanism: sspi
principal: <host kerberos principal>

proxytype

The proxytype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this Proxy Module, set this to vcenter.

vcenter

The location of the VMware vCenter server (host of ip). Required

username

The username used to login to the vcenter, such as root. Required only for userpass.

mechanism

The mechanism used to connect to the vCenter server. Supported values are userpass and sspi. Required.

passwords

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is userpass

The proxy integration will try the passwords listed in order.

domain

User domain. Required if mechanism is sspi
principal

Kerberos principal. Required if mechanism is sspi.

protocol

If the vCenter is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id of the cluster>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the vcenter host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the vCenter. For example, you can get if the proxy can actually connect to the vCenter:

```
salt <id> vsphere.test_vcenter_connection
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. Salt.modules.vsphere is a standard Salt execution module.

If you pull up the docs for it you'll see that almost every function in the module takes credentials and a targets either a vcenter or a host. When credentials and a host aren't passed, Salt runs commands through pyVmomi against the
local machine. If you wanted, you could run functions from this module on any host where an appropriate version
of pyVmomi is installed, and that host would reach out over the network and communicate with the ESXi host.

salt.proxy.vcenter.find_credentials()
  Cycle through all the possible credentials and return the first one that works.

salt.proxy.vcenter.get_details()
  Function that returns the cached details

salt.proxy.vcenter.init(opts)
  This function gets called when the proxy starts up. For login the protocol and port are cached.

salt.proxy.vcenter.ping()
  Returns True.
  CLI Example:
  ```
  salt vcenter test.ping
  ```

salt.proxy.vcenter.shutdown()
  Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

23.14 queue modules

<table>
<thead>
<tr>
<th>pgjsonb_queue</th>
<th>New in version 2016.3.0.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlite_queue</td>
<td>New in version 2014.7.0.</td>
</tr>
</tbody>
</table>

23.14.1 salt.queues.pgjsonb_queue

New in version 2016.3.0.

This is a queue with postgres as the backend. It uses the jsonb store to store information for queues.

```
depends python-psycopg2
```

To enable this queue, the following needs to be configured in your master config. These are the defaults:

```
queue.pgjsonb.host: 'salt'
queue.pgjsonb.user: 'salt'
queue.pgjsonb.password: 'salt'
queue.pgjsonb.dbname: 'salt'
queue.pgjsonb.port: 5432
```

Use the following Pg database schema:

```
CREATE DATABASE salt WITH ENCODING 'utf-8';
```

```
--
-- Table structure for table `salt`
```

```
DROP TABLE IF EXISTS salt;
CREATE OR REPLACE TABLE salt(
  id SERIAL PRIMARY KEY,
```

(continues on next page)
data jsonb NOT NULL
);

salt-run queue.insert test '{"name": "redis", "host": "172.16.0.8", "port": 6379}" _backend=pgjsonb
salt-run queue.process_queue test all backend=pgjsonb

salt.queues.pgjsonb_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.pgjsonb_queue.handle_queue_creation(queue)
salt.queues.pgjsonb_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.pgjsonb_queue.list_items(queue)
    List contents of a queue
salt.queues.pgjsonb_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.pgjsonb_queue.list_queues()
    Return a list of Salt Queues on the Salt Master
salt.queues.pgjsonb_queue.pop(queue, quantity=1, is_runner=False)
    Pop one or more or all items from the queue return them.

23.14.2 salt.queues.sqlite_queue

New in version 2014.7.0.

This is the default local master event queue built on sqlite. By default, an sqlite3 database file is created in the
sqlite_queue_dir which is found at:

/var/cache/salt/master/queues

It's possible to store the sqlite3 database files by setting sqlite_queue_dir to another location:

sqlite_queue_dir: /home/myuser/salt/master/queues

salt.queues.sqlite_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.sqlite_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.sqlite_queue.list_items(queue)
    List contents of a queue
salt.queues.sqlite_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.sqlite_queue.list_queues()
    Return a list of Salt Queues on the Salt Master
salt.queues.sqlite_queue.pop(queue, quantity=1, is_runner=False)
    Pop one or more or all items from the queue return them.
23.15 roster modules

<table>
<thead>
<tr>
<th>roster</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ansible</td>
<td>Read in an Ansible inventory file or script</td>
</tr>
<tr>
<td>cache</td>
<td>The cache roster provides a flexible interface to the Salt Masters' minion cache to access regular minions over salt-ssh.</td>
</tr>
<tr>
<td>cloud</td>
<td>Use the cloud cache on the master to derive IPv4 addresses based on minion ID.</td>
</tr>
<tr>
<td>clustershell</td>
<td>This roster resolves hostname in a pdsh/clustershell style.</td>
</tr>
<tr>
<td>flat</td>
<td>Read in the roster from a flat file using the renderer system</td>
</tr>
<tr>
<td>range</td>
<td>This roster resolves targets from a range server.</td>
</tr>
<tr>
<td>scan</td>
<td>Scan a netmask or ipaddr for open ssh ports</td>
</tr>
<tr>
<td>sshconfig</td>
<td>Parses roster entries out of Host directives from SSH config</td>
</tr>
<tr>
<td>terraform</td>
<td>Dynamic roster from terraform current state</td>
</tr>
</tbody>
</table>

23.15.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```yaml
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password'

[computers:children]
desktop
servers

[names:vars]
http_port=80
```

then salt-ssh can be used to hit any of them

```bash
[~]$ salt-ssh -N all test.ping
salt.gtmanfred.com:
  True
home:
  True
[~]$ salt-ssh -N desktop test.ping
home:
  True
[~]$ salt-ssh -N computers test.ping
salt.gtmanfred.com:
  True
home:
  True
```

(continues on next page)
There is also the option of specifying a dynamic inventory, and generating it on the fly

```
#!/bin/bash

echo "{
    "servers": ["salt.gtmanfred.com"],
    "desktop": ["home"],
    "computers": {
        "hosts": [],
        "children": [
            "desktop",
            "servers"
        ]
    },
    "_meta": {
        "hostvars": {
            "salt.gtmanfred.com": {
                "ansible_ssh_user": "gtmanfred",
                "ansible_ssh_host": "127.0.0.1",
                "ansible_sudo_pass": "password",
                "ansible_ssh_port": 22
            },
            "home": {
                "ansible_ssh_user": "gtmanfred",
                "ansible_ssh_host": "12.34.56.78",
                "ansible_sudo_pass": "password",
                "ansible_ssh_port": 23
            }
        }
    }
}
"
```

This is the format that an inventory script needs to output to work with ansible, and thus here.

```
[~]# salt-ssh --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com:
    True
```

Any of the [groups] or direct hostnames will return. The ‘all’ is special, and returns everything.

```
salt.roster.ansible.targets(tgt, tgt_type='glob', **kwargs)
```

Return the targets from the ansible inventory_file Default: /etc/salt/roster
23.15.2 salt.roster.cache

The cache roster provides a flexible interface to the Salt Masters’ minion cache to access regular minions over salt-ssh.

New in version 2017.7.0: grains, pillar, mine data matching SDB URLs IPv6 support roster_order per config key default order changed to industry-wide best practices CIDR range selection

Targeting

This roster supports all matching and targeting of the Salt Master. The matching will be done using only the Salt Master’s cache.

The Roster Order

The roster’s composition can be configured using roster_order. In the roster_order you can define any roster key and fill it with a parameter overriding the one in roster_defaults:

```
roster_order:
  host: id  # use the minion id as hostname
```

You can define lists of parameters as well, the first result from the list will become the value.

Selecting a host

```
# default
roster_order:
  host:
    - ipv6-private  # IPv6 addresses in private ranges
    - ipv6-global   # IPv6 addresses in global ranges
    - ipv4-private  # IPv4 addresses in private ranges
    - ipv4-public   # IPv4 addresses in public ranges
    - ipv4-local    # loopback addresses
```

This is the default roster_order. It prefers IPv6 over IPv4 addresses and private addresses over public ones. The relevant data will be fetched from the cache in-order, and the first match will fill the host key.

Other address selection parameters are also possible:

```
roster_order:
  host:
    - global|public|private|local       # Both IPv6 and IPv4 addresses in that range
    - 2000::/3                             # CIDR networks, both IPv4 and IPv6 are supported
```
Using cached data

Several cached libraries can be selected using the library:``` prefix, followed by the library key. This can be referenced using the same ``` syntax as e.g. pillar.get. Lists of references are also supported during the lookup, as are Salt SDB URLs.

This should be especially useful for the other roster keys:

```yaml
roster_order:
  host:
    - grain: fqdn_ip4 # Lookup this grain
    - mine: network.ip_addrs # Mine data lookup works the same
  password: sdb://vault/ssh_pass # Salt SDB URLs are also supported
user:
  - pillar: ssh:auth:user # Lookup this pillar key
  - sdb://osenv/USER # Lookup this env var through sdb
priv:
  - pillar: # Lists are also supported
    - salt:ssh:private_key
    - ssh:auth:private_key
```

`salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets from the Salt Masters’ minion cache. All targets and matchers are supported.

The resulting roster can be configured using `roster_order` and `roster_default`.

### 23.15.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.

This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

To connect as a user other than root, modify the cloud configuration file usually located at `/etc/salt/cloud`. For example, add the following:

```yaml
ssh_username: my_user
sudo: True
```

`salt.roster.cloud.extract_ipv4(roster_order, ipv4)`

Extract the preferred IP address from the ipv4 grain

`salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets from the flat yaml file, checks opts for location but defaults to `/etc/salt/roster`
23.15.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

depends clustershell, https://github.com/cea-hpc/clustershell

When you want to use host globs for target matching, use --roster clustershell. For example:

```bash
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping
```

salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)

Return the targets

23.15.5 salt.roster.flat

Read in the roster from a flat file using the renderer system

salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

23.15.6 salt.roster.range

This roster resolves targets from a range server.

depends seco.range, https://github.com/ytoolshed/range

When you want to use a range query for target matching, use --roster range. For example:

```bash
salt-ssh --roster range '%%%example.range.cluster' test.ping
```

salt.roster.range.target_glob(tgt, hosts)
salt.roster.range.target_range(tgt, hosts)
salt.roster.range.targets(tgt, tgt_type='range', **kwargs)

Return the targets from a range query

23.15.7 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports

class salt.roster.scan.RosterMatcher(tgt, tgt_type)

Matcher for the roster data structure

targets()

Return ip addrs based on netmask, sitting in the "glob" spot because it is the default

salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
23.15.8 salt.roster.sshconfig

Parses roster entries out of Host directives from SSH config

```bash
class salt.roster.sshconfig.RosterMatcher(raw, tgt, tgt_type)
    Matcher for the roster data structure
    get_data(minion)
        Return the configured ip
    ret_glob_minions()
        Return minions that match via glob
    targets()
        Execute the correct tgt_type routine and return

salt.roster.sshconfig.parse_ssh_config(lines)
    Parses lines from the SSH config to create roster targets.
    Parameters lines -- Individual lines from the ssh config file
    Returns Dictionary of targets in similar style to the flat roster

salt.roster.sshconfig.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
```

23.15.9 salt.roster.terraform

Dynamic roster from terraform current state

This roster module allows you dynamically generate the roster from the terraform resources defined with the Terraform Salt provider.

It exposes all salt_host resources with the same attributes to the salt-ssh roster, making it completely independent of the type of terraform resource, and providing the integration using terraform constructs with interpolation.

Basic Example

Given a simple salt-ssh tree with a Saltfile:

```yaml
salt-ssh:
    config_dir: etc/salt
    max_procs: 30
    wipe_ssh: True
```

and etc/salt/master:

```yaml
root_dir: .
file_roots:
    base:
        - srv/salt
pillar_roots:
    base:
        - srv/pillar
roster: terraform
```
In the same folder as your **Saltfile**, create terraform file with resources like cloud instances, virtual machines, etc. For every single one of those that you want to manage with Salt, create a `salt_host` resource:

```hcl
resource "salt_host" "dbminion" {
  salt_id = "dbserver"
  host = "${libvirt_domain.vm-db.network_interface.0.addresses.0}"
  user = "root"
  passwd = "linux"
}
```

You can use the count attribute to create multiple roster entries with a single definition. Please refer to the Terraform Salt provider for more detailed examples.

```hcl
salt.roster.terraform.targets(tgt, tgt_type='glob', **kwargs)
```

Returns the roster from the terraform state file, checks opts for location, but defaults to terraform.tfstate

### 23.16 runner modules

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asam</code></td>
<td>Novell ASAM Runner</td>

**maintainer** SaltStack

**venafiapi** | Support for Venafi
**virt**      | Control virtual machines via Salt
**vistara**   | Vistara Runner
**winrepo**   | Runner to manage Windows software repo

### 23.16.1 salt.runners.asam

**Novell ASAM Runner**

New in version 2015.8.0.

Runner to interact with Novell ASAM Fan-Out Driver

**codeauthor** Nitin Madhok <nmadhok@g.clemson.edu>

To use this runner, set up the Novell Fan-Out Driver URL, username and password in the master configuration at `/etc/salt/master` or `/etc/salt/master.d/asam.conf`:

```yaml
asam:
  prov1.domain.com
  username: "testuser"
  password: "verybadpass"
  verify_ssl: true
  prov2.domain.com
  username: "testuser"
  password: "verybadpass"
  verify_ssl: true
```

23.16. runner modules 3325
Note: Optionally, protocol and port can be specified if the Fan-Out Driver server is not using the defaults. Default is protocol: https and port: 3451.

salt.runners.asam.add_platform(name, platform_set, server_url)
   To add an ASAM platform using the specified ASAM platform set on the Novell Fan-Out Driver
   CLI Example:
   ```
salt-run asam.add_platform my-test-vm test-platform-set prov1.domain.com
   ```

salt.runners.asam.list_platform_sets(server_url)
   To list all ASAM platform sets present on the Novell Fan-Out Driver
   CLI Example:
   ```
salt-run asam.list_platform_sets prov1.domain.com
   ```

salt.runners.asam.list_platforms(server_url)
   To list all ASAM platforms present on the Novell Fan-Out Driver
   CLI Example:
   ```
salt-run asam.list_platforms prov1.domain.com
   ```

salt.runners.asam.remove_platform(name, server_url)
   To remove specified ASAM platform from the Novell Fan-Out Driver
   CLI Example:
   ```
salt-run asam.remove_platform my-test-vm prov1.domain.com
   ```

23.16.2 salt.runners.auth

Authentication runner for creating, deleting, and managing eauth tokens.

New in version 2016.11.0.

salt.runners.auth.del_token(token)
   Delete an eauth token by name
   CLI Example:
   ```
salt-run auth.del_token 6556760736e4077daa601baec2b67c24
   ```

salt.runners.auth.mk_token(**load)
   Create an eauth token using provided credentials
   Non-root users may specify an expiration date -- if allowed via the token_expire_user_override setting -- by passing an additional token_expire param. This overrides the token_expire setting of the same name in the Master config and is how long a token should live in seconds.
   CLI Example:
   ```
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto
   # Create a token valid for three years.
   ```
   ```
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \\
   ```
   (continues on next page)
23.16.3 salt.runners.bgp

BGP Finder

New in version 2017.7.0.
Runner to search BGP neighbors details.

Configuration

• Minion (proxy) config

The `bgp.neighbors` function must be appended in the list of `mine_functions`:

```
mine_functions:
  bgp.neighbors: []
```

Which instructs Salt to cache the data returned by the `neighbors` function from the `NAPALM BGP module`.

How often the mines are refreshed, can be specified using:

```
mine_interval: <X minutes>
```

• Master config

By default the following options can be configured on the master. They are not mandatory, but available in case the user has different requirements.

tgt: * From what minions will collect the mine data. Default: * (collect mine data from all minions)

Some fields cannot be removed:

- `as_number`: the AS number of the neighbor
- `device`: the minion ID
- `neighbor_address`: the neighbor remote IP address

By default, the following extra fields are returned (displayed):

- `connection_stats`: connection stats, as described below
- `import_policy`: the name of the import policy
- `export_policy`: the name of the export policy

---

```
token_expire=94670856

# Calculate the number of seconds using expr.
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \
  token_expire=$(expr \( 365 \* 24 \* 60 \* 60 \) \* 3)
```
Special fields:

- `vrf`: return the name of the VRF.
- `connection_stats`: returning an output of the form `<State> <Active>/ <Received>/<Accepted>/<Damped>`, e.g. Established 398/399/399/0 similar to the usual output from network devices.
- `interface_description`: matches the neighbor details with the corresponding interface and returns its description. This will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.
- `interface_name`: matches the neighbor details with the corresponding interface and returns the name. Similar to `interface_description`, this will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.

**display:** **True** Display on the screen or return structured object? Default: **True** (return on the CLI).

**outputter:** **table** Specify the outputter name when displaying on the CLI. Default: **table**.

Configuration example:

```python
runners:
bgp:
  tgt: 'edge*'  
tgt_type: 'glob'
  return_fields:
    - up
    - connection_state
    - previous_connection_state
    - suppress_4byte_as
    - holdtime
    - flap_count
  outputter: yaml
```

`salt.runners.bgp.neighbors`(*asns, **kwargs*)

Search for BGP neighbors details in the mines of the `bgp.neighbors` function.

Arguments:

- `asns` A list of AS numbers to search for. The runner will return only the neighbors of these AS numbers.
- `device` Filter by device name (minion ID).
- `ip` Search BGP neighbor using the IP address. In multi-VRF environments, the same IP address could be used by more than one neighbors, in different routing tables.
- `network` Search neighbors within a certain IP network.
- `title` Custom title.

**display:** **True** Display on the screen or return structured object? Default: **True** (return on the CLI).

**outputter:** **table** Specify the outputter name when displaying on the CLI. Default: **table**.

In addition, any field from the output of the `neighbors` function from the `NAPALM BGP module` can be used as a filter.

CLI Example:

```
salt-run bgp.neighbors 13335 15169
salt-run bgp.neighbors 13335 ip=172.17.19.1
salt-run bgp.neighbors multipath=True
salt-run bgp.neighbors up=False export_policy=my-export-policy multihop=False
salt-run bgp.neighbors network=192.168.0.0/16
```
Output example:

<table>
<thead>
<tr>
<th>Device</th>
<th>AS Number</th>
<th>Neighbor Address</th>
<th>State</th>
<th>#Active/Received/Accepted/Damped</th>
<th>Policy IN</th>
<th>Policy OUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>13335</td>
<td>172.17.109.11</td>

<td>export-policy</td>
</tr>
</tbody>
</table>

23.16.4 salt.runners.cache

Return cached data from minions

```python
salt.runners.cache.clear_all(tgt=None, tgt_type='glob')
```

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:

```bash
salt-run cache.clear_all
```

```python
salt.runners.cache.clear_git_lock(role, remote=None, **kwargs)
```

New in version 2015.8.2.
Remove the update locks for Salt components (gitfs, git_pillar, winrepo) which use gitfs backend code from salt.utils.gitfs.

Note: Running `cache.clear_all` will not include this function as it does for pillar, grains, and mine.

Additionally, executing this function with a role of `gitfs` is equivalent to running `salt-run fileserver.clear_lock backend=git`.

**role** Which type of lock to remove (gitfs, git_pillar, or winrepo)
**remote** If specified, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `github` will remove the lock from all github.com remotes.
**type** [update, checkout, mountpoint] The types of lock to clear. Can be one or more of `update`, `checkout`, and `mountpoint`, and can be passed either as a comma-separated or Python list.

Changed in version 2018.3.0: mountpoint lock type added

CLI Examples:

```
salt-run cache.clear_git_lock gitfs
salt-run cache.clear_git_lock git_pillar
salt-run cache.clear_git_lock git_pillar type=update
salt-run cache.clear_git_lock git_pillar type=update,checkout
salt-run cache.clear_git_lock git_pillar type='["update", "mountpoint"]'
```

salt.runners.cache.clear_grains(tgt=None, tgt_type='glob')

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached grains data of the targeted minions

CLI Example:

```
salt-run cache.clear_grains
```

salt.runners.cache.clear_mine(tgt=None, tgt_type='glob')

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine data of the targeted minions

CLI Example:

```
salt-run cache.clear_mine
```

salt.runners.cache.clear_mine_func(tgt=None, tgt_type='glob', clear_mine_func_flag=None)

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine function data of the targeted minions

CLI Example:

```
salt-run cache.clear_mine_func tgt='*' clear_mine_func_flag='network.interfaces'
```

salt.runners.cache.clear_pillar(tgt=None, tgt_type='glob')

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`. 
Clear the cached pillar data of the targeted minions

CLI Example:

```
salt-run cache.clear_pillar
```

**salt.runners.cache.cloud** *(tgt, provider=None)*

Return cloud cache data for target.

Note: Only works with glob matching

tgt  Glob Target to match minion ids
provider  Cloud Provider

CLI Example:

```
salt-run cache.cloud 'salt*'  
salt-run cache.cloud glance.example.org provider=openstack
```

**salt.runners.cache.fetch** *(bank, key, cachedir=None)*

Fetch data from a salt.cache bank.

CLI Example:

```
salt-run cache.fetch cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

**salt.runners.cache.flush** *(bank, key=None, cachedir=None)*

Remove the key from the cache bank with all the key content. If no key is specified remove the entire bank with all keys and sub-banks inside.

CLI Examples:

```
salt-run cache.flush cloud/active/ec2/myec2  
salt-run cache.flush cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

**salt.runners.cache.grains** *(tgt, tgt_type='glob', **kwargs)*

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Return cached grains of the targeted minions.

tgt  Target to match minion ids.

Changed in version 2017.7.5,2018.3.0: The tgt argument is now required to display cached grains. If not used, the function will not return grains. This optional argument will become mandatory in the Salt 3001 release.

tgt_type  The type of targeting to use for matching, such as glob, list, etc.

CLI Example:

```
salt-run cache.grains '*'
```

**salt.runners.cache.list** *(bank, cachedir=None)*

Lists entries stored in the specified bank.

CLI Example:

```
salt-run cache.list cloud/active/ec2/myec2 cachedir=/var/cache/salt/
```
salt.runners.cache.mine(tgt=None, tgt_type='glob', **kwargs)

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Return cached mine data of the targeted minions

CLI Example:
```
salt-run cache.mine
```

salt.runners.cache.pillar(tgt=None, tgt_type='glob', **kwargs)

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Return cached pillars of the targeted minions if tgt is set. If tgt is not set will return cached pillars for all minions.

CLI Example:
```
salt-run cache.pillar
```

salt.runners.cache.store(bank, key, data, cachedir=None)

Lists entries stored in the specified bank.

CLI Example:
```
salt-run cache.store mycache mykey 'The time has come the walrus said'
```

23.16.5 salt.runners.cloud

The Salt Cloud Runner

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, opts=None, **kwargs)

Execute a single action on the given map/provider/instance

CLI Example:
```
salt-run cloud.action start my-salt-vm
```

salt.runners.cloud.create(provider, instances, opts=None, **kwargs)

Create an instance using Salt Cloud

CLI Example:
```
salt-run cloud.create my-ec2-config myinstance
    image=ami-1624987f size='t1.micro' ssh_username=ec2-user
    securitygroup=default delvol_on_destroy=True
```

salt.runners.cloud.destroy(instances, opts=None)

Destroy the named vm(s)

salt.runners.cloud.full_query(query_type='list_nodes_full')

List all available cloud provider data
salt.runners.cloud.list_images(provider='all')
List cloud provider images for the given providers

salt.runners.cloud.list_locations(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.list_sizes(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.map_run(path=None, opts=None, **kwargs)
Execute a salt cloud map file

salt.runners.cloud.profile(prof=None, instances=None, opts=None, **kwargs)
Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3

salt.runners.cloud.query(query_type='list_nodes')
List cloud provider data for all providers

salt.runners.cloud.select_query(query_type='list_nodes_select')
List selected nodes

23.16.6 salt.runners.config

This runner is designed to mirror the execution module config.py, but for master settings

salt.runners.config.get(key, default='', delimiter=':')
Retrieve master config options, with optional nesting via the delimiter argument.

Arguments

default
If the key is not found, the default will be returned instead
delimiter
Override the delimiter used to separate nested levels of a data structure.

CLI Example:
salt-run config.get gitfs_remotes
salt-run config.get file_roots:base
salt-run config.get file_roots,base delimiter=','

23.16.7 salt.runners.ddns

Dynamic DNS Runner

New in version 2015.8.0.

Runner to interact with DNS server and create/delete/update DNS records

codeauthor Nitin Madhok <nmadhok@g.clemson.edu>
salt.runners.ddns.add_host(zone, name, ttl, ip, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')
Create both A and PTR (reverse) records for a host.

CLI Example:
salt-run ddns.add_host domain.com my-test-vm 3600 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5

salt.runners.ddns.create(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')
Create a DNS record. The nameserver must be an IP address and the master running this runner must have create privileges on that server.

CLI Example:
salt-run ddns.create domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5

salt.runners.ddns.delete(zone, name, keyname, keyfile, nameserver, timeout, rdtype=None, data=None, port=53, keyalgorithm='hmac-md5')
Delete a DNS record.

CLI Example:
salt-run ddns.delete domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5 A

salt.runners.ddns.delete_host(zone, name, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')
Delete both forward (A) and reverse (PTR) records for a host only if the forward (A) record exists.

CLI Example:
salt-run ddns.delete_host domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5

salt.runners.ddns.update(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, replace=False, port=53, keyalgorithm='hmac-md5')
Replace, or update a DNS record. The nameserver must be an IP address and the master running this runner must have update privileges on that server.

Note: If replace is set to True, all records for this name and type will first be deleted and then recreated. Default is replace=False.

CLI Example:
salt-run ddns.update domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5

23.16.8 salt.runners.digicertapi
Support for Digicert. Heavily based on the Venafi runner by Joseph Hall (jphall@saltstack.com).
Before using this module you need to register an account with Digicert’s CertCentral.
Login to CertCentral, ensure you have a payment method configured and/or there are adequate funds attached to your account. Click the Account item in the left sidebar, and select Account Access. The right hand pane should show "Account Access" and a link to create an API key. Create a new API key and assign it to the user that should be attached to requests coming from Salt.
NOTE CertCentral will not show the API key again after revealing it the first time. Make sure you copy it right away or you will have to revoke it and generate a new one.

Now open `/etc/salt/master` and add the API key as shown below.

```
digicert:
    api_key: 8
       ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABC
```

Restart your Salt Master.

You can also include default values of the following variables to help with creating CSRs:

```
digicert:
    api_key: 8
       ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABC
    shatype: sha256
```

This API currently only supports RSA key types. Support for other key types will be added if interest warrants.

```
salt.runners.digicertapi.del_cached_domain(domains)
    Delete cached domains from the master
    CLI Example:
    salt-run digicert.del_cached_domain domain1.example.com, domain2.example.com
```

```
salt.runners.digicertapi.gen_csr(minion_id, dns_name, organization_id, ou_name=None, key_len=2048, shatype='sha256', password=None)
    CLI Example:
    salt-run digicert.gen_csr <minion_id> <dns_name>
```

```
salt.runners.digicertapi.gen_key(minion_id, dns_name=None, password=None, key_len=2048)
    Generate and return a private_key. If a dns_name is passed in, the private_key will be cached under that name.
    CLI Example:
    salt-run digicert.gen_key <minion_id> [dns_name] [password]
```

```
salt.runners.digicertapi.get_certificate(order_id=None, certificate_id=None, minion_id=None, cert_format='pem_all', file_name=None)
    Retrieve a certificate by order_id or certificate_id and write it to stdout or a filename.
    A list of permissible cert_formats is here: https://www.digicert.com/services/v2/documentation/appendix-certificate-formats
    CLI Example:
    salt-run digicert.get_certificate order_id=48929454 cert_format=apache
```

Including a ‘filename’ will write the certificate to the desired file. Note that some cert formats are zipped files, and some are binary.

If the certificate has not been issued, this function will return the order details inside of which will be a status (one of pending, rejected, processing, issued, revoked, canceled, needs_csr, and needs_approval)

If for some reason you want to pipe the output of this command to a file or other command you will want to leave off the `filename` argument and make sure to include `--no-color` so there will be no terminal ANSI escape sequences.
salt.runners.digicertapi.get_org_details(organization_id)

Return the details for an organization

CLI Example:

salt-run digicert.get_org_details 34

Returns a dictionary with the org details, or with 'error' and 'status' keys.

salt.runners.digicertapi.list_domain_cache()

List domains that have been cached

CLI Example:

salt-run digicert.list_domain_cache

salt.runners.digicertapi.list_domains(container_id=None)

List domains that CertCentral knows about. You can filter by container_id (also known as "Division") by passing a container_id.

CLI Example:

salt-run digicert.list_domains

salt.runners.digicertapi.list_orders(status=None)

List certificate orders made to CertCentral.

CLI Example:

salt-run digicert.list_orders

salt.runners.digicertapi.list_organizations(container_id=None, include_validation=True)

List organizations that CertCentral knows about. You can filter by container_id (also known as "Division") by passing a container_id. This function returns validation information by default; pass include_validation=False to turn it off.

CLI Example:

salt-run digicert.list_organizations

salt.runners.digicertapi.list_requests(status=None)

List certificate requests made to CertCentral. You can filter by status: pending, approved, rejected

CLI Example:

salt-run digicert.list_requests pending

salt.runners.digicertapi.order_certificate(minion_id, common_name, organization_id, validity_years, cert_key_passphrase=None, signature_hash=None, key_len=2048, dns_names=None, organization_units=None, server_platform=None, custom_expiration_date=None, comments=None, disable_renewal_notifications=False, product_type_hint=None, renewal_of_order_id=None)

Order a certificate. Requires that an Organization has been created inside Digicert's CertCentral.
See here for API documentation: [https://www.digicert.com/services/v2/documentation/order/order-ssl-determinator](https://www.digicert.com/services/v2/documentation/order/order-ssl-determinator)

CLI Example:

```bash
salt-run digicert.order_certificate my_minionid my.domain.com 10 30
signature_hash=sha256 dns_names=['this.domain.com', 'that.domain.com']
organization_units='My Domain Org Unit'
organisation=Comments go here for the approver
```

This runner can also be used to renew a certificate by passing `renewal_of_order_id`. Previous order details can be retrieved with `digicertapi.list_orders`.

```python
salt.runners.digicertapi.show_csrs()
Show certificate requests for this API key

CLI Example:

```bash
salt-run digicert.show_csrs
```

```python
salt.runners.digicertapi.show_organization(domain)
Show organization information, especially the company id

CLI Example:

```bash
salt-run digicert.show_company example.com
```

```python
salt.runners.digicertapi.show_rsa(minion_id, dns_name)
Show a private RSA key

CLI Example:

```bash
salt-run digicert.show_rsa myminion domain.example.com
```

### 23.16.9 salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

```python
salt.runners.doc.execution()
Collect all the sys.doc output from each minion and return the aggregate

CLI Example:

```bash
salt-run doc.execution
```

```python
salt.runners.doc.runner()
Return all inline documentation for runner modules

CLI Example:

```bash
salt-run doc.runner
```

```python
salt.runners.doc.wheel()
Return all inline documentation for wheel modules

CLI Example:

```bash
salt-run doc.wheel
```
23.16.10 salt.runners.drac

Manage Dell DRAC from the Master

The login credentials need to be configured in the Salt master configuration file.

```
[drac]
  username: admin
  password: secret
```

salt.runners.drac.poweroff( hostname, timeout=20, username=None, password=None )

Power server off

CLI Example:
```
salt-run drac.poweroff example.com
```

salt.runners.drac.poweron( hostname, timeout=20, username=None, password=None )

Power server on

CLI Example:
```
salt-run drac.poweron example.com
```

salt.runners.drac.pxe( hostname, timeout=20, username=None, password=None )

Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot

CLI Example:
```
salt-run drac.pxe example.com
```

salt.runners.drac.reboot( hostname, timeout=20, username=None, password=None )

Reboot a server using the Dell DRAC

CLI Example:
```
salt-run drac.reboot example.com
```

salt.runners.drac.version( hostname, timeout=20, username=None, password=None )

Display the version of DRAC

CLI Example:
```
salt-run drac.version example.com
```

23.16.11 salt.runners.error

Error generator to enable integration testing of salt runner error handling

salt.runners.error.error( name=None, message='' )

If name is None Then return empty dict

Otherwise raise an exception with __name__ from name, message from message

CLI Example:
```
salt-run error
salt-run error.error name="Exception" message="This is an error."
```
23.16.12  salt.runners.event

Module for sending events using the runner system.

New in version 2016.11.0.

```
salt.runners.event.send(tag, data=None)
```

Send an event with the given tag and data.

This is useful for sending events directly to the master from the shell with salt-run. It is also quite useful for sending events in orchestration states where the fire_event requisite isn't sufficient because it does not support sending custom data with the event.

Note that event tags will not be namespaced like events sent with the fire_event requisite! Whereas events produced from fire_event are prefixed with salt/state_result/<jid>/<minion_id>/<name>, events sent using this runner module will have no such prefix. Make sure your reactors don't expect a prefix!

**Parameters**

- `tag` -- the tag to send with the event
- `data` -- an optional dictionary of data to send with the event

CLI Example:

```
salt-run event.send my/custom/event '{"foo": "bar"}'
```

Orchestration Example:

```
# orch/command.sls

run_a_command:
  salt.function:
    - name: cmd.run
    - tgt: my_minion
    - arg:
      - exit {{ pillar['exit_code'] }}

send_success_event:
  salt.runner:
    - name: event.send
    - tag: my_event/success
    - data:
      - foo: bar
      - require:
        - salt: run_a_command

send_failure_event:
  salt.runner:
    - name: event.send
    - tag: my_event/failure
    - data:
      - baz: qux
      - onfail:
        - salt: run_a_command
```

```
salt-run state.orchestrate orch.command pillar='{"exit_code": 0}''
salt-run state.orchestrate orch.command pillar='{"exit_code": 1}''
```
23.16.13 salt.runners.f5

Runner to provide F5 Load Balancer functionality

depends
  • pycontrol Python module

configuration In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

```
load_balancers:
  bigip1.example.com:
    username: admin
    password: secret
  bigip2.example.com:
    username: admin
    password: secret
```

class salt.runners.f5.F5Mgmt (lb, username, password)

```
add_pool_member (name, port, pool_name)
  Add a node to a pool

check_member_pool (member, pool_name)
  Check a pool member exists in a specific pool

check_pool (name)
  Check to see if a pool exists

check_virtualserver (name)
  Check to see if a virtual server exists

create_pool (name, method='ROUND_ROBIN')
  Create a pool on the F5 load balancer

create_vs (name, ip, port, protocol, profile, pool_name)
  Create a virtual server

lbmethods ()
  List all the load balancer methods
```

salt.runners.f5.add_pool_member (lb, name, port, pool_name)

Add a node to a pool

CLI Examples:

```
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool
```

salt.runners.f5.check_member_pool (lb, member, pool_name)

Check a pool member exists in a specific pool

CLI Examples:

```
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool
```

salt.runners.f5.check_pool (lb, name)

Check to see if a pool exists

CLI Examples:
**salt-run f5.check_pool load_balancer pool_name**

```python
salt.runners.f5.check_virtualserver(lb, name)
Check to see if a virtual server exists
```

**CLI Examples:**

```text
salt-run f5.check_virtualserver load_balancer virtual_server
```

**salt.runners.f5.create_pool(lb, name, method='ROUND_ROBIN')**

Create a pool on the F5 load balancer

**CLI Examples:**

```text
salt-run f5.create_pool load_balancer pool_name loadbalance_method
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
```

**salt.runners.f5.create_vs(lb, name, ip, port, protocol, profile, pool_name)**

Create a virtual server

**CLI Examples:**

```text
salt-run f5.create_vs lbalancer vs_name 10.0.0.1 80 tcp http poolname
```

### 23.16.14 salt.runners.fileserver

Directly manage the Salt fileserver plugins

**salt.runners.fileserver.clear_cache(backend=None)**

New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (*git*, *hg*, *svn*). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the `backend` argument.

- **backend**: Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

**CLI Example:**

```text
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots
```

**salt.runners.fileserver.clear_file_list_cache(saltenv=None, backend=None)**

New in version 2016.11.0.

The Salt fileserver caches the files/directories/symlinks for each fileserver backend and environment as they are requested. This is done to help the fileserver scale better. Without this caching, when hundreds/thousands of minions simultaneously ask the master what files are available, this would cause the master's CPU load to spike as it obtains the same information separately for each minion.

- **saltenv**: By default, this runner will clear the file list caches for all environments. This argument allows for a list of environments to be passed, to clear more selectively. This list can be passed either as a comma-separated string, or a Python list.
backend  Similar to the saltenv parameter, this argument will restrict the cache clearing to specific fileserver
backends (the default behavior is to clear from all enabled fileserver backends). This list can be passed
either as a comma-separated string, or a Python list.
Since the ability to clear these caches is often required by users writing custom runners which add/remove
files, this runner can easily be called from within a custom runner using any of the following examples:

```
# Clear all file list caches
__salt__['fs.clear_file_list_cache']()

# Clear just the 'base' saltenv file list caches
__salt__['fs.clear_file_list_cache'](saltenv='base')

# Clear just the 'base' saltenv file list caches from just the 'roots' fileserver backend
__salt__['fs.clear_file_list_cache'](saltenv='base', backend='roots')

# Clear all file list caches from the 'roots' fileserver backend
__salt__['fs.clear_file_list_cache'](backend='roots')
```

Note: In runners, the __salt__ dictionary will likely be renamed to __runner__ in a future Salt release
to distinguish runner functions from remote execution functions. See this GitHub issue for discussion/updates
on this.

If using Salt’s Python API (not a runner), the following examples are equivalent to the ones above:

```
import salt.config
import salt.runner

opts = salt.config.master_config('/etc/salt/master')
opts['fun'] = 'fs.clear_file_list_cache'

# Clear all file list caches
opts['arg'] = []  # No arguments
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches
opts['arg'] = ['base', None]
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches from just the 'roots' fileserver backend
opts['arg'] = ['base', 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear all file list caches from the 'roots' fileserver backend
opts['arg'] = [None, 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()
```

This function will return a dictionary showing a list of environments which were cleared for each backend.
An empty return dictionary means that no changes were made.

CLI Examples:

```
# Clear all file list caches
salt-run fileserver.clear_file_list_cache
```
salt.runners.fileserver.clear_lock\(\text{(backend}={\text{None}}, \text{remote}={\text{None}})\)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (\textit{git}, \textit{hg}, \textit{svn}). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master’s log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

\textbf{backend} Only clear the update lock for the specified backend(s).

\textbf{remote} If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of \textit{github} will remove the lock from all github.com remotes.

CLI Example:

\begin{verbatim}
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
\end{verbatim}

salt.runners.fileserver.dir_list\(\text{(saltenv}={\text{'base'}}, \text{backend}={\text{None}})\)

Return a list of directories in the given environment

\textbf{saltenv} [base] The salt fileserver environment to be listed

\textbf{backend} Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

\begin{verbatim}
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
\end{verbatim}

salt.runners.fileserver.empty_dir_list\(\text{(saltenv}={\text{'base'}}, \text{backend}={\text{None}})\)

New in version 2015.5.0.

Return a list of empty directories in the given environment

\textbf{saltenv} [base] The salt fileserver environment to be listed

\textbf{backend} Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Note: Some backends (such as \textit{git} and \textit{hg}) do not support empty directories. So, passing backend=git or backend=hg will result in an empty list being returned.
salt runners.fileserver.envs(backend=None, sources=False)

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

backend Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots, git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend="['roots', 'git']")

CLI Examples:

```
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

salt runners.fileserver.file_list(saltenv='base', backend=None)

Return a list of files from the salt fileserver

saltenv [base] The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots, git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:

```
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

salt runners.fileserver.lock(backend=None, remote=None)

Set a fileserver update lock for VCS fileserver backends (git, hg, svn).

Note: This will only operate on enabled backends (those configured in fileserver_backend).

backend Only set the update lock for the specified backend(s).

remote If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of *github.com* will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.lock
salt-run fileserver.lock backend=git,hg
salt-run fileserver.lock backend=git remote='*github.com*'
salt-run fileserver.lock remote=bitbucket
salt.runners.fileserver.symlink_list(saltenv='base', backend=None)

Return a list of symlinked files and dirs

saltenv [base]: The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```
salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git
```

salt.runners.fileserver.update(backend=None, **kwargs)

Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.

backend Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend="[ 'roots', 'git']")

kwargs Pass additional arguments to backend. See example below

CLI Example:

```
salt-run fileserver.update
salt-run fileserver.update backend=roots,git
salt-run fileserver.update backend=git remotes=myrepo,yourrepo
```

23.16.15 salt.runners.git_pillar

Runner module to directly manage the git external pillar

salt.runners.git_pillar.update(branch=None, repo=None)

New in version 2014.1.0.

Changed in version 2015.8.4: This runner function now supports the `git_pillar configuration schema` introduced in 2015.8.0. Additionally, the branch and repo can now be omitted to update all `git_pillar` remotes. The return data has also changed to a dictionary. The values will be `True` only if new commits were fetched, and `False` if there were errors or no new commits were fetched.

Changed in version 2018.3.0: The return for a given `git_pillar` remote will now be `None` when no changes were fetched. `False` now is reserved only for instances in which there were errors.

Changed in version 3001: The repo parameter also matches against the repo name.

Fetch one or all configured `git_pillar` remotes.

Note: This will not fast-forward the `git_pillar` cachedir on the master. All it does is perform a `git fetch`. If this runner is executed with `-l debug`, you may see a log message that says that the repo is up-to-date. Keep in mind that Salt automatically fetches `git_pillar` repos roughly every 60 seconds (or whatever
loop_interval is set to). So, it is possible that the repo was fetched automatically in the time between when changes were pushed to the repo, and when this runner was executed. When in doubt, simply refresh pillar data using saltutil.refresh_pillar and then use pillar.item to check if the pillar data has changed as expected.

CLI Example:

```
# Update specific branch and repo
salt-run git_pillar.update branch='branch' repo='https://foo.com/bar.git'
# Update specific repo, by name
salt-run git_pillar.update repo=myrepo
# Update all repos
salt-run git_pillar.update
# Run with debug logging
salt-run git_pillar.update -l debug
```

23.16.16 salt.runners.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

```
salt.runners.http.query(url, output=True, **kwargs)
```

Query a resource, and decode the return data

Passes through all the parameters described in the utils.http.query function:

CLI Example:

```
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST data='\xml
somecontent</xml>'
```

```
salt.runners.http.update_ca_bundle(target=None, source=None, merge_files=None)
```

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```
salt-run http.update_ca_bundle
salt-run http.update_ca_bundle target=/path/to/cacerts.pem
salt-run http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the target is not specified, it will be pulled from the ca_cert configuration variable available to the master. If it cannot be found there, it will be placed at <<FILE_ROOTS>>/cacerts.pem.

If the source is not specified, it will be pulled from the ca_cert_url configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

merge_files may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:
```bash
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```

### 23.16.17 salt.runners.jobs

A convenience system to manage jobs, both active and already run

**salt.runners.jobs.active** *(display_progress=False)*

Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```bash
salt-run jobs.active
```

**salt.runners.jobs.exit_success** *(jid, ext_source=None)*

Check if a job has been executed and exit successfully

- **jid** The jid to look up.
- **ext_source** The external job cache to use. Default: *None.*

CLI Example:

```bash
salt-run jobs.exit_success 20160520145827701627
```

**salt.runners.jobs.last_run** *(ext_source=None, outputter=None, metadata=None, function=None, target=None, display_progress=False)*

New in version 2015.8.0.

List all detectable jobs and associated functions

CLI Example:

```bash
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
salt-run jobs.last_run function='cmd.run'
```

**salt.runners.jobs.list_job** *(jid, ext_source=None, display_progress=False)*

List a specific job given by its jid

- **ext_source** If provided, specifies which external job cache to use.
- **display_progress** [False] If True, fire progress events.

CLI Example:

```bash
salt-run jobs.list_job 20130916125524463507
salt-run jobs.list_job 20130916125524463507 --out=pprint
```

**salt.runners.jobs.list_jobs** *(ext_source=None, outputter=None, search_metadata=None, search_function=None, search_target=None, start_time=None, end_time=None, display_progress=False)*

List all detectable jobs and associated functions

- **ext_source** If provided, specifies which external job cache to use.

**FILTER OPTIONS**

**Note:** If more than one of the below options are used, only jobs which match all of the filters will be returned.

- **search_metadata** Specify a dictionary to match to the job's metadata. If any of the key-value pairs in this dictionary match, the job will be returned. Example:
search_function Can be passed as a string or a list. Returns jobs which match the specified function. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_function='test.*'
salt-run jobs.list_jobs search_function=['"test.*", "pkg.install"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_function='test.*,pkg.install'
```

search_target Can be passed as a string or a list. Returns jobs which match the specified minion name. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_target='*.mydomain.tld'
salt-run jobs.list_jobs search_target=['"db\*", "myminion"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_target='db*,myminion'
```

start_time Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started after this timestamp.

end_time Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started before this timestamp.

CLI Example:

```
salt-run jobs.list_jobs
salt-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='{"bar": "foo"}''
salt-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'
```

salt.runners.jobs.list_jobs_filter(count=None, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)

List all detectable jobs and associated functions

ext_source The external job cache to use. Default: None.

CLI Example:

```
salt-run jobs.list_jobs_filter 50
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, display_progress=False)

Return the printout from a previously executed job

jid The jid to look up.

ext_source The external job cache to use. Default: None.

returned [True] If True, include the minions that did return from the command.

missing [False] If True, include the minions that did not return from the command.

display_progress [False] If True, fire progress events.

CLI Example:
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 --out=highstate

salt.runners.jobs.master()
Return the actively executing runners for the master

    salt-run jobs.master

salt.runners.jobs.print_job(jid, ext_source=None)
Print a specific job's detail given by its jid, including the return data.

    salt-run jobs.print_job 20130916125524463507

23.16.18 salt.runners.launchd

Manage launchd plist files

salt.runners.launchd.write_launchd_plist(program)
Write a launchd plist for managing salt-master or salt-minion

    salt-run launchd.write_launchd_plist salt-master

23.16.19 salt.runners.lxc

Control Linux Containers via Salt

    depends lxc execution module

salt.runners.lxc.cloud_init(names, host=None, quiet=False, **kwargs)
Wrapper for using lxc.init in saltcloud compatibility mode

    names  Name of the containers, supports a single name or a comma delimited list of names.
    host  Minion to start the container on. Required.
    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
    saltcloud_mode  init the container with the saltcloud opts format instead

salt.runners.lxc.find_guest(name, quiet=False, path=None)
Returns the host for a container.

    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.

    salt-run lxc.find_guest name

salt.runners.lxc.find_guests(names, path=None)
Return a dict of hosts and named guests

    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
salt.runners.lxc.freeze\(\text{name, quiet=False, path=None}\)
Freeze the named container
\text{path} path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.freeze name

salt.runners.lxc.info\(\text{name, quiet=False, path=None}\)
Returns information about a container.
\text{path} path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.info name

salt.runners.lxc.init\(\text{names, host=None, saltcloud_mode=False, quiet=False, **kwargs}\)
Initialize a new container

salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset] \(\text{\textbackslash}\)
\text{\textbackslash}\[cpushare=cgroups_cpushare] [memory=cgroups_memory] \(\text{\textbackslash}\)
\text{\textbackslash}[template=lxc_template_name] [clone=original name] \(\text{\textbackslash}\)
\text{\textbackslash}[profile=lxc_profile] [network_profile=network_profile] \(\text{\textbackslash}\)
\text{\textbackslash}[nic=network_profile] [nic_opts=nic_opts] \(\text{\textbackslash}\)
\text{\textbackslash}[start=(true|false)] [seed=(true|false)] \(\text{\textbackslash}\)
\text{\textbackslash}[install=(true|false)] [config=minion_config] \(\text{\textbackslash}\)
\text{\textbackslash}[snapshot=(true|false)]

names Name of the containers, supports a single name or a comma delimited list of names.
host Minion on which to initialize the container (required)
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
saltcloud_mode init the container with the saltcloud opts format instead See lxc.init_interface module documentation
cpuset cgroups cpuset.
cpushare cgroups cpu shares.
copy memmory cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass memory=0 to set no limit.
template Name of LXC template on which to base this container
ci Close this container from an existing container
profile A LXC profile (defined in config or pillar).
network_profile Network profile to use for the container

New in version 2015.5.2.
nic Deprecated since version 2015.5.0: Use network_profile instead
nic_opts Extra options for network interfaces. E.g.:

\{"eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6": "2001:db8::ff00:42:8329"}}
start Start the newly created container.
seed Seed the container with the minion config and autosign its key. Default: true
install If salt-minion is not already installed, install it. Default: true
config Optional config parameters. By default, the id is set to the name of the container.
salt.runners.lxc.list_(host=None, quiet=False, path=None)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.list [host=minion_id]
```

salt.runners.lxc.purge(name, delete_key=True, quiet=False, path=None)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with
the container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.purge name
```

salt.runners.lxc.start(name, quiet=False, path=None)
Start the named container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.start name
```

salt.runners.lxc.stop(name, quiet=False, path=None)
Stop the named container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.stop name
```

salt.runners.lxc.unfreeze(name, quiet=False, path=None)
Unfreeze the named container
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.unfreeze name
```

23.16.20 salt.runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down

salt.runners.manage.alived(subset=None, show_ip=False)
New in version 2015.8.0.

Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.
CLI Example:

```bash
salt-run manage.alived
```
salt.runners.manage.allowed(
    subset=None, show_ip=False)

    New in version 2015.8.0.
    Changed in version 2019.2.0.
    Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to
    minitions)
    subset [None] Pass in a CIDR range to filter minions by IP address.
    show_ip [False] Also show the IP address each minion is connecting from.
    CLI Example:

    ```
    salt-run manage.allowed
    ```

salt.runners.manage.bootstrap(
    version='develop', script=None, hosts='', script_args='', roster='flat', ssh_user=None, ssh_password=None, ssh_priv_key=None,
    tmp_dir='/tmp/.bootstrap', http_backend='tornado')

    Bootstrap minions with salt-bootstrap
    version [develop] Git tag of version to install
    script [https://bootstrap.saltstack.com] URL containing the script to execute
    hosts Comma-separated hosts [example: hosts='host1.local,host2.local']. These hosts need to exist in the specified roster.
    script_args Any additional arguments that you want to pass to the script.
    New in version 2016.11.0.
    roster [flat] The roster to use for Salt SSH. More information about roster files can be found in Salt's Roster Documentation.
    A full list of roster types, see the builtin roster modules documentation.
    New in version 2016.11.0.
    ssh_user If user isn't found in the roster, a default SSH user can be set here. Keep in mind that ssh_user will not override the roster user value if it is already defined.
    New in version 2016.11.0.
    ssh_password If passwd isn't found in the roster, a default SSH password can be set here. Keep in mind that ssh_password will not override the roster passwd value if it is already defined.
    New in version 2016.11.0.
    ssh_privkey If priv isn't found in the roster, a default SSH private key can be set here. Keep in mind that ssh_password will not override the roster passwd value if it is already defined.
    New in version 2016.11.0.
    tmp_dir [/tmp/.bootstrap] The temporary directory to download the bootstrap script in. This directory will have -<uuid4> appended to it. For example: /tmp/.bootstrap-a19a728e-d40a-4801-aba9-d00655c143a7/
    New in version 2016.11.0.
    http_backend [tornado] The backend library to use to download the script. If you need to use a file:/// URL, then you should set this to urllib2.
    New in version 2016.11.0.
    CLI Example:

    ```
    salt-run manage.bootstrap host1,host2
    salt-run manage.bootstrap host1,host2 version='v0.17'
    salt-run manage.bootstrap host1,host2 version='v0.17' script='https://bootstrap.saltstack.com/develop'
    ```
salt.runners.manage.bootstrap_psexec(*hosts='', master=None, version=None, arch='win32', installer_url=None, username=None, password=None*)

Bootstrap Windows minions via PsExec.

- **hosts** Comma separated list of hosts to deploy the Windows Salt minion.
- **master** Address of the Salt master passed as an argument to the installer.
- **version** Point release of installer to download. Defaults to the most recent.
- **arch** Architecture of installer to download. Defaults to win32.
- **installer_url** URL of minion installer executable. Defaults to the latest version from https://repo.saltstack.com/windows/
- **username** Optional user name for login on remote computer.
- **password** Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:
```
salt-run manage.bootstrap_psexec hosts='host1,host2'
salt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17' username='\DOMAIN\Administrator'
salt-run manage.bootstrap_psexec hosts='host1,host2' installer_url='http://\exampledomain/salt-installer.exe'
```

salt.runners.manage.down(*removekeys=False, tgt='*', tgt_type='glob', timeout=None, gather_job_timeout=None*)

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:
```
salt-run manage.down
salt-run manage.down removekeys=True
salt-run manage.down tgt="webservers" tgt_type="nodegroup"
```

salt.runners.manage.joined(*subset=None, show_ip=False*)

New in version 2015.8.0.

Changed in version 2019.2.0.

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

- **subset** [None] Pass in a CIDR range to filter minions by IP address.
- **show_ip** [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.joined
```

salt.runners.manage.key_regen()

This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED!!

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a salt-key -A command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!
CLI Example:

```
salt-run manage.key_regen
```

```
salt.runners.manage.list_not_state(subset=None, show_ip=False)
```
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent to minions)
`subset` [None] Pass in a CIDR range to filter minions by IP address.
`show_ip` [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.list_not_state
```

```
salt.runners.manage.list_state(subset=None, show_ip=False)
```
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
`subset` [None] Pass in a CIDR range to filter minions by IP address.
`show_ip` [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.list_state
```

```
salt.runners.manage.not_alived(subset=None, show_ip=False)
```
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
`subset` [None] Pass in a CIDR range to filter minions by IP address.
`show_ip` [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_alived
```

```
salt.runners.manage.not_allowed(subset=None, show_ip=False)
```
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
`subset` [None] Pass in a CIDR range to filter minions by IP address.
`show_ip` [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_allowed
```

```
salt.runners.manage.not_joined(subset=None, show_ip=False)
```
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.not_joined
```

`salt.runners.manage.not_present(subset=None, show_ip=False)`
New in version 2015.5.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.
CLI Example:
```
salt-run manage.not_present
```

`salt.runners.manage.not_reaped(subset=None, show_ip=False)`
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.
CLI Example:
```
salt-run manage.not_reaped
```

`salt.runners.manage.present(subset=None, show_ip=False)`
Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.
CLI Example:
```
salt-run manage.present
```

`salt.runners.manage.reaped(subset=None, show_ip=False)`
New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ip [False] Also show the IP address each minion is connecting from.
CLI Example:
```
salt-run manage.reaped
```

`salt.runners.manage.safe_accept(target, tgt_type='glob')`
Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.
Accept a minion’s public key after checking the fingerprint over salt-ssh
CLI Example:

```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2  tgt_type=list
```

```
salt.runners.manage.status(output=True, tgt='*', tgt_type='glob', timeout=None, gather_job_timeout=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Print the status of all known salt minions

CLI Example:

```
salt-run manage.status
salt-run manage.status tgt="webservers" tgt_type="nodegroup"
salt-run manage.status timeout=5  gather_job_timeout=10
```

```
salt.runners.manage.up(tgt='*', tgt_type='glob', timeout=None, gather_job_timeout=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Print a list of all of the minions that are up

CLI Example:

```
salt-run manage.up
salt-run manage.up tgt="webservers" tgt_type="nodegroup"
salt-run manage.up timeout=5  gather_job_timeout=10
```

```
salt.runners.manage.versions()
```

Check the version of active minions

CLI Example:

```
salt-run manage.versions
```

### 23.16.21 salt.runners.mattermost

**Note for 2017.7 releases!**

Due to the `salt.runners.config` module not being available in this release series, importing the `salt.runners.config` module from the master branch is required to make this module work.

Ref: Mattermost runner failing to retrieve config values due to unavailable config runner #43479

Module for sending messages to Mattermost

New in version 2017.7.0.

**configuration** This module can be used by either passing an `api_url` and `hook` directly or by specifying both in a configuration profile in the salt master/minion config. For example:

```
mattermost:
  hook: peWcBiMOS9HzG15peWcBiMOS9HzG15
  api_url: https://example.com
```
salt.runners.mattermost.post_event(event, channel=None, username=None, api_url=None, hook=None)

Send an event to a Mattermost channel. :param channel: The channel name, either will work. :param username: The username of the poster. :param event: The event to send to the Mattermost channel. :param api_url: The Mattermost api url, if not specified in the configuration. :param hook: The Mattermost hook, if not specified in the configuration. :return: Boolean if message was sent successfully.

salt.runners.mattermost.post_message(message, channel=None, username=None, api_url=None, hook=None)

Send a message to a Mattermost channel. :param channel: The channel name, either will work. :param username: The username of the poster. :param message: The message to send to the Mattermost channel. :param api_url: The Mattermost api url, if not specified in the configuration. :param hook: The Mattermost hook, if not specified in the configuration. :return: Boolean if message was sent successfully.

CLI Example:

```bash
salt-run mattermost.post_message message='Build is done'
```

### 23.16.22 salt.runners.mine

A runner to access data from the salt mine

salt.runners.mine.get(tgt, fun, tgt_type='glob')

Gathers the data from the specified minions’ mine, pass in the target, function to look up and the target type

CLI Example:

```bash
salt-run mine.get '*' network.interfaces
```

salt.runners.mine.update(tgt, tgt_type='glob', clear=False, mine_functions=None)

New in version 2017.7.0.

Update the mine data on a certain group of minions.

tgt Which minions to target for the execution.
tgt_type: glob The type of tgt.
clear: False Boolean flag specifying whether updating will clear the existing mines, or will update. Default: False (update).
mine_functions Update the mine data on certain functions only. This feature can be used when updating the mine for functions that require refresh at different intervals than the rest of the functions specified under mine_functions in the minion/master config or pillar.

CLI Example:

```bash
salt-run mine.update '*'
salt-run mine.update 'juniper-edges' tgt_type='nodegroup'
```

### 23.16.23 salt.runners.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

```bash
depends libnacl, https://github.com/saltstack/libnacl
```

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.

configuration The following configuration defaults can be define (pillar or config files) Avoid storing private keys in pillars! Ensure master does not have pillar_opts=True:
The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your `sk_file` and `pk_file` use:

```
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl
```

Now with your keypair, you can encrypt data:

You have two option, `sealedbox` or `secretbox`.

SecretBox is data encrypted using private key `pk`. Sealedbox is encrypted using public key `pk`.

Recommend using Sealedbox because the one way encryption permits developers to encrypt data for source control but not decrypt. Sealedbox only has one key that is for both encryption and decryption.

```
salt-run nacl.enc asecretpass pk=/kfGX7PbWeu099782PbbKWlpG/9p06IQRswkdWHCDk0=
tqXzeIjntAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58=
salt-run nacl.dec data=tqXzeIjnTAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58= sk=SVWut5SqNpuPeNzb1b9y6b2eXg2PLIo43GBzp48Sow=
```

When the keys are defined in the master config you can use them from the nacl runner without extra parameters:

```
salt-run nacl.enc 'asecretpass' salt-run nacl.dec 'tqXzeIjnTAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58='
```

# cat /etc/salt/master.d/nacl.conf
```python
nacl.config:
# NOTE: `key` and `key_file` have been renamed to `sk`, `sk_file`
# also `box_type` default changed from secretbox to sealedbox.
box_type: sealedbox (default)
sk_file: /etc/salt/pki/master/nacl (default)
pk_file: /etc/salt/pki/master/nacl.pub (default)
sk: None
pk: None
```
Usage can override the config defaults:

```
salt-run nacl.enc sk_file=/etc/salt/pki/master/nacl pk_file=/etc/salt/pki/master/nacl.pub
```

The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your `sk_file` and `pk_file` use:

```
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl
```

Now with your keypair, you can encrypt data:

You have two option, `sealedbox` or `secretbox`.

SecretBox is data encrypted using private key `pk`. Sealedbox is encrypted using public key `pk`.

Recommend using Sealedbox because the one way encryption permits developers to encrypt data for source control but not decrypt. Sealedbox only has one key that is for both encryption and decryption.

```
salt-run nacl.enc asecretpass pk=/kfGX7PbWeu099782PbbKWlpG/9p06IQRswkdWHCDk0=
tqXzeIjntAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58=
salt-run nacl.dec data=tqXzeIjnTAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58= sk=SVWut5SqNpuPeNzb1b9y6b2eXg2PLIo43GBzp48Sow=
```

When the keys are defined in the master config you can use them from the nacl runner without extra parameters:

```
salt-run nacl.enc 'asecretpass'
salt-run nacl.dec 'tqXzeIjnTAM9Xf0mdLcpEdk1MbfbBGpj2oTkmlgRm3S1DTVHNNh9h8mU1GKllGq/+cYsk6m5WhGdk58='
```

# cat /etc/salt/master.d/nacl.conf
```python
nacl.config:
# NOTE: `key` and `key_file` have been renamed to `sk`, `sk_file`
# also `box_type` default changed from secretbox to sealedbox.
box_type: sealedbox (default)
sk_file: /etc/salt/pki/master/nacl (default)
pk_file: /etc/salt/pki/master/nacl.pub (default)
sk: None
pk: None
```
A salt developer's minion could have pillar data that includes a nacl public key

```
nacl.config:
  pk: '/kfGX7PbWeu99782PBbkWlpG/9p6IQRsWkdWHCDk8='
```

The developer can then use a less-secure system to encrypt data.

```
salt-run nacl.enc apassword
```

Pillar files can include protected data that the salt master decrypts:

```
pillarexample:
  user: root
    password1: {{salt.nacl.dec('DRB7Q6/X5gGSRCTpZyxS6hllbWj0llUA+uAvChou3vJ4=')|json}}
  cert_key: {{salt.nacl.dec_file('/srv/salt/certs/example.com/key.nacl')|json}}
  cert_key2: {{salt.nacl.dec_file('salt://certs/example.com/key.nacl')|json}}
```

Larger files like certificates can be encrypted with:

```
salt-run nacl.enc_file /tmp/cert.crt out=/tmp/cert.nacl
```

```
salt.runners.nacl.dec(data,**kwargs)
    Alias to [box_type]_decrypt
    box_type: secretbox, sealedbox(default)
```

```
salt.runners.nacl.dec_file(name, out=None, **kwargs)
    This is a helper function to decrypt a file and return its contents.
    You can provide an optional output file using out
    name can be a local file or when not using salt-run can be a url like salt://, https:// etc.
    CLI Examples:

    salt-run nacl.dec_file name=/tmp/id_rsa.nacl
    salt-run nacl.dec_file name=/tmp/id_rsa.nacl box_type=secretbox
    →file=/etc/salt/pki/master/nacl.pub
```

```
salt.runners.nacl.enc(data, **kwargs)
    Alias to [box_type]_encrypt
    box_type: secretbox, sealedbox(default)
```

```
salt.runners.nacl.enc_file(name, out=None, **kwargs)
    This is a helper function to encrypt a file and return its contents.
    You can provide an optional output file using out
    name can be a local file or when not using salt-run can be a url like salt://, https:// etc.
    CLI Examples:

    salt-run nacl.enc_file name=/tmp/id_rsa
    salt-run nacl.enc_file name=/tmp/id_rsa box_type=secretbox
    →etc/salt/pki/master/nacl.pub
```

```
salt.runners.nacl.keygen(sk_file=None, pk_file=None, **kwargs)
    Use libnacl to generate a keypair.
    If no sk_file is defined return a keypair.
    If only the sk_file is defined pk_file will use the same name with a postfix .pub.
```
When the sk_file is already existing, but pk_file is not. The pk_file will be generated using the sk_file.

CLI Examples:

```
salt-run nacl.keygen
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl pk_file=/etc/salt/pki/master/nacl.pub
salt-run nacl.keygen
```

```
salt.runners.nacl.sealedbox_decrypt(data, **kwargs)
Decrypt data using a secret key that was encrypted using a public key with nacl.sealedbox_encrypt.

CLI Examples:

```
salt-run nacl.sealedbox_decrypt pEXHQM6cuaF7A=
salt-run nacl.sealedbox_decrypt data='pEXHQM6cuaF7A=' sk_file=/etc/salt/pki/master/nacl
salt-run nacl.sealedbox_decrypt data='pEXHQM6cuaF7A=' sk='YmFkcGFzcwo=
```

```
salt.runners.nacl.sealedbox_encrypt(data, **kwargs)
Encrypt data using a public key generated from nacl.keygen. The encryptd data can be decrypted using nacl.sealedbox_decrypt only with the secret key.

CLI Examples:

```
salt-run nacl.sealedbox_encrypt datatoenc
```

```
salt.runners.nacl.secretbox_decrypt(data, **kwargs)
Decrypt data that was encrypted using nacl.secretbox_encrypt using the secret key that was generated from nacl.keygen.

CLI Examples:

```
salt-run nacl.secretbox_decrypt pEXHQM6cuaF7A=
salt-run nacl.secretbox_decrypt data='pEXHQM6cuaF7A=' sk_file=/etc/salt/pki/master/nacl
salt-run nacl.secretbox_decrypt data='pEXHQM6cuaF7A=' sk='YmFkcGFzcwo=
```

```
salt.runners.nacl.secretbox_encrypt(data, **kwargs)
Encrypt data using a secret key generated from nacl.keygen. The same secret key can be used to decrypt the data using nacl.secretbox_decrypt.

CLI Examples:

```
salt-run nacl.secretbox_encrypt datatoenc
salt-run nacl.secretbox_encrypt datatoenc sk_file=/etc/salt/pki/master/nacl
salt-run nacl.secretbox_encrypt datatoenc sk='YmFkcGFzcwo=
```
23.16.24  salt.runners.net

NET Finder

New in version 2017.7.0.
A runner to find network details easily and fast. It’s smart enough to know what you are looking for.

Configuration

• Minion (proxy) config

To have the complete features, one needs to add the following mine configuration in the minion (proxy) config file:

```
mine_functions:

  net.ipaddrs: []
  net.lldp: []
  net.mac: []
  net.arp: []
  net.interfaces: []
```

Which instructs Salt to cache the data returned by the NAPALM-functions. While they are not mandatory, the less functions configured, the less details will be found by the runner.

How often the mines are refreshed, can be specified using:

```
mine_interval: <X minutes>
```

• Master config

By default the following options can be configured on the master. They are not necessary, but available in case the user has different requirements.

- **target**: From what minions will collect the mine data. Default: * (collect from all minions).
- **expr_form**: glob Minion matching expression form. Default: glob.
- **ignore_interfaces**: A list of interfaces name to ignore. By default will consider all interfaces.
- **display**: True Display on the screen or return structured object? Default: True (return on the CLI).
- **outputter**: table Specify the outputter name when displaying on the CLI. Default: table.

Configuration example:

```
runners:
  net.find:
    target: 'edge*'  
    expr_form: 'glob'
    ignore_interfaces:
      - lo0
      - em1
      - jsrv
      - fxp0
    outputter: yaml
```
salt.runners.net.find\( (addr, best=True, display=True) \)
Search in all possible entities (Interfaces, MAC tables, ARP tables, LLDP neighbors), using the following mine functions:
- net.mac
- net.arp
- net.lldp
- net.ipaddrs
- net.interfaces
This function has the advantage that it knows where to look, but the output might become quite long as returns all possible matches.

Optional arguments:
- **best:** True  Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.
- **display:** True  Display on the screen or return structured object? Default: True (return on the CLI).

CLI Example:

```bash
$ sudo salt-run net.find 10.10.10.7
```

Output Example:

```
Details for all interfaces that include network 10.10.10.7/32 - only best match

```

```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>UP</th>
<th>Enabled</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>

<th>Interface</th>
<th>MAC Address</th>
<th>IP Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.flw01</td>
<td>irb</td>
<td>5C:5E:AB:AC:52:B4</td>
<td>10.10.10.1/22</td>
</tr>
</tbody>
</table>
```

ARP Entries for IP 10.10.10.7

```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC Address</th>
<th>IP</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.flw01</td>
<td>irb.349</td>
<td>2C:60:0C:2A:4C:0A</td>
<td>10.10.10.7</td>
<td>832.0</td>
</tr>
</tbody>
</table>
```

salt.runners.net.findarp\( (device=None, interface=None, mac=None, ip=None, display=True) \)
Search for entries in the ARP tables using the following mine functions:
- net.arp

Optional arguments:
- **device**  Return interface data from a certain device only.
- **interface**  Return data selecting by interface name.
- **mac**  Search using a specific MAC Address.
- **ip**  Search using a specific IP Address.
- **display:** True  Display on the screen or return structured object? Default: True, will return on the CLI.

CLI Example:

```bash
$ sudo salt-run net.findarp mac=8C:60:0F:78:EC:41
```

Output Example:
ARP Entries for MAC 8C:60:0F:78:EC:41

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>IP</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>irb.171 [ae0.171]</td>
<td>8C:60:0F:78:EC:41</td>
<td>172.172.17.19</td>
<td>956.0</td>
</tr>
</tbody>
</table>

salt.runners.net.findmac(device=None, mac=None, interface=None, vlan=None, display=True)

Search in the MAC Address tables, using the following mine functions:

- **net.mac**
  
  Optional arguments:
  - **device** Return interface data from a certain device only.
  - **interface** Return data selecting by interface name.
  - **mac** Search using a specific MAC Address.
  - **vlan** Search using a VLAN ID.
  - **display**: True Display on the screen or return structured object? Default: True, will return on the CLI.

  CLI Example:

  ```
  $ sudo salt-run net.findmac mac=8C:60:0F:78:EC:41
  ```

  Output Example:

  **MAC Address(es)**

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>VLAN</th>
<th>Static</th>
<th>Active</th>
<th>Moves</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>ae0.171</td>
<td>8C:60:0F:78:EC:41</td>
<td>171</td>
<td>False</td>
<td>True</td>
<td>0</td>
</tr>
</tbody>
</table>

salt.runners.net.interfaces(device=None, interface=None, title=None, pattern=None, ipnet=None, best=True, display=True)

Search for interfaces details in the following mine functions:

- **net.interfaces**
- **net.ipaddrs**

Optional arguments:
- **device** Return interface data from a certain device only.
- **interface** Return data selecting by interface name.
- **pattern** Return interfaces that contain a certain pattern in their description.
- **ipnet** Return interfaces whose IP networks associated include this IP network.
- **best**: True When **ipnet** is specified, this argument says if the runner should return only the best match (the output will contain at most one row). Default: True (return only the best match).
- **display**: True Display on the screen or return structured object? Default: True (return on the CLI).
- **title** Display a custom title for the table.

  CLI Example:

  ```
  $ sudo salt-run net.interfaces interface=vt-0/0/10
  ```

  Output Example:
Details for interface xe-0/0/0

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>UP</th>
<th>Enabled</th>
<th>Speed [Mbps]</th>
<th>MAC Address</th>
<th>IP Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>vt-0/0/10</td>
<td></td>
<td>True</td>
<td>True</td>
<td>1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge01.flw01</td>
<td>vt-0/0/10</td>
<td></td>
<td>True</td>
<td>True</td>
<td>1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge01.pos01</td>
<td>vt-0/0/10</td>
<td></td>
<td>True</td>
<td>True</td>
<td>1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge01.oua01</td>
<td>vt-0/0/10</td>
<td></td>
<td>True</td>
<td>True</td>
<td>1000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

salt.runners.net.lldp(device=None, interface=None, title=None, pattern=None, chassis=None, display=True)

Search in the LLDP neighbors, using the following mine functions:
  - net.lldp

Optional arguments:
  device Return interface data from a certain device only.
  interface Return data selecting by interface name.
  pattern Return LLDP neighbors that have contain this pattern in one of the following fields:
    - Remote Port ID
    - Remote Port Description
    - Remote System Name
    - Remote System Description

chassis Search using a specific Chassis ID.

display: True Display on the screen or return structured object? Default: True (return on the CLI).
display: True Display on the screen or return structured object? Default: True (return on the CLI).
title Display a custom title for the table.

CLI Example:

```
$ sudo salt-run net.lldp pattern=Ethernet1/48
```

Output Example:

Pattern "Ethernet1/48" found in one of the following LLDP details

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Parent Interface</th>
<th>Remote Chassis ID</th>
<th>Remote PortID</th>
<th>Remote Port Description</th>
<th>Remote System Name</th>
<th>Remote System Description</th>
</tr>
</thead>
</table>

(continues on next page)
salt.runners.net.multi_find(*patterns, **kwargs)

Execute multiple search tasks. This function is based on the find function. Depending on the search items, some information might overlap.

Optional arguments:

- **best:** True Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.
- **display:** True Display on the screen or return structured object? Default: True (return on the CLI).

CLI Example:
$ sudo salt-run net.multi_find Ethernet1/49 xe-0/1/2

Output Example:

Pattern "Ethernet1/49" found in one of the following LLDP details

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Parent Interface</th>
<th>Remote Chassis ID</th>
<th>Remote Port Description</th>
<th>Remote Port ID</th>
<th>Remote System Description</th>
<th>Remote System Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.oua04</td>
<td>xe-0/1/2</td>
<td>ae1</td>
<td>DE:AD:BE:EF:DE:AD</td>
<td>Ethernet1/49</td>
<td></td>
<td>Cisco NX-OS(tm) n6000, Software (n6000-uk9)</td>
<td>edge07.oua04.dummy.net</td>
</tr>
</tbody>
</table>

Details for interface xe-0/1/2

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>IP Addresses</th>
<th>Enabled</th>
<th>MAC Address</th>
<th>Speed [Mbps]</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.oua04</td>
<td>xe-0/1/2</td>
<td>ae1 sw01.oua04</td>
<td></td>
<td>True</td>
<td>BE:EF:DE:AD:BE:EF</td>
<td>10000</td>
</tr>
</tbody>
</table>

LLDP Neighbors for interface xe-0/1/2

<table>
<thead>
<tr>
<th>Device</th>

</tbody>
</table>
23.16.25 salt.runners.network

Network tools to run from the Master

```python
salt.runners.network.wol(mac, bcast='255.255.255.255', destport=9)
```

Send a "Magic Packet" to wake up a Minion

CLI Example:

```
salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
```

```python
salt.runners.network.wollist(maclist, bcast='255.255.255.255', destport=9)
```

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line

CLI Example:

```
salt-run network.wollist '/path/to/maclist'
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
```

```python
salt.runners.network.wolmatch(tgt, tgt_type='glob', bcast='255.255.255.255', destport=9)
```

Send a "Magic Packet" to wake up Minions that are matched in the grains cache

CLI Example:

```
salt-run network.wolmatch minion_id
salt-run network.wolmatch 192.168.0.0/16 tgt_type='ipcidr' bcast=255.255.255.255 destport=7
```

23.16.26 salt.runners.pagerduty

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

```python
configuration
```

This module can be used by specifying the name of a configuration profile in the master config.

For example:

```
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbve43rfWf2214
pagerduty.subdomain: mysubdomain
```

```python
salt.runners.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)
```

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt-run pagerduty.create_event <service_key> <description> <details> → profile=my-pagerduty-account
```

The following parameters are required:

- **service_key** This key can be found by using pagerduty.list_services.
- **description** This is a short description of the event.
- **details** This can be a more detailed description of the event.
profile  This refers to the configuration profile to use to connect to the PagerDuty service.
salt.runners.pagerduty.list_escalation_policies(profile=None, api_key=None)
This function is an alias of list_policies.
List escalation policies belonging to this account
    CLI Example:
        salt-run pagerduty.list_policies my-pagerduty-account
        salt-run pagerduty.list_escalation_policies my-pagerduty-account
salt.runners.pagerduty.list_incidents(profile=None, api_key=None)
List incidents belonging to this account
    CLI Example:
        salt-run pagerduty.list_incidents my-pagerduty-account
salt.runners.pagerduty.list_maintenance_windows(profile=None, api_key=None)
This function is an alias of list_windows.
List maintenance windows belonging to this account
    CLI Example:
        salt-run pagerduty.list_windows my-pagerduty-account
        salt-run pagerduty.list_maintenance_windows my-pagerduty-account
salt.runners.pagerduty.list_policies(profile=None, api_key=None)
List escalation policies belonging to this account
    CLI Example:
        salt-run pagerduty.list_policies my-pagerduty-account
        salt-run pagerduty.list_escalation_policies my-pagerduty-account
salt.runners.pagerduty.list_schedules(profile=None, api_key=None)
List schedules belonging to this account
    CLI Example:
        salt-run pagerduty.list_schedules my-pagerduty-account
salt.runners.pagerduty.list_services(profile=None, api_key=None)
List services belonging to this account
    CLI Example:
        salt-run pagerduty.list_services my-pagerduty-account
salt.runners.pagerduty.list_users(profile=None, api_key=None)
List users belonging to this account
    CLI Example:
        salt-run pagerduty.list_users my-pagerduty-account
salt.runners.pagerduty.list_windows(profile=None, api_key=None)
List maintenance windows belonging to this account
    CLI Example:
        salt-run pagerduty.list_windows my-pagerduty-account
        salt-run pagerduty.list_maintenance_windows my-pagerduty-account
23.16.27 salt.runners.pillar

Functions to interact with the pillar compiler on the master

salt.runners.pillar.clear_pillar_cache

Clears the cached values when using pillar_cache

New in version 3003.

CLI Example:

Clears the pillar cache for a specific minion:

```
salt-run pillar.clear_pillar_cache 'minion'
```

salt.runners.pillar.show_pillar

Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes that no minion has the id *. Function also accepts pillarenv as attribute in order to limit to a specific pillar branch of git

CLI Example:

shows minion specific pillar:

```
salt-run pillar.show_pillar 'www.example.com'
```

shows global pillar:

```
salt-run pillar.show_pillar
```

shows global pillar for 'dev' pillar environment: (note that not specifying pillarenv will merge all pillar environments using the master config option pillar_source_merging_strategy.)

```
salt-run pillar.show_pillar 'pillarenv=dev'
```

shows global pillar for 'dev' pillar environment and specific pillarenv = dev:

```
salt-run pillar.show_pillar 'saltenv=dev' 'pillarenv=dev'
```

API Example:

```
import salt.config
import salt.runner
opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)
```

salt.runners.pillar.show_pillar_cache

Shows the cached values in pillar_cache

New in version 3003.

CLI Example:

Shows the pillar cache for a specific minion:

```
salt-run pillar.show_pillar_cache 'minion'
```
**salt.runners.pillar.show_top** *(minion=None, saltenv='base')*

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:

```
salt-run pillar.show_top
```

---

### 23.16.28 salt.runners.pkg

Package helper functions using `salt.modules.pkg`

New in version 2015.8.0.

**salt.runners.pkg.list_upgrades** *(jid, style='group', outputter='nested', ext_source=None)*

Show list of available pkg upgrades using a specified format style

CLI Example:

```
salt-run pkg.list_upgrades jid=20141120114114417719 style=group
```

---

### 23.16.29 salt.runners.queue

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues.

The queue functions such as **insert**, **delete**, and **pop** can be used for typical management of the queue.

The **process_queue** function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The **process_queue** function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.

There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the **process_queue** runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use salt-cloud to destroy the vm, or some other custom action.

**Queued runners**

Using the Salt Queues, references to the commandline arguments of other runners can be saved to be processed later. The queue runners require a queue backend that can store json data (default: pgjsonb).

Once the queue is setup, the **runner_queue** will need to be configured.

```
runner_queue:
  queue: runners
  backend: pgjsonb
```

---
Note: only the queue is required, this defaults to using pgjsonb

Once this is set, then the following can be added to the scheduler on the master and it will run the specified amount of commands per time period.

```
schedule:
  runner queue:
    schedule:
      function: queue.process_runner
      minutes: 1
      kwargs:
        quantity: 2
```

The above configuration will pop 2 runner jobs off the runner queue, and then run them. And it will do this every minute, unless there are any jobs that are still running from the last time the process_runner task was executed.

salt.runners.queue.delete(queue, items, backend='sqlite')
Delete an item or items from a queue

CLI Example:

```
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqlite
salt-run queue.delete myqueue "['item1', 'item2', 'item3']"
```

salt.runners.queue.insert(queue, items, backend='sqlite')
Add an item or items to a queue

CLI Example:

```
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue "['item1', 'item2', 'item3']"
salt-run queue.insert myqueue myitem backend=sqlite
salt-run queue.insert myqueue "['item1', 'item2', 'item3']" backend=sqlite
```

salt.runners.queue.insert_runner(fun, args=None, kwargs=None, queue=None, backend=None)
Insert a reference to a runner into the queue so that it can be run later.

fun The runner function that is going to be run
args list or comma-separated string of args to send to fun
kwargs dictionary of keyword arguments to send to fun
queue queue to insert the runner reference into
backend backend that to use for the queue

CLI Example:

```
salt-run queue.insert_runner test.stdout_print
salt-run queue.insert_runner event.send test_insert_runner kwargs='{"data": {"foo →": "bar"}}'}
```

salt.runners.queue.list_items(queue, backend='sqlite')
List contents of a queue

CLI Example:

```
salt-run queue.list_items myqueue
salt-run queue.list_items myqueue backend=sqlite
```
salt.runners.queue.list_length(queue, backend='sqlite')

Provide the number of items in a queue

CLI Example:

```python
salt-run queue.list_length myqueue
salt-run queue.list_length myqueue backend=sqlite
```

salt.runners.queue.list_queues(backend='sqlite')

Return a list of Salt Queues on the backend

CLI Example:

```python
salt-run queue.list_queues
salt-run queue.list_queues backend=sqlite
```

salt.runners.queue.pop(queue, quantity=1, backend='sqlite', is_runner=False)

Pop one or more or all items from a queue

CLI Example:

```python
salt-run queue.pop myqueue
salt-run queue.pop myqueue 6
salt-run queue.pop myqueue all
salt-run queue.pop myqueue 6 backend=sqlite
salt-run queue.pop myqueue all backend=sqlite
```

salt.runners.queue.process_queue(queue, quantity=1, backend='sqlite', is_runner=False)

Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.

CLI Example:

```python
salt-run queue.process_queue myqueue
salt-run queue.process_queue myqueue 6
salt-run queue.process_queue myqueue all backend=sqlite
```

salt.runners.queue.process_runner(quantity=1, queue=None, backend=None)

Process queued runners

CLI Example:

```python
salt-run queue.process_runner
salt-run queue.process_runner 5
```

23.16.30  salt.runners.reactor

A convenience system to manage reactors

Beginning in the 2017.7 release, the reactor runner requires that the reactor system is running. This is accomplished one of two ways, either by having reactors configured or by including reactor in the engine configuration for the Salt master.
• reactor

\`
salt.runners.reactor.add(event, reactors, saltenv='base', test=None)
``

Add a new reactor

CLI Example:

```
salt-run reactor.add 'salt/cloud/*/destroyed' reactors='/srv/reactor/destroy/*.sls`
```

\`
salt.runners.reactor.delete(event, saltenv='base', test=None)
``

Delete a reactor

CLI Example:

```
salt-run reactor.delete 'salt/cloud/*/destroyed'
```

\`
salt.runners.reactor.is_leader()
``

Return whether the running reactor is acting as a leader (responding to events).

CLI Example:

```
salt-run reactor.is_leader
```

\`
salt.runners.reactor.list_(saltenv='base', test=None)
``

List currently configured reactors

CLI Example:

```
salt-run reactor.list
```

\`
salt.runners.reactor.set_leader(value=True)
``

Set the current reactor to act as a leader (responding to events). Defaults to True

CLI Example:

```
salt-run reactor.set_leader True
```

23.16.31 salt.runners.salt

This runner makes Salt’s execution modules available on the salt master.

New in version 2016.11.0. Salt’s execution modules are normally available on the salt minion. Use this runner to call execution modules on the salt master. Salt execution modules are the functions called by the salt command.

Execution modules can be called with salt-run:

```
salt-run salt.cmd test.ping
# call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 key=value a=1
```

Execution modules are also available to salt runners:

```
__salt__['salt.cmd'](fun=fun, args=args, kwargs=kwargs)
```

```
salt.runners.salt.cmd(fun, *args, **kwargs)
```

Changed in version 2018.3.0: Added with_pillar argument
Execute `fun` with the given `args` and `kwargs`. Parameter `fun` should be the string `name` of the execution module to call.

**Note:** Execution modules will be loaded every time this function is called. Additionally, keep in mind that since runners execute on the master, custom execution modules will need to be synced to the master using `salt-run saltutil.sync_modules`, otherwise they will not be available.

`with_pillar` [False] If `True`, pillar data will be compiled for the master.

**Note:** To target the master in the pillar top file, keep in mind that the default `id` for the master is `<hostname>_master`. This can be overridden by setting an `id` configuration parameter in the master config file.

CLI Example:

```
salt-run salt.cmd test.ping
# call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 a=1
salt-run salt.cmd mymod.myfunc with_pillar=True
```

```python
salt.runners.salt.execute(tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', jid='', kwarg=None, **kwargs)
```

New in version 2017.7.0.

Execute `fun` on all minions matched by `tgt` and `tgt_type`. Parameter `fun` is the name of execution module function to call.

This function should mainly be used as a helper for runner modules, in order to avoid redundant code. For example, when inside a runner one needs to execute a certain function on arbitrary groups of minions, only has to:

```python
ret1 = __salt__['salt.execute']('*', 'mod.fun')
ret2 = __salt__['salt.execute']('my_nodegroup', 'mod2.fun2', tgt_type='nodegroup')
```

It can also be used to schedule jobs directly on the master, for example:

```yaml
schedule:
    collect_bgp_stats:
        function: salt.execute
        args:
            - edge-routers
            - bgp.neighbors
        kwargs:
            tgt_type: nodegroup
        days: 1
        returner: redis
```
23.16.32  salt.runners.saltutil

The Saltutil runner is used to sync custom types to the Master. See the saltutil module for documentation on managing updates to minions.

New in version 2016.3.0.

salt.runners.saltutil.sync_all(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync all custom types

saltenv  [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist  [None] dictionary of modules to sync based on type
extmod_blacklist  [None] dictionary of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_all
salt-run saltutil.sync_all  extmod_whitelist={'runners': ['custom_runner'], 'grains': []}
```

salt.runners.saltutil.sync_cache(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync cache modules from salt://_cache to the master

saltenv  [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist  [None] comma-separated list of modules to sync
extmod_blacklist  [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_cache
```

salt.runners.saltutil.sync_clouds(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync cloud modules from salt://_clouds to the master

saltenv  [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist  [None] comma-separated list of modules to sync
extmod_blacklist  [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_clouds
```

salt.runners.saltutil.sync_eauth_tokens(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2018.3.0.

Sync eauth token modules from salt://_tokens to the master

saltenv  [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist  [None] comma-separated list of modules to sync
extmod_blacklist  [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_eauth_tokens
```
salt.runners.saltutil.sync_engines(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync engines from salt://_engines to the master
	saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
	extmod_whitelist [None] comma-separated list of modules to sync	extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_engines

salt.runners.saltutil.sync_executors(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 3000.

Sync executor modules from salt://_executors to the master
	saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
	extmod_whitelist [None] comma-separated list of modules to sync	extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_executors

salt.runners.saltutil.sync_fileserver(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2018.3.0.

Sync fileserver modules from salt://_fileserver to the master
	saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
	extmod_whitelist [None] comma-separated list of modules to sync	extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_fileserver

salt.runners.saltutil.sync_grains(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync grains modules from salt://_grains to the master
	saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
	extmod_whitelist [None] comma-separated list of modules to sync	extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_grains

salt.runners.saltutil.sync_modules(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync execution modules from salt://_modules to the master
	saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
	extmod_whitelist [None] comma-separated list of modules to sync	extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_modules

salt.runners.saltutil.sync_output(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync output modules from salt://_output to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_output

salt.runners.saltutil.sync_pillar(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync pillar modules from salt://_pillar to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_pillar

salt.runners.saltutil.sync_proxymodules(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync proxy modules from salt://_proxy to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_proxymodules

salt.runners.saltutil.sync_queues(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync queue modules from salt://_queues to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_queues

salt.runners.saltutil.sync_renderers(salenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync renderer modules from from salt://_renderers to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_renderers

collections.saltutil.sync_returners(saltenv='base',
                                   extmod_whitelist=None,
                                   extmod_blacklist=None)

Sync returner modules from salt://_returners to the master

- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- extmod_whitelist [None] comma-separated list of modules to sync
- extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
	salt-run saltutil.sync_returners

collections.saltutil.sync_roster(saltenv='base',
                                 extmod_whitelist=None,
                                 extmod_blacklist=None)

New in version 2017.7.0.

Sync roster modules from salt://_roster to the master

- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- extmod_whitelist [None] comma-separated list of modules to sync
- extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
	salt-run saltutil.sync_roster

collections.saltutil.sync_runners(saltenv='base',
                                    extmod_whitelist=None,
                                    extmod_blacklist=None)

Sync runners from salt://_runners to the master

- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- extmod_whitelist [None] comma-separated list of modules to sync
- extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
	salt-run saltutil.sync_runners

collections.saltutil.sync_sdb(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync sdb modules from salt://_sdb to the master

- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- extmod_whitelist [None] comma-separated list of modules to sync
- extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
	salt-run saltutil.sync_sdb

collections.saltutil.sync_serializers(saltenv='base',
                                       extmod_whitelist=None,
                                       extmod_blacklist=None)

New in version 2019.2.0.

Sync serializer modules from salt://_serializers to the master

- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
```
salt-run saltutil.sync_utils
```

salt.runners.saltutil.sync_states(saltenv='base',
                                 extmod_whitelist=None,
                                 extmod_blacklist=None)
Sync state modules from salt://_states to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment,
pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
```
salt-run saltutil.sync_states
```

salt.runners.saltutil.sync_thorium(saltenv='base',
                                  extmod_whitelist=None,
                                  extmod_blacklist=None)
New in version 2018.3.0.
Sync Thorium from salt://_thorium to the master
saltenv: base The fileserver environment from which to sync. To sync from more than one environment,
pass a comma-separated list.
extmod_whitelist comma-separated list of modules to sync
extmod_blacklist comma-separated list of modules to blacklist based on type
CLI Example:
```
salt-run saltutil.sync_thorium
```

salt.runners.saltutil.sync_tops(saltenv='base',
                                extmod_whitelist=None,
                                extmod_blacklist=None)
New in version 2016.3.7, 2016.11.4, 2017.7.0.
Sync master_tops modules from salt://_tops to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment,
pass a comma-separated list.
CLI Example:
```
salt-run saltutil.sync_tops
```

salt.runners.saltutil.sync_utils(saltenv='base',
                                  extmod_whitelist=None,
                                  extmod_blacklist=None)
New in version 2016.11.0.
Sync utils modules from salt://_utils to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment,
pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
```
salt-run saltutil.sync_utils
```

salt.runners.saltutil.sync_wheel(saltenv='base',
                                 extmod_whitelist=None,
                                 extmod_blacklist=None)
Sync wheel modules from salt://_wheel to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment,
pass a comma-separated list.

23.16. runner modules

3379
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:
salt-run saltutil.sync_wheel

23.16.33 salt.runners.sdb

Runner for setting and querying data via the sdb API on the master

salt.runners.sdb.delete(uri)
Delete a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully deleted, return False.

CLI Example:
salt-run sdb.delete sdb://mymemcached/foo

salt.runners.sdb.get(uri)
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:
salt-run sdb.get sdb://mymemcached/foo

salt.runners.sdb.get_or_set_hash(uri, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#$%^&*(-_=+))
Perform a one-time generation of a hash and write it to sdb. If that value has already been set return the value instead.

This is useful for generating passwords or keys that are specific to multiple minions that need to be stored somewhere centrally.

CLI Example:
salt-run sdb.get_or_set_hash 'SECRET_KEY' 50

Warning: This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with %’. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

salt.runners.sdb.set_(uri, value)
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
salt-run sdb.set sdb://mymemcached/foo bar
23.16.34  salt.runners.smartos_vmadm

Runner for SmartOS minions control vmadm

```
salt.runners.smartos_vmadm.get(search, one=True)
```

Return information for vms

- `search` [string] filter vms, see the execution module.
- `one` [boolean] return only one vm

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

**CLI Example:**
```
salt-run vmadm.get 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.get search='alias=saskia'
```

```
salt.runners.smartos_vmadm.is_running(search)
```

Return true if vm is running

- `search` [string] filter vms, see the execution module.

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

**Note:** If multiple vms are matched, the result will be true of ALL vms are running

**CLI Example:**
```
salt-run vmadm.is_running 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.is_running search='alias=julia'
```

```
salt.runners.smartos_vmadm.list_vms(search=None, verbose=False)
```

List all vms

- `search` [string] filter vms, see the execution module
- `verbose` [boolean] print additional information about the vm

**CLI Example:**
```
salt-run vmadm.list
salt-run vmadm.list search='type=KVM'
salt-run vmadm.list verbose=True
```

```
salt.runners.smartos_vmadm.nodes(verbose=False)
```

List all compute nodes

- `verbose` [boolean] print additional information about the node e.g. platform version, hvm capable, ...

**CLI Example:**
```
salt-run vmadm.nodes
salt-run vmadm.nodes verbose=True
```

```
salt.runners.smartos_vmadm.reboot(search, one=True, force=False)
```

Reboot one or more vms

- `search` [string] filter vms, see the execution module.
- `one` [boolean] reboot only one vm
force [boolean] force reboot, faster but no graceful shutdown

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.reboot 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.reboot search='alias=marije'
salt-run vmadm.reboot search='type=KVM' one=False
```

salt.runners.smartos_vmadm.start(search, one=True)
Start one or more vms

search [string] filter vms, see the execution module.

one [boolean] start only one vm

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.start 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.start search='alias=jiska'
salt-run vmadm.start search='type=KVM' one=False
```

salt.runners.smartos_vmadm.stop(search, one=True)
Stop one or more vms

search [string] filter vms, see the execution module.

one [boolean] stop only one vm

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.stop 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.stop search='alias=jody'
salt-run vmadm.stop search='type=KVM' one=False
```

23.16.35 salt.runners.spacewalk

Spacewalk Runner

New in version 2016.3.0.

Runner to interact with Spacewalk using Spacewalk API

codeauthor Nitin Madhok <nmadhok@g.clemson.edu>, Joachim Werner <joe@suse.com>, Benedikt Werner <1benediktwerner@gmail.com>
maintainer Benedikt Werner <1benediktwerner@gmail.com>

To use this runner, set up the Spacewalk URL, username and password in the master configuration at /etc/salt/master or /etc/salt/master.d/spacewalk.conf:
spacewalk:
spacewalk01.domain.com:
  username: 'testuser'
  password: 'verybadpass'
spacewalk02.domain.com:
  username: 'testuser'
  password: 'verybadpass'

Note: Optionally, protocol can be specified if the spacewalk server is not using the defaults. Default is protocol: https.

salt.runners.spacewalk.addGroupsToKey(server, activation_key, groups)
Add server groups to a activation key

CLI Example:
salt-run spacewalk.addGroupsToKey spacewalk01.domain.com 1-my-key '[group1, group2]'

salt.runners.spacewalk.api(server, command, *args, **kwargs)
Call the Spacewalk xmlrpc api.

CLI Example:
salt-run spacewalk.api spacewalk01.domain.com systemgroup.create MyGroup "Description"
salt-run spacewalk.api spacewalk01.domain.com systemgroup.create arguments='[ "MyGroup", "Description"]'

State Example:
create_group:
salt.runner:
  - name: spacewalk.api
  - server: spacewalk01.domain.com
  - command: systemgroup.create
  - arguments:
    - MyGroup
    - Description

salt.runners.spacewalk.deleteAllActivationKeys(server)
Delete all activation keys from Spacewalk

CLI Example:
salt-run spacewalk.deleteAllActivationKeys spacewalk01.domain.com

salt.runners.spacewalk.deleteAllGroups(server)
Delete all server groups from Spacewalk

salt.runners.spacewalk.deleteAllSystems(server)
Delete all systems from Spacewalk

CLI Example:
salt-run spacewalk.deleteAllSystems spacewalk01.domain.com
salt.runners.spacewalk.unregister(name, server_url)

Unregister specified server from Spacewalk

CLI Example:

```
salt-run spacewalk.unregister my-test-vm spacewalk01.domain.com
```

### 23.16.36 salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.

This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.

salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, tgt_type='glob', kwarg=None)

New in version 2015.5.0.

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Execute a single command via the salt-ssh subsystem and return all routines at once

A wrapper around the SSHClient.cmd method.

### 23.16.37 salt.runners.state

Execute orchestration functions

salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False, node='master')

Watch Salt's event bus and block until the given tag is matched

New in version 2014.7.0.

Changed in version 2019.2.0: tagmatch can now be either a glob or regular expression.

This is useful for utilizing Salt’s event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

**Parameters**

- **tagmatch** -- the event is written to stdout for each tag that matches this glob or regular expression.
- **count** -- this number is decremented for each event that matches the tagmatch parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.
- **node** -- Watch the minion-side or master-side event bus.

**CLI Examples:**

```
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot && \
    salt-run state.event 'salt/minion/jerry/start' count=1 quiet= True && \
    salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot && \
    salt-run state.event 'salt/minion/*/start' count=3 quiet= True && \
```

(continues on next page)
salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do
echo $tag
echo $data | jq --color-output .
done

See also:

See https://github.com/saltstack/salt/blob/master/tests/eventlisten.sh for an example of usage within a shell script.

salt.runners.state.orchestrate(mods, saltenv='base', test=None, exclude=None, pillar=None, pillar_enc=None, orchestration_jid=None)

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation
- Full Orchestrate Tutorial
- Docs for the master-side state module

CLI Examples:

salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
salt-run state.orchestrate webserver saltenv=dev pillarenv=aws

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestrate

Changed in version 2014.7.0: Runner uses the pillar variable

Changed in version 2017.5: Runner uses the pillar_enc variable that allows renderers to render the pillar. This is usable when supplying the contents of a file as pillar, and the file contains gpg-encrypted entries.

See also:

GPG renderer documentation

CLI Examples:

salt-run state.orchestrate webserver pillar_enc=gpg pillar="$(cat somefile.json)"

salt.runners.state.orchestrate_high(data, test=None, queue=False, pillar=None, **kwargs)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

salt-run state.orchestrate_high '{
  stage_one:
    {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]),
  stage_two:
    {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
      require: [{salt: stage_one}],
    }],
  }
}'}
salt.runners.state.orchestrate_show_sls(mods, saltenv='base', test=None, queue=False, pillar=None, pillarenv=None, pillar_enc=None)

Display the state data from a specific sls, or list of sls files, after being render using the master minion.

Note, the master minion adds a "_master" suffix to its minion id.

See also:
The state.show_sls module function

CLI Example:

```
salt-run state.orch_show_sls my-orch-formula.my-orch-state 'pillar={ nodegroup:ng1 }'
```

salt.runners.state.orchestrate_single(fun, name, test=None, queue=False, pillar=None, **kwargs)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

salt.runners.state.pause(jid, state_id=None, duration=None)

Set up a state id pause, this instructs a running state to pause at a given state id. This needs to pass in the jid of the running state and can optionally pass in a duration in seconds.

salt.runners.state.resume(jid, state_id=None)

Remove a pause from a jid, allowing it to continue

salt.runners.state.rm_pause(jid, state_id=None)

This function is an alias of resume.

Remove a pause from a jid, allowing it to continue

salt.runners.state.set_pause(jid, state_id=None, duration=None)

This function is an alias of pause.

Set up a state id pause, this instructs a running state to pause at a given state id. This needs to pass in the jid of the running state and can optionally pass in a duration in seconds.

salt.runners.state.soft_kill(jid, state_id=None)

Setupastateruntodiebeforeexecutingthegivenstateid,thisinstructsarunningstatetosafelyexitatagiven state id. This needs to pass in the jid of the running state. If a state_id is not passed then the jid referenced will be safely exited at the beginning of the next state run.

23.16.38 salt.runners.survey

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.

salt.runners.survey.diff(*args, **kwargs)

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.
These pools are determined from the aggregated and sorted results of a salt command. This command displays the "difs" as a series of 2-way differences -- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set. Differences are displayed according to the Python `difflib.unified_diff()` as in the case of the salt execution module `file.get_diff`.

This command is submitted via a salt runner using the general form:

```plaintext
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (Example to display the "differences of files")

```plaintext
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

```plaintext
salt.runners.survey.hash(*args,**kwargs)
```

Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```plaintext
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (functionally equivalent to `salt-run manage.up`)

```plaintext
salt-run survey.hash "*" test.ping
```

CLI Example #2: (find an "outlier" minion config file)

```plaintext
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

### 23.16.39 `salt.runners.test`

This runner is used only for test purposes and servers no production purpose

```plaintext
salt.runners.test.arg(*args,**kwargs)
```

Output the given args and kwargs

Kwargs will be filtered for 'private' keynames.

```plaintext
salt.runners.test.get_opts()
```

New in version 2018.3.0.

Return the configuration options of the master.

CLI Example:

```plaintext
salt-run test.get_opts
```

```plaintext
salt.runners.test.metasyntactic(locality='us')
```

Return common metasyntactic variables for the given locality.
salt.runners.test.raw_arg(*args, **kwargs)
    Output the given args and kwargs

salt.runners.test.sleep(s_time=10)
    Sleep t seconds, then return True

salt.runners.test.stdout_print()
    Print 'foo' and return 'bar'

salt.runners.test.stream()
    Return True

23.16.40 salt.runners.thin

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

salt.runners.thin.generate(extra_mods='', overwrite=False, so_mods='', python2_bin='python2', python3_bin='python3', absonly=True, compress='gzip')
    Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.
    CLI Example:

    salt-run thin.generate
    salt-run thin.generate mako
    salt-run thin.generate mako,wempy 1
    salt-run thin.generate overwrite=1

salt.runners.thin.generate_min(extra_mods='', overwrite=False, so_mods='', python2_bin='python2', python3_bin='python3')
    Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.
    CLI Example:

    salt-run thin.generate_min

23.16.41 salt.runners.vault

    maintainer SaltStack
    maturity new
    platform all

Runner functions supporting the Vault modules. Configuration instructions are documented in the execution module docs.

salt.runners.vault.generate_token(minion_id, signature, impersonated_by_master=False, ttl=None, uses=None)
    Generate a Vault token for minion minion_id
    minion_id The id of the minion that requests a token
    signature Cryptographic signature which validates that the request is indeed sent by the minion (or the master, see impersonated_by_master).
    impersonated_by_master If the master needs to create a token on behalf of the minion, this is True. This happens when the master generates minion pillars.
ttl  Ticket time to live in seconds, 1m minutes, or 2h hrs
uses  Number of times a token can be used

`salt.runners.vault.show_policies(minion_id)`
Show the Vault policies that are applied to tokens for the given minion

*minion_id*  The minions id

CLI Example:
```
salt-run vault.show_policies myminion
```

`salt.runners.vault.unseal()`
Unseal Vault server

This function uses the 'keys' from the 'vault' configuration to unseal vault server

*vault:
**keys:**
- n63/TbrQuL3xaLW7ZZpuXJ/tlfnK1/MbVxo4vT3wYD2A
- S9OwCvMrHErEA4NVVELYB6w/Me6+urgUr24xGK44Uy3
- F1j4b7Jkq850Ns6Kboiy5la0xy8dWjvB3fwc+w+SraYI
- 1cYtvjKJNDVam9c7HNgjUfNk4PYyAYpjkpN/sluzPv
- 3pPK5x6GtwLhNOFv1U2elahECz3HpRUfNXjFylw6id
```

CLI Examples:
```
salt-run vault.unseal
```

### 23.16.42 `salt.runners.venafiapi`

Support for Venafi

*depends*
- vcert Python module

*configuration*  In order to connect to Venafi services you need to specify it in Salt master configuration.

Example for Venafi Cloud (using env variables):
```
venafi: api_key: "sdb://osenv/CLOUDAPIKEY"
```

Example for Venafi Platform (using env variables):
```
venafi: base_url: "https://tpp.example.com/"
tpp_user: admin
tpp_password: "sdb://osenv/TPP_PASSWORD"
trust_bundle: "/opt/venafi/bundle.pem"
```

`salt.runners.venafiapi.del_cached_domain(domains)`
Delete cached domains from the master

CLI Example:
```
salt-run venafi.del_cached_domain domain1.example.com,domain2.example.com
```

`salt.runners.venafiapi.list_domain_cache()`
List domains that have been cached

CLI Example:
salt-run venafi.list_domain_cache

salt.runners.venafiapi.renew(minion_id, dns_name=None, zone=None, country=None, state=None, loc=None, org=None, org_unit=None, key_password=None, csr_path=None, pkey_path=None)

Request a new certificate

CLI Example:

salt-run venafi.request <minion_id> <dns_name>

salt.runners.venafiapi.request(minion_id, dns_name=None, zone=None, country=None, state=None, loc=None, org=None, org_unit=None, key_password=None, csr_path=None, pkey_path=None)

Request a new certificate

CLI Example:

salt-run venafi.request <minion_id> <dns_name>

salt.runners.venafiapi.show_cert(dns_name)

Show issued certificate for domain

CLI Example:

salt-run venafi.show_cert example.com

23.16.43 salt.runners.virt

Control virtual machines via Salt

salt.runners.virt.force_off(name)

Force power down the named virtual machine

salt.runners.virt.host_info(host=None)

Return information about the host connected to this master

salt.runners.virt.init(name, cpu, mem, image, hypervisor='kvm', host=None, seed=True, nic='default', install=True, start=True, disk='default', saltenv='base', enable_vnc=False, seed_cmd='seed.apply', enable_qcow=False, serial_type='None')

This routine is used to create a new virtual machine. This routines takes a number of options to determine what the newly created virtual machine will look like.

name The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.

cpu The number of cpus to allocate to this new virtual machine.

mem The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.

image The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.

hypervisor The hypervisor to use for the new virtual machine. Default is kvm.

host The host to use for the new virtual machine, if this is omitted Salt will automatically detect what host to use.

seed Set to False to prevent Salt from seeding the new virtual machine.

nic The nic profile to use, defaults to the "default" nic profile which assumes a single network interface per VM associated with the "br0" bridge on the master.

install Set to False to prevent Salt from installing a minion on the new VM before it spins up.
The disk profile to use

The Salt environment to use

Whether a VNC screen is attached to resulting VM. Default is False.

If seed is True, use this execution module function to seed new VM. Default is seed.apply.

Clone disk image as a copy-on-write qcow2 image, using downloaded image as backing file.

Enable serial console. Set to 'pty' for serial console or 'tcp' for telnet. Default is 'None'

List the virtual machines on each host, this is a simplified query, showing only the virtual machine names belonging to each host. A single host can be passed in to specify an individual host to list.

Migrate a VM from one host to another. This routine will just start the migration and display information on how to look up the progress.

Return the host to use for the next autodeployed VM. This queries the available host and executes some math the determine the most "available" next host.

Pause the named VM

Destroy the named VM

Query the virtual machines. When called without options all hosts are detected and a full query is returned. A single host can be passed in to specify an individual host to query.

Force power down and restart an existing VM

Resume a paused VM

Start a named virtual machine

Return the information on the named VM

23.16.44 salt.runners.vistara

Vistara Runner

Runner to interact with the Vistara (http://www.vistarait.com/) REST API

codeauthor Brad Thurber <brad.thurber@gmail.com>

To use this runner, the Vistara client_id and Vistara oauth2 client_key and client_secret must be set in the master config.

For example /etc/salt/master.d/_vistara.conf:

```json
vistara:
  client_id: client_012345
  client_key: N0tReallyaR3alKeyButShouldB12345
  client_secret: ThisIS5AreallyLongsecretKeyIwonderwhyTheMakethemSoBigTheseDays00
```
salt.runners.vistara.delete_device(name, safety_on=True)

Deletes a device from Vistara based on DNS name or partial name. By default, delete_device will only perform the delete if a single host is returned. Set safety_on=False to delete all matches (up to default API search page size).

CLI Example:

```
salt-run vistara.delete_device 'hostname-101.mycompany.com'
salt-run vistara.delete_device 'hostname-101'
salt-run vistara.delete_device 'hostname-1' safety_on=False
```

23.16.45 salt.runners.winrepo

Runner to manage Windows software repo

salt.runners.winrepo.genrepo(opts=None, fire_event=True)

Generate winrepo_cachefile based on sls files in the winrepo_dir

- **opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
- **fire_event** [True] Fire an event on failure. Only supported on the master.

CLI Example:

```
salt-run winrepo.genrepo
```

salt.runners.winrepo.update_git_repos(opts=None, clean=False, masterless=False)

Checkout git repos containing Windows Software Package Definitions

- **opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
- **clean** [False] Clean repo cachedirs which are not configured under `winrepo_remotes`.

```
Warning: This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.
```

New in version 2015.8.0.

CLI Examples:

```
salt-run winrepo.update_git_repos
salt-run winrepo.update_git_repos clean=True
```

23.17.1 salt.sdb.cache

cache Module

**maintainer** SaltStack

**maturity** New

**platform** all

New in version 2017.7.0.

This module provides access to Salt’s cache subsystem.

Like all sdb modules, the cache module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mastercloudcache:
  driver: cache
  bank: cloud/active/ec2/my-ec2-conf/saltmaster
  cachedir: /var/cache/salt
```

The `driver` refers to the cache module, `bank` refers to the cache bank that contains the data and `cachedir` (optional), if used, points to an alternate directory for cache data storage.

```yaml
master_ip: sdb://mastercloudcache/public_ips
```

It is also possible to override both the `bank` and `cachedir` options inside the SDB URI:

```yaml
```

For this reason, both the `bank` and the `cachedir` options can be omitted from the SDB profile. However, if the `bank` option is omitted, it must be specified in the URI:

```yaml
```

**salt.sdb.cache.delete(key, service=None, profile=None)**

Get a value from the cache service

**salt.sdb.cache.get(key, service=None, profile=None)**

Get a value from the cache service

**salt.sdb.cache.set(key, value, service=None, profile=None)**

Set a key/value pair in the cache service
23.17.2 salt.sdb.confidant

An SDB module for getting credentials from confidant.

Configuring the Confidant module

The module can be configured via sdb in the minion config:

```yaml
confidant:
  driver: confidant
  # The URL of the confidant web service
  url: 'https://confidant-production.example.com'
  # The context to use for KMS authentication
  auth_context:
    from: example-production-iad
    to: confidant-production-iad
    user_type: service
  # The KMS master key to use for authentication
  auth_key: "alias/authnz"
  # Cache file for KMS auth token
  token_cache_file: /run/confidant/confidant_token
  # The duration of the validity of a token, in minutes
  token_duration: 60
  # key, keyid and region can be defined in the profile, but it's generally
  # best to use IAM roles or environment variables for AWS auth.
  keyid: 98nh9h9h08h09kjjk
  key: jhf908gyegehe0he0g8h9u0j0n0n09hj09h0
  region: us-east-1
```

*depends* confidant-common, confidant-client

Module Documentation

**salt.sdb.confidant.get**(*key, profile=None*)

Read pillar data from Confidant via its API.

CLI Example:

```
salt myminion sdb.get 'sdb://confidant/credentials'
```

Valid keys are: credentials, credentials_metadata, result. credentials returns a dict of joined credential_pairs, credentials_metadata returns a dict of metadata relevant to the credentials mapped to the confidant service, and result returns a bool that can be used to determine if the sdb call succeeded or failed to fetch credentials from confidant (or from local cache). If result is false, the data in credentials or credentials_metadata can't be trusted.
23.17.3 salt.sdb.consul

Consul sdb Module

maintainer SaltStack

maturity New

platform all

This module allows access to Consul using an sdb:// URI

Like all sdb modules, the Consul module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
myconsul:
    driver: consul
    host: 127.0.0.1
    port: 8500
    token: b6376760-a8bb-edd5-fcda-33bc13bfc556
    scheme: http
    consistency: default
    dc: dev
    verify: True
```

The driver refers to the Consul module, all other options are optional. For option details see: https://python-consul.readthedocs.io/en/latest/#consul

salt.sdb.consul.get(key, profile=None)
salt.sdb.consul.get_conn(profile)
    Return a client object for accessing consul
salt.sdb.consul.set_(key, value, profile=None)

23.17.4 salt.sdb.couchdb

CouchDB sdb Module

maintainer SaltStack

maturity New

depends python2-couchdb

platform all

This allow interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in salt configuration files.

To use the couchbase sdb module, it must first be configured in the salt master or minion config. The following arguments are required:

```
couchdb_sdb:
    driver: couchdb
    host: localhost
    port: 5984
    database: salt_sdb
```

One could then query the CouchDB instance via an sdb:// URI such as the following:
**password:** sdb://couchdb_sdb/mykey

To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

```python
salt.sdb.couchdb.get(key, profile=None)
```
Get a value from couchdb by id

```python
salt.sdb.couchdb.set_(key, value, profile=None)
```
Set a key/value pair in couchdb

### 23.17.5 salt.sdb.env

Environment sdb Module

- **maintainer:** SaltStack
- **maturity:** New
- **depends:** None
- **platform:** all

This module allows access to environment variables using an sdb:// URI.

Example configuration for this module:

```yaml
osenv:
  driver: env
```

**WARNING:**

OS environment variables will be available to read via SDB. Please make sure you don't have any sensitive data in your environment variables‼

Example usage of sdb env module:

```python
set some env var:
  cmd.run:
    - name: echo {{ salt['sdb.set']('sdb://osenv/foo', 'bar') }}
    - order: 1

{% if salt['sdb.get']('sdb://osenv/foo') == 'bar' %}
always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo
{% else %}
always-changes-and-fails:
  test.fail_with_changes:
    - name: foo
{% endif %}
```

The above example will return success.

The env sdb module can also be used with salt cloud. Assuming you have exported the environment variable named `compute` (and have `osenv` defined). The example below will look for the salt cloud config key `compute_name` in the environment:
my-openstack-config:
  compute_name: sdb://osenv/compute

salt.sdb.env.get(key, profile=None)
  Get a value

salt.sdb.env.set_(key, value, profile=None)
  Set a key/value pair

23.17.6 salt.sdb.etcd_db

etcd Database Module

  maintainer  SaltStack
  maturity    New
  depends     python-etcd
  platform    all

New in version 2015.5.0.

This module allows access to the etcd database using an sdb:// URL. This package is located at https://pypi.python.org/pypi/python-etcd.

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
myetcd:
  driver: etcd
  etcd.host: 127.0.0.1
  etcd.port: 2379
```

The driver refers to the etcd module, etcd.host refers to the host that is hosting the etcd database and etcd.port refers to the port on that host.

password: sdb://myetcd/mypassword

salt.sdb.etcd_db.delete(key, service=None, profile=None)
  Get a value from the etcd service

salt.sdb.etcd_db.get(key, service=None, profile=None)
  Get a value from the etcd service

salt.sdb.etcd_db.set_(key, value, service=None, profile=None)
  Set a key/value pair in the etcd service
23.17.7  salt.sdb.keyring_db

Keyring Database Module

maintainer SaltStack
maturity New
depends keyring
platform all

This module allows access to the keyring package using an sdb:// URI. This package is located at https://pypi.python.org/pypi/keyring.

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mykeyring:
    driver: keyring
    service: system
```

The driver refers to the keyring module, service refers to the service that will be used inside of keyring (which may be likened unto a database table) and mykeyring refers to the name that will appear in the URI:

```
password: sdb://mykeyring/mypassword
```

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

```
salt.sdb.keyring_db.get(key, service=None, profile=None)
    Get a value from a keyring service
```

```
salt.sdb.keyring_db.set_(key, value, service=None, profile=None)
    Set a key/value pair in a keyring service
```

23.17.8  salt.sdb.memcached

Memcached sdb Module

maintainer SaltStack
maturity New
depends python-memcached
platform all

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.
Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mymemcache:
    driver: memcached
    memcached.host: localhost
    memcached.port: 11211
```

The `driver` refers to the memcached module, `host` and `port` the memcached server to connect to (defaults to localhost and 11211, and `mymemcached` refers to the name that will appear in the URI:

```
password: sdb://mymemcached/mykey
```

```python
salt.sdb.memcached.get(key, profile=None)
    Get a value from memcached
salt.sdb.memcached.set_(key, value, profile=None)
    Set a key/value pair in memcached
```

23.17.9 salt.sdb.redis_sdb

Redis SDB module

New in version 2019.2.0.

This module allows access to Redis using an `sdb://` URI.

Like all SDB modules, the Redis module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
sdb_redis:
    driver: redis
    host: 127.0.0.1
    port: 6379
    password: pass
    db: 1
```

The `driver` refers to the Redis module, all other options are optional. For option details see: https://redis-py.readthedocs.io/en/latest/.

```python
salt.sdb.redis_sdb.delete(key, profile=None)
    Delete a key from the Redis SDB.

salt.sdb.redis_sdb.get(key, profile=None)
    Get a value from the Redis SDB.

salt.sdb.redis_sdb.set_(key, value, profile=None)
    Set a value into the Redis SDB.
```
23.17.10  salt.sdb.rest

Generic REST API SDB Module

   maintainer  SaltStack
   maturity   New
   platform   all

New in version 2015.8.0.

This module allows access to a REST interface using an sdb:// URL.

Like all REST modules, the REST module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
my-rest-api:
   driver: rest
   urls:
      url: https://api.github.com/
   keys:
      url: https://api.github.com/users/{{user}}/keys
      backend: requests
```

The **driver** refers to the REST module, and must be set to **rest** in order to use this driver. Each of the other items inside this block refers to a separate set of HTTP items, including a URL and any options associated with it. The options used here should match the options available in **salt.utils.http.query()**.

In order to call the **urls** item in the example, the following reference can be made inside a configuration file:

```yaml
github_urls: sdb://my-rest-api/urls
```

Key/Value pairs may also be used with this driver, and merged into the URL using the configured renderer (**jinja**, by default). For instance, in order to use the **keys** item in the example, the following reference can be made:

```yaml
github_urls: sdb://my-rest-api/keys?user=myuser
```

This will cause the following URL to actually be called:

```
https://api.github.com/users/myuser/keys
```

Key/Value pairs will **NOT** be passed through as GET data. If GET data needs to be sent to the URL, then it should be configured in the SDB configuration block. For instance:

```yaml
another-rest-api:
   driver: rest
   user_data:
      url: https://api.example.com/users/
      params:
         user: myuser
```

**salt.sdb.rest.get**(*key*, *service=None, profile=None*)
Get a value from the REST interface

**salt.sdb.rest.query**(*key*, *value=None, service=None, profile=None*)
Get a value from the REST interface

**salt.sdb.rest.set**(*key*, *value, service=None, profile=None*)
Set a key/value pair in the REST interface
23.17.11 salt.sdb.sqlite3

SQLite sdb Module

maintainer SaltStack
maturity New
platform all

This module allows access to sqlite3 using an sdb:// URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
mysqlite:
    driver: sqlite3
database: /tmp/sdb.sqlite
table: sdb
create_table: True
```

The `driver` refers to the sqlite3 module, `database` refers to the sqlite3 database file. `table` is the table within the db that will hold keys and values (defaults to `sdb`). The database and table will be created if they do not exist.

Advanced Usage:

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

```
myadvanced
    driver: sqlite3
database: /tmp/sdb-advanced.sqlite
create_statements:
    - "CREATE TABLE advanced (a text, b text, c blob, d blob)"
    - "CREATE INDEX myidx ON advanced (a)"
get_query: "SELECT d FROM advanced WHERE a=:key"
set_query: "INSERT OR REPLACE INTO advanced (a, d) VALUES (:key, :value)"
```

```
salt.sdb.sqlite3.get(key, profile=None)
Get a value from sqlite3
```
```
salt.sdb.sqlite3.set_(key, value, profile=None)
Set a key/value pair in sqlite3
```

23.17.12 salt.sdb.tism

tISM - the Immutable Secrets Manager SDB Module

maintainer tISM
maturity New
platform all

New in version 2017.7.0.

This module will decrypt PGP encrypted secrets against a tISM server.
A profile must be setup in the minion configuration or pillar. If you want to use sdb in a runner or pillar you must also place a profile in the master configuration.

```
salt.sdb.tism.get(key, service=None, profile=None)
Get a decrypted secret from the tISMd API
```

### 23.17.13 salt.sdb.vault

Vault SDB Module

- **maintainer**: SaltStack
- **maturity**: New
- **platform**: all

New in version 2016.11.0.

This module allows access to Hashicorp Vault using an `sdb://` URL.

Base configuration instructions are documented in the execution module docs. Below are noted extra configuration required for the sdb module, but the base configuration must also be completed.

Like all sdb modules, the vault module requires a configuration profile to be configured in either the minion configuration file or a pillar. This profile requires only setting the `driver` parameter to `vault`:

```
myvault:
  driver: vault
```

Once configured you can access data using a URL such as:

```
password: sdb://myvault/secret/passwords/mypassword
```

In this URL, `myvault` refers to the configuration profile, `secret/passwords` is the path where the data resides, and `mypassword` is the key of the data to return.

The above URI is analogous to running the following vault command:

```
$ vault read -field=mypassword secret/passwords
```

```
salt.sdb.vault.get(key, profile=None)
Get a value from the vault service
```
salt.sdb.vault.set_(key, value, profile=None)
   Set a key/value pair in the vault service

23.17.14 salt.sdb.yaml

Pull sdb values from a YAML file

   maintainer SaltStack
   maturity New
   platform all

New in version 2017.7.0.

Configuration:

```yaml
my-yaml-file:
   driver: yaml
   files:
      - /path/to/foo.yaml
      - /path/to/bar.yaml
```

The files are merged together and the result is searched using the same mechanism Salt uses for searching Grains and Pillar data structures.

Optional configuration:

```yaml
my-yaml-file:
   driver: yaml
   files:
      - /path/to/foo.yaml
      - /path/to/bar.yaml
   merge:
      strategy: smart
      merge_list: false
   gpg: true
```

New in version 2018.3.0.

Setting the gpg option to true (default is false) will decrypt embedded GPG-encrypted data using the GPG renderer.

salt.sdb.yaml.get(key, profile=None)
   Get a value from the dictionary

salt.sdb.yaml.set_(*args, **kwargs)
   Setting a value is not supported; edit the YAML files directly
23.18 serializer modules

<table>

</tbody>
</table>

23.18.1 salt.serializers.configparser

salt.serializers.configparser

New in version 2016.3.0.

Implements a configparser serializer.

salt.serializers.configparser.deserialize(stream_or_string, **options)

Deserialize any string or stream like object into a Python data structure.

Parameters

- stream_or_string -- stream or string to deserialize.
- options -- options given to lower configparser module.

salt.serializers.configparser.serialize(obj, **options)

Serialize Python data to a configparser formatted string or file.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower configparser module.

23.18.2 salt.serializers.json

salt.serializers.json

Implements JSON serializer.

It's just a wrapper around json (or simplejson if available).

salt.serializers.json.deserialize(stream_or_string, **options)

Deserialize any string or stream like object into a Python data structure.

Parameters

- stream_or_string -- stream or string to deserialize.
- options -- options given to lower json/simplejson module.

salt.serializers.json.serialize(obj, **options)

Serialize Python data to JSON.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower json/simplejson module.
23.18.3 salt.serializers.msgpack

salt.serializers.msgpack

Implements MsgPack serializer.

salt.serializers.msgpack.deserializer(stream_or_string, **options)
Deserialize any string of stream like object into a Python data structure.

Parameters
- stream_or_string -- stream or string to deserialize.
- options -- options given to lower msgpack module.

salt.serializers.msgpack.serialize(obj, **options)
Serialize Python data to MsgPack.

Parameters
- obj -- the data structure to serialize
- options -- options given to lower msgpack module.

23.18.4 salt.serializers.plist

salt.serializers.plist

New in version 3001.

Implements plist serializer.

Wrapper around plistlib.

salt.serializers.plist.deserializer(stream_or_string, **options)
Deserialize any string or stream like object into a Python data structure.

Parameters
- stream_or_string -- stream or string to deserialize.
- options -- options given to lower plist module.

Returns Deserialized data structure.

salt.serializers.plist.serialize(value, **options)
Serialize Python data to plist. To create a binary plist pass fmt: FMT_BINARY as an option.

Parameters
- obj -- the data structure to serialize
- options -- options given to lower plist module.

Returns bytes of serialized plist.

23.18.5 salt.serializers.python

salt.serializers.python

New in version 2016.3.0.

Implements a Python serializer (via pprint.format)

salt.serializers.python.serialize(obj, **options)
Serialize Python data to a Python string representation (via pprint.format)

Parameters
- obj -- the data structure to serialize
- options -- options given to pprint.format
23.18.6 salt.serializers.toml

salt.serializers.toml

Implements TOML serializer.
It’s just a wrapper around the python toml module.

salt.serializers.toml.deserialize(stream_or_string, **options)
Deserialize from TOML into Python data structure.
Parameters
- **stream_or_string** -- toml stream or string to deserialize.
- **options** -- options given to the python toml module.

salt.serializers.toml.serialize(obj, **options)
Serialize Python data to TOML.
Parameters
- **obj** -- the data structure to serialize.
- **options** -- options given to the python toml module.

23.18.7 salt.serializers.yaml

salt.serializers.yaml

Implements YAML serializer.
Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.

salt.serializers.yaml.deserialize(stream_or_string, **options)
Deserialize any string of stream like object into a Python data structure.
Parameters
- **stream_or_string** -- stream or string to deserialize.
- **options** -- options given to lower yaml module.

salt.serializers.yaml.serialize(obj, **options)
Serialize Python data to YAML.
Parameters
- **obj** -- the data structure to serialize
- **options** -- options given to lower yaml module.

23.18.8 salt.serializers.yamlex

salt.serializers.yamlex

YAMLEX is a format that allows for things like sls files to be more intuitive.
It’s an extension of YAML that implements all the salt magic: - it implies omap for any dict like. - it implies that string like data are str, not unicode - ...
For example, the file `states.sls` has this contents:

```
foo:
  bar: 42
  baz: [1, 2, 3]
```

The file can be parsed into Python like this
from salt.serializers import yamlex

with open('state.sls', 'r') as stream:
    obj = yamlex.deserialize(stream)

Check that `obj` is an OrderedDict

from salt.utils.odict import OrderedDict
assert isinstance(obj, dict)
assert isinstance(obj, OrderedDict)

`yamlex` objects’ methods render YAML understandable string. It means that they are template friendly.

```python
print '{{0}}'.format(obj)
```

returns:

```
{foo: {bar: 42, baz: [1, 2, 3]}}
```

and they are still valid YAML:

```python
from salt.serializers import yaml
yml_obj = yaml.deserialize(str(obj))
assert yml_obj == obj
```

`yamlex` implements also custom tags:

- `!aggregate` this tag allows structures aggregation.

For example:

```yaml
placeholder: !aggregate foo
placeholder: !aggregate bar
placeholder: !aggregate baz
```

is rendered as

```yaml
placeholder: [foo, bar, baz]
```

- `!reset` this tag flushes the computing value.

```yaml
placeholder: {{!aggregate foo: {foo: 42}}}
placeholder: {{!aggregate foo: {bar: null}}}
!reset placeholder: {{!aggregate foo: {baz: inga}}}
```

is roughly equivalent to

```yaml
placeholder: {{!aggregate foo: {baz: inga}}}
```

Document is defacto an aggregate mapping.

```python
salt.serializers.yamlex.deserialize(stream_or_string, **options)
```

Deserialize any string of stream like object into a Python data structure.
Parameters

- **stream_or_string** -- stream or string to deserialize.
- **options** -- options given to lower yaml module.

```python
salt.serializers.yamlx.serialize(obj, **options)
```

Serialize Python data to YAML.

Parameters

- **obj** -- the data structure to serialize
- **options** -- options given to lower yaml module.

23.19.1 salt.states.acme

ACME / Let's Encrypt certificate management state

New in version 2016.3.

See also the module documentation

```
reload-gitlab:
    cmd.run:
        - name: gitlab-ctl hup
dev.example.com:
    acme.cert:
        - aliases:
          - gitlab.example.com
        - email: acmemaster@example.com
        - webroot: /opt/gitlab/embedded/service/gitlab-rails/public
        - renew: 14
        - fire_event: acme/dev.example.com
        - onchanges_in:
            - cmd: reload-gitlab

salt.states.acme.cert(name, aliases=None, email=None, webroot=None, test_cert=False, renew=None, keysize=None, server=None, owner='root', group='root', mode='0640', certname=None, preferred_challenges=None, tls_sni_01_port=None, tls_sni_01_address=None, http_01_port=None, http_01_address=None, dns_plugin=None, dns_plugin_credentials=None)
```

Obtain/renew a certificate from an ACME CA, probably Let's Encrypt.

Parameters

- **name** -- Common Name of the certificate (DNS name of certificate)
- **aliases** -- subjectAltNames (Additional DNS names on certificate)
- **email** -- e-mail address for interaction with ACME provider
- **webroot** -- True or a full path to webroot. Otherwise use standalone mode
- **test_cert** -- Request a certificate from the Happy Hacker Fake CA (mutually exclusive with 'server')
- **renew** -- True/‘force’ to force a renewal, or a window of renewal before expiry in days
- **keysize** -- RSA key bits
- **server** -- API endpoint to talk to
- **owner** -- owner of the private key file
- **group** -- group of the private key file
- **mode** -- mode of the private key file
- **certname** -- Name of the certificate to save
- **preferred_challenges** -- A sorted, comma delimited list of the preferred challenge to use during authorization with the most preferred challenge listed first.
- **tls_sni_01_port** -- Port used during tls-sni-01 challenge. This only affects the port Certbot listens on. A conforming ACME server will still attempt to connect on port 443.
- **tls_sni_01_address** -- The address the server listens to during tls-sni-01 challenge.
- **http_01_port** -- Port used in the http-01 challenge. This only affects the port Certbot listens on. A conforming ACME server will still attempt to connect on port 80.
- **http_01_address** -- The address the server listens to during http-01 challenge.
- **dns_plugin** -- Name of a DNS plugin to use (currently only 'cloudflare')
23.19.2 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```
username:
    alias.present:
        - target: user@example.com

thomas:
    alias.present:
        - target: thomas@example.com
```

The default alias file is set to `/etc/aliases`, as defined in Salt's `config execution module`. To change the alias file from the default location, set the following in your minion config:

```
aliases.file: /my/alias/file
```

- `salt.states.alias.absent(name)`
  Ensure that the named alias is absent
  - `name` The alias to remove

- `salt.states.alias.present(name, target)`
  Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.
  - `name` The local user/address to assign an alias to
  - `target` The forwarding address

23.19.3 salt.states.alternatives

Configuration of the alternatives system

Control the alternatives system

```
{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
    file.directory

hadoop-0.20-conf:
    alternatives.install:
        - name: hadoop-0.20-conf
        - link: /etc/hadoop-0.20/conf
        - path: {{ my_hadoop_conf }}
        - priority: 30
        - require:
            - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
    alternatives.remove:
```

(continues on next page)
- name: hadoop-0.20-conf
  - path: {{ my_hadoop_conf }}

salt.states.alternatives.auto(name)
New in version 0.17.0.

Instruct alternatives to use the highest priority path for <name>
name is the master name for this link group (e.g. pager)

salt.states.alternatives.install(name, link, path, priority)

Install new alternative for defined <name>
name is the master name for this link group (e.g. pager)
link is the symlink pointing to /etc/alternatives/<name>. (e.g. /usr/bin/pager)
path is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)
priority is an integer; options with higher numbers have higher priority in automatic mode.

salt.states.alternatives.remove(name, path)

Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.
name is the master name for this link group (e.g. pager)
path is the location of one of the alternative target files. (e.g. /usr/bin/less)

salt.states.alternatives.set_(name, path)
New in version 0.17.0.

Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.
name is the master name for this link group (e.g. pager)
path is the location of one of the alternative target files. (e.g. /usr/bin/less)

```python
foo:
  alternatives.set:
    - path: /usr/bin/foo-2.0
```

23.19.4 salt.states.ansiblegate

Execution of Ansible modules from within states

With ansible.call these states allow individual Ansible module calls to be made via states. To call an Ansible module function use a module.run state:

```python
some_set_of_tasks:
  ansible:
    - system.ping
    - packaging.os.zypper
    - name: emacs
      state: installed
```

class salt.states.ansiblegate.AnsibleState

An Ansible state caller.

```python
get_args(argset)
  Get args and kwargs from the argset.
  Parameters argset --
  Returns
```
salt.states.ansiblegate.playbooks(name, rundir=None, git_repo=None, gitkwars=None, ansiblekwars=None)

Run Ansible Playbooks

Parameters

- **name** -- path to playbook. This can be relative to rundir or the git repo
- **rundir** -- location to run ansible-playbook from.
- **git_repo** -- git repository to clone for ansible playbooks. This is cloned using the `git.latest` state, and is cloned to the `rundir` if specified, otherwise it is clone to the `cache_dir`
- **gitkwars** -- extra kwargs to pass to `git.latest` state module besides the `name` and `target`
- **ansiblekwars** -- extra kwargs to pass to `ansible.playbooks` execution module besides the `name` and `target`

Returns Ansible playbook output.

```yaml
run nginx install:
  ansible.playbooks:
    - name: install.yml
    - git_repo: git://github.com/gituser/playbook.git
    - gitkwars:
      rev: master
```

23.19.5 salt.states.apache

Apache state

New in version 2014.7.0.

Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable `this` is special and signifies what should be included with the above word between angle brackets (<>).

```yaml
/etc/httpd/conf.d/website.com.conf:
  apache.configfile:
    - config:
      - VirtualHost:
        this: '*:80'
        ServerName:
          - website.com
        ServerAlias:
          - www.website.com
          - dev.website.com
        ErrorLog: logs/website.com-error_log
        CustomLog: logs/website.com-access_log combined
        DocumentRoot: /var/www/vhosts/website.com
        Directory:
          this: /var/www/vhosts/website.com
          Order: Deny, Allow
          Deny from: all
          Allow from:
          - 127.0.0.1
          - 192.168.100.0/24
        Options:
          - Indexes
          - FollowSymlinks
        AllowOverride: All
```
Changed in version 2018.3.

Allows having the same section container multiple times (e.g. `<Directory /path/to/dir>`).

YAML structure stays the same only replace dictionary with a list.

When a section container does not have mandatory attribute, such as `<Else>`, it still needs keyword `this` with empty string (or `''` if nicer output is required - without space).

```
/etc/httpd/conf.d/website.com.conf:
  apache.configfile:
    - config:
      - VirtualHost:
        - this: '*:80'
      - ServerName:
        - website.com
      - DocumentRoot: /var/www/vhosts/website.com
      - Directory:
        - this: /var/www/vhosts/website.com
          Order: Deny,Allow
          Deny from: all
          Allow from:
            - 127.0.0.1
            - 192.168.100.0/24
          Options:
            - Indexes
            - FollowSymlinks
          AllowOverride: All
        - Directory:
          - this: /var/www/vhosts/website.com/private
            Order: Deny,Allow
            Deny from: all
            Allow from:
              - 127.0.0.1
              - 192.168.100.0/24
            If:
              - this: some condition
                do: something
            Else:
              - this:
            Else:
              - this: ""
                do: another thing
```

salt.states.apache.configfile(name, config)

23.19.6  salt.states.apache_conf

Manage Apache Confs

New in version 2016.3.0.

Enable and disable apache confs.

Enable security conf:
  apache_conf.enabled:
    - name: security
Disable security conf:
  apache_conf.disabled:
    - name: security

salt.states.apache_conf.disabled(name)
  Ensure an Apache conf is disabled.
  name  Name of the Apache conf

salt.states.apache_conf.enabled(name)
  Ensure an Apache conf is enabled.
  name  Name of the Apache conf

23.19.7  salt.states.apache_module

Manage Apache Modules
New in version 2014.7.0.
Enable and disable apache modules.

Enable cgi module:
  apache_module.enabled:
    - name: cgi

Disable cgi module:
  apache_module.disabled:
    - name: cgi

salt.states.apache_module.disabled(name)
  Ensure an Apache module is disabled.
  New in version 2016.3.0.
  name  Name of the Apache module

salt.states.apache_module.enabled(name)
  Ensure an Apache module is enabled.
  New in version 2016.3.0.
  name  Name of the Apache module

23.19.8  salt.states.apache_site

Manage Apache Sites
New in version 2016.3.0.
Enable and disable apache sites.

Enable default site:
  apache_site.enabled:
    - name: default

Disable default site:
  apache_site.disabled:
    - name: default
salt.states.apache_site.disabled(name)
   Ensure an Apache site is disabled.
   name Name of the Apache site

salt.states.apache_site.enabled(name)
   Ensure an Apache site is enabled.
   name Name of the Apache site

23.19.9 salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

salt.states.aptpkg.held(name)
   Set package in 'hold' state, meaning it will not be upgraded.
   name The name of the package, e.g., 'tmux'

23.19.10 salt.states.archive

Extract an archive
New in version 2014.1.0.

salt.states.archive.extracted(name, source, source_hash=None, source_hash_name=None, source_hash_update=False, skip_files_list_verify=False, skip_verify=False, password=None, options=None, list_options=None, force=False, overwrite=False, clean=False, clean_parent=False, user=None, group=None, if_missing=None, trim_output=False, use_cmd_unzip=None, extract_perms=True, enforce_toplevel=True, enforce_ownership_on=None, archive_format=None, **kwargs)

New in version 2014.1.0.

Changed in version 2016.11.0: This state has been rewritten. Some arguments are new to this release and will not be available in the 2016.3 release cycle (and earlier). Additionally, the ZIP Archive Handling section below applies specifically to the 2016.11.0 release (and newer).

Ensure that an archive is extracted to a specific directory.

Important: Changes for 2016.11.0

In earlier releases, this state would rely on the if_missing argument to determine whether or not the archive needed to be extracted. When this argument was not passed, then the state would just assume if_missing is the same as the name argument (i.e. the parent directory into which the archive would be extracted).

This caused a number of annoyances. One such annoyance was the need to know beforehand a path that would result from the extraction of the archive, and setting if_missing to that directory, like so:

```
exectract_myapp:
    archive.extracted:
        - name: /var/www
        - source: salt://apps/src/myapp-16.2.4.tar.gz
        - user: www
        - group: www
        - if_missing: /var/www/myapp-16.2.4
```
If `/var/www` already existed, this would effectively make `if_missing` a required argument, just to get Salt to extract the archive.

Some users worked around this by adding the top-level directory of the archive to the end of the `name` argument, and then used `--strip` or `--strip-components` to remove that top-level dir when extracting:

```yaml
extract_myapp:
  archive.extracted:
    - name: /var/www/myapp-16.2.4
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
```

With the rewrite for 2016.11.0, these workarounds are no longer necessary. `if_missing` is still a supported argument, but it is no longer required. The equivalent SLS in 2016.11.0 would be:

```yaml
extract_myapp:
  archive.extracted:
    - name: /var/www
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
```

Salt now uses a function called `archive.list` to get a list of files/directories in the archive. Using this information, the state can now check the minion to see if any paths are missing, and know whether or not the archive needs to be extracted. This makes the `if_missing` argument unnecessary in most use cases.

---

### Important: ZIP Archive Handling

*Note: this information applies to 2016.11.0 and later.*

Salt has two different functions for extracting ZIP archives:

1. `archive.unzip`, which uses Python's `zipfile` module to extract ZIP files.
2. `archive.cmd_unzip`, which uses the `unzip` CLI command to extract ZIP files.

Salt will prefer the use of `archive.cmd_unzip` when CLI options are specified (via the `options` argument), and will otherwise prefer the `archive.unzip` function. Use of `archive.cmd_unzip` can be forced however by setting the `use_cmd_unzip` argument to `True`. By contrast, setting this argument to `False` will force usage of `archive.unzip`. For example:

```yaml
/var/www:
  archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - use_cmd_unzip: True
```

When `use_cmd_unzip` is omitted, Salt will choose which extraction function to use based on the source archive and the arguments passed to the state. When in doubt, simply do not set this argument; it is provided as a means of overriding the logic Salt uses to decide which function to use.

There are differences in the features available in both extraction functions. These are detailed below.

- **Command-line options** (only supported by `archive.cmd_unzip`) - When the `options` argument is used, `archive.cmd_unzip` is the only function that can be used to extract the archive. Therefore, if `use_cmd_unzip` is specified and set to `False`, and `options` is also set, the state will not proceed.
- **Permissions** - Due to an upstream bug in Python, permissions are not preserved when the `zipfile` module is used to extract an archive. As of the 2016.11.0 release, `archive.unzip` (as well as this state) has an `extract_perms` argument which, when set to `True` (the default), will attempt to match the permissions of the extracted files/directories to those defined within the archive. To disable this functionality
and have the state not attempt to preserve the permissions from the ZIP archive, set `extract_perms` to `False`:

```yaml
!/var/www:
  archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - extract_perms: False
```

**name** Directory into which the archive should be extracted

**source** Archive to be extracted

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

**source_hash** Hash of source file, or file with list of hash-to-file mappings

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

Changed in version 2016.11.0: If this argument specifies the hash itself, instead of a URI to a file containing hashes, the hash type can now be omitted and Salt will determine the hash type based on the length of the hash. For example, both of the below states are now valid, while before only the second one would be:

```yaml
foo_app:
  archive.extracted:
    - name: /var/www
    - source: https://mydomain.tld/foo.tar.gz
    - source_hash: 3360db35e682f1c5f9c58aa307de16d41361618c

bar_app:
  archive.extracted:
    - name: /var/www
    - source: https://mydomain.tld/bar.tar.gz
    - source_hash: sha1=5edb7d584b82dcbf76e311601f5d4442974aa5
```

**source_hash_name** When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename part of the `source` URI. When managing a file with a `source` of `salt://files/foo.tar.gz`, then the following line in a hash file would match:

```plaintext
acbd18db4cc2f85cedef654fccc4a4d8 foo.tar.gz
```

This line would also match:

```plaintext
acbd18db4cc2f85cedef654fccc4a4d8 ./dir1/foo.tar.gz
```

However, sometimes a hash file will include multiple similar paths:

```plaintext
37b51d194a7513e45b56f6524f2d51f2 .dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8 .dir2/foo.txt
73feffa4b766b6644cf984c85f6e88 .dir3/foo.txt
```

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:
/var/www:
archive.extracted:
- `source`: https://mydomain.tld/dir2/foo.tar.gz
- `source_hash`: https://mydomain.tld/hashe
- `source_hash_name`: ./dir2/foo.tar.gz

**Note:** This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using `foo.txt` would not match.

New in version 2016.11.0.

`source_hash_update` [False] Set this to `True` if archive should be extracted if `source_hash` has changed and there is a difference between the archive and the local files. This would extract regardless of the `if_missing` parameter.

Note that this is only checked if the `source` value has not changed. If it has (e.g. to increment a version number in the path) then the archive will not be extracted even if the hash has changed.

**Note:** Setting this to `True` along with `keep_source` set to `False` will result the source re-download to do a archive file list check. If it's not desirable please consider the `skip_files_list_verify` argument.

New in version 2016.3.0.

`skip_files_list_verify` [False] Set this to `True` if archive should be extracted if `source_hash` has changed but only checksums of the archive will be checked to determine if the extraction is required.

It will try to find a local cache of the `source` and check its hash against the `source_hash`. If there is no local cache available, for example if you set the `keep_source` to `False`, it will try to find a cached source hash file in the Minion archives cache directory.

**Note:** The current limitation of this logic is that you have to set minions `hash_type` config option to the same one that you're going to pass via `source_hash` argument.

**Warning:** With this argument set to `True` Salt will only check for the `source_hash` against the local hash of the `source`. So if you, for example, remove extracted files without clearing the Salt Minion cache next time you execute the state Salt will not notice that extraction is required if the hashes are still match.

New in version 3000.

`skip_verify` [False] If `True`, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the `source_hash` argument will be ignored.

New in version 2016.3.4.

`keep_source` [True] For `source` archives not local to the minion (i.e. from the Salt fileserver or a remote source such as http(s) or ftp), Salt will need to download the archive to the minion cache before they can be extracted. To remove the downloaded archive after extraction, set this argument to `False`.

New in version 2017.7.3.

`keep` [True] Same as `keep_source`, kept for backward-compatibility.
Note: If both keep_source and keep are used, keep will be ignored.

**password** For ZIP archives only. Password used for extraction.

New in version 2016.3.0.

Changed in version 2016.11.0: The newly-added `archive.is_encrypted` function will be used to determine if the archive is password-protected. If it is, then the `password` argument will be required for the state to proceed.

**options** For tar and zip archives only. This option can be used to specify a string of additional arguments to pass to the tar/zip command.

If this argument is not used, then the minion will attempt to use Python’s native `tarfile/zipfile` support to extract it. For zip archives, this argument is mostly used to overwrite existing files with o.

Using this argument means that the tar or unzip command will be used, which is less platform-independent, so keep this in mind when using this option; the CLI options must be valid options for the tar/unzip implementation on the minion’s OS.

New in version 2016.11.0.

Changed in version 2015.8.11,2016.3.2: XZ-compressed tar archives no longer require J to manually be set in the options, they are now detected automatically and decompressed using the `xz` CLI command and extracted using `tar xvf`. This is a more platform-independent solution, as not all tar implementations support the J argument for extracting archives.

Note: For tar archives, main operators like -x, --extract, --get, -c and -f/--file should not be used here.

**list_options** For tar archives only. This state uses `archive.list` to discover the contents of the source archive so that it knows which file paths should exist on the minion if the archive has already been extracted. For the vast majority of tar archives, `archive.list` "just works". Archives compressed using gzip, bzip2, and xz/lzma (with the help of the `xz` CLI command) are supported automatically. However, for archives compressed using other compression types, CLI options must be passed to `archive.list`.

This argument will be passed through to `archive.list` as its `options` argument, to allow it to successfully list the archive's contents. For the vast majority of archives, this argument should not need to be used, it should only be needed in cases where the state fails with an error stating that the archive's contents could not be listed.

New in version 2016.11.0.

**force** [False] If a path that should be occupied by a file in the extracted result is instead a directory (or vice-versa), the state will fail. Set this argument to `True` to force these paths to be removed in order to allow the archive to be extracted.

Warning: Use this option very carefully.

New in version 2016.11.0.

**overwrite** [False] Set this to `True` to force the archive to be extracted. This is useful for cases where the filenames/directories have not changed, but the content of the files have.

New in version 2016.11.1.

**clean** [False] Set this to `True` to remove any top-level files and recursively remove any top-level directory paths before extracting.
Note: Files will only be cleaned first if extracting the archive is deemed necessary, either by paths missing on the minion, or if overwrite is set to True.

New in version 2016.11.1.

**clean_parent** [False] If True, and the archive is extracted, delete the parent directory (i.e. the directory into which the archive is extracted), and then re-create that directory before extracting. Note that clean and clean_parent are mutually exclusive.

New in version 3000.

**user** The user to own each extracted file. Not available on Windows.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the enforce_ownership_on argument.

**group** The group to own each extracted file. Not available on Windows.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the enforce_ownership_on argument.

**if_missing** If specified, this path will be checked, and if it exists then the archive will not be extracted. This path can be either a directory or a file, so this option can also be used to check for a semaphore file and conditionally skip extraction.

Changed in version 2016.3.0: When used in combination with either user or group, ownership will only be enforced when if_missing is a directory.

Changed in version 2016.11.0: Ownership enforcement is no longer tied to this argument, it is simply checked for existence and extraction will be skipped if if is present.

**trim_output** [False] Useful for archives with many files in them. This can either be set to True (in which case only the first 100 files extracted will be in the state results), or it can be set to an integer for more exact control over the max number of files to include in the state results.

New in version 2016.3.0.

**use_cmd_unzip** [False] Set to True for zip files to force usage of the `archive.cmd_unzip` function to extract.

New in version 2016.11.0.

**extract_perms** [True] For ZIP archives only. When using `archive.unzip` to extract ZIP archives, Salt works around an upstream bug in Python to set the permissions on extracted files/directories to match those encoded into the ZIP archive. Set this argument to False to skip this workaround.

New in version 2016.11.0.

**enforce_toplevel** [True] This option will enforce a single directory at the top level of the source archive, to prevent extracting a ‘tar-bomb’. Set this argument to False to allow archives with files (or multiple directories) at the top level to be extracted.

New in version 2016.11.0.
enforce_ownership_on  When user or group is specified, Salt will default to enforcing permissions on the file/directory paths detected by running `archive.list` on the source archive. Use this argument to specify an alternate directory on which ownership should be enforced.

**Note**: This path must be within the path specified by the `name` argument.

New in version 2016.11.0.

**archive_format**  One of tar, zip, or rar.

Changed in version 2016.11.0: If omitted, the archive format will be guessed based on the value of the `source` argument. If the minion is running a release older than 2016.11.0, this option is required.

**Examples**

1. tar with lmza (i.e. xz) compression:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.lzma
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   ```

2. tar archive with flag for verbose output, and enforcement of user/group ownership:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.gz
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   - options: v
   - user: foo
   - group: foo
   ```

3. tar archive, with `source_hash_update` set to `True` to prevent state from attempting extraction unless the `source_hash` differs from the previous time the archive was extracted:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.lzma
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   - source_hash_update: True
   ```

### 23.19.11 salt.states.artifactory

This state downloads artifacts from artifactory.

```python
salt.states.artifactory.downloaded(name, artifact, target_dir='/tmp', target_file=None, use_literal_group_id=False)
```

Ensures that the artifact from artifactory exists at given location. If it doesn't exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

**artifact**  Details of the artifact to be downloaded from artifactory. Various options are:

- artifactory_url: URL of the artifactory instance
- repository: Repository in artifactory
• artifact_id: Artifact ID
• group_id: Group ID
• packaging: Packaging
• classifier: Classifier .. versionadded:: 2015.8.0
• version: Version One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
• username: Artifactory username .. versionadded:: 2015.8.0
• password: Artifactory password .. versionadded:: 2015.8.0

target_dir Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.
target_file Target file to download artifact to. By default file name is resolved by artifactory.

An example to download an artifact to a specific file:

```
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_dir: /opt/jboss7/modules/com/company/lib
```

23.19.12 salt.states.at

Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.
salt.states.at.absent(name, jobid=None, **kwargs)

Changed in version 2017.7.0.

Remove a job from queue
jobid: string/int Specific jobid to remove
tag [string] Job's tag
runas [string] Runs user-specified jobs
kwargs Addition kwargs can be provided to filter jobs. See output of at.jobcheck for more.

```
example1:
  at.absent:
```

23.19. state modules
salt.states.at.mod_watch(name, **kwargs)

The at watcher, called to invoke the watch command.

Note: This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

name The name of the atjob

salt.states.at.present(name, timespec, tag=None, user=None, job=None, unique_tag=False)

Changed in version 2017.7.0.

Add a job to queue.

job [string] Command to run.
timespec [string] The ‘timespec’ follows the format documented in the at(1) manpage.
tag [string] Make a tag for the job.
user [string] The user to run the at job .. versionadded:: 2014.1.4
unique_tag [boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

rose:

salt.states.at.watch(name, timespec, tag=None, user=None, job=None, unique_tag=False)

New in version 2017.7.0.

Add an at job if trigger by watch

job [string] Command to run.
timespec [string] The ‘timespec’ follows the format documented in the at(1) manpage.
tag [string] Make a tag for the job.
user [string] The user to run the at job .. versionadded:: 2014.1.4
unique_tag  [boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

```
minion_restart:
    at.watch:
      - job: 'salt-call --local service.restart salt-minion'
      - timespec: 'now +1 min'
      - tag: minion_restart
      - unique_tag: trye
      - watch:
        - file: /etc/salt/minion
```

### salt.states.augeas

Configuration management using Augeas

New in version 0.17.0.

This state requires the augeas Python module.

Augeas can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

salt.states.augeas.change(name, context=None, changes=None, lens=None, load_path=None, **kwargs)

New in version 2014.7.0.

This state replaces setvalue().

Issue changes to Augeas, optionally for a specific context, with a specific lens.

name  State name
context  A file path, prefixed by /files. Should resolve to an actual file (not an arbitrary augeas path). This is used to avoid duplicating the file name for each item in the changes list (for example, set bind 0.0.0.0 in the example below operates on the file specified by context). If context is not specified, a file path prefixed by /files should be included with the set command.

The file path is examined to determine if the specified changes are already present.

```
redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
      - set maxmemory 1G
```

changes  List of changes that are issued to Augeas. Available commands are set, setm, mv/move, ins/insert, and rm/remove.
lens  The lens to use, needs to be suffixed with .lns, e.g.: Nginx.lns. See the list of stock lenses shipped with Augeas.

### 23.19.13  state modules

23.19. state modules 3431
New in version 2016.3.0.

load_path A list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUGEAS_LENS_LIB.

Usage examples:

Set the bind parameter in /etc/redis/redis.conf:

```yaml
redis-conf:
  augeas.change:
    - changes:
      - set /files/etc/redis/redis.conf/bind 0.0.0.0
```

Note: Use the context parameter to specify the file you want to manipulate. This way you don't have to include this in the changes every time:

```yaml
redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
      changes:
        - set bind 0.0.0.0
        - set databases 4
        - set maxmemory 1G
```

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with lenses, which provide mappings between the Augeas tree and the file.

There are many preconfigured lenses that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn't know about, you can specify the lens to use like this:

```yaml
redis-conf:
  augeas.change:
    - lens: redis.lns
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
```

Note: Even though Augeas knows that /etc/redis/redis.conf is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

```yaml
zabbix-service:
  augeas.change:
    - lens: services.lns
    - context: /files/etc/services
    - changes:
      - ins service-name after service-name[last()]
      - set service-name[last()] "zabbix-agent"
      - set "service-name[. = 'zabbix-agent']/port" 10050
      - set "service-name[. = 'zabbix-agent']/protocol" tcp
```

(continues on next page)
- set "service-name[. = 'zabbix-agent']/#comment" "Zabbix Agent service"
- rm "service-name[. = 'im-obsolete']"
- unless: grep "zabbix-agent" /etc/services

**Warning:** Don't forget the `unless` here, otherwise it will fail on next runs because the service is already defined. Additionally you have to quote lines containing `service-name[. = 'zabbix-agent']` otherwise `augeas_cfg execute` will fail because it will receive more parameters than expected.

**Note:** Order is important when defining a service with Augeas, in this case it's `port`, `protocol` and `#comment`. For more info about the lens check `services lens documentation`.

http://augeas.net/docs/reference/lenses/files/services-aug.html#Services.record

### 23.19.14 `salt.states.aws_sqs`  
Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses the `awscli` tool provided by Amazon. This can be downloaded from `pip`. Also check the documentation for `awscli` for configuration information.

```yaml
myqueue:
  aws_sqs.exists:
    - region: eu-west-1

salt.states.aws_sqs.absent(name, region, user=None, opts=False)
Remove the named SQS queue if it exists.
  name  Name of the SQS queue.
  region Region to remove the queue from
  user  Name of the user performing the SQS operations
  opts  Include additional arguments and options to the aws command line

salt.states.aws_sqs.exists(name, region, user=None, opts=False)
Ensure the SQS queue exists.
  name  Name of the SQS queue.
  region Region to create the queue
  user  Name of the user performing the SQS operations
  opts  Include additional arguments and options to the aws command line
```

### 23.19.15 `salt.states.azurearm_compute`  
Azure (ARM) Compute State Module

New in version 2019.2.0.

```
maintainer  <devops@decisionlab.io>
maturity   new
depends
```
• azure >= 2.0.0
• azure-common >= 1.1.8
• azure-mgmt >= 1.0.0
• azure-mgmt-compute >= 1.0.0
• azure-mgmt-network >= 1.7.1
• azure-mgmt-resource >= 1.1.0
• azure-mgmt-storage >= 1.0.0
• azure-mgmt-web >= 0.32.0
• azure-storage >= 0.34.3
• msrestazure >= 0.4.21

platform  linux

configuration  This module requires Azure Resource Manager credentials to be passed as a dictionary of keyword arguments to the connection_auth parameter in order to work properly. Since the authentication parameters are sensitive, it's recommended to pass them to the states via pillar.

Required provider parameters:

if using username and password:
  • subscription_id
  • username
  • password

if using a service principal:
  • subscription_id
  • tenant
  • client_id
  • secret

Optional provider parameters:

cloud_environment: Used to point the cloud driver to different API endpoints, such as Azure GovCloud. Possible values:

• AZURE_PUBLIC_CLOUD (default)
• AZURE_CHINA_CLOUD
• AZURE_US_GOV_CLOUD
• AZURE_GERMAN_CLOUD

Example Pillar for Azure Resource Manager authentication:

```yaml
azurearm:
  user_pass_auth:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    username: fletch
    password: 123pass
  mysubscription:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
```

(continues on next page)
Example states using Azure Resource Manager authentication:

```yaml
{% set profile = salt['pillar.get']('azurearm:mysubscription') %}

Ensure availability set exists:
    azurearm_compute.availability_set_present:
        - name: my_avail_set
        - resource_group: my_rg
        - virtual_machines:
            - my_vm1
            - my_vm2
        - tags:
            how_awesome: very
            contact_name: Elmer Fudd Gantry
        - connection_auth: {{ profile }}

Ensure availability set is absent:
    azurearm_compute.availability_set_absent:
        - name: other_avail_set
        - resource_group: my_rg
        - connection_auth: {{ profile }}

salt.states.azurearm_compute.availability_set_absent(name, resource_group, connection_auth=None)

New in version 2019.2.0.

Ensure an availability set does not exist in a resource group.

Parameters
- **name** -- Name of the availability set.
- **resource_group** -- Name of the resource group containing the availability set.
- **connection_auth** -- A dict with subscription and authentication parameters to
  be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_compute.availability_set_present(name, resource_group, tags=None, platform_update_domain_count=None, platform_fault_domain_count=None, virtual_machines=None, sku=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure an availability set exists.

Parameters
- **name** -- Name of the availability set.
- **resource_group** -- The resource group assigned to the availability set.
- **tags** -- A dictionary of strings can be passed as tag metadata to the availability set object.
- **platform_update_domain_count** -- An optional parameter which indicates groups of virtual machines and underlying physical hardware that can be rebooted at the same time.
• **platform_fault_domain_count** -- An optional parameter which defines the
group of virtual machines that share a common power source and network switch.
• **virtual_machines** -- A list of names of existing virtual machines to be included
  in the availability set.
• **sku** -- The availability set SKU, which specifies whether the availability set is man-
  aged or not. Possible values are 'Aligned' or 'Classic'. An 'Aligned' availability set is
  managed, 'Classic' is not.
• **connection_auth** -- A dict with subscription and authentication parameters to
  be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure availability set exists:
  azurearm_compute.availability_set_present:
    - name: aset1
    - resource_group: group1
    - platform_update_domain_count: 5
    - platform_fault_domain_count: 3
    - sku: aligned
    - tags:
      - connection_auth: {{ profile }}
  require:
    - azurearm_resource: Ensure resource group exists
```

### 23.19.16 salt.states.azurearm_dns

Azure (ARM) DNS State Module

New in version 3000.

**maintainer** <devops@eitr.tech>

**maturity** new

**depends**

- azure >= 2.0.0
- azure-common >= 1.1.8
- azure-mgmt >= 1.0.0
- azure-mgmt-compute >= 1.0.0
- azure-mgmt-dns >= 1.0.1
- azure-mgmt-network >= 1.7.1
- azure-mgmt-resource >= 1.1.0
- azure-mgmt-storage >= 1.0.0
- azure-mgmt-web >= 0.32.0
- azure-storage >= 0.34.3
- msrestazure >= 0.4.21

**platform** linux
**configuration** This module requires Azure Resource Manager credentials to be passed as a dictionary of keyword arguments to the `connection_auth` parameter in order to work properly. Since the authentication parameters are sensitive, it's recommended to pass them to the states via pillar.

Required provider parameters:

if using username and password:
- `subscription_id`
- `username`
- `password`

if using a service principal:
- `subscription_id`
- `tenant`
- `client_id`
- `secret`

Optional provider parameters:

**cloud_environment**: Used to point the cloud driver to different API endpoints, such as Azure GovCloud.
Possible values:

Possible values:
- `AZURE_PUBLIC_CLOUD` (default)
- `AZURE_CHINA_CLOUD`
- `AZURE_US_GOV_CLOUD`
- `AZURE_GERMAN_CLOUD`

Example Pillar for Azure Resource Manager authentication:

```yaml
azurearm:
  user_pass_auth:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    username: fletch
    password: 123pass
  mysubscription:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    tenant: ABCDEFAB-1234-ABCD-1234-ABCDEFABCDEF
    client_id: ABCDEFAB-1234-ABCD-1234-ABCDEFABCDEF
    secret: XXXXXXXXXXXXXXXXXXXXXX
    cloud_environment: AZURE_PUBLIC_CLOUD
```

Example states using Azure Resource Manager authentication:

```yaml
{% set profile = salt['pillar.get']('azurearm:mysubscription') %}
Ensure DNS zone exists:
  azurearm_dns.zone_present:
    - name: contoso.com
    - resource_group: my_rg
    - tags:
      - how_awesome: very
      - contact_name: Elmer Fudd Gantry
    - connection_auth: {{ profile }}
```

(continues on next page)
Ensure DNS record set exists:
```yaml
azurearm_dns.record_set_present:
- name: web
- zone_name: contoso.com
- resource_group: my_rg
- record_type: A
- ttl: 300
- arecords:
  - ipv4_address: 10.0.0.1
- tags:
  how_awesome: very
  contact_name: Elmer Fudd Gantry
- connection_auth: {{ profile }}
```
Ensure DNS record set is absent:
```yaml
azurearm_dns.record_set_absent:
- name: web
- zone_name: contoso.com
- resource_group: my_rg
- record_type: A
- connection_auth: {{ profile }}
```
Ensure DNS zone is absent:
```yaml
azurearm_dns.zone_absent:
- name: contoso.com
- resource_group: my_rg
- connection_auth: {{ profile }}
```
salt.states.azurearm_dns.record_set_absent(name, zone_name, resource_group, connection_auth=None)

New in version 3000.

Ensure a record set does not exist in the DNS zone.

Parameters

- **name** -- Name of the record set.
- **zone_name** -- Name of the DNS zone.
- **resource_group** -- The resource group assigned to the DNS zone.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_dns.record_set_present(name, zone_name, resource_group, record_type, if_match=None, if_none_match=None, etag=None, metadata=None, ttl=None, arecords=None, aaaa_records=None, mx_records=None, ns_records=None, ptr_records=None, srv_records=None, txt_records=None, cname_record=None, soa_record=None, caa_records=None, connection_auth=None, **kwargs)

New in version 3000.

Ensure a record set exists in a DNS zone.

Parameters

- **name** -- The name of the record set, relative to the name of the zone.
- **zone_name** -- Name of the DNS zone (without a terminating dot).
• **resource_group** -- The resource group assigned to the DNS zone.
• **record_type** -- The type of DNS record in this record set. Record sets of type SOA can be updated but not created (they are created when the DNS zone is created). Possible values include: ‘A’, ‘AAAA’, ‘CAA’, ‘CNAME’, ‘MX’, ‘NS’, ‘PTR’, ‘SOA’, ‘SRV’, ‘TXT’
• **if_match** -- The etag of the record set. Omit this value to always overwrite the current record set. Specify the last-seen etag value to prevent accidentally overwriting any concurrent changes.
• **if_none_match** -- Set to ‘’ to allow a new record set to be created, but to prevent updating an existing record set. Other values will be ignored.
• **etag** -- The etag of the record set. Etags are used to handle concurrent changes to the same resource safely.
• **metadata** -- A dictionary of strings can be passed as tag metadata to the record set object.
• **ttl** -- The TTL (time-to-live) of the records in the record set. Required when specifying record information.
• **arecords** -- The list of A records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **aaaaa_records** -- The list of AAAA records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **mx_records** -- The list of MX records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **ns_records** -- The list of NS records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **ptr_records** -- The list of PTR records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **srv_records** -- The list of SRV records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **txt_records** -- The list of TXT records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **cname_record** -- The CNAME record in the record set. View the Azure SDK documentation to create a dictionary representing the record object.
• **soa_record** -- The SOA record in the record set. View the Azure SDK documentation to create a dictionary representing the record object.
• **caa_records** -- The list of CAA records in the record set. View the Azure SDK documentation to create a list of dictionaries representing the record objects.
• **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure record set exists:
  azurearm_dns.record_set_present:
    - name: web
    - zone_name: contoso.com
    - resource_group: my_rg
    - record_type: A
    - ttl: 300
    - arecords:
      - ipv4_address: 10.0.0.1
    - metadata:
      how_awesome: very
      contact_name: Elmer Fudd Gantry
    - connection_auth: {{ profile }}

salt.states.azurearm_dns.zone_absent(name, resource_group, connection_auth= None)
```
New in version 3000.

Ensure a DNS zone exists.

Parameters

- **name** -- Name of the DNS zone.
- **resource_group** -- The resource group assigned to the DNS zone.
- **etag** -- The etag of the zone. Etags are used to handle concurrent changes to the same resource safely.
- **if_match** -- The etag of the DNS zone. Omit this value to always overwrite the current zone. Specify the last-seen etag value to prevent accidentally overwriting any concurrent changes.
- **if_none_match** -- Set to '*' to allow a new DNS zone to be created, but to prevent updating an existing zone. Other values will be ignored.
- **registration_virtual_networks** -- A list of references to virtual networks that register hostnames in this DNS zone. This is only when zone_type is Private. (requires azure-mgmt-dns >= 2.0.0rc1)
- **resolution_virtual_networks** -- A list of references to virtual networks that resolve records in this DNS zone. This is only when zone_type is Private. (requires azure-mgmt-dns >= 2.0.0rc1)
- **tags** -- A dictionary of strings can be passed as tag metadata to the DNS zone object.
- **zone_type** -- The type of this DNS zone (Public or Private). Possible values include: 'Public', 'Private'. Default value: 'Public' (requires azure-mgmt-dns >= 2.0.0rc1)
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```
Ensure DNS zone exists:

azurearm_dns.zone_present:
  - name: contoso.com
  - resource_group: my_rg
  - zone_type: Private
  - registration_virtual_networks:
  - /subscriptions/{{ sub }}/resourceGroups/my_rg/providers/Microsoft.
  - tags:
  - how_awesome: very
  - contact_name: Elmer Fudd Gantry
  - connection_auth: {{ profile }}
```
23.19.17  salt.states.azurearm_network

Azure (ARM) Network State Module
New in version 2019.2.0.

maintainer  <devops@decisionlab.io>
maturity  new
depends
  • azure >= 2.0.0
  • azure-common >= 1.1.8
  • azure-mgmt >= 1.0.0
  • azure-mgmt-compute >= 1.0.0
  • azure-mgmt-network >= 1.7.1
  • azure-mgmt-resource >= 1.1.0
  • azure-mgmt-storage >= 1.0.0
  • azure-mgmt-web >= 0.32.0

```
salt.states.azurearm_network.virtual_network_absent:
  - name: other_vnet
  - resource_group: my_rg
  - connection_auth: {{ profile }}
```

```
salt.states.azurearm_network.load_balancer_absent(name, resource_group, connection_auth=None)
```

New in version 2019.2.0.

Ensure a load balancer does not exist in the resource group.

Parameters

- `name` -- Name of the load balancer.
- `resource_group` -- The resource group assigned to the load balancer.
- `connection_auth` -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

```
salt.states.azurearm_network.load_balancer_present(name, resource_group,sku=None,frontend_ip_configurations=None,backend_address_pools=None,load_balancing_rules=None,probes=None,inbound_nat_rules=None,inbound_nat_pools=None,outbound_nat_rules=None,tags=None,connection_auth=None,**kwargs)
```

```
New in version 2019.2.0.

Ensure a load balancer exists.

**Parameters**

- **name** -- Name of the load balancer.
- **resource_group** -- The resource group assigned to the load balancer.
- **sku** -- The load balancer SKU, which can be 'Basic' or 'Standard'.
- **tags** -- A dictionary of strings can be passed as tag metadata to the load balancer object.
- **frontend_ip_configurations** -- An optional list of dictionaries representing valid FrontendIPConfiguration objects. A frontend IP configuration can be either private (using private IP address and subnet parameters) or public (using a reference to a public IP address object). Valid parameters are:
  - **name**: The name of the resource that is unique within a resource group.
  - **private_ip_address**: The private IP address of the IP configuration. Required if 'private_ip_allocation_method' is 'Static'.
  - **private_ip_allocation_method**: The Private IP allocation method. Possible values are: 'Static' and 'Dynamic'.
  - **subnet**: Name of an existing subnet inside of which the frontend IP will reside.
  - **public_ip_address**: Name of an existing public IP address which will be assigned to the frontend IP object.
- **backend_address_pools** -- An optional list of dictionaries representing valid BackendAddressPool objects. Only the 'name' parameter is valid for a BackendAddressPool dictionary. All other parameters are read-only references from other objects linking to the backend address pool. Inbound traffic is randomly load balanced across IPs in the backend IPs.
- **probes** -- An optional list of dictionaries representing valid Probe objects. Valid parameters are:
  - **name**: The name of the resource that is unique within a resource group.
  - **protocol**: The protocol of the endpoint. Possible values are 'Http' or 'Tcp'. If 'Tcp' is specified, a received ACK is required for the probe to be successful. If 'Http' is specified, a 200 OK response from the specified URI is required for the probe to be successful.
  - **port**: The port for communicating the probe. Possible values range from 1 to 65535, inclusive.
  - **interval_in_seconds**: The interval, in seconds, for how frequently to probe the endpoint for health status. Typically, the interval is slightly less than half the allocated timeout period (in seconds) which allows two full probes before taking the instance out of rotation. The default value is 15, the minimum value is 5.
  - **number_of_probes**: The number of probes where if no response, will result in stopping further traffic from being delivered to the endpoint. This value allows endpoints to be taken out of rotation faster or slower than the typical times used in Azure.
  - **request_path**: The URI used for requesting health status from the VM. Path is required if a protocol is set to 'Http'. Otherwise, it is not allowed. There is no default value.
- **load_balancing_rules** -- An optional list of dictionaries representing valid LoadBalancingRule objects. Valid parameters are:
  - **name**: The name of the resource that is unique within a resource group.
  - **load_distribution**: The load distribution policy for this rule. Possible values are 'Default', 'SourceIP', and 'SourceIPProtocol'.
  - **frontend_port**: The port for the external endpoint. Port numbers for each rule must be unique within the Load Balancer. Acceptable values are between
– backend_port: The port used for internal connections on the endpoint. Acceptable values are between 0 and 65535. Note that value 0 enables 'Any Port'.

– idle_timeout_in_minutes: The timeout for the TCP idle connection. The value can be set between 4 and 30 minutes. The default value is 4 minutes. This element is only used when the protocol is set to TCP.

– enable_floating_ip: Configures a virtual machine's endpoint for the floating IP capability required to configure a SQL AlwaysOn Availability Group. This setting is required when using the SQL AlwaysOn Availability Groups in SQL server. This setting can't be changed after you create the endpoint.

– disable_outbound_snat: Configures SNAT for the VMs in the backend pool to use the public IP address specified in the frontend of the load balancing rule.

– frontend_ip_configuration: Name of the frontend IP configuration object used by the load balancing rule object.

– backend_address_pool: Name of the backend address pool object used by the load balancing rule object. Inbound traffic is randomly load balanced across IPs in the backend IPs.

– probe: Name of the probe object used by the load balancing rule object.

• inboundNat_rules -- An optional list of dictionaries representing valid InboundNatRule objects. Defining inbound NAT rules on your load balancer is mutually exclusive with defining an inbound NAT pool. Inbound NAT pools are referenced from virtual machine scale sets. NICs that are associated with individual virtual machines cannot reference an Inbound NAT pool. They have to reference individual inbound NAT rules. Valid parameters are:

  – name: The name of the resource that is unique within a resource group.

  – frontend_ip_configuration: Name of the frontend IP configuration object used by the inbound NAT rule object.

  – protocol: Possible values include 'Udp', 'Tcp', or 'All'.

  – frontend_port: The port for the external endpoint. Port numbers for each rule must be unique within the Load Balancer. Acceptable values range from 1 to 65534.

  – backend_port: The port used for the internal endpoint. Acceptable values range from 1 to 65535.

  – idle_timeout_in_minutes: The timeout for the TCP idle connection. The value can be set between 4 and 30 minutes. The default value is 4 minutes. This element is only used when the protocol is set to TCP.

  – enable_floating_ip: Configures a virtual machine's endpoint for the floating IP capability required to configure a SQL AlwaysOn Availability Group. This setting is required when using the SQL AlwaysOn Availability Groups in SQL server. This setting can't be changed after you create the endpoint.

• inboundNat_pools -- An optional list of dictionaries representing valid InboundNatPool objects. They define an external port range for inbound NAT to a single backend port on NICs associated with a load balancer. Inbound NAT rules are created automatically for each NIC associated with the Load Balancer using an external port from this range. Defining an Inbound NAT pool on your Load Balancer is mutually exclusive with defining inbound NAT rules. Inbound NAT pools are referenced from virtual machine scale sets. NICs that are associated with individual virtual machines cannot reference an inbound NAT pool. They have to reference individual inbound NAT rules. Valid parameters are:

  – name: The name of the resource that is unique within a resource group.

  – frontend_ip_configuration: Name of the frontend IP configuration object used by the inbound NAT pool object.

  – protocol: Possible values include 'Udp', 'Tcp', or 'All'.
- `frontend_port_range_start`: The first port number in the range of external ports that will be used to provide Inbound NAT to NICs associated with a load balancer. Acceptable values range between 1 and 65534.
- `frontend_port_range_end`: The last port number in the range of external ports that will be used to provide Inbound NAT to NICs associated with a load balancer. Acceptable values range between 1 and 65535.
- `backend_port`: The port used for internal connections to the endpoint. Acceptable values are between 1 and 65535.

- **outbound_nat_rules** -- An optional list of dictionaries representing valid OutboundNatRule objects. Valid parameters are:
  - `name`: The name of the resource that is unique within a resource group.
  - `frontend_ip_configuration`: Name of the frontend IP configuration object used by the outbound NAT rule object.
  - `backend_address_pool`: Name of the backend address pool object used by the outbound NAT rule object. Outbound traffic is randomly load balanced across IPs in the backend IPs.
  - `allocated_outbound_ports`: The number of outbound ports to be used for NAT.

- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```
Ensure load balancer exists:
azurearm_network.load_balancer_present:
  - `name`: lb1
  - `resource_group`: group1
  - `location`: eastus
  - `frontend_ip_configurations`:
    - `name`: lb1_feip1
      `public_ip_address`: pub_ip1
  - `backend_address_pools`:
    - `name`: lb1_bepool1
  - `probes`:
    - `name`: lb1_webprobe1
      `protocol`: tcp
      `port`: 80
      `interval_in_seconds`: 5
      `number_of_probes`: 2
  - `load_balancing_rules`:
    - `name`: lb1_webprobe1
      `protocol`: tcp
      `frontend_port`: 80
      `backend_port`: 80
      `idle_timeout_in_minutes`: 4
      `frontend_ip_configuration`: lb1_feip1
      `backend_address_pool`: lb1_bepool1
      `probe`: lb1_webprobe1
  - `tags`:
    - `contact_name`: Elmer Fudd Gantry
  - `connection_auth`: `{{ profile }}`
  - `require`:
    - `azurearm_resource`: Ensure resource group exists
    - `azurearm_network`: Ensure public IP exists
```

salt.states.azurearm_network.network_interface_absent(`name`, `resource_group`, `connection_auth=None`)
Ensure a network interface does not exist in the resource group.

Parameters

- **name** -- Name of the network interface.
- **resource_group** -- The resource group assigned to the network interface.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

```python
salt.states.azurearm_network.network_interface_present(
    name, ip_configurations, subnet, virtual_network, resource_group, tags=None, virtual_machine=None, network_security_group=None, dns_settings=None, mac_address=None, primary=None, enable_accelerated_networking=None, enable_ip_forwarding=None, connection_auth=None, **kwargs)
```

New in version 2019.2.0.

Ensure a network interface exists.

Parameters

- **name** -- Name of the network interface.
- **ip_configurations** -- A list of dictionaries representing valid NetworkInterfaceIPConfiguration objects. The 'name' key is required at minimum. At least one IP Configuration must be present.
- **subnet** -- Name of the existing subnet assigned to the network interface.
- **virtual_network** -- Name of the existing virtual network containing the subnet.
- **resource_group** -- The resource group assigned to the virtual network.
- **tags** -- A dictionary of strings can be passed as tag metadata to the network interface object.
- **network_security_group** -- The name of the existing network security group to assign to the network interface.
- **virtual_machine** -- The name of the existing virtual machine to assign to the network interface.
- **dns_settings** -- An optional dictionary representing a valid NetworkInterfaceDnsSettings object. Valid parameters are:
  - `dns_servers`: List of DNS server IP addresses. Use 'AzureProvidedDNS' to switch to Azure provided DNS resolution. 'AzureProvidedDNS' value cannot be combined with other IPs, it must be the only value in dns_servers collection.
  - `internal_dns_name_label`: Relative DNS name for this NIC used for internal communications between VMs in the same virtual network.
  - `internal_fqdn`: Fully qualified DNS name supporting internal communications between VMs in the same virtual network.
  - `internal_domain_name_suffix`: Even if internal_dns_name_label is not specified, a DNS entry is created for the primary NIC of the VM. This DNS name can be constructed by concatenating the VM name with the value of internal_domain_name_suffix.
- **mac_address** -- Optional string containing the MAC address of the network interface.
- **primary** -- Optional boolean allowing the interface to be set as the primary network interface on a virtual machine with multiple interfaces attached.
- **enable_accelerated_networking** -- Optional boolean indicating whether
accelerated networking should be enabled for the interface.

- **enable_ip_forwarding** -- Optional boolean indicating whether IP forwarding should be enabled for the interface.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure network interface exists:
azurearm_network.network_interface_present:
  - name: iface1
  - subnet: vnet1_sn1
  - virtual_network: vnet1
  - resource_group: group1
  - ip_configurations:
    - name: iface1_ipc1
      public_ip_address: pub_ip2
    - dns_settings:
      - internal_dns_name_label: decisionlab-int-test-label
      - primary: True
  - enable_accelerated_networking: True
  - enable_ip_forwarding: False
  - network_security_group: nsg1
  - connection_auth: {{ profile }}
  - require:
    - azurearm_network: Ensure subnet exists
    - azurearm_network: Ensure network security group exists
    - azurearm_network: Ensure another public IP exists
```

New in version 2019.2.0.

Ensure a network security group does not exist in the resource group.

Parameters

- **name** -- Name of the network security group.
- **resource_group** -- The resource group assigned to the network security group.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

New in version 2019.2.0.

Ensure a network security group exists.

Parameters

- **name** -- Name of the network security group.
- **resource_group** -- The resource group assigned to the network security group.
- **tags** -- A dictionary of strings can be passed as tag metadata to the network security group object.
- **security_rules** -- An optional list of dictionaries representing valid SecurityRule objects. See the documentation for the security_rule_present state or security_rule_create_or_update execution module for more information on required and
optional parameters for security rules. The rules are only managed if this parameter is present. When this parameter is absent, implemented rules will not be removed, and will merely become unmanaged.

- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure network security group exists:
azurearm_network.network_security_group_present:
  - name: nsg1
    - resource_group: group1
    - security_rules:
      - name: nsg1_rule1
        priority: 100
        protocol: tcp
        access: allow
        direction: outbound
        source_address_prefix: virtualnetwork
        destination_address_prefix: internet
        source_port_range: '
        destination_port_range: '
      - name: nsg1_rule2
        priority: 101
        protocol: tcp
        access: allow
        direction: inbound
        source_address_prefix: internet
        destination_address_prefix: virtualnetwork
        source_port_range: '
        destination_port_ranges: 
          - '80'
          - '443'
      - tags:
        contact_name: Elmer Fudd Gantry
      - connection_auth: {{ profile }}
    - require:
      - azurearm_resource: Ensure resource group exists

salt.states.azurearm_network.public_ip_address_absent(name, resource_group, connection_auth=None)

New in version 2019.2.0.

Ensure a public IP address does not exist in the resource group.

Parameters

- **name** -- Name of the public IP address.
- **resource_group** -- The resource group assigned to the public IP address.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_network.public_ip_address_present(name, resource_group, tags=None, sku=None, public_ip_allocation_method=None, public_ip_address_version=None, dns_settings=None, idle_timeout_in_minutes=None, connection_auth=None, **kwargs)
New in version 2019.2.0.

Ensure a public IP address exists.

Parameters

- **name** -- Name of the public IP address.
- **resource_group** -- The resource group assigned to the public IP address.
- **dns_settings** -- An optional dictionary representing a valid PublicIPAddressDnsSettings object. Parameters include 'domain_name_label' and 'reverse_fqdn', which accept strings. The 'domain_name_label' parameter is concatenated with the region-alized DNS zone make up the fully qualified domain name associated with the public IP address. If a domain name label is specified, an A DNS record is created for the public IP in the Microsoft Azure DNS system. The 'reverse_fqdn' parameter is a user-visible, fully qualified domain name that resolves to this public IP address. If the reverse FQDN is specified, then a PTR DNS record is created pointing from the IP address in the in-addr.arpa domain to the reverse FQDN.
- **sku** -- The public IP address SKU, which can be 'Basic' or 'Standard'.
- **public_ip_allocation_method** -- The public IP allocation method. Possible values are: 'Static' and 'Dynamic'.
- **public_ip_address_version** -- The public IP address version. Possible values are: 'IPv4' and 'IPv6'.
- **idle_timeout_in_minutes** -- An integer representing the idle timeout of the public IP address.
- **tags** -- A dictionary of strings can be passed as tag metadata to the public IP address object.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure public IP exists:
  azurearm_network.public_ip_address_present:
    - name: pub_ip1
    - resource_group: group1
    - dns_settings:
      domain_name_label: decisionlab-ext-test-label
    - sku: basic
    - public_ip_allocation_method: static
    - public_ip_address_version: ipv4
    - idle_timeout_in_minutes: 4
    - tags:
      contact_name: Elmer Fudd Gantry
    - connection_auth: {{ profile }}
    - require:
      - azurearm_resource: Ensure resource group exists
```

salt.states.azurearm_network.route_absent(name, route_table, resource_group, connection_auth=None)

New in version 2019.2.0.

Ensure a route table does not exist in the resource group.

Parameters

- **name** -- Name of the route table.
- **route_table** -- The name of the existing route table containing the route.
- **resource_group** -- The resource group assigned to the route table.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.
salt.states.azurearm_network.route_present(name, address_prefix, next_hop_type, route_table, next_hop_ip_address=None, resource_group, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a route exists within a route table.

Parameters

- **name** -- Name of the route.
- **address_prefix** -- The destination CIDR to which the route applies.
- **next_hop_type** -- The type of Azure hop the packet should be sent to. Possible values are: 'VirtualNetworkGateway', 'VnetLocal', 'Internet', 'VirtualAppliance', and 'None'.
- **next_hop_ip_address** -- The IP address packets should be forwarded to. Next hop values are only allowed in routes where the next hop type is 'VirtualAppliance'.
- **route_table** -- The name of the existing route table which will contain the route.
- **resource_group** -- The resource group assigned to the route table.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure route exists:
  azurearm_network.route_present:
    - name: rt1_route2
    - route_table: rt1
    - resource_group: group1
    - address_prefix: '192.168.0.0/16'
    - next_hop_type: vnetlocal
    - connection_auth: {{ profile }}
    - require:
      - azurearm_network: Ensure route table exists
```

salt.states.azurearm_network.route_table_absent(name, resource_group, connection_auth=None)

New in version 2019.2.0.

Ensure a route table does not exist in the resource group.

Parameters

- **name** -- Name of the route table.
- **resource_group** -- The resource group assigned to the route table.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_network.route_table_present(name, resource_group, tags=None, routes=None, disable_bgp_route_propagation=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a route table exists.

Parameters

- **name** -- Name of the route table.
- **resource_group** -- The resource group assigned to the route table.
- **routes** -- An optional list of dictionaries representing valid Route objects contained within a route table. See the documentation for the route_present state or route_create_or_update execution module for more information on required and optional parameters for routes. The routes are only managed if this parameter is present.
When this parameter is absent, implemented routes will not be removed, and will merely become unmanaged.

- **disable_bgp_route_propagation** -- An optional boolean parameter setting whether to disable the routes learned by BGP on the route table.
- **tags** -- A dictionary of strings can be passed as tag metadata to the route table object.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure route table exists:
azurearm_network.route_table_present:
  - name: rt1
  - resource_group: group1
  - routes:
    - name: rt1_route1
      address_prefix: '0.0.0.0/0'
      next_hop_type: internet
    - name: rt1_route2
      address_prefix: '192.168.0.0/16'
      next_hop_type: vnetlocal
  - tags:
    - contact_name: Elmer Fudd Gantry
  - connection_auth: {{ profile }}
  - require:
    - azurearm_resource: Ensure resource group exists
```

salt.states.azurearm_network.security_rule_absent(name, security_group, resource_group, connection_auth=None)

New in version 2019.2.0.

Ensure a security rule does not exist in the network security group.

Parameters

- **name** -- Name of the security rule.
- **security_group** -- The network security group containing the security rule.
- **resource_group** -- The resource group assigned to the network security group.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_network.security_rule_present(name, access, direction, priority, protocol, security_group, resource_group, destination_address_prefix=None, destination_port_range=None, source_address_prefix=None, source_port_range=None, description=None, destination_address_prefixes=None, destination_port_ranges=None, source_address_prefixes=None, source_port_ranges=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a security rule exists.

Parameters

- **name** -- Name of the security rule.
- **access** -- 'allow' or 'deny'
- **direction** -- 'inbound' or 'outbound'
- **priority** -- Integer between 100 and 4096 used for ordering rule application.
- **protocol** -- 'tcp', 'udp', or '*'
- **security_group** -- The name of the existing network security group to contain the security rule.
- **resource_group** -- The resource group assigned to the network security group.
- **description** -- Optional description of the security rule.
- **destination_address_prefix** -- The CIDR or destination IP range. Asterix '*' can also be used to match all destination IPs. Default tags such as 'VirtualNetwork', 'AzureLoadBalancer' and 'Internet' can also be used. If this is an ingress rule, specifies where network traffic originates from.
- **destination_port_range** -- The destination port or range. Integer or range between 0 and 65535. Asterix '*' can also be used to match all ports.
- **source_address_prefix** -- The CIDR or source IP range. Asterix '*' can also be used to match all source IPs. Default tags such as 'VirtualNetwork', 'AzureLoadBalancer' and 'Internet' can also be used. If this is an ingress rule, specifies where network traffic originates from.
- **source_port_range** -- The source port or range. Integer or range between 0 and 65535. Asterix '*' can also be used to match all ports.
- **destination_address_prefixes** -- A list of destination_address_prefix values. This parameter overrides destination_address_prefix and will cause any value entered there to be ignored.
- **destination_port_ranges** -- A list of destination_port_range values. This parameter overrides destination_port_range and will cause any value entered there to be ignored.
- **source_address_prefixes** -- A list of source_address_prefix values. This parameter overrides source_address_prefix and will cause any value entered there to be ignored.
- **source_port_ranges** -- A list of source_port_range values. This parameter overrides source_port_range and will cause any value entered there to be ignored.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure security rule exists:
  azurearm_network.security_rule_present:
    name: nsg1_rule2
    security_group: nsg1
    resource_group: group1
    priority: 101
    protocol: tcp
    access: allow
    direction: inbound
    source_address_prefix: internet
    destination_address_prefix: virtualnetwork
    source_port_range: '*'
    destination_port_ranges:
      - '80'
      - '443'
    connection_auth: {{ profile }}
    require:
      - azurearm_network: Ensure network security group exists
```

salt.states.azurearm_network.subnet_absent(name, virtual_network, resource_group, connection_auth=None)
New in version 2019.2.0.

Ensure a virtual network does not exist in the virtual network.

**Parameters**
- `name` -- Name of the subnet.
- `virtual_network` -- Name of the existing virtual network containing the subnet.
- `resource_group` -- The resource group assigned to the virtual network.
- `connection_auth` -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

`salt.states.azurearm_network.virtual_network_absent(name, resource_group, connection_auth=None)`

New in version 2019.2.0.

Ensure a subnet exists.

**Parameters**
- `name` -- Name of the subnet.
- `address_prefix` -- A CIDR block used by the subnet within the virtual network.
- `virtual_network` -- Name of the existing virtual network to contain the subnet.
- `resource_group` -- The resource group assigned to the virtual network.
- `security_group` -- The name of the existing network security group to assign to the subnet.
- `route_table` -- The name of the existing route table to assign to the subnet.
- `connection_auth` -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```yaml
Ensure subnet exists:
  azurearm_network.subnet_present:
    - name: vnet1_sn1
    - virtual_network: vnet1
    - resource_group: group1
    - address_prefix: '192.168.1.0/24'
    - security_group: nsg1
    - route_table: rt1
    - connection_auth: {{ profile }}
    - require:
      - azurearm_network: Ensure virtual network exists
      - azurearm_network: Ensure network security group exists
      - azurearm_network: Ensure route table exists
```

`salt.states.azurearm_network.virtual_network_absent(name, resource_group, connection_auth=None)`

New in version 2019.2.0.

Ensure a virtual network does not exist in the resource group.

**Parameters**
- `name` -- Name of the virtual network.
- `resource_group` -- The resource group assigned to the virtual network.
- `connection_auth` -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.
salt.states.azurearm_network.virtual_network_present(name, address_prefixes, resource_group, dns_servers=None, tags=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a virtual network exists.

Parameters
- **name** -- Name of the virtual network.
- **resource_group** -- The resource group assigned to the virtual network.
- **address_prefixes** -- A list of CIDR blocks which can be used by subnets within the virtual network.
- **dns_servers** -- A list of DNS server addresses.
- **tags** -- A dictionary of strings can be passed as tag metadata to the virtual network object.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```
Ensure virtual network exists:

azurearm_network.virtual_network_present:
  - name: vnet1
  - resource_group: group1
  - address_prefixes:

    - azurearm_resource: Ensure resource group exists
```

23.19.18 salt.states.azurearm_resource

Azure (ARM) Resource State Module

New in version 2019.2.0.

**maintainer** <devops@decisionlab.io>

**maturity** new

**depends**
- azure >= 2.0.0
- azure-common >= 1.1.8
- azure-mgmt >= 1.0.0
- azure-mgmt-compute >= 1.0.0
- azure-mgmt-network >= 1.7.1
- azure-mgmt-resource >= 1.1.0
- azure-mgmt-storage >= 1.0.0
• azure-mgmt-web >= 0.32.0
• azure-storage >= 0.34.3
• msrestazure >= 0.4.21

platform  linux
configuration  This module requires Azure Resource Manager credentials to be passed as a dictionary of keyword arguments to the connection_auth parameter in order to work properly. Since the authentication parameters are sensitive, it’s recommended to pass them to the states via pillar.

Required provider parameters:
if using username and password:
  • subscription_id
  • username
  • password
if using a service principal:
  • subscription_id
  • tenant
  • client_id
  • secret

Optional provider parameters:
cloud_environment: Used to point the cloud driver to different API endpoints, such as Azure GovCloud. Possible values:

  • AZURE_PUBLIC_CLOUD (default)
  • AZURE_CHINA_CLOUD
  • AZURE_US_GOV_CLOUD
  • AZURE_GERMAN_CLOUD

Example Pillar for Azure Resource Manager authentication:

```
azurearm:
  user_pass_auth:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    username: fletch
    password: 123pass
  mysubscription:
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    tenant: ABCDEFA-B1234-ABCD-1234-ABCDEFA
    client_id: ABCDEFA-B1234-ABCD-1234-ABCDEFA
    secret: Xxxxxxxxxxxxxxxxxxx
    cloud_environment: AZURE_PUBLIC_CLOUD
```

Example states using Azure Resource Manager authentication:

```
{% set profile = salt['pillar.get']('azurearm:mysubscription') %}
Ensure resource group exists:
  azurearm_resource.resource_group_present:
    - name: my_rg
```
- location: westus
- tags:
  how_awesome: very
  contact_name: Elmer Fudd Gantry
- connection_auth: {{ profile }}

Ensure resource group is absent:
```
azurearm_resource.resource_group_absent:
  - name: other_rg
  - connection_auth: {{ profile }}
```

salt.states.azurearm_resource.policy_assignment_absent(name, scope, connection_auth=None)

New in version 2019.2.0.

Ensure a policy assignment does not exist in the provided scope.

Parameters

- **name** -- Name of the policy assignment.
- **scope** -- The scope of the policy assignment.
- **connection_auth** A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_resource.policy_assignment_present(name, scope, definition_name, display_name=None, description=None, assignment_type=None, parameters=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a security policy assignment exists.

Parameters

- **name** -- Name of the policy assignment.
- **scope** -- The scope of the policy assignment.
- **definition_name** -- The name of the policy definition to assign.
- **display_name** -- The display name of the policy assignment.
- **description** -- The policy assignment description.
- **assignment_type** -- The type of policy assignment.
- **parameters** -- Required dictionary if a parameter is used in the policy rule.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:
```
Ensure policy assignment exists:
    azurearm_resource.policy_assignment_present:
      - name: testassign
      - scope: /subscriptions/bc75htn-a0fhsi-349b-56gh-4fghti-f84852
      - definition_name: testpolicy
      - display_name: Test Assignment
      - description: Test assignment for testing assignments.
      - connection_auth: {{ profile }}
```

salt.states.azurearm_resource.policy_definition_absent(name, connection_auth=None)
New in version 2019.2.0.

Ensure a policy definition does not exist in the current subscription.

Parameters

- **name** -- Name of the policy definition.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

```python
salt.states.azurearm_resource.policy_definition_present(name, policy_rule=None, policy_type=None, mode=None, display_name=None, description=None, metadata=None, parameters=None, policy_rule_json=None, policy_rule_file=None, template='jinja', source_hash=None, source_hash_name=None, skip_verify=False, connection_auth=None, **kwargs)
```

New in version 2019.2.0.

Ensure a security policy definition exists.

Parameters

- **name** -- Name of the policy definition.
- **policy_rule** -- A YAML dictionary defining the policy rule. See Azure Policy Definition documentation for details on the structure. One of policy_rule, policy_rule_json, or policy_rule_file is required, in that order of precedence for use if multiple parameters are used.
- **policy_rule_json** -- A text field defining the entirety of a policy definition in JSON. See Azure Policy Definition documentation for details on the structure. One of policy_rule, policy_rule_json, or policy_rule_file is required, in that order of precedence for use if multiple parameters are used. Note that the name field in the JSON will override the name parameter in the state.
- **policy_rule_file** -- The source of a JSON file defining the entirety of a policy definition. See Azure Policy Definition documentation for details on the structure. One of policy_rule, policy_rule_json, or policy_rule_file is required, in that order of precedence for use if multiple parameters are used. Note that the name field in the JSON will override the name parameter in the state.
- **skip_verify** -- Used for the policy_rule_file parameter. If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.
- **source_hash** -- This can be a source hash string or the URI of a file that contains source hash strings.
- **source_hash_name** -- When source_hash refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash.
- **policy_type** -- The type of policy definition. Possible values are NotSpecified, BuiltIn, and Custom. Only used with the policy_rule parameter.
- **mode** -- The policy definition mode. Possible values are NotSpecified, Indexed, and All. Only used with the policy_rule parameter.
- **display_name** -- The display name of the policy definition. Only used with the policy_rule parameter.
- **description** -- The policy definition description. Only used with the
policy_rule parameter.

- **metadata** -- The policy definition metadata defined as a dictionary. Only used with the policy_rule parameter.
- **parameters** -- Required dictionary if a parameter is used in the policy rule. Only used with the policy_rule parameter.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```python
Ensure policy definition exists:
  azurearm_resource.policy_definition_present:
    - name: testpolicy
    - display_name: Test Policy
    - description: Test policy for testing policies.
    - policy_rule:
        if:
          allOf:
            - equals: Microsoft.Compute/virtualMachines/write
              source: action
              field: location
              in:
                - eastus
                - eastus2
                - centralus
            then:
              effect: deny
        - connection_auth: {{ profile }}
```

salt.states.azurearm_resource.resource_group_absent(name, connection_auth=None)

New in version 2019.2.0.

Ensure a resource group does not exist in the current subscription.

Parameters

- **name** -- Name of the resource group.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

salt.states.azurearm_resource.resource_group_present(name, location, managed_by=None, tags=None, connection_auth=None, **kwargs)

New in version 2019.2.0.

Ensure a resource group exists.

Parameters

- **name** -- Name of the resource group.
- **location** -- The Azure location in which to create the resource group. This value cannot be updated once the resource group is created.
- **managed_by** -- The ID of the resource that manages this resource group. This value cannot be updated once the resource group is created.
- **tags** -- A dictionary of strings can be passed as tag metadata to the resource group object.
- **connection_auth** -- A dict with subscription and authentication parameters to be used in connecting to the Azure Resource Manager API.

Example usage:

```python
Ensure resource group exists:
  azurearm_resource.resource_group_present:
```

(continues on next page)
- name: group1
  location: eastus
  tags:
    - contact_name: Elmer Fudd Gantry
  connection_auth: {{ profile }}

23.19.19 salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

```python
ps:
  beacon.present:
    - save: True
    - enable: False
    - services:
      salt-master: running
      apache2: stopped

sh:
  beacon.present: []

load:
  beacon.present:
    - averages:
      1m:
        - 0.0
        - 2.0
      5m:
        - 0.0
        - 1.5
      15m:
        - 0.1
        - 1.0

.. versionadded:: 3000

Beginning in the 3000 release, multiple copies of a beacon can be configured using the `beacon_module` parameter.

inotify_infs:
  beacon.present:
    - save: True
    - enable: True
    - files:
      /etc/infs.conf:
        mask:
          - create
          - delete
          - modify
        recurse: True
        auto_add: True
        - interval: 10
```

(continues on next page)
- `beacon_module`: `inotify`
- `disable_during_state_run`: `True`

**inotify_npt**

- `beacon.present`
  - `save`: `True`
  - `enable`: `True`
  - `files`:
    - `/etc/ntp.conf`:
      - `mask`:
        - `create`
        - `delete`
        - `modify`
      - `recurse`: `True`
      - `auto_add`: `True`
  - `interval`: `10`
  - `beacon_module`: `inotify`
  - `disable_during_state_run`: `True`

---

salt.states.beacon.absent(name, save=False, **kwargs)

Ensure beacon is absent.

- **name**: The name of the beacon that is ensured absent.
- **save**: True/False, if True the beacons.conf file be updated too. Default is False.

Example:

```
remove_beacon:
  beacon.absent:
    - name: ps
    - save: True
```

salt.states.beacon.disabled(name, **kwargs)

Disable a beacon.

- **name**: The name of the beacon to disable.

Example:

```
disable_beacon:
  beacon.disabled:
    - name: psp
```

salt.states.beacon.enabled(name, **kwargs)

Enable a beacon.

- **name**: The name of the beacon to enable.

Example:

```
enable_beacon:
  beacon.enabled:
    - name: ps
```

salt.states.beacon.present(name, save=False, **kwargs)

Ensure beacon is configured with the included beacon data.

- **name**: The name of the beacon to ensure is configured.
- **save**: True/False, if True the beacons.conf file be updated too. Default is False.

Example:
ps beacon:
  beacon.present:
    - name: ps
    - save: True
    - enable: False
    - services:
      salt-master: running
      apache2: stopped

23.19.20 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.

    maturity develop
    platform f5_bigip_11.6

salt.states.bigip.add_pool_member(hostname, username, password, name, member)
A function to connect to a bigip device and add a new member to an existing pool.
    hostname The host/address of the bigip device
    username The iControl REST username
    password The iControl REST password
    name The name of the pool to modify
    member The member to add to the pool

salt.states.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
A function to connect to a bigip device and create a monitor.
    hostname The host/address of the bigip device
    username The iControl REST username
    password The iControl REST password
    monitor_type The type of monitor to create
    name The name of the monitor to create
    kwargs [ arg=val ] ...

    Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.create_node(hostname, username, password, name, address)
Create a new node if it does not already exist.
    hostname The host/address of the bigip device
    username The iControl REST username
    password The iControl REST password
    name The name of the node to create
    address The address of the node

salt.states.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

23.19. state modules
Create a new node if it does not already exist.

hostname The host/address of the bigip device

slow_ramp_time [integer]

salt.states.bigip.create_profile (hostname, username, password, profile_type, name, **kwargs)

A function to connect to a bigip device and create a profile.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwgars [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

Special Characters | , and : must be escaped using \ when used within strings.
salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit Src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

A function to connect to a bigip device and create a virtual server if it does not already exists.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual to create
destination \[ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] \]

salt.states.bigip.delete_monitor( hostname, username, password, monitor_type, name )
  Modify an existing monitor. If it does exists, only the parameters specified will be enforced.
  hostname The host/address of the bigip device
  username The iControl REST username
  password The iControl REST password
  monitor_type The type of monitor to create
  name The name of the monitor to create
  kwargs [ arg=val ] ...
    Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.delete_node( hostname, username, password, name )
  Delete an existing node.
  hostname The host/address of the bigip device
  username The iControl REST username
  password The iControl REST password
  name The name of the node which will be deleted.

salt.states.bigip.delete_pool( hostname, username, password, name )
  Delete an existing pool.
  hostname The host/address of the bigip device
  username The iControl REST username
  password The iControl REST password
  name The name of the pool which will be deleted

salt.states.bigip.delete_pool_member( hostname, username, password, name, member )
  Delete an existing pool member.
  hostname The host/address of the bigip device
  username The iControl REST username
  password The iControl REST password
  name The name of the pool to be modified
  member The name of the member to delete from the pool

salt.states.bigip.delete_profile( hostname, username, password, profile_type, name )
  Modify an existing profile. If it does exists, only the parameters specified will be enforced.
  hostname The host/address of the bigip device
  username The iControl REST username
  password The iControl REST password
  profile_type The type of profile to create
  name The name of the profile to create
  kwargs [ arg=val ] ...
    Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.delete_virtual( hostname, username, password, name )
  Delete an existing virtual.
  hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual which will be deleted

salt.states.bigip.list_monitor(hostname, username, password, monitor_type, name)
A function to list an existing monitor.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to list
name The name of the monitor to list

salt.states.bigip.list_node(hostname, username, password, name)
A function to connect to a bigip device and list a specific node.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node to list.

salt.states.bigip.list_pool(hostname, username, password, name)
A function to connect to a bigip device and list a specific pool.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to list.

salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
A function to list an existing profile.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to list
name The name of the profile to list

salt.states.bigip.list_virtual(hostname, username, password, name)
A function to list a specific virtual.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual to list

salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.manage_node(hostname, username, password, name, address, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)

Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the properties which are different than the existing will be updated.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the node to manage.
- **address**: The address of the node
- **connection_limit** (integer)
- **description** (string)
- **dynamic_ratio** (integer)
- **logging** ([enabled | disabled])
- **monitor** ([name] | none | default)
- **rate_limit** (integer)
- **ratio** (integer)
- **session** ([user-enabled | user-disabled])
- **node_state** (state) ([user-down | user-up])

salt.states.bigip.manage_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Create a new pool if it does not already exist. Pool members are managed separately. Only the parameters specified are enforced.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the pool to create
- **allow_nat** [yes | no]
- **allow_snat** [yes | no]
- **description** (string)
- **gateway_failsafe_device** [string]
- **ignore_persisted_weight** [enabled | disabled]
- **ip_tos_to_client** [pass-through | [integer]]
- **ip_tos_to_server** [pass-through | [integer]]
- **link_qos_to_client** [pass-through | [integer]]
- **link_qos_to_server** [pass-through | [integer]]
- **load_balancing_mode** [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]
- **min_active_members** (integer)
- **min_up_members** (integer)
- **min_up_members_action** [failover | reboot | restart-all]
min_up_members_checking [enabled | disabled]
monitor [name]
profiles [none | profile_name]
queue_depth_limit [integer]
queue_on_connection_limit [enabled | disabled]
queue_time_limit [integer]
reselect_tries [integer]
service_down_action [drop | none | reselect | reset]
slow_ramp_time [integer]

salt.states.bigip.manage_pool_members( hostname, username, password, name, members)
Manage the members of an existing pool. This function replaces all current pool members. Only the parameters specified are enforced.

- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the pool to modify
- members: list of pool members to manage.

salt.states.bigip.manage_profile( hostname, username, password, profile_type, name, **kwargs)
Create a new profile if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.

- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- profile_type: The type of profile to create
- name: The name of the profile to create
- kwargs: Dictionary of other profile attributes

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.manage_virtual( hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bw_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

Manage a virtual server. If a virtual does not exists it will be created, otherwise only the parameters specified will be enforced.

- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the virtual to create
- destination: [virtual_address_name:port] | [ipv4:port] | [ipv6:port]
- pool: [pool_name] | none
- address_status: [yes | no]
- auto_lasthop: [default | enabled | disabled]

      enabled  [ true | false ]
salt.states.bigip.modify_monitor( hostname, username, password, monitor_type, name, **kwargs)

Modify an existing monitor. If it does exists, only the parameters specified will be enforced.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to create
name  The name of the monitor to create
kwargs  [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.modify_node(hostname, username, password, name, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)

Modify an existing node. Only a node which already exists will be modified and only the parameters specified will be enforced.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**password** The iControl REST password

**name** The name of the node to modify

**connection_limit** [integer]

**description** [string]

**dynamic_ratio** [integer]

**logging** [enabled | disabled]

**monitor** [[name] | none | default]

**rate_limit** [integer]

**ratio** [integer]

**session** [user-enabled | user-disabled]

**node_state** (state) [user-down | user-up]

salt.states.bigip.modify_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Modify an existing pool. Pool members are managed separately. Only the parameters specified are enforced.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**password** The iControl REST password

**name** The name of the pool to create

**allow_nat** [yes | no]

**allow_snat** [yes | no]

**description** [string]

**gateway_failsafe_device** [string]

**ignore_persisted_weight** [enabled | disabled]

**ip_tos_to_client** [pass-through | [integer]]

**ip_tos_to_server** [pass-through | [integer]]

**link_qos_to_client** [pass-through | [integer]]

**link_qos_to_server** [pass-through | [integer]]

**load_balancing_mode** [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]

**min_active_members** [integer]

**min_up_members** [integer]

**min_up_members_action** [failover | reboot | restart-all]

**min_up_members_checking** [enabled | disabled]

**monitor** [name]
profiles [none | profile_name]
queue_depth_limit [integer]
queue_on_connection_limit [enabled | disabled]
queue_time_limit [integer]
reselect_tries [integer]
service_down_action [drop | none | reselect | reset]
slow_ramp_time [integer]

salt.states.bigip.modify_pool_member(hostname, username, password, name, member, connection_limit=None, description=None, dynamic_ratio=None, inherit_profile=None, logging=None, monitor=None, priority_group=None, profiles=None, rate_limit=None, ratio=None, session=None, member_state=None)

A function to connect to a bigip device and modify a member of an existing pool.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
member The member modify
connection_limit [integer]
description [string]
dynamic_ratio [integer]
inherit_profile [enabled | disabled]
logging [enabled | disabled]
monitor [name]
priority_group [integer]
profiles [none | profile_name]
rate_limit [integer]
ratio [integer]
session [user-enabled | user-disabled]
member_state (state) [ user-up | user-down ]

salt.states.bigip.modify_profile(hostname, username, password, profile_type, name, **kwargs)

Modify an existing profile. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
**salt.states.bigip.modify_virtual**

Modify an existing virtual. Only parameters specified will be enforced.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the virtual to create
- **destination** `[[virtual_address_name:port] | [ipv4:port] | [ipv6:port]]`
- **pool** `[[pool_name] | none]`
- **address_status** `[yes | no]`
- **auto_lasthop** `[default | enabled | disabled]`
- **bwc_policy** `[none] | string`
- **cmp_enabled** `[yes | no]`
- **dhcp_relay** `[yes | no]`
- **connection_limit** `[integer]`
- **description** `[string]`
- **state** `[disabled | enabled]`
- **fallback_persistence** `[[profile name]]`
- **flow_eviction_policy** `[[eviction policy name]]`
- **gtm_score** `[integer]`
- **ip_forward** `[yes | no]`
- **ip_protocol** `[[any | protocol]]`
- **internal** `[yes | no]`
- **twelve_forward** `[yes | no]`
- **last_hop_pool** `[[pool_name] | none]`
- **mask** `[[ipv4] | [ipv6]]`
- **mirror** `[[disabled | enabled | none]]`
- **nat64** `[enabled | disabled]`
- **persist** `[[list]]`
- **profiles** `[[none] | default | list]`
- **policies** `[[none] | default | list]`
- **rate_class** `[[name]]`
- **rate_limit** `[integer]`
- **rate_limit-mode** `[[destination | object | object-destination | object-source | object-source-destination | source | source-destination]]`
- **rate_limit_dst** `[[integer]]`
- **rate_limit_src** `[[integer]]`
- **rules** `[[list]]`
- **related_rules** `[[none] | list]`
- **reject** `[[yes | no]]`
- **source** `[[ipv4[/prefixlen]]] | [ipv6[/prefixlen]]`
- **source_address_translation** `[[none] | snat:pool_name | lsn | automap | dictionary]`
source_port [change | preserve | preserve-strict]
state [enabled | disabled]
traffic_classes [none | default | list]
translate_address [enabled | disabled]
translate_port [enabled | disabled]
vlans [none | default | dictionary]
    vlan_ids [ list]
    enabled [ true | false]

23.19.21 salt.states.blockdev

Management of Block Devices
A state module to manage blockdevices

```
/dev/sda:
    blockdev.tuned:
        - read-only: True

master-data:
    blockdev.tuned:
        - name: /dev/vg/master-data
        - read-only: True
        - read-ahead: 1024
```

New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', force=False, **kwargs)

Manage filesystems of partitions.
name The name of the block device
fs_type The filesystem it should be formatted as
force Force mke2fs to create a filesystem, even if the specified device is not a partition on a block special device. This option is only enabled for ext and xfs filesystems

This option is dangerous, use it with caution.

New in version 2016.11.0.

salt.states.blockdev.tuned(name, **kwargs)

Manage options of block device
name The name of the block device
opts:
    - read-ahead Read-ahead buffer size
    - filesystem-read-ahead Filesystem Read-ahead buffer size
    - read-only Set Read-Only
    - read-write Set Read-Write
23.19.22 salt.states.boto3_elasticache

Manage Elasticache with boto3

New in version 2017.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto3 behind the scenes - as a result it inherits any limitations it boto3's implementation of the AWS API. It is also designed to as directly as possible leverage boto3’s parameter naming and semantics. This allows one to use http://boto3.readthedocs.io/en/latest/reference/services/elasticache.html as an excellent source for details too involved to reiterate here.

Note: This module is designed to be transparent ("intentionally ignorant" is the phrase I used to describe it to my boss) to new AWS / boto options - since all AWS API params are passed directly through both the state and executions modules, any new args to existing functions which become available after this documentation is written should work immediately.

Brand new API calls, of course, would still require new functions to be added :)

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information is available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```python
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  region: us-east-1
```

Ensure myelasticache exists:
```python
boto3_elasticache.present:
- name: myelasticache
- engine: redis
- cache_node_type: cache.t1.micro
- num_cache_nodes: 1
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

# Using a profile from pillars

Ensure myelasticache exists:
```python
boto3_elasticache.present:
- name: myelasticache
- engine: redis
- cache_node_type: cache.t1.micro
- num_cache_nodes: 1
```

(continues on next page)
# Passing in a profile

Ensure myelasticache exists:

```yaml
boto3_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile:
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkgHUpUjasdflkdfklgjsdfjajkgghs
```

salt.states.boto3_elasticache.cache_cluster_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster is deleted.

- **name**: Name of the cache cluster.
- **wait**: Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.
- **CacheClusterId**: The node group (shard) identifier. Note: In general this parameter is not needed, as 'name' is used if it's not provided.
- **FinalSnapshotIdentifier**: The user-supplied name of a final cache cluster snapshot. This is the unique name that identifies the snapshot. ElastiCache creates the snapshot, and then deletes the cache cluster immediately afterward.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto3_elasticache.cache_cluster_present(name, wait=900, security_groups=None, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster exists.

- **name**: Name of the cache cluster (cache cluster id).
- **wait**: Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.
- **security_groups**: One or more VPC security groups (names and/or IDs) associated with the cache cluster.

**Note**: This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use this parameter ONLY when you are creating a cluster in a VPC.

- **CacheClusterId**: The node group (shard) identifier. This parameter is stored as a lowercase string.

  Constraints:
• A name must contain from 1 to 20 alphanumeric characters or hyphens.
• The first character must be a letter.
• A name cannot end with a hyphen or contain two consecutive hyphens.

**Note:** In general this parameter is not needed, as ‘name’ is used if it’s not provided.

**ReplicationGroupId**  The ID of the replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster is added to the specified replication group as a read replica; otherwise, the cache cluster is a standalone primary that is not part of any replication group. If the specified replication group is Multi-AZ enabled and the Availability Zone is not specified, the cache cluster is created in Availability Zones that provide the best spread of read replicas across Availability Zones.

**AZMode**  Specifies whether the nodes in this Memcached cluster are created in a single Availability Zone or created across multiple Availability Zones in the cluster’s region. If the AZMode and PreferredAvailabilityZones are not specified, ElastiCache assumes single-az mode.

**Note:** This parameter is ONLY supported for Memcached cache clusters.

**PreferredAvailabilityZone**  The EC2 Availability Zone in which the cache cluster is created. All nodes belonging to this Memcached cache cluster are placed in the preferred Availability Zone. If you want to create your nodes across multiple Availability Zones, use PreferredAvailabilityZones.

Default: System chosen Availability Zone.

**PreferredAvailabilityZones**  A list of the Availability Zones in which cache nodes are created. The order of the zones in the list is not important. The number of Availability Zones listed must equal the value of NumCacheNodes. If you want all the nodes in the same Availability Zone, use PreferredAvailabilityZone instead, or repeat the Availability Zone multiple times in the list.

Default: System chosen Availability Zones.

**Note:** This option is ONLY supported on Memcached.

If you are creating your cache cluster in an Amazon VPC (recommended) you can only locate nodes in Availability Zones that are associated with the subnets in the selected subnet group.

**NumCacheNodes**  The initial (integer) number of cache nodes that the cache cluster has.

**Note:** For clusters running Redis, this value must be 1.
For clusters running Memcached, this value must be between 1 and 20.

**CacheNodeType**  The compute and memory capacity of the nodes in the node group (shard). Valid node types (and pricing for them) are exhaustively described at [https://aws.amazon.com/elasticache/pricing/](https://aws.amazon.com/elasticache/pricing/)

**Note:**
All T2 instances must be created in a VPC
Redis backup/restore is not supported for Redis (cluster mode disabled) T1 and T2 instances.
Backup/restore is supported on Redis (cluster mode enabled) T2 instances.
Redis Append-only files (AOF) functionality is not supported for T1 or T2 instances.

**Engine**  The name of the cache engine to be used for this cache cluster. Valid values for this parameter are: memcached | redis

**EngineVersion**  The version number of the cache engine to be used for this cache cluster. To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.
Note: You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.

**CacheParameterGroupName** The name of the parameter group to associate with this cache cluster. If this argument is omitted, the default parameter group for the specified engine is used. You cannot use any parameter group which has cluster-enabled='yes' when creating a cluster.

**CacheSubnetGroupName** The name of the Cache Subnet Group to be used for the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.

Note: If you're going to launch your cluster in an Amazon VPC, you need to create a subnet group before you start creating a cluster.

**CacheSecurityGroupNames** A list of Cache Security Group names to associate with this cache cluster. Use this parameter ONLY when you are creating a cache cluster outside of a VPC.

**SecurityGroupIds** One or more VPC security groups associated with the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.

**Tags** A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for ElastiCache, these can only be set during resource creation - later modification is not (currently) supported.

**SnapshotArns** A single-element string list containing an Amazon Resource Name (ARN) that uniquely identifies a Redis RDB snapshot file stored in Amazon S3. The snapshot file is used to populate the node group (shard). The Amazon S3 object name in the ARN cannot contain any commas.

Note: This parameter is ONLY valid if the Engine parameter is redis.

**SnapshotName** The name of a Redis snapshot from which to restore data into the new node group (shard). The snapshot status changes to restoring while the new node group (shard) is being created.

Note: This parameter is ONLY valid if the Engine parameter is redis.

**PreferredMaintenanceWindow** Specifies the weekly time range during which maintenance on the cache cluster is permitted. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed, thu, fri, sat

Example: sun:23:00-mon:01:30

**Port** The port number on which each of the cache nodes accepts connections.

Default: 6379

**NotificationTopicArn** The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications are sent.

Note: The Amazon SNS topic owner must be the same as the cache cluster owner.

**AutoMinorVersionUpgrade** This (boolean) parameter is currently disabled.

**SnapshotRetentionLimit** The number of days for which ElastiCache retains automatic snapshots before deleting them.

Default: 0 (i.e., automatic backups are disabled for this cache cluster).

Note: This parameter is ONLY valid if the Engine parameter is redis.
SnapshotWindow  The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an appropriate time range.

Example: 05:00-09:00

Note: This parameter is ONLY valid if the Engine parameter is redis.

AuthToken  The password used to access a password protected server.

Password constraints:
- Must be only printable ASCII characters.
- Must be at least 16 characters and no more than 128 characters in length.
- Cannot contain any of the following characters: '/', '"', or '@'.

CacheNodeIdsToRemove  A list of cache node IDs to be removed. A node ID is a numeric identifier (0001, 0002, etc.). This parameter is only valid when NumCacheNodes is less than the existing number of cache nodes. The number of cache node IDs supplied in this parameter must match the difference between the existing number of cache nodes in the cluster or pending cache nodes, whichever is greater, and the value of NumCacheNodes in the request.

NewAvailabilityZones  The list of Availability Zones where the new Memcached cache nodes are created. This parameter is only valid when NumCacheNodes in the request is greater than the sum of the number of active cache nodes and the number of cache nodes pending creation (which may be zero). The number of Availability Zones supplied in this list must match the cache nodes being added in this request. Note: This option is only supported on Memcached clusters.

NotificationTopicStatus  The status of the SNS notification topic. Notifications are sent only if the status is active.

Valid values: active | inactive

region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure a given cache subnet group is deleted.

name  Name of the cache subnet group.

CacheSubnetGroupName  A name for the cache subnet group. Note: In general this parameter is not needed, as 'name' is used if it's not provided.

region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure cache subnet group exists.

name  A name for the cache subnet group. This value is stored as a lowercase string. Constraints: Must contain no more than 255 alphanumeric characters or hyphens.
subnets  A list of VPC subnets (IDs, Names, or a mix) for the cache subnet group.
CacheSubnetGroupName  A name for the cache subnet group. This value is stored as a lowercase string.
Constraints: Must contain no more than 255 alphanumeric characters or hyphens. Note: In general this parameter is not needed, as 'name' is used if it's not provided.

CacheSubnetGroupDescription A description for the cache subnet group.

SubnetIds A list of VPC subnet IDs for the cache subnet group. This is ADDITIVE with 'subnets' above.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto3_elasticache.replication_group_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)
```

Ensure a given replication group is deleted.

name Name of the replication group.
wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

ReplicationGroupId The replication group identifier. Note: In general this parameter is not needed, as 'name' is used if it's not provided.

RetainPrimaryCluster If set to true, all of the read replicas are deleted, but the primary node is retained.

FinalSnapshotIdentifier The name of a final node group (shard) snapshot. ElastiCache creates the snapshot from the primary node in the cluster, rather than one of the replicas; this is to ensure that it captures the freshest data. After the final snapshot is taken, the replication group is immediately deleted.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto3_elasticache.replication_group_present(name, wait=900, security_groups=None, region=None, key=None, keyid=None, profile=None, **args)
```

Ensure a replication group exists and is in the given state.

name Name of replication group.
wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

security_groups One or more VPC security groups (names and/or IDs) associated with the cache cluster.

Note: This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use this parameter ONLY when you are creating a cluster in a VPC.

ReplicationGroupId The replication group identifier. This parameter is stored as a lowercase string.

Constraints:

- A name must contain from 1 to 20 alphanumeric characters or hyphens.
- The first character must be a letter.
- A name cannot end with a hyphen or contain two consecutive hyphens.
ReplicationGroupDescription  A user-created description for the replication group.

PrimaryClusterId  The identifier of the cache cluster that serves as the primary for this replication group.

This cache cluster must already exist and have a status of available. This parameter is not required if NumCacheClusters, NumNodeGroups, or ReplicasPerNodeGroup is specified.

AutomaticFailoverEnabled  Specifies whether a read-only replica is automatically promoted to read/write primary if the existing primary fails. If true, Multi-AZ is enabled for this replication group. If false, Multi-AZ is disabled for this replication group.

Default: False

Note:  AutomaticFailoverEnabled must be enabled for Redis (cluster mode enabled) replication groups.

ElastiCache Multi-AZ replication groups is not supported on:
- Redis versions earlier than 2.8.6.
- Redis (cluster mode disabled): T1 and T2 node types.
- Redis (cluster mode enabled): T2 node types.

NumCacheClusters  The number of clusters this replication group initially has. This parameter is not used if there is more than one node group (shard). You should use ReplicasPerNodeGroup instead. If Multi-AZ is enabled, the value of this parameter must be at least 2. The maximum permitted value for NumCacheClusters is 6 (primary plus 5 replicas).

PreferredCacheClusterAZs  A list of EC2 Availability Zones in which the replication group's cache clusters are created. The order of the Availability Zones in the list is the order in which clusters are allocated. The primary cluster is created in the first AZ in the list. This parameter is not used if there is more than one node group (shard). You should use NodeGroupConfiguration instead. The number of Availability Zones listed must equal the value of NumCacheClusters.

Default: System chosen Availability Zones.

Note:  If you are creating your replication group in an Amazon VPC (recommended), you can only locate cache clusters in Availability Zones associated with the subnets in the selected subnet group.

NumNodeGroups  An optional parameter that specifies the number of node groups (shards) for this Redis (cluster mode enabled) replication group. For Redis (cluster mode disabled) either omit this parameter or set it to 1.

Default: 1

ReplicasPerNodeGroup  An optional parameter that specifies the number of replica nodes in each node group (shard). Valid values are: 0 to 5

NodeGroupConfiguration  A list of node group (shard) configuration options. Each node group (shard) configuration has the following: Slots, PrimaryAvailabilityZone, ReplicaAvailabilityZones, ReplicaCount. If you're creating a Redis (cluster mode disabled) or a Redis (cluster mode enabled) replication group, you can use this parameter to configure one node group (shard) or you can omit this parameter. For fiddly details of the expected data layout of this param, see https://boto3.readthedocs.io/en/latest/reference/services/elasticache.html?#ElastiCache.Client.create_replication_group

CacheNodeType  The compute and memory capacity of the nodes in the node group (shard). See https://aws.amazon.com/elasticache/pricing/ for current sizing, prices, and constraints.

Engine  The name of the cache engine to be used for the cache clusters in this replication group.

EngineVersion  The version number of the cache engine to be used for the cache clusters in this replication group. To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.
Note: You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.

CacheParameterGroupName The name of the parameter group to associate with this replication group. If this argument is omitted, the default cache parameter group for the specified engine is used.

Note: If you are running Redis version 3.2.4 or later, only one node group (shard), and want to use a default parameter group, we recommend that you specify the parameter group by name.

To create a Redis (cluster mode disabled) replication group, use CacheParameterGroupName=default.redis3.2

To create a Redis (cluster mode enabled) replication group, use CacheParameterGroupName=default.redis3.2.cluster.on

CacheSubnetGroupName The name of the cache subnet group to be used for the replication group.

Note: If you're going to launch your cluster in an Amazon VPC, you need to create a subnet group before you start creating a cluster. For more information, see Subnets and Subnet Groups.

CacheSecurityGroupNames A list of cache security group names to associate with this replication group.

SecurityGroupIds One or more Amazon VPC security groups associated with this replication group. Use this parameter only when you are creating a replication group in an VPC.

Tags A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for Elasticache, these can only be set during resource creation - later modification is not (currently) supported.

SnapshotArns A list of ARNs that uniquely identify the Redis RDB snapshot files stored in Amazon S3. These snapshot files are used to populate the replication group. The Amazon S3 object name in the ARN cannot contain any commas. The list must match the number of node groups (shards) in the replication group, which means you cannot repartition.

Note: This parameter is only valid if the Engine parameter is redis.

SnapshotName The name of a snapshot from which to restore data into the new replication group. The snapshot status changes to restoring while the new replication group is being created. Note: This parameter is only valid if the Engine parameter is redis.

PreferredMaintenanceWindow Specifies the weekly time range during which maintenance on the cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed, thu, fri, sat

Example: sun:23:00-mon:01:30

Port The port number on which each member of the replication group accepts connections.

NotificationTopicArn The ARN of an SNS topic to which notifications are sent.

Note: The SNS topic owner must be the same as the cache cluster owner.

AutoMinorVersionUpgrade This parameter is currently disabled.

SnapshotRetentionLimit The number of days for which ElastiCache will retain automatic snapshots before deleting them.

Default: 0 (that is, automatic backups are disabled for this cache cluster).
Note: This parameter is only valid if the Engine parameter is redis.

**SnapshotWindow** The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an appropriate time range.

Example: 05:00-09:00

Note: This parameter is only valid if the Engine parameter is redis.

**AuthToken** The password used to access a password protected server. Password constraints:
- Must be only printable ASCII characters.
- Must be at least 16 characters and no more than 128 characters in length.
- Cannot contain any of the following characters: '/', '"', or '@'.

**SnapshottingClusterId** The cache cluster ID that is used as the daily snapshot source for the replication group.

**NotificationTopicStatus** The status of the SNS notification topic. Notifications are sent only if the status is active. Valid values: active | inactive

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 23.19.23 salt.states.boto3_elasticsearch

Manage Elasticsearch Service

New in version 3001.

**configuration** This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
es.keyid: GKTADJGHEIQSXMKKRBJ08H
es.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
es.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:  
  keyid: GKTADJGHEIQSXMKKRBJ08H  
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs  
  region: us-east-1
```
salt.states.boto3_elasticsearch.absent(name, blocking=True, region=None, keyid=None, key=None, profile=None)

Ensure the Elasticsearch Domain specified does not exist.

Parameters

- **name (str)** -- The name of the Elasticsearch domain to be made absent.
- **blocking (bool)** -- Whether or not the state should wait for the deletion to be completed. Default: True

New in version 3001.

Example:

```yaml
Remove Elasticsearch Domain:
boto3_elasticsearch.absent:
  - name: my_domain
  - region: eu-west-1
```

salt.states.boto3_elasticsearch.latest(name, minor_only=True, region=None, keyid=None, key=None, profile=None)

Ensures the Elasticsearch domain specifies runs on the latest compatible version of elasticsearch, upgrading it if it is not.

Note that this operation is blocking until the upgrade is complete.

Parameters

- **name (str)** -- The name of the Elasticsearch domain to upgrade.
- **minor_only (bool)** -- Only upgrade to the latest minor version.

New in version 3001.

Example:

The following example will ensure the elasticsearch domain `my_domain` is upgraded to the latest minor version. So if it is currently 5.1 it will be upgraded to 5.6.

```yaml
Upgrade Elasticsearch Domain:
boto3_elasticsearch.latest:
  - name: my_domain
  - minor_only: True
  - region: eu-west-1
```

salt.states.boto3_elasticsearch.present(name, elasticsearch_version=None, elasticsearch_cluster_config=None, ebs_options=None, access_policies=None, snapshot_options=None, vpc_options=None, cognito_options=None, encryption_at_rest_options=None, node_to_node_encryption_options=None, advanced_options=None, log_publishing_options=None, blocking=True, tags=None, region=None, keyid=None, key=None, profile=None)

Ensure an Elasticsearch Domain exists.

Parameters

- **name (str)** -- The name of the Elasticsearch domain that you are creating. Domain names are unique across the domains owned by an account within an AWS region. Domain names must start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
• **elasticsearch_version** (*str*) -- String of format X.Y to specify version for the Elasticsearch domain eg. "1.5" or "2.3".

• **elasticsearch_cluster_config** (*dict*) -- Dict specifying the configuration options for an Elasticsearch domain. Keys (case sensitive) in here are:
  - `InstanceType` (*str*): The instance type for an Elasticsearch cluster.
  - `InstanceCount` (*int*): The instance type for an Elasticsearch cluster.
  - `DedicatedMasterEnabled` (*bool*): Indicate whether a dedicated master node is enabled.
  - `ZoneAwarenessEnabled` (*bool*): Indicate whether zone awareness is enabled.
  - `ZoneAwarenessConfig` (*dict*): Specifies the zone awareness configuration for a domain when zone awareness is enabled. Keys (case sensitive) in here are:
    - `AvailabilityZoneCount` (*int*): An integer value to indicate the number of availability zones for a domain when zone awareness is enabled. This should be equal to number of subnets if VPC endpoints is enabled.
    - `DedicatedMasterType` (*str*): The instance type for a dedicated master node.
    - `DedicatedMasterCount` (*int*): Total number of dedicated master nodes, active and on standby, for the cluster.

• **ebs_options** (*dict*) -- Dict specifying the options to enable or disable and specifying the type and size of EBS storage volumes. Keys (case sensitive) in here are:
  - `EBSEnabled` (*bool*): Specifies whether EBS-based storage is enabled.
  - `VolumeType` (*str*): Specifies the volume type for EBS-based storage.
  - `VolumeSize` (*int*): Integer to specify the size of an EBS volume.
  - `Iops` (*int*): Specifies the IOPD for a Provisioned IOPS EBS volume (SSD).

• **access_policies** (*str or dict*) -- Dict or JSON string with the IAM access policy.

• **snapshot_options** (*dict*) -- Dict specifying the snapshot options. Keys (case sensitive) in here are:
  - `AutomatedSnapshotStartHour` (*int*): Specifies the time, in UTC format, when the service takes a daily automated snapshot of the specified Elasticsearch domain. Default value is 0 hours.

• **vpc_options** (*dict*) -- Dict with the options to specify the subnets and security groups for the VPC endpoint. Keys (case sensitive) in here are:
  - `SubnetIds` (*list*): The list of subnets for the VPC endpoint.
  - `SecurityGroupIds` (*list*): The list of security groups for the VPC endpoint.

• **cognito_options** (*dict*) -- Dict with options to specify the cognito user and identity pools for Kibana authentication. Keys (case sensitive) in here are:
  - `Enabled` (*bool*): Specifies the option to enable Cognito for Kibana authentication.
  - `UserPoolId` (*str*): Specifies the Cognito user pool ID for Kibana authentication.
  - `IdentityPoolId` (*str*): Specifies the Cognito identity pool ID for Kibana authentication.
  - `RoleArn` (*str*): Specifies the role ARN that provides Elasticsearch permissions for accessing Cognito resources.

• **encryption_at_rest_options** (*dict*) -- Dict specifying the encryption at rest options. This option can only be used for the creation of a new Elasticsearch domain. Keys (case sensitive) in here are:
  - `Enabled` (*bool*): Specifies the option to enable Encryption At Rest.
  - `KmsKeyId` (*str*): Specifies the KMS Key ID for Encryption At Rest options.

• **node_to_node_encryption_options** (*dict*) -- Dict specifying the node to node encryption options. This option can only be used for the creation of a new Elasticsearch domain. Keys (case sensitive) in here are:
  - `Enabled` (*bool*): Specify True to enable node-to-node encryption.

• **advanced_options** (*dict*) -- Dict with option to allow references to indices in an HTTP request body. Must be False when configuring ac-
cess to individual sub-resources. By default, the value is True. See http://docs.aws.amazon.com/elasticsearch-service/latest/developerguide/es-createupdatedomains.html#es-createdomain-configure-advanced-options for more information.

- **log_publishing_options (dict)** -- Dict with options for various type of logs. The keys denote the type of log file and can be one of the following:
  - INDEX_SLOW_LOGS
  - SEARCH_SLOW_LOGS
  - ES_APPLICATION_LOGS
  The value assigned to each key is a dict with the following case sensitive keys:
  - CloudWatchLogsLogGroupArn (str): The ARN of the Cloudwatch log group to which the log needs to be published.
  - Enabled (bool): Specifies whether given log publishing option is enabled or not.

- **blocking (bool)** -- Whether or not the state should wait for all operations (create/update/upgrade) to be completed. Default: True

- **tags (dict)** -- Dict of tags to ensure are present on the Elasticsearch domain.

New in version 3001.

Example:

This will create an elasticsearch domain consisting of a single t2.small instance in the eu-west-1 region (Ireland) and will wait until the instance is available before returning from the state.

```yaml
Create new domain:
  boto3_elasticsearch.present:
    - name: my_domain
    - elasticsearch_version: '5.1'
    - elasticsearch_cluster_config:
      InstanceType: t2.small.elasticsearch
      InstanceCount: 1
      DedicatedMasterEnabled: False
      ZoneAwarenessEnabled: False
    - ebs_options:
      EBSEnabled: True
      VolumeType: gp2
      VolumeSize: 10
    - snapshot_options:
      AutomatedSnapshotStartHour: 3
    - vpc_options:
      SubnetIds:
        - subnet-12345678
      SecurityGroupIds:
        - sg-12345678
    - node_to_node_encryption_options:
      Enabled: False
    - region: eu-west-1
    - tags:
      foo: bar
      baz: qux
```

salt.states.boto3_elasticsearch.tagged(name, tags=None, replace=False, region=None, keyid=None, key=None, profile=None)

Ensures the Elasticsearch domain has the tags provided. Adds tags to the domain unless replace is set to True, in which case all existing tags will be replaced with the tags provided in tags. (This will remove all tags if replace is True and tags is empty).

Parameters

- **name (str)** -- The Elasticsearch domain to work with.
• **tags (dict)** -- The tags to add to/replace on the Elasticsearch domain.

• **replace (bool)** -- Whether or not to replace (True) all existing tags on the Elasticsearch domain, or add (False) tags to the ES domain.

New in version 3001.

```python
salt.states.boto3_elasticsearch.upgraded(name, elasticsearch_version, blocking=True, region=None, keyid=None, key=None, profile=None)
```

Ensures the Elasticsearch domain specified runs on the specified version of elasticsearch. Only upgrades are possible as downgrades require a manual snapshot and an S3 bucket to store them in.

Note that this operation is blocking until the upgrade is complete.

**Parameters**

• **name (str)** -- The name of the Elasticsearch domain to upgrade.

• **elasticsearch_version (str)** -- String of format X.Y to specify version for the Elasticsearch domain eg. "1.5" or "2.3".

New in version 3001.

Example:

```
Upgrade Elasticsearch Domain:
   boto3_elasticsearch.upgraded:
    - name: my_domain
    - elasticsearch_version: '7.2'
    - region: eu-west-1
```

---

23.19.24 **salt.states.boto3_route53**

Manage Route53 records with Boto 3

New in version 2017.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
   keyid: GKTADJGHEIQSXMKKRBJ08H
   key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
   region: us-east-1
```

```
An exciting new AWS Route 53 Hosted Zone:
   boto_route53.hosted_zone_present:
    - Name: example.com.
    - PrivateZone: true
    - VPCs:
      - VPCName: MyLittleVPC
```

(continues on next page)
VPCRegion: us-east-1
  - VPCId: vpc-12345678
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

mycnamerecord:
  boto_route53.rr_present:
    - Name: test.example.com.
    - ResourceRecords:
      - my-elb.us-east-1.elb.amazonaws.com.
    - DomainName: example.com.
    - TTL: 60
    - Type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

salt.states.boto3_route53.hosted_zone_absent(name, Name=None, PrivateZone=False, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 Hosts Zone described is absent.

name  The name of the state definition.

Name  The name of the domain. This should be a fully-specified domain, and should terminate with a period. If not provided, the value of name will be used.

PrivateZone  Set True if deleting a private hosted zone.

salt.states.boto3_route53.hosted_zone_present(name, Name=None, PrivateZone=False, CallerReference=None, Comment=None, VPCs=None, region=None, key=None, keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes.

name  The name of the state definition.

Name  The name of the domain. This should be a fully-specified domain, and should terminate with a period. This is the name you have registered with your DNS registrar. It is also the name you will delegate from your registrar to the Amazon Route 53 delegation servers returned in response to this request. If not provided, the value of name will be used.

PrivateZone  Set True if creating a private hosted zone. If true, then 'VPCs' is also required.

Comment  Any comments you want to include about the hosted zone.

CallerReference  A unique string that identifies the request and that allows create_hosted_zone() calls to be retried without the risk of executing the operation twice. This helps ensure idempotency across state calls, but can cause issues if a zone is deleted and then an attempt is made to recreate it with the same CallerReference. If not provided, a unique UUID will be generated at each state run, which can potentially lead to duplicate zones being created if the state is run again while the previous zone creation is still in PENDING status (which can occasionally take several minutes to clear). Maximum length of 128.

VPCs  A list of dicts, each dict composed of a VPCRegion, and either a VPCId or a VPCName. Note that this param is ONLY used if PrivateZone == True

VPCId  When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with VPCName.

VPCName  When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with VPCId.

VPCRegion  When creating a private hosted zone, the region of the associated VPC is required. If not provided, an effort will be made to determine it from VPCId or VPCName, if possible. This will fail if a given VPCName exists in multiple regions visible to the bound account, in which case you'll need to provide an explicit value for VPCRegion.
salt.states.boto3_route53.rr_absent(name, HostedZoneId=None, DomainName=None, PrivateZone=False, Name=None, Type=None, SetIdentifier=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 record is deleted.

**name** The name of the state definition. This will be used for Name if the latter is not provided.

**HostedZoneId** The ID of the zone to delete the record from. Exclusive with DomainName.

**DomainName** The domain name of the zone to delete the record from. Exclusive with HostedZoneId.

**PrivateZone** Set to True if the RR to be removed is in a private zone, False if public.

**Name** Name of the resource record.

**Type** The record type (A, NS, MX, TXT, etc.)

**SetIdentifier** Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.

salt.states.boto3_route53.rr_present(name, HostedZoneId=None, DomainName=None, PrivateZone=False, Name=None, Type=None, SetIdentifier=None, Weight=None, Region=None, GeoLocation=None, Failover=None, TTL=None, ResourceRecords=None, AliasTarget=None, HealthCheckId=None, TrafficPolicyInstanceId=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 record is present.

**name** The name of the state definition. This will be used for Name if the latter is not provided.

**HostedZoneId** The ID of a zone to create the record in. Exclusive with DomainName.

**DomainName** The domain name of a zone to create the record in. Exclusive with HostedZoneId.

**PrivateZone** Set to True if the resource record should be in a private zone, False if public.

**Name** Name of the Route 53 resource record being managed.

**Type** The record type (A, NS, MX, TXT, etc.)

**SetIdentifier** Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.

**Weight** Valid for Weighted resource record sets only. Among resource record sets that have the same combination of DNS name and type, a value that determines the proportion of DNS queries that Amazon Route 53 responds to using the current resource record set. Amazon Route 53 calculates the sum of the weights for the resource record sets that have the same combination of DNS name and type. Amazon Route 53 then responds to queries based on the ratio of a resource's weight to the total.

Note the following:

- You must specify a value for the Weight element for every weighted resource record set.
- You can only specify one ResourceRecord per weighted resource record set.
- You can't create latency, failover, or geolocation resource record sets that have the same values for the Name and Type elements as weighted resource record sets.
- You can create a maximum of 100 weighted resource record sets that have the same values for the Name and Type elements.
- For weighted (but not weighted alias) resource record sets, if you set Weight to 0 for a resource record set, Amazon Route 53 never responds to queries with the applicable value for that resource record set. However, if you set Weight to 0 for all resource record sets that have the same combination of DNS name and type, traffic is routed to all resources with equal probability. The effect of setting Weight to 0 is different when you associate health checks with weighted resource record.
sets. For more information, see Options for Configuring Amazon Route 53 Active-Active and Active-Passive Failover in the Amazon Route 53 Developer Guide.

**Region** Valid for Latency-based resource record sets only. The Amazon EC2 Region where the resource that is specified in this resource record set resides. The resource typically is an AWS resource, such as an EC2 instance or an ELB load balancer, and is referred to by an IP address or a DNS domain name, depending on the record type.

**GeoLocation** Geo location resource record sets only. A dict that lets you control how Route 53 responds to DNS queries based on the geographic origin of the query. For example, if you want all queries from Africa to be routed to a web server with an IP address of 192.0.2.111, create a resource record set with a Type of A and a ContinentCode of AF.

| ContinentCode | The two-letter code for the continent.  
|---------------|-----------------------------------|
|               | Valid values: AF | AN | AS | EU | OC | NA | SA  
|               | Constraint: Specifying ContinentCode with either CountryCode or ContinentalCode  
| SubdivisionCode | returns an InvalidInput error.  
| CountryCode   | The two-letter code for the country.  
| SubdivisionCode | The code for the subdivision, for example, a state in the United States or a province in Canada.  

**Notes**

- Creating geolocation and geolocation alias resource record sets in private hosted zones is not supported.
- If you create separate resource record sets for overlapping geographic regions (for example, one resource record set for a continent and one for a country on the same continent), priority goes to the smallest geographic region. This allows you to route most queries for a continent to one resource and to route queries for a country on that continent to a different resource.
- You can't create two geolocation resource record sets that specify the same geographic location.
- The value * in the CountryCode element matches all geographic locations that aren't specified in other geolocation resource record sets that have the same values for the Name and Type elements.
- Geolocation works by mapping IP addresses to locations. However, some IP addresses aren't mapped to geographic locations, so even if you create geolocation resource record sets that cover all seven continents, Amazon Route 53 will receive some DNS queries from locations that it can't identify. We recommend that you create a resource record set for which the value of CountryCode is *, which handles both queries that come from locations for which you haven't created geolocation resource record sets and queries from IP addresses that aren't mapped to a location. If you don't create a * resource record set, Amazon Route 53 returns a "no answer" response for queries from those locations.
- You can't create non-geolocation resource record sets that have the same values for the Name and Type elements as geolocation resource record sets.

**TTL** The resource record cache time to live (TTL), in seconds. Note the following:

- If you're creating an alias resource record set, omit TTL. Amazon Route 53 uses the value of TTL for the alias target.
- If you're associating this resource record set with a health check (if you're adding a HealthCheckId element), we recommend that you specify a TTL of 60 seconds or less so clients respond quickly to changes in health status.
- All of the resource record sets in a group of weighted, latency, geolocation, or failover resource record sets must have the same value for TTL.
- If a group of weighted resource record sets includes one or more weighted alias resource record sets for which the alias target is an ELB load balancer, we recommend that you specify a TTL of 60 seconds for all of the non-alias weighted resource record sets that have the same name and type.
Values other than 60 seconds (the TTL for load balancers) will change the effect of the values that you specify for Weight.

**ResourceRecords**  A list, containing one or more values for the resource record. No single value can exceed 4,000 characters. For details on how to format values for different record types, see Supported DNS Resource Record Types in the Amazon Route 53 Developer Guide.

Note: You can specify more than one value for all record types except CNAME and SOA.

It is also possible to pass "magic" strings as resource record values. This functionality can easily be extended, but for the moment supports the following:

'\magic:ec2_instance_tag:some_tag_name:some_string:some_instance_attr'

This tells salt to lookup an EC2 instance with a tag 'some_tag_name' which has the value 'some_string' and substitute the 'some_instance_attr' attribute of that instance as the resource record value being evaluated.

This should work generally for any EC2 instance tags, as long as the instance attribute being fetched is available to getattr(instance, 'attribute') as seen in the code below. Anything else will most likely require this function to be extended to handle it.

The canonical use-case for this (at least at our site) is to query the Name tag (which we always populate with the host's FQDN) to lookup the public or private IPs bound to the instance, so we can then automically create Route 53 records for them.

**AliasTarget**  The rules governing how to define an AliasTarget for the various supported use-cases are obtuse beyond reason and attempting to paraphrase them (or even worse, cut-and-paste them in their entirety) would be silly and counterproductive. If you need this feature, then Read The Fine Materials at the Boto 3 Route 53 page and/or the AWS Route 53 docs and suss them for yourself - I sure won't claim to understand them particularly well.

- **region**  The region to connect to.
- **key**  Secret key to be used.
- **keyid**  Access key to be used.
- **profile**  Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.

### 23.19.25  salt.states.boto3_sns

**Manage SNS Topics**

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

---

23.19.  state modules  3489
mytopic:

boto3_sns.topic_present:
  - region: us-east-1
  - keyid: GKTADJGHEIQXSXMRRB5Q8H
  - key: askdjghsdfjkgHUpUjasdfklgjsdfjajkghs

Using a profile from pillars

mytopic:

boto3_sns.topic_present:
  - region: us-east-1
  - profile: mysnsprofile

Passing in a profile

mytopic:

boto3_sns.topic_present:
  - region: us-east-1
  - profile:
    - keyid: GKTADJGHEIQXSXMRRB5Q8H
    - key: askdjghsdfjkgHUpUjasdfklgjsdfjajkghs

salt.states.boto3_sns.topic_absent(name, unsubscribe=False, region=None, key=None, keyid=None, profile=None)

Ensure the named sns topic is deleted.

name Name of the SNS topic.
unsubscribe If True, unsubscribe all subscriptions to the SNS topic before deleting the SNS topic
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

class attributes

dictionary of attributes to set on the SNS topic
Valid attribute keys are:
• Policy: the JSON serialization of the topic's access control policy
• DisplayName: the human-readable name used in the "From" field for notifications to email and email-json endpoints
• DeliveryPolicy: the JSON serialization of the topic's delivery policy

region Region to connect to.

3490 Chapter 23. Salt Module Reference
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.26 salt.states.boto_apigateway

Manage Apigateway Rest APIs

New in version 2016.11.0.

depends
  • boto >= 2.8.0
  • boto3 >= 1.2.1
  • botocore >= 1.4.49

Create and destroy rest apis depending on a swagger version 2 definition file. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure Apigateway API exists:

```
boto_apigateway.present:
  - name: myfunction
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_apigateway.absent(name, api_name, stage_name, nuke_api=False, region=None, key=None, keyid=None, profile=None)

Ensure the stage_name associated with the given api_name deployed by boto_apigateway's present state is removed. If the currently associated deployment to the given stage_name has no other stages associated with it, the deployment will also be removed.

name  Name of the swagger file in YAML format
api_name  Name of the rest api on AWS ApiGateway to ensure is absent.
stage_name  Name of the stage to be removed irrespective of the swagger file content. If the current deployment associated with the stage_name has no other stages associated with it, the deployment will also be removed.
**nuke_api** If True, removes the API itself only if there are no other stages associated with any other deployments once the given stage_name is removed.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_apigateway.present(name, api_name, swagger_file, stage_name, api_key_required, lambda_integration_role, lambda_region=None, stage_variables=None, region=None, key=None, keyid=None, profile=None, lambda_funcname_format='{stage}_{api}_{resource}_{method}', authorization_type='NONE', error_response_template=None, response_template=None)
```

Ensure the specified api_name with the corresponding swaggerfile is deployed to the given stage_name in AWS ApiGateway.

This state currently only supports ApiGateway integration with AWS Lambda, and CORS support is handled through a Mock integration.

There may be multiple deployments for the API object, each deployment is tagged with a description (i.e. unique label) in pretty printed json format consisting of the following key/values:

```
{
    "api_name": api_name,
    "swagger_file": basename_of_swagger_file
    "swagger_file_md5sum": md5sum_of_swagger_file,
    "swagger_info_object": info_object_content_in_swagger_file
}
```

Please note that the name of the lambda function to be integrated will be derived via the provided lambda_funcname_format parameters:

- the default lambda_funcname_format is a string with the following substitutable keys: 
  - "[stage]_[api]_[resource]_[method]". The user can choose to reorder the known keys.
  - the stage key corresponds to the stage_name passed in.
  - the api key corresponds to the api_name passed in.
  - the resource corresponds to the resource path defined in the passed swagger file.
  - the method corresponds to the method for a resource path defined in the passed swagger file.

For the default lambda_funcname_format, given the following input:

```
api_name = 'Test Service'
stage_name = 'alpha'
basePath = '/api'
path = '/a/{b}/c'
method = 'POST'
```

We will end up with the following Lambda Function Name that will be looked up: 'test_service_alpha_a_b_c_post'

The canonicalization of these input parameters is done in the following order:

1. lambda_funcname_format is formatted with the input parameters as passed,
2. resulting string is stripped for leading/trailing spaces,
3. path parameter's curly braces are removed from the resource path,
4. consecutive spaces and forward slashes in the paths are replaced with '_'
5. consecutive '_' are replaced with '_'

Please note that for error response handling, the swagger file must have an error response model with the fol-
lowing schema. The lambda functions should throw exceptions for any non successful responses. An optional pattern field can be specified in errorMessage field to aid the response mapping from Lambda to the proper error return status codes.

```json
Error:
  type: object
  properties:
    stackTrace:
      type: array
      items:
        type: array
        items:
          type: string
    errorType:
      type: string
    errorMessage:
      type: string
    description: |
      Error message, will be matched based on pattern.
      If no pattern is specified, the default pattern used for response mapping will be "+.*".
```

name The name of the state definition
api_name The name of the rest api that we want to ensure exists in AWS API Gateway
swagger_file Name of the location of the swagger rest api definition file in YAML format.
stage_name Name of the stage we want to be associated with the given api_name and swagger_file definition
api_key_required True or False - whether the API Key is required to call API methods
lambda_integration_role The name or ARN of the IAM role that the AWS ApiGateway assumes when it executes your lambda function to handle incoming requests
lambda_region The region where we expect to find the lambda functions. This is used to determine the region where we should look for the Lambda Function for integration purposes. The region determination is based on the following priority:
  1. lambda_region as passed in (is not None)
  2. if lambda_region is None, use the region as if a boto_lambda function were executed without explicitly specifying lambda region.
  3. if region determined in (2) is different than the region used by boto_apigateway functions, a final lookup will be attempted using the boto_apigateway region.
stage_variables A dict with variables and their values, or a pillar key (string) that contains a dict with variables and their values. key and values in the dict must be strings. {'string': 'string'}
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
lambda_funcname_format Please review the earlier example for the usage. The only substitutable keys in the funcname format are {stage}, {api}, {resource}, {method}. Any other keys or positional substitution parameters will be flagged as an invalid input.
authorization_type This field can be either 'NONE', or 'AWS_IAM'. This will be applied to all methods in the given swagger spec file. Default is set to 'NONE'
error_response_template String value that defines the response template mapping that should be applied in cases error occurs. Refer to AWS documentation for details: http://docs.aws.amazon.com/apigateway/latest/developerguide/api-gateway-mapping-template-reference.html

If set to None, the following default value is used:
New in version 2017.7.0.

**response_template** String value that defines the response template mapping applied in case of success (including OPTIONS method) If set to None, empty ([]) template is assumed, which will transfer response from the lambda function as is.

New in version 2017.7.0.

```
{  
  "errorMessage" : "$inputRoot.errorMessage",
  "errorType" : "$inputRoot.errorType",
  "stackTrace" : [
    
    #foreach($stackTrace in $inputRoot.stackTrace)
    [
      
      #foreach($elem in $stackTrace)
      "$elem",
      
      #if($foreach.hasNext),#end
      
      #end
    
    #if($foreach.hasNext),#end
    
    #end
    
    
  ]
}
```

salt.states.boto_apigateway.usage_plan_absent(name, plan_name, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is no longer present

New in version 2017.7.0.

- **name** name of the state
- **plan_name** name of the plan to remove

```
usage_plan_absent:
  boto_apigateway.usage_plan_absent:
    - plan_name: my_usage_plan
    - profile: my_profile
```

salt.states.boto_apigateway.usage_plan_association_absent(name, plan_name, api_stages, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is removed from provided api_stages If a plan is associated to stages not listed in api_stages parameter, those associations remain intact.

New in version 2017.7.0.

- **name** name of the state
- **plan_name** name of the plan to use
- **api_stages** list of dictionaries, where each dictionary consists of the following keys:
  - **apiId** apid of the api to detach usage plan from
  - **stage** stage name of the api to detach usage plan from

```
UsagePlanAssociationAbsent:
  boto_apigateway.usage_plan_association_absent:
    - plan_name: my_plan
    - api_stages:
      - apiId: 9kb0404ec0
        stage: my_stage
```

Ensure the specified usage plan with the corresponding metrics is deployed

New in version 2017.7.0.

- **name** name of the state
- **plan_name** [Required] name of the usage plan
- **throttle** [Optional] throttling parameters expressed as a dictionary. If provided, at least one of the throttling parameters must be present
  - **rateLimit** rate per second at which capacity bucket is populated
  - **burstLimit** maximum rate allowed
- **quota** [Optional] quota on the number of api calls permitted by the plan. If provided, limit and period must be present
  - **limit** [Required] number of calls permitted per quota period
  - **offset** [Optional] number of calls to be subtracted from the limit at the beginning of the period
  - **period** [Required] period to which quota applies. Must be DAY, WEEK or MONTH

**UsagePlanPresent:**

boto_apigateway.usage_plan_present:
- **plan_name**: my_usage_plan
- **throttle**:
  - **rateLimit**: 70
  - **burstLimit**: 100

23.19.27 salt.states.boto_asg

Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myasg exists:

```
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - suspended_processes:
      - AddToLoadBalancer
      - AlarmNotification
    - scaling_policies
      - adjustment_type: ChangeInCapacity
      - as_name: api-production-iad
      - cooldown: 1800
      - min_adjustment_step: None
      - name: ScaleDown
      - scaling_adjustment: -1
```
- `region`: us-east-1
- `keyid`: GKTADJGHEIQSXMKKRBJ08H
- `key`: askdjghsdfjkgHwUpUjasdfklgksfjajkghs

# Using a profile from pillars.
Ensure myasg exists:
```
boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile
```

# Passing in a profile.
Ensure myasg exists:
```
boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile:
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkgHwUpUjasdfklgksfjajkghs
      - region: us-east-1
```

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
```
boto_asg.absent:
    - name: myasg

# If instances exist, we must force the deletion of the asg.
    - force: True
```

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the name attribute defined, plus the ASG resource name.
- `desired_capacity`: 1
- `load_balancers`:
  - `myelb`
- `profile`: `myprofile`
- `alarms`:
  - `CPU`:
    - `name`: `'ASG CPU **MANAGED BY SALT**'`
    - `attributes`:
      - `metric`: `CPUUtilization`
      - `namespace`: `AWS/EC2`
      - `statistic`: `Average`
      - `comparison`: `'>='`
      - `threshold`: 65.0
      - `period`: 60
      - `evaluation_periods`: 30
      - `unit`: `null`
      - `description`: `'ASG CPU'`
      - `alarm_actions`: `[ 'arn:aws:sns:us-east-1:12345:myalarm' ]`
      - `insufficient_data_actions`: `[]`
      - `ok_actions`: `[ 'arn:aws:sns:us-east-1:12345:myalarm' ]`

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```python
my_asg_alarm:
CPU:
    - `name`: `'ASG CPU **MANAGED BY SALT**'`
    - `attributes`:
      - `metric`: `CPUUtilization`
      - `namespace`: `AWS/EC2`
      - `statistic`: `Average`
      - `comparison`: `'>='`
      - `threshold`: 65.0
      - `period`: 60
      - `evaluation_periods`: 30
      - `unit`: `null`
      - `description`: `'ASG CPU'`
      - `alarm_actions`: `[ 'arn:aws:sns:us-east-1:12345:myalarm' ]`
      - `insufficient_data_actions`: `[]`
      - `ok_actions`: `[ 'arn:aws:sns:us-east-1:12345:myalarm' ]`
```

Overriding the alarm values on the resource:

```python
Ensure_myasg_exists:
boto_asg.present:
    - `name`: `myasg`
    - `launch_config_name`: `mylc`
    - `availability_zones`:
      - `us-east-1a`
      - `us-east-1b`
    - `min_size`: 1
    - `max_size`: 1
    - `desired_capacity`: 1
    - `load_balancers`:
```

(continues on next page)
- `myelb`
- `profile`: myprofile
- `alarms_from_pillar`: my_asg_alarm

# override CPU:attributes:threshold
- `alarms`: 
  - `CPU`:
    - `attributes`: 
      - `threshold`: 50.0

```python
salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None, remove_lc=False)
```

Ensure the named autoscale group is deleted.
- **name** Name of the autoscale group.
- **force** Force deletion of autoscale group.
- **remove_lc** Delete the launch config as well.
- **region** The region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_asg.present(name, launch_config_name, availability_zones, min_size, max_size, launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, subnet_names=None, tags=None, termination_policies_from_pillar='boto_asg_termination_policies', suspended_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies', scheduled_actions=None, scheduled_actions_from_pillar='boto_asg_scheduled_actions', alarms=None, alarms_from_pillar='boto_asg_alarms', region=None, key=None, keyid=None, profile=None, notification_arn=None, notification_arn_from_pillar='boto_asg_notification_arn', notification_types=None, notification_types_from_pillar='boto_asg_notification_types')
```

Ensure the autoscale group exists.
- **name** Name of the autoscale group.
- **launch_config_name** Name of the launch config to use for the group. Or, if `launch_config` is specified, this will be the launch config name's prefix. (see below)
- **launch_config** A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the `launch_config_name` followed by a hyphen followed by a hash of the launch_config dict contents. Example:

```python
my_asg:
    boto_asg.present:
        - launch_config:
            - ebs_optimized: false
            - instance_profile_name: my_iam_profile
            - kernel_id: ''
            - ramdisk_id: ''
            - key_name: my_ssh_key
            - image_name: aws2015091-hvm
```
- **instance_type**: c3.xlarge
- **instance_monitoring**: false
- **security_groups**:
  - my_sec_group_01
  - my_sec_group_02

**availability_zones**  List of availability zones for the group.

**min_size**  Minimum size of the group.

**max_size**  Maximum size of the group.

**desired_capacity**  The desired capacity of the group.

**load_balancers**  List of load balancers for the group. Once set this cannot be updated (Amazon restriction).

**default_cooldown**  Number of seconds after a Scaling Activity completes before any further scaling activities can start.

**health_check_type**  The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).

**health_check_period**  Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.

**placement_group**  Physical location of your cluster placement group created in Amazon EC2. Once set this cannot be updated (Amazon restriction).

**vpc_zone_identifier**  A list of the subnet identifiers of the Virtual Private Cloud.

**subnet_names**  For VPC, a list of subnet names (NOT subnet IDs) to deploy into. Exclusive with **vpc_zone_identifier**.

**tags**  A list of tags. Example:

- **key**: 'key'
  - **value**: 'value'
  - **propagate_at_launch**: true

**termination_policies**  A list of termination policies. Valid values are:

- OldestInstance
- NewestInstance
- OldestLaunchConfiguration
- ClosestToNextInstanceHour
- Default

If no value is specified, the Default value is used.

**termination_policies_from_pillar**: name of pillar dict that contains termination policy settings. Termination policies defined for this specific state will override those from pillar.

**scaling_policies_from_pillar**: name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state will override those from pillar.

**scheduled_actions**: a dictionary of scheduled actions. Each key is the name of scheduled action and each value is dictionary of options. For example:

- **scheduled_actions**:
  
  - **scale_up_at_10**:
    - **desired_capacity**: 4
    - **min_size**: 3
    - **max_size**: 5
    - **recurrence**: "@ 9 * * 1-5"
  
  - **scale_down_at_7**:
    - **desired_capacity**: 1
    - **min_size**: 1

(continues on next page)
scheduled_actions_from_pillar: name of pillar dict that contains scheduled_actions settings. Scheduled actions for this specific state will override those from pillar.

alarms: a dictionary of name--->boto_cloudwatch_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

If any alarm actions include ":self:" this will be replaced with the asg name. For example, alarm_actions reading "["scaling_policy:self:ScaleUp"]" will map to the arn for this asg's scaling policy named "ScaleUp". In addition, any alarms that have only scaling_policy as actions will be ignored if min_size is equal to max_size for this ASG.

alarms_from_pillar: name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

notification_arn The AWS arn that notifications will be sent to
notification_arn_from_pillar name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.

notification_types A list of event names that will trigger a notification. The list of valid notification types is:

- autoscaling:EC2_INSTANCE_LAUNCH
- autoscaling:EC2_INSTANCE_LAUNCH_ERROR
- autoscaling:EC2_INSTANCE_TERMINATE
- autoscaling:EC2_INSTANCE_TERMINATE_ERROR
- autoscaling:TEST_NOTIFICATION

notification_types_from_pillar name of the pillar dict that contains notification_types settings. notification_types defined for this specific state will override those from the pillar.

23.19.28 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

depends boto

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```plaintext
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

stack_present:
boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json
Stack absent:

```
stack_absent:
  boto_cfn.absent:
    - name: mystack
```

The `salt.states.boto_cfn.absent` function is used to delete a CloudFormation stack. It accepts the following arguments:

- `name` (string): The name of the stack to delete.
- `region` (string): Region to connect to.
- `key` (string): Secret key to be used.
- `keyid` (string): Access key to be used.
- `profile` (dict): A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Stack present:

```
salt.states.boto_cfn.present(
  name, 
  template_body=None, 
  template_url=None, 
  parameters=None, 
  notification_arns=None, 
  disable_rollback=None, 
  timeout_in_minutes=None, 
  capabilities=None, 
  tags=None, 
  on_failure=None, 
  stack_policy_body=None, 
  stack_policy_url=None, 
  use_previous_template=None, 
  stack_policy_during_update_body=None, 
  stack_policy_during_update_url=None, 
  region=None, 
  key=None, 
  keyid=None, 
  profile=None
)
```

The `salt.states.boto_cfn.present` function is used to ensure a CloudFormation stack is present. It accepts the following arguments:

- `name` (string): Name of the stack.
- `template_body` (string): Structure containing the template body. Can also be loaded from a file by using salt://.
- `template_url` (string): Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.
- `parameters` (list): A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.
- `notification_arns` (list): The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the `SNS_console` or your Command Line Interface (CLI).
- `disable_rollback` (bool): Indicates whether or not to rollback on failure.
- `timeout_in_minutes` (integer): The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.
- `capabilities` (list): The list of capabilities you want to allow in the stack. Currently, the only valid capability is 'CAPABILITY_IAM'.
- `tags` (dict): A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.
- `on_failure` (string): Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.
stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using `salt://`.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass `StackPolicyBody` and `StackPolicyURL`, only `StackPolicyBody` is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via `TemplateBody` or `TemplateURL`.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass `StackPolicyDuringUpdateBody` and `StackPolicyDuringUpdateURL`, only `StackPolicyDuringUpdateBody` is used. Can also be loaded from a file by using `salt://`.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass `StackPolicyDuringUpdateBody` and `StackPolicyDuringUpdateURL`, only `StackPolicyDuringUpdateBody` is used.

region (string) - Region to connect to.

dict (string) - Secret key to be used.

keyid (string) - Access key to be used.

profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 23.19.29 salt.states.boto_cloudfront

Manage CloudFront distributions

New in version 2018.3.0.

Create, update and destroy CloudFront distributions.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them, either in a pillar file or in the minion's config file:

```yaml
cloudfront.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudfront.key: askdjghsdfjkgwupUjasdkfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid`, and `region` via a profile, either passed in as a dict, or a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgwupUjasdkfklgjsdfjajkghs
  region: us-east-1

aws:
  region: us-east-1:
    profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
```

(continues on next page)
depends boto3

salt.states.boto_cloudfront.present(name, config, tags, region=None, key=None, keyid=None, profile=None)

Ensure the CloudFront distribution is present.

**name (string)** Name of the CloudFront distribution

**config (dict)** Configuration for the distribution

**tags (dict)** Tags to associate with the distribution

**region (string)** Region to connect to

**key (string)** Secret key to use

**keyid (string)** Access key to use

**profile (dict or string)** A dict with region, key, and keyid, or a pillar key (string) that contains such a dict.

Example:

```yaml
Manage my_distribution CloudFront distribution:
  boto_cloudfront.present:
    - name: my_distribution
    - config:
        Comment: 'partial config shown, most parameters elided'
        Enabled: True
    - tags:
        testing_key: testing_value
```

## 23.19.30 salt.states.boto_cloudtrail

Manage CloudTrail Objects

New in version 2016.3.0.

Create and destroy CloudTrail objects. Be aware that this interacts with Amazon’s services, and so may incur charges.

depends

- boto
- boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQXSXMZRBJ08H
vpc.key: askdjghsdfjkgWupUjasdfklkgjsdfajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKRBJ08H
```

(continues on next page)
Ensure trail exists:

```yaml
boto_cloudtrail.present:
  - Name: mytrail
  - S3BucketName: mybucket
  - S3KeyPrefix: prefix
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdlgjsdfajkghs
```

```python
salt.states.boto_cloudtrail.absent(name, Name, region=None, key=None, keyid=None, profile=None)
```

Ensure trail with passed properties is absent.

- name The name of the state definition.
- Name Name of the trail.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_cloudtrail.present(name, S3BucketName, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=True, IsMultiRegionTrail=None, EnableLogFileValidation=False, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, LoggingEnabled=True, Tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure trail exists.

- name The name of the state definition.
- Name Name of the trail.
- S3BucketName Specifies the name of the Amazon S3 bucket designated for publishing log files.
- S3KeyPrefix Specifies the Amazon S3 key prefix that comes after the name of the bucket you have designated for log file delivery.
- SnsTopicName Specifies the name of the Amazon SNS topic defined for notification of log file delivery. The maximum length is 256 characters.
- IncludeGlobalServiceEvents Specifies whether the trail is publishing events from global services such as IAM to the log files.
- EnableLogFileValidation Specifies whether log file integrity validation is enabled. The default is false.
- CloudWatchLogsLogGroupArn Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.
- CloudWatchLogsRoleArn Specifies the role for the CloudWatch Logs endpoint to assume to write to a user's log group.
- KmsKeyId Specifies the KMS key ID to use to encrypt the logs delivered by CloudTrail. The value can be an alias name prefixed by "alias/", a fully specified ARN to an alias, a fully specified ARN to a key, or a globally unique identifier.
- LoggingEnabled Whether logging should be enabled for the trail.
- Tags A dictionary of tags that should be set on the trail.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.31 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary.

More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
cloudwatch:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfkldfkgjgsdjfajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjhgsdfjkgWupUjasdfkldfkgjgsdjfajkghs
  region: us-east-1
```

```yaml
my test alarm:
  boto_cloudwatch_alarm.present:
    name: my test alarm
    attributes:
      metric: ApproximateNumberOfMessagesVisible
      namespace: AWS/SQS
      statistic: Average
      comparison: "\geq"
      threshold: 20000.0
      period: 60
      evaluation_periods: 1
      description: test alarm via salt
      dimensions:
        QueueName:
          - the-sqs-queue-name
      alarm_actions:
        - arn:aws:sns:us-east-1:111111111111111:myalerting-action
```

```yaml
salt.states.boto_cloudwatch_alarm.absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure the named cloudwatch alarm is deleted.

name  Name of the alarm.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None,
keyid=None, profile=None)

Ensure the cloudwatch alarm exists.

name  Name of the alarm
attributes  A dict of key/value cloudwatch alarm attributes.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

23.19.32  salt.states.boto_cloudwatch_event

Manage CloudTrail Objects

New in version 2016.11.0.

Create and destroy CloudWatch event rules. Be aware that this interacts with Amazon’s services, and so may incur
charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance
Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is neces-
sary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

| cloudwatch_event.keyid: GKTADJGHEIQSXMKKRBJ08H |
| cloudwatch_event.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs |

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

| myprofile: |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs |
| region: us-east-1 |

Ensure event rule exists:

| boto_cloudwatch_event.present: |
| Name: mytrail |
| ScheduleExpression: 'rate(120 minutes)' |
| State: 'DISABLED' |
| Targets: |
| Id: "target1" |
| Input: '{"arbitrary": "json"}' |
| region: us-east-1 |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs |
**salt.states.boto_cloudwatch_event.absent** *(name, Name=None, region=None, key=None, keyid=None, profile=None)*

Ensure CloudWatch event rule with passed properties is absent.

- **name**: The name of the state definition.
- **Name**: Name of the event rule. Defaults to the value of the 'name' param if not provided.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_cloudwatch_event.present** *(name, Name=None, ScheduleExpression=None, EventPattern=None, Description=None, RoleArn=None, State=None, Targets=None, region=None, key=None, keyid=None, profile=None)*

Ensure trail exists.

- **name**: The name of the state definition.
- **Name**: Name of the event rule. Defaults to the value of the 'name' param if not provided.
- **ScheduleExpression**: The scheduling expression. For example, `cron(0 20 * * ? *)`, "rate(5 minutes)"
- **EventPattern**: The event pattern.
- **Description**: A description of the rule.
- **State**: Indicates whether the rule is ENABLED or DISABLED.
- **RoleArn**: The Amazon Resource Name (ARN) of the IAM role associated with the rule.
- **Targets**: A list of resources to be invoked when the rule is triggered.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 23.19.33 salt.states.boto_cognitoidentity

**Manage CognitoIdentity Functions**

New in version 2016.11.0.

Create and destroy CognitoIdentity identity pools. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

<table>
<thead>
<tr>
<th>vpc.keyid: GKTADJGHEIQSXMKKRBJ08H</th>
</tr>
</thead>
<tbody>
<tr>
<td>vpc.key: askdjghsdfjkghWupUjasdflkdfklgjhsdfjkghs</td>
</tr>
</tbody>
</table>

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

<table>
<thead>
<tr>
<th>myprofile:</th>
</tr>
</thead>
<tbody>
<tr>
<td>key: GKTADJGHEIQSXMKKRBJ08H</td>
</tr>
</tbody>
</table>

(continues on next page)
**Ensure function exists:**

```
key: askdjghsfjkgwhwpUjasdfklkdfklgjsdfjajkghs
region: us-east-1
```

```python
salt.states.boto_cognitoidentity.pool_present
```

- `name` The name of the state definition.
- `IdentityPoolName` Name of the Cognito Identity Pool. Please note that this may match multiple pools with the same given name, in which case, all will be removed.
- `RemoveAllMatched` If True, all identity pools with the matching IdentityPoolName will be removed. If False and there are more than one identity pool with the matching IdentityPoolName, no action will be taken. If False and there is only one identity pool with the matching IdentityPoolName, the identity pool will be removed.
- `region` Region to connect to.
- `key` Secret key to be used.
- `keyid` Access key to be used.
- `profile` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_cognitoidentity.pool_absent
```

- `name` The name of the state definition.
- `IdentityPoolName` Name of the Cognito Identity Pool.
- `RemoveAllMatched` If True, all identity pools with the matching IdentityPoolName will be removed. If False and there are more than one identity pool with the matching IdentityPoolName, no action will be taken. If False and there is only one identity pool with the matching IdentityPoolName, the identity pool will be removed.
- `region` Region to connect to.
- `key` Secret key to be used.
- `keyid` Access key to be used.
- `profile` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**Ensure Cognito Identity Pool exists:**

```python
salt.states.boto_cognitoidentity.pool_present
```

- `name` The name of the state definition.
- `IdentityPoolName` Name of the Cognito Identity Pool.
- `AuthenticatedRole` An IAM role name or ARN that will be associated with temporary AWS credentials for an authenticated cognito identity.
- `AllowUnauthenticatedIdentities` Whether to allow anonymous user identities.
- `UnauthenticatedRole` An IAM role name or ARN that will be associated with anonymous user identities.
- `SupportedLoginProviders` A dictionary or pillar that contains key:value pairs mapping provider names to provider app IDs.
- `DeveloperProviderName` A string which is the domain by which Cognito will refer to your users. This name acts as a placeholder that allows your backend and the Cognito service to communicate about the developer provider. Once you have set a developer provider name, you cannot change it. Please take care in setting this parameter.
- `OpenIdConnectProviderARNs` A list or pillar name that contains a list of OpenID Connect provider ARNs.
- `region` Region to connect to.
- `key` Secret key to be used.
- `keyid` Access key to be used.
- `profile` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
**23.19.34 salt.states.boto_datapipeline**

Manage Data Pipelines

New in version 2016.3.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
datapipeline.keyid: GKTADJGHEIQXSXMKKRBJ08H
datapipeline.key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  region: us-east-1
```

In SaltStack, we can use the `boto_datapipeline` module to manage Data Pipelines on AWS. To ensure a daily data pipeline exists, we can use the following function:

```python
boto_datapipeline.present:
  
  name: my-datapipeline
  pipeline_objects:
    DefaultSchedule:
      name: Every 1 day
      fields:
        period: 1 Day
        type: Schedule
        startAt: FIRST_ACTIVATION_DATE_TIME
  parameter_values:
    myDDBTableName: my-dynamo-table
```

The `boto_datapipeline.present` function ensures the data pipeline exists with the specified definition. The parameters include:

- **name**: Name of the service to ensure a data pipeline exists for.
- **pipeline_objects**: Dictionary of pipeline objects.
- **pipeline_objects_from_pillars**: Pillar key containing pipeline objects.
- **parameter_objects**: Dictionary of parameter objects.
- **parameter_objects_from_pillars**: Pillar key containing parameter objects.
- **parameter_values**: Dictionary of parameter values.
- **parameter_values_from_pillars**: Pillar key containing parameter values.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

To ensure a pipeline with the service name does not exist, we can use the `boto_datapipeline.absent` function:

```python
boto_datapipeline.absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure a pipeline with the service name does not exist.

- **name**: Name of the service to ensure a data pipeline does not exist for.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

The `boto_datapipeline.absent` function removes a data pipeline with the specified service name.
pipeline_objects  Pipeline objects to use. Will override objects read from pillars.
pipeline_objects_from_pillars  The pillar key to use for lookup.
parameter_objects  Parameter objects to use. Will override objects read from pillars.
parameter_objects_from_pillars  The pillar key to use for lookup.
parameter_values  Parameter values to use. Will override values read from pillars.
parameter_values_from_pillars  The pillar key to use for lookup.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.35 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.
Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
region: us-east-1
```
It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
    region: us-east-1
```

Ensure DynamoDB table does not exist:
```
boto_dynamodb.absent:
  - table_name: new_table
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
    - region: us-east-1
```
Ensure DynamoDB table exists:
```
boto_dynamodb.present:
  - table_name: new_table
    - read_capacity_units: 1
    - write_capacity_units: 2
    - hash_key: primary_id
    - hash_key_data_type: N
    - range_key: start_timestamp
    - range_key_data_type: N
```

(continues on next page)
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdlkdfklgjsdfajkghs
region: us-east-1
local_indexes:
  - name: "primary_id_end_timestamp_index"
    hash_key: primary_id
    range_key: end_timestamp
    range_key_data_type: N
  - name: "name_end_timestamp_index"
    hash_key: name
    range_key: end_timestamp
    range_key_data_type: N

global_indexes:
  - name: "primary_id_end_timestamp_index"
    hash_key: primary_id
    range_key: end_timestamp
    range_key_data_type: N

It's possible to specify cloudwatch alarms that will be setup along with the DynamoDB table. Note the alarm name will be defined by the name attribute provided, plus the DynamoDB resource name.

Ensure DynamoDB table exists:

```python
boto_dynamodb.present:
  - name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - alarms:
    ConsumedWriteCapacityUnits:
      name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
      attributes:
        metric: ConsumedWriteCapacityUnits
        namespace: AWS/DynamoDB
        statistic: Sum
        comparison: '>= '
        # threshold_percent is used to calculate the actual threshold
        # based on the provisioned capacity for the table.
        threshold_percent: 0.75
        period: 300
        evaluation_periods: 2
        unit: Count
        description: 'DynamoDB ConsumedWriteCapacityUnits'
        alarm_actions: ['arn:aws:sns:us-east-1:1234:my-alarm']
        insufficient_data_actions: []
        ok_actions: ['arn:aws:sns:us-east-1:1234:my-alarm']
```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_dynamodb_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.
Setting the alarms in a pillar:

```yaml
boto_dynamodb_alarms:
  ConsumedWriteCapacityUnits:
    name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
    attributes:
      metric: ConsumedWriteCapacityUnits
      namespace: AWS/DynamoDB
      statistic: Sum
      comparison: '>='
      # threshold_percent is used to calculate the actual threshold
      # based on the provisioned capacity for the table.
      threshold_percent: 0.75
      period: 300
      evaluation_periods: 2
      unit: Count
      description: 'DynamoDB ConsumedWriteCapacityUnits'
    alarm_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
```

Ensure DynamoDB table exists:

```yaml
boto_dynamodb.present:
  - name: new_table
    - read_capacity_units: 1
    - write_capacity_units: 2
    - hash_key: primary_id
    - hash_key_data_type: N
    - range_key: start_timestamp
    - range_key_data_type: N
    - alarms:
      ConsumedWriteCapacityUnits:
        attributes:
          threshold_percent: 0.90
          period: 900
```

**exception** salt.states.boto_dynamodb.GsiNotUpdatableError

Raised when a global secondary index cannot be updated.

salt.states.boto_dynamodb.absent(name=None, region=None, key=None, keyid=None, profile=None)

Ensure the DynamoDB table does not exist.

- **name** Name of the DynamoDB table.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_dynamodb.present(name=None, table_name=None, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, alarms=None, alarms_from_pillar='boto_dynamodb_alarms', hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=0, global_indexes=0, backup_configs_from_pillars='boto_dynamodb_backup_configs')

Ensure the DynamoDB table exists. Table throughput can be updated after table creation.

Global secondary indexes (GSIs) are managed with some exceptions:
• If a GSI deletion is detected, a failure will occur (deletes should be done manually in the AWS console).
• If multiple GSIs are added in a single Salt call, a failure will occur (boto supports one creation at a time).
  Note that this only applies after table creation; multiple GSIs can be created during table creation.
• Updates to existing GSIs are limited to read/write capacity only (DynamoDB limitation).

name Name of the DynamoDB table
table_name Name of the DynamoDB table (deprecated)
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
  keyid.
read_capacity_units The read throughput for this table
write_capacity_units The write throughput for this table
hash_key The name of the attribute that will be used as the hash key for this table
hash_key_data_type The DynamoDB datatype of the hash key
range_key The name of the attribute that will be used as the range key for this table
range_key_data_type The DynamoDB datatype of the range key
local_indexes The local indexes you would like to create
global_indexes The global indexes you would like to create
backup_configs_from_pillars Pillars to use to configure DataPipeline backups

23.19.36 salt.states.boto_ec2

Manage EC2

New in version 2015.8.0.

This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.

The below code creates a key pair:

```
create-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - save_private: /root/
    - region: eu-west-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgwhWupUjasdflkdfklgjjsdfjajkghs
```

```
import-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - upload_public: 'ssh-rsa AAAA'
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgwhWupUjasdflkdfklgjjsdfjajkghs
```

You can also use salt:// in order to define the public key.

```
import-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - upload_public: salt://mybase/public_key.pub
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgwhWupUjasdflkdfklgjjsdfjajkghs
```

The below code deletes a key pair:
### delete-key-pair:

```python
boto_ec2.key_absent:
   - name: mykeypair
   - region: eu-west-1
   - keyid: GKTADJGHEIQSXMKKRBJ08H
   - key: askdjghsdfjkghWupUjasdfsflkdjsdfjaksdfjghs
```

**salt.states.boto_ec2.eni_absent**

```python
(name, release_eip=False, region=None, key=None, keyid=None, profile=None)
```

Ensure the EC2 ENI is absent.

New in version 2016.3.0.

- **name** Name tag associated with the ENI.
- **release_eip** True/False - release any EIP associated with the ENI
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_ec2.eni_present**

```python
(name, subnet_id=None, subnet_name=None, private_ip_address=None, description=None, groups=None, source_dest_check=True, allocate_eip=None, arecords=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the EC2 ENI exists.

New in version 2016.3.0.

- **name** Name tag associated with the ENI.
- **subnet_id** The VPC subnet ID the ENI will exist within.
- **subnet_name** The VPC subnet name the ENI will exist within.
- **private_ip_address** The private ip address to use for this ENI. If this is not specified AWS will automatically assign a private IP address to the ENI. Must be specified at creation time; will be ignored afterward.
- **description** Description of the key.
- **groups** A list of security groups to apply to the ENI.
- **source_dest_check** Boolean specifying whether source/destination checking is enabled on the ENI.
- **allocate_eip** allocate and associate an EIP to the ENI. Could be 'standard' to allocate Elastic IP to EC2 region or 'vpc' to get it for a particular VPC.

Changed in version 2016.11.0.

- **arecords** A list of arecord dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. By default, the private ENI IP address will be used, set 'public: True' in the arecord dict to use the ENI's public IP address

New in version 2016.3.0.

- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_ec2.instance_absent**

```python
(name, instance_name=None, instance_id=None, release_eip=False, region=None, key=None, keyid=None, profile=None, filters=None)
```

Ensure an EC2 instance does not exist (is stopped and removed).

Changed in version 2016.11.0.
name (string) - The name of the state definition.
instance_name (string) - The name of the instance.
instance_id (string) - The ID of the instance.
release_eip (bool) - Release any associated EIPs during termination.
region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
filters (dict) - A dict of additional filters to use in matching the instance to delete.

YAML example fragment:

```
- filters:
  vpc-id: vpc-abcdef12
```

```
salt.states.boto_ec2.instance_present(name, instance_name=None, instance_id=None, image_id=None, image_name=None, tags=None, key_name=None, security_groups=None, user_data=None, instance_type=None, placement=None, kernel_id=None, ramdisk_id=None, vpc_id=None, vpc_name=None, monitoring_enabled=None, subnet_id=None, subnet_name=None, private_ip_address=None, block_device_map=None, disable_api_termination=None, instance_initiated_shutdown_behavior=None, placement_group=None, client_token=None, security_group_ids=None, security_group_names=None, additional_info=None, tenancy=None, instance_profile_arn=None, instance_profile_name=None, ebs_optimized=None, network_interfaces=None, network_interface_name=None, network_interface_id=None, attributes=None, target_state=None, public_ip=None, allocation_id=None, allocate_eip=False, region=None, key=None, keyid=None, profile=None)
```

Ensure an EC2 instance is running with the given attributes and state.

name (string) - The name of the state definition. Recommended that this match the instance_name attribute (generally the FQDN of the instance).
instance_name (string) - The name of the instance, generally its FQDN. Exclusive with 'instance_id'.
instance_id (string) - The ID of the instance (if known). Exclusive with 'instance_name'.
image_id (string) - The ID of the AMI image to run.
image_name (string) - The name of the AMI image to run.
tags (dict) - Tags to apply to the instance.
key_name (string) - The name of the key pair with which to launch instances.
security_groups (list of strings) - The names of the EC2 classic security groups with which to associate instances
user_data (string) - The Base64-encoded MIME user data to be made available to the instance(s) in this reservation.
instance_type (string) - The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.
placement (string) - The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.
kern

3516 Chapter 23. Salt Module Reference
Salt Documentation, Release 3003.1

**ramdisk_id** (string) – The ID of the RAM disk with which to launch the instances.

**vpc_id** (string) - The ID of a VPC to attach the instance to.

**vpc_name** (string) - The name of a VPC to attach the instance to.

**monitoring_enabled** (bool) – Enable detailed CloudWatch monitoring on the instance.

**subnet_id** (string) – The ID of the subnet within which to launch the instances for VPC.

**subnet_name** (string) – The name of the subnet within which to launch the instances for VPC.

**private_ip_address** (string) – If you’re using VPC, you can optionally use this parameter to assign the instance a specific available IP address from the subnet (e.g., 10.0.0.25).

**block_device_map** (boto.ec2.blockdevicemapping.BlockDeviceMapping) – A BlockDeviceMapping data structure describing the EBS volumes associated with the Image.

**disable_api_termination** (bool) – If True, the instances will be locked and will not be able to be terminated via the API.

**instance_initiated_shutdown_behavior** (string) – Specifies whether the instance stops or terminates on instance-initiated shutdown. Valid values are:
- 'stop'
- 'terminate'

**placement_group** (string) – If specified, this is the name of the placement group in which the instance(s) will be launched.

**client_token** (string) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. Maximum 64 ASCII characters.

**security_group_ids** (list of strings) – The IDs of the VPC security groups with which to associate instances.

**security_group_names** (list of strings) – The names of the VPC security groups with which to associate instances.

**additional_info** (string) – Specifies additional information to make available to the instance(s).

**tenancy** (string) – The tenancy of the instance you want to launch. An instance with a tenancy of ‘dedicated’ runs on single-tenant hardware and can only be launched into a VPC. Valid values are: "default" or "dedicated". NOTE: To use dedicated tenancy you MUST specify a VPC subnet-ID as well.

**instance_profile_arn** (string) – The Amazon resource name (ARN) of the IAM Instance Profile (IIP) to associate with the instances.

**instance_profile_name** (string) – The name of the IAM Instance Profile (IIP) to associate with the instances.

**ebs_optimized** (bool) – Whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and a tuned configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types.

**network_interfaces** (boto.ec2.networkinterface.NetworkInterfaceCollection) – A NetworkInterfaceCollection data structure containing the ENI specifications for the instance.

**network_interface_name** (string) - The name of Elastic Network Interface to attach

New in version 2016.11.0.

**network_interface_id** (string) - The id of Elastic Network Interface to attach

New in version 2016.11.0.

**attributes** (dict) - Instance attributes and value to be applied to the instance. Available options are:
- `instanceType` - A valid instance type (m1.small)
- `kernel` - Kernel ID (None)
- `ramdisk` - Ramdisk ID (None)
- `userData` - Base64 encoded String (None)
- `disableApiTermination` - Boolean (true)
- `instanceInitiatedShutdownBehavior` - stop|terminate
- `blockDeviceMapping` - List of strings - ie: ['/dev/sda=false']
- `sourceDestCheck` - Boolean (true)
- `groupSet` - Set of Security Groups or IDs
- `ebsOptimized` - Boolean (false)
- `sriovNetSupport` - String - ie: 'simple'

**target_state** (string) - The desired target state of the instance. Available options are:

23.19. state modules 3517
This documentation entry provides information about the Salt module `boto_ec2` for managing Amazon EC2 instances, focusing on the `key_absent`, `key_present`, `private_ips_absent`, `private_ips_present`, and `snapshot_created` states.

### key_absent

Deletes a key pair

**Arguments**
- `name` (String): State definition name

### key_present

Ensure key pair is present.

**Arguments**
- `name` (String): State definition name
- `save_private` (Optional): Whether to save the private key
- `upload_public` (Optional): Whether to upload the public key
- `network_interface_id` (Optional): The EC2 network interface id, example eni-123456789
- `private_ip_addresses` (List or String): The secondary private ip address(es) that should be present on the ENI
- `region` (String): Region to connect to.
- `key` (String): Secret key to be used.
- `keyid` (String): Access key to be used.
- `profile` (variable): A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### private_ips_absent

Ensure an ENI does not have secondary private ip addresses associated with it

**Arguments**
- `name` (String): State definition name
- `network_interface_id` (String): The EC2 network interface id, example eni-123456789
- `private_ip_addresses` (List or String): The secondary private ip address(es) that should be absent on the ENI
- `region` (String): Region to connect to.
- `key` (String): Secret key to be used.
- `keyid` (String): Access key to be used.
- `profile` (variable): A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### private_ips_present

Ensure an ENI has secondary private ip addresses associated with it

**Arguments**
- `name` (String): State definition name
- `network_interface_id` (String): The EC2 network interface id, example eni-123456789
- `private_ip_addresses` (List or String): The secondary private ip address(es) that should be present on the ENI
- `allow_reassignment` (Boolean): If true, will reassign a secondary private ip address associated with another ENI. If false, state will fail if the secondary private ip address is associated with another ENI.
- `region` (String): Region to connect to.
- `key` (String): Secret key to be used.
- `keyid` (String): Access key to be used.
- `profile` (variable): A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### snapshot_created

Create a new snapshot of an EC2 image.

**Arguments**
- `name` (String): State definition name
- `ami_name` (String): AMI name
- `instance_name` (String): Instance name
- `wait_until_available` (Optional): Whether to wait until the snapshot is available.
- `wait_timeout_seconds` (Optional): Timeout in seconds for waiting for the snapshot to be available.
- `**kwargs` (Optional): Additional keyword arguments.
Create a snapshot from the given instance

New in version 2016.3.0.

```
salt.states.boto_ec2.volume_absent(name, volume_name=None, volume_id=None, instance_name=None, instance_id=None, device=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the EC2 volume is detached and absent.

New in version 2016.11.0.

```
name State definition name.
volume_name Name tag associated with the volume. For safety, if this matches more than one volume, the state will refuse to apply.
volume_id Resource ID of the volume.
instance_name Only remove volume if it is attached to instance with this Name tag. Exclusive with 'instance_id'. Requires 'device'.
instance_id Only remove volume if it is attached to this instance. Exclusive with 'instance_name'. Requires 'device'.
device Match by device rather than ID. Requires one of 'instance_name' or 'instance_id'.
region Region to connect to.
key Secret key to be used.
kidy Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```

```
salt.states.boto_ec2.volume_present(name, volume_name=None, volume_id=None, instance_name=None, instance_id=None, device=None, size=None, snapshot_id=None, volume_type=None, iops=None, encrypted=False, kms_key_id=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the EC2 volume is present and attached.

```
name State definition name.
volume_name The Name tag value for the volume. If no volume with that matching name tag is found, a new volume will be created. If multiple volumes are matched, the state will fail.
volume_id Resource ID of the volume. Exclusive with 'volume_name'.
instance_name Attach volume to instance with this Name tag. Exclusive with 'instance_id'.
instance_id Attach volume to instance with this ID. Exclusive with 'instance_name'.
device The device on the instance through which the volume is exposed (e.g. /dev/sdh)
size The size of the new volume, in GiB. If you're creating the volume from a snapshot and don’t specify a volume size, the default is the snapshot size. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'.
snapshot_id The snapshot ID from which the new Volume will be created. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'.
volume_type The type of the volume. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'. Valid volume types for AWS can be found here: http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolumeTypes.html
iops The provisioned IOPS you want to associate with this volume. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'.
encrypted Specifies whether the volume should be encrypted. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'.
kms_key_id If encrypted is True, this KMS Key ID may be specified to encrypt volume with this key. Optionally specified at volume creation time; will be ignored afterward. Requires 'volume_name'. e.g.: arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef
region Region to connect to.
key Secret key to be used.
kidy Access key to be used.
**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_ec2.volumes_tagged(name, tag_maps, authoritative=False, region=None, key=None, keyid=None, profile=None)
```

Ensure EC2 volume(s) matching the given filters have the defined tags.

New in version 2016.11.0.

**name** State definition name.

**tag_maps** List of dicts of filters and tags, where ‘filters’ is a dict suitable for passing to the ‘filters’ argument of boto_ec2.get_all_volumes(), and ‘tags’ is a dict of tags to be set on volumes as matched by the given filters. The filter syntax is extended to permit passing either a list of volume_ids or an instance_name (with instance_name being the Name tag of the instance to which the desired volumes are mapped). Each mapping in the list is applied separately, so multiple sets of volumes can be all tagged differently with one call to this function.

**YAML example fragment:**

```
- filters:
  attachment.instance_id: i-abcdef12
  tags:
    Name: dev-int-abcdef12.aws-foo.com
- filters:
  attachment.device: /dev/sdf
  tags:
    ManagedSnapshots: true
    BillingGroup: bubba.hotep@aws-foo.com
- filters:
  instance_name: prd-foo-01.aws-foo.com
  tags:
    Name: prd-foo-01.aws-foo.com
    BillingGroup: infra-team@aws-foo.com
- filters:
  volume_ids: [ vol-12345689, vol-abcdef12 ]
  tags:
    BillingGroup: infra-team@aws-foo.com
```

**authoritative** Should un-declared tags currently set on matched volumes be deleted? Boolean.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

---

23.19.37 **salt.states.boto_elasticache**

**Manage Elasticache**

New in version 2014.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.
This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```
Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
# Using a profile from pillars
Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile: myprofile
```

```
# Passing in a profile
Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile:
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
salt.states.boto_elasticache.absent(name, wait=True, region=None, key=None, keyid=None, profile=None)
```

Ensure the named elasticache cluster is deleted.

- **name** Name of the cache cluster.
- **wait** Boolean. Wait for confirmation from boto that the cluster is in the deleting state.
- **region** Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_elasticache.cache_cluster_absent**(*args, **kwargs*)

**salt.states.boto_elasticache.cache_cluster_present**(*args, **kwargs*)

**salt.states.boto_elasticache.creategroup**(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the a replication group is create.

name  Name of replication group
wait  Waits for the group to be available
primary_cluster_id  Name of the master cache node
replication_group_description  Description for the group
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_elasticache.present**(name, engine=None, cache_node_type=None, num_cache_nodes=None, preferred_availability_zone=None, port=None, cache_parameter_group_name=None, cache_security_group_names=None, replication_group_id=None, auto_minor_version_upgrade=True, security_group_ids=None, cache_subnet_group_name=None, engine_version=None, notification_topic_arn=None, preferred_maintenance_window=None, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the cache cluster exists.

name  Name of the cache cluster (cache cluster id).
engine  The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.
cache_node_type  The compute and memory capacity of the nodes in the cache cluster. cache.t1.micro, cache.m1.small, etc. See: https://boto.readthedocs.io/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cluster
num_cache_nodes  The number of cache nodes that the cache cluster will have.
preferred_availability_zone  The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.
port  The port number on which each of the cache nodes will accept connections.
cache_parameter_group_name  The name of the cache parameter group to associate with this cache cluster.
    If this argument is omitted, the default cache parameter group for the specified engine will be used.
cache_security_group_names  A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.
replication_group_id  The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
auto_minor_version_upgrade  Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.
security_group_ids  One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
**cache_subnet_group_name**  The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

**engine_version**  The version number of the cache engine to be used for this cluster.

**notification_topic_arn**  The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.

**preferred_maintenance_window**  The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00

**wait**  Boolean. Wait for confirmation from boto that the cluster is in the available state.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_elasticache.replication_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

```python
salt.states.boto_elasticache.replication_group_present(*args, **kwargs)
```

```python
salt.states.boto_elasticache.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

```python
salt.states.boto_elasticache.subnet_group_present(name, subnet_ids=None, subnet_names=None, description=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure ElastiCache subnet group exists.

New in version 2015.8.0.

**name**  The name for the ElastiCache subnet group. This value is stored as a lowercase string.

**subnet_ids**  A list of VPC subnet IDs for the cache subnet group. Exclusive with subnet_names.

**subnet_names**  A list of VPC subnet names for the cache subnet group. Exclusive with subnet_ids.

**description**  Subnet group description.

**tags**  A list of tags.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

---

### 23.19.38  `salt.states.boto_elasticsearch_domain`

**Manage Elasticsearch Domains**

New in version 2016.11.0.

Create and destroy Elasticsearch domains. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto3`, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkgWuUpUjasdfsdfkldfkgjgsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWuUpUjasdfsdfkldfkgjgsdfjajkghs
  region: us-east-1
```

Ensure domain exists:

```yaml
Ensure domain exists:
  boto_elasticsearch_domain.present:
    - DomainName: mydomain
    - profile='user-credentials'
    - ElasticsearchVersion: "2.3"
    - ElasticsearchClusterConfig:
      InstanceType": "t2.micro.elasticsearch"
      InstanceCount: 1
      DedicatedMasterEnabled: False
      ZoneAwarenessEnabled: False
    - EBSOptions:
      EBSEnabled: True
      VolumeType: "gp2"
      VolumeSize: 10
      Iops: 0
    - AccessPolicies:
      Version: "2012-10-17"
      Statement:
        - Effect: "Allow"
        - Principal:
          AWS: "*
        - Action:
          - "es:*"
        - Condition:
          IpAddress:
            "aws:SourceIp":
            - "127.0.0.1"
            - "127.0.0.2"
    - SnapshotOptions:
      AutomatedSnapshotStartHour: 0
    - AdvancedOptions:
      rest.action.multi.allow_explicit_index": "true"
    - Tags:
      a: "b"
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWuUpUjasdfsdfkldfkgjgsdfjajkghs
```

```python
salt.states.boto_elasticsearch_domain.absent(name, DomainName, region=None, key=None, keyid=None, profile=None)
```

Ensure domain with passed properties is absent.

- **name** The name of the state definition.
- **DomainName** Name of the domain.
- **region** Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticsearch_domain.present(name, DomainName, ElasticsearchClusterConfig=None, EBSOptions=None, AccessPolicies=None, SnapshotOptions=None, AdvancedOptions=None, Tags=None, region=None, key=None, keyid=None, profile=None, ElasticsearchVersion='1.5')

Ensure domain exists.
name  The name of the state definition
DomainName  Name of the domain.
ElasticsearchClusterConfig  Configuration options for an Elasticsearch domain. Specifies the instance type and number of instances in the domain cluster.
  InstanceType (string) -- The instance type for an Elasticsearch cluster.
  InstanceCount (integer) -- The number of instances in the specified domain cluster.
  DedicatedMasterEnabled (boolean) -- A boolean value to indicate whether a dedicated master node is enabled. See About Dedicated Master Nodes for more information.
  ZoneAwarenessEnabled (boolean) -- A boolean value to indicate whether zone awareness is enabled. See About Zone Awareness for more information.
  DedicatedMasterType (string) -- The instance type for a dedicated master node.
  DedicatedMasterCount (integer) -- Total number of dedicated master nodes, active and on standby, for the cluster.
EBSOptions  Options to enable, disable and specify the type and size of EBS storage volumes.
  EBSEnabled (boolean) -- Specifies whether EBS-based storage is enabled.
  VolumeType (string) -- Specifies the volume type for EBS-based storage.
  VolumeSize (integer) -- Integer to specify the size of an EBS volume.
  Iops (integer) -- Specifies the IOPD for a Provisioned IOPS EBS volume (SSD).
AccessPolicies  IAM access policy
SnapshotOptions  Option to set time, in UTC format, of the daily automated snapshot. Default value is 0 hours.
  AutomatedSnapshotStartHour (integer) -- Specifies the time, in UTC format, when the service takes a daily automated snapshot of the specified Elasticsearch domain. Default value is 0 hours.
AdvancedOptions  Option to allow references to indices in an HTTP request body. Must be false when configuring access to individual sub-resources. By default, the value is true.
  region  Region to connect to.
  key  Secret key to be used.
  keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
ElasticsearchVersion  String of format XY to specify version for the Elasticsearch domain eg, "1.5" or "2.3".
23.19.39 salt.states.boto_elb

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkgHwUpUjasdfklkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwUpUjasdfklkdfklgjsdfjajkghs
  region: us-east-1
```

```yaml
Ensure myelb ELB exists:
boto_elb.present:
  - name: myelb
    - region: us-east-1
    - availability_zones:
      - us-east-1a
      - us-east-1c
      - us-east-1d
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwUpUjasdfklkdfklgjsdfjajkghs
    - listeners:
      - elb_port: 443
        instance_port: 80
        elb_protocol: HTTPS
        instance_protocol: HTTP
        certificate: 'arn:aws:iam::111111111111:server-certificate/myclcert'
        policies:
          - my-ssl-policy
          - cookie-policy
        - elb_port: 8210
          instance_port: 8210
          elb_protocol: TCP
          - backends:
            - instance_port: 80
              policies:
                - enable-proxy-protocol
              - health_check:
                target: 'HTTP:80/'
              - attributes:
                cross_zone_load_balancing: enabled: true
                access_log:
```

(continues on next page)
enabled: true
s3_bucket_name: 'mybucket'
s3_bucket_prefix: 'my-logs'
emit_interval: 5
connecting_settings:
  idle_timeout: 60
  cnames:
    - name: mycname.example.com.
      zone: example.com.
      ttl: 60
    - name: myothercname.example.com.
      zone: example.com.
  security_groups:
    - my-security-group
  policies:
    - policy_name: my-ssl-policy
      policy_type: SSLNegotiationPolicyType
      policy:
        Protocol-TLSv1.2: true
        Protocol-SSLv3: false
        Server-Defined-Cipher-Order: true
        ECDHE-ECDSA-AES128-GCM-SHA256: true
    - policy_name: cookie-policy
      policy_type: LBCookieStickinessPolicyType
      policy: {}
      # no policy means this is a session cookie
    - policy_name: enable-proxy-protocol
      policy_type: ProxyProtocolPolicyType
      policy:
        ProxyProtocol: true

# Using a profile from pillars
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile

# Passing in a profile
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

It's possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillard by setting the attributes on the resource. The module will use the default pillar key 'boto_elb_attributes', which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:

my_elb_attributes:
  cross_zone_load_balancing:
    enabled: true
  connection_draining:
    enabled: true

(continues on next page)
timeout: 20
access_log:
  enabled: true
s3_bucket_name: 'mybucket'
s3_bucket_prefix: 'my-logs'
emit_interval: 5

Overriding the attribute values on the resource:

```yaml
Ensure myelb ELB exists:
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - attributes_from_pillar: my_elb_attributes
    # override cross_zone_load_balancing:enabled
  - attributes:
      cross_zone_load_balancing:
        enabled: false
  - profile: myelbprofile
```

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

```yaml
Ensure myelb ELB exists:
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
  - alarms:
      UnHealthyHostCount:
        name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
        attributes:
          metric: UnHealthyHostCount
          namespace: AWS/ELB
          statistic: Average
          comparison: '>='
          threshold: 1.0
          period: 600
          evaluation_periods: 6
          unit: null
          description: ELB UnHealthyHostCount
        insufficient_data_actions: []
        ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_elb_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```yaml
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
```

statistic: Average
comparison: '>='
threshold: 1.0
period: 600
evaluation_periods: 6
unit: null
description: ELB UnHealthyHostCount
insufficient_data_actions: []
ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']

Overriding the alarm values on the resource:

```yaml
Ensure myelb ELB exists:
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
  - alarms_from_pillar: my_elb_alarm
    # override UnHealthyHostCount:attributes:threshold
  - alarms:
      UnHealthyHostCount:
        attributes:
        threshold: 2.0
```

Tags can also be set:

New in version 2016.3.0.

```yaml
Ensure myelb ELB exists:
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
  - tags:
    MyTag: 'My Tag Value'
    OtherTag: 'My Other Value'
```

salt.states.boto_elb.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure an ELB does not exist
name name of the ELB

salt.states.boto_elb.present(name, listeners, availability_zones=None, subnets=None, subnet_names=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', policies=None, policies_from_pillar='boto_elb_policies', backends=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, tags=None, instance_ids=None, instance_names=None)
Ensure the ELB exists.
name Name of the ELB.
availability_zones A list of availability zones for this ELB.
listeners A list of listener lists; example:
```python
]
```

**subnets** A list of subnet IDs in your VPC to attach to your LoadBalancer.

**subnet_names** A list of subnet names in your VPC to attach to your LoadBalancer.

**security_groups** The security groups assigned to your LoadBalancer within your VPC. Must be passed either as a list or a comma-separated string.

For example, a list:

```
- security_groups:
  - secgroup-one
  - secgroup-two
```

Or as a comma-separated string:

```
- security_groups: secgroup-one,secgroup-two
```

**scheme** The type of a LoadBalancer, internet-facing or internal. Once set, can not be modified.

**health_check** A dict defining the health check for this ELB.

**attributes** A dict defining the attributes to set on this ELB. Unknown keys will be silently ignored.

See the `salt.modules.boto_elb.set_attributes` function for recognized attributes.

**attributes_from_pillar** name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

**cnames** A list of cname dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. The cnames dict will be passed to the state as kwargs.

See the `salt.states.boto_route53` state for information about these attributes.

**alarms** a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB.

See the `salt.states.boto_cloudwatch_alarm` state for information about these attributes.

**alarms_from_pillar** name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**wait_for_sync** Wait for an INSYNC change status from Route53.

**tags** dict of tags

**instance_ids** list of instance ids. The state will ensure that these, and ONLY these, instances are registered with the ELB. This is additive with instance_names.

**instance_names** list of instance names. The state will ensure that these, and ONLY these, instances are registered with the ELB. This is additive with instance_ids.

`salt.states.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)`

Add EC2 instance(s) to an Elastic Load Balancer. Removing an instance from the instances list does not remove it from the ELB.

**name** The name of the Elastic Load Balancer to add EC2 instances to.

**instances** A list of EC2 instance IDs that this Elastic Load Balancer should distribute traffic to. This state will
only ever append new instances to the ELB. EC2 instances already associated with this ELB will not be removed if they are not in the `instances` list.

New in version 2015.8.0.

```yaml
add-instances:
boto_elb.register_instances:
  - name: myloadbalancer
  - instances:
    - instance-id1
    - instance-id2
```

23.19.40 salt.states.boto_elbv2

Manage AWS Application Load Balancer

New in version 2017.7.0.

Add and remove targets from an ALB target group.

This module uses `boto3`, which can be installed via package, or pip.

This module accepts explicit alb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elbv2.keyid: GKTADJGHEIQSXMKKRBJ08H
elbv2.key: askdjghsdfjkgHUpUjasdfklkdfklgjsdfjajkghs
elbv2.region: us-west-2
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: asdkjghsdfjkgHUpUjasdfklkdfklgjsdfjajkghs
  region: us-east-1
```

salt.states.boto_elbv2.create_target_group(name, protocol, port, vpc_id, region=None, keyid=None, profile=None, health_check_protocol='HTTP', health_check_port='traffic-port', health_check_path='/', health_check_interval_seconds=30, health_check_timeout_seconds=5, healthy_threshold_count=5, unhealthy_threshold_count=2, **kwargs)

New in version 2017.11.0.

Create target group if not present.

name (string) - The name of the target group.

protocol (string) - The protocol to use for routing traffic to the targets

port (int) - The port on which the targets receive traffic. This port is used unless you specify a port override when registering the traffic.

vpc_id (string) - The identifier of the virtual private cloud (VPC).

health_check_protocol (string) - The protocol the load balancer uses when performing health check on targets. The default is the HTTP protocol.
**health_check_port** (string) - The port the load balancer uses when performing health checks on targets. The default is 'traffic-port', which indicates the port on which each target receives traffic from the load balancer.

**health_check_path** (string) - The ping path that is the destination on the targets for health checks. The default is '/.

**health_check_interval_seconds** (integer) - The approximate amount of time, in seconds, between health checks of an individual target. The default is 30 seconds.

**health_check_timeout_seconds** (integer) - The amount of time, in seconds, during which no response from a target means a failed health check. The default is 5 seconds.

**healthy_threshold_count** (integer) - The number of consecutive health checks successes required before considering an unhealthy target healthy. The default is 5.

**unhealthy_threshold_count** (integer) - The number of consecutive health check failures required before considering a target unhealthy. The default is 2.

**returns** (bool) - True on success, False on failure.

**CLI Example:**

```python
create-target:
    boto_elb2.create_targets_group:
        - name: myALB
        - protocol: https
        - port: 443
        - vpc_id: myVPC
```

```
salt.states.boto_elbv2.delete_target_group(name, region=None, key=None, keyid=None, profile=None)
```

Delete target group.

**name** (string) - The Amazon Resource Name (ARN) of the resource.

**returns** (bool) - The Amazon Resource Name (ARN) of the resource.

**CLI Example:**

```python
check-target:
    boto_elb2.delete_targets_group:
        - name: myALB
        - protocol: https
        - port: 443
        - vpc_id: myVPC
```

```
salt.states.boto_elbv2.targets_deregistered(name, targets, region=None, key=None, keyid=None, profile=None, **kwargs)
```

Remove targets to an Application Load Balancer target group.

**name** The ARN of the Application Load Balancer Target Group to remove targets from.

**targets** A list of target IDs or a string of a single target registered to the target group to be removed

New in version 2017.7.0.

```python
remove-targets:
    boto_elb2.targets_deregistered:
        - name: arn:myloadbalancer
        - targets: instance-id1
        - targets: instance-id2
```

```
salt.states.boto_elbv2.targets_registered(name, targets, region=None, key=None, keyid=None, profile=None, **kwargs)
```

Add targets to an Application Load Balancer target group. This state will not remove targets.

**name** The ARN of the Application Load Balancer Target Group to add targets to.

New in version 2017.7.0.
targets A list of target IDs or a string of a single target that this target group should distribute traffic to.

```
add-targets:
boto_elb.targets_registered:
  - name: arn:myloadbalancer
  - targets:
     - instance-id1
     - instance-id2
```

23.19.41 salt.states.boto_iam

Manage IAM objects

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
delete-user:
boto_iam.user_absent:
  - name: myuser
  - delete_keys: true
```

```
delete-keys:
boto_iam.keys_absent:
  - access_keys:

                                      region=None, key=None, keyid=None, profile=None)

Change account policy.

New in version 2015.8.0.
name (string) The name of the account policy
allow_users_to_change_password (bool) Allows all IAM users in your account to use the AWS Management
                                      Console to change their own passwords.
hard_expiry (bool) Prevents IAM users from setting a new password after their password has expired.
max_password_age (int) The number of days that an IAM user password is valid.
minimum_password_length (int) The minimum number of characters allowed in an IAM user password.
password_reuse_prevention (int) Specifies the number of previous passwords that IAM users are prevented
                                      from reusing.
require_lowercase_characters (bool) Specifies whether IAM user passwords must contain at least one lower-
                                       case character from the ISO basic Latin alphabet (a to z).
require_numbers (bool) Specifies whether IAM user passwords must contain at least one numeric character
                                      (0 to 9).
require_symbols (bool) Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: ! @ # $ % ^ & * ( ) _ + - = [ ] { }
require_uppercase_characters (bool) Specifies whether IAM user passwords must contain at least one upper-
                                       case character from the ISO basic Latin alphabet (A to Z).
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string)

salt.states.boto_iam.group_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM group is absent.
name (string) The name of the group.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
                                      and keyid.

salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None,
                                        managed_policies=None, users=None, path='/',
                                        region=None, key=None, keyid=None, profile=None,
                                        delete_policies=True)

New in version 2015.8.0.
Ensure the IAM group is present
name (string) The name of the new group.
path (string) The path for the group, defaults to '/'
policies (dict) A dict of IAM group policy documents.
policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
managed_policies (list) A list of policy names or ARNs that should be attached to this group.
users (list) A list of users to be added to the group.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
delete_policies (boolean) Delete or detach existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted or detached allowing manual modifications on the IAM group to be persistent.

salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM user access_key_id is absent.
access_key_id (list) A list of access key ids
user_name (string) The username of the user
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None, save_format='{2}\n{0}\n{3}\n{1}\n')

New in version 2015.8.0.
Ensure the IAM access keys are present.
name (string) The name of the new user.
number (int) Number of keys that user should have.
save_dir (string) The directory that the key/keys will be saved. Keys are saved to a file named according to the username privided.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
save_format (dict) Save format is repeated for each key. Default format is "[2]\n{0}\n{3}\n{1}\n" where {0} and {1} are placeholders for new key_id and key respectively, whereas {2} and {3} are "key_id-{number}" and 'key-{number}' strings kept for compatibility.

salt.states.boto_iam.policy_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM managed policy with the specified name is absent
name (string) The name of the new policy.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam.policy_present(name, policy_document, path=None, description=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM managed policy is present
name (string) The name of the new policy.
policy_document (dict) The document of the new policy
path (string) The path in which the policy will be created. Default is '/'.
description (string) Description
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam.saml_provider_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.
Ensure the SAML provider with the specified name is absent.
name (string) The name of the SAML provider.
saml_metadata_document (string) The xml document of the SAML provider.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam.saml_provider_present(name, saml_metadata_document, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.
Ensure the SAML provider with the specified name is present.
name (string) The name of the SAML provider.
saml_metadata_document (string) The xml document of the SAML provider.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam.server_cert_absent(name, region=None, key=None, keyid=None, profile=None)

Deletes a server certificate.
New in version 2015.8.0.
name (string) The name for the server certificate. Do not include the path in this value.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid
salt.states.boto_iam.server_cert_present(name, public_key, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)

Create server certificate.

New in version 2015.8.0.

name (string) The name for the server certificate. Do not include the path in this value.

public_key (string) The contents of the public key certificate in PEM-encoded format.

private_key (string) The contents of the private key in PEM-encoded format.

cert_chain (string) The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.

path (string) The path for the server certificate.

region (string) The name of the region to connect to.

key (string) The key to be used in order to connect

keyid (string) The keyid to be used in order to connect

profile (string) The profile that contains a dict of region, key, keyid

salt.states.boto_iam.user_absent(name, delete_keys=True, delete_mfa_devices=True, delete_profile=True, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM user is absent. User cannot be deleted if it has keys.

name (string) The name of the new user.

delete_keys (bool) Delete all keys from user.

delete_mfa_devices (bool) Delete all mfa devices from user.

New in version 2016.3.0.

delete_profile (bool) Delete profile from user.

New in version 2016.3.0.

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, managed_policies=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM user is present

name (string) The name of the new user.

policies (dict) A dict of IAM group policy documents.

policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

managed_policies (list) A list of managed policy names or ARNs that should be attached to this user.

password (string) The password for the new user. Must comply with account policy.

path (string) The path of the user. Default is "/".

New in version 2015.8.2.

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.
profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.42 salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```yaml
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    - policies_from_pillars:
        - shared_iam_bootstrap_policy
    - policies:
        MySQSPolicy:
          Statement:
            - Action:
              - sqs:*  
            Effect: Allow
            Resource:
              - arn:aws:sqs:*::*
            Sid: MyPolicySQS1
        MyS3Policy:
          Statement:
            - Action:
              - s3:GetObject
            Effect: Allow
            Resource:
              - arn:aws:s3:::*:mybucket/*

# Using a credentials profile from pillars
myrole:
```

(continues on next page)
boto_iam_role.present:
  - profile: myiamprofile

# Passing in a credentials profile
myrole:
  boto_iam_role.present:
    - profile:
        key: GKTADJGHEIQSXMKKRBJ08H
        keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfajkgjs
        region: us-east-1

If `delete_policies`: `False` is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.

---

Note: When using the `profile` parameter and `region` is set outside of the profile group, region is ignored and a default region will be used.

If `region` is missing from the `profile` data set, `us-east-1` will be used as the default region.

---

salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the IAM role is deleted.

- name Name of the IAM role.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam_role.present(name, policy_document=None, policy_document_from_pillars=None, policies=None, policies_from_pillars=None, managed_policies=None, create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)
Ensure the IAM role exists.

- name Name of the IAM role.
- policy_document The policy that grants an entity permission to assume the role. (See https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
- policy_document_from_pillars A pillar key that contains a role policy document. The statements defined here will be appended with the policy document statements defined in the policy_document argument.
  - New in version 2017.7.0.
- policies The path to the role/instance profile. (See https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
- policies_from_pillars A list of policies that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
- managed_policies A dict of (AWS or Customer) managed policies to be attached to the role.
- create_instance_profile A boolean of whether or not to create an instance profile and associate it with this role.
- region Region to connect to.
- key Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.
delete_policies  Deletes existing policies that are not in the given list of policies. Default value is True. If
False is specified, existing policies will not be deleted allowing manual modifications on the IAM role
to be persistent.

New in version 2015.8.0.

23.19.43  salt.states.boto_iot

Manage IoT Objects

New in version 2016.3.0.

Create and destroy IoT objects. Be aware that this interacts with Amazon’s services, and so may incur charges.

depends

• boto

• boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance
Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is neces-
sary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdjfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdjfjajkghs
  region: us-east-1
```

Ensure policy exists:

```
Ensure policy exists:
  exec
    name: boto_iot.policy_present:
      - policyName: mypolicy
      - policyDocument:
        Version: "2012-10-17"
        Statement:
          - Action:
            - iot:Publish
          Resource:
            - "*"
        Effect: "Allow"
      - region: us-east-1
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdjfjajkghs
```

Ensure topic rule exists:

(continues on next page)
boto_iot.topic_rule_present:
- ruleName: myrule
- sql: "SELECT * FROM 'iot/test'
- description: 'test rule'
- ruleDisabled: false
- actions:
  - lambda:
    functionArn: "arn:aws:us-east-1:1234:function/functionname"
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs

salt.states.boto_iot.policy_absent(name, policyName, region=None, key=None, keyid=None, profile=None)
Ensure policy with passed properties is absent.
name The name of the state definition.
policyName Name of the policy.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_attached(name, policyName, principal, region=None, key=None, keyid=None, profile=None)
Ensure policy is attached to the given principal.
name The name of the state definition.
policyName Name of the policy.
principal The principal which can be a certificate ARN or a Cognito ID.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_detached(name, policyName, principal, region=None, key=None, keyid=None, profile=None)
Ensure policy is attached to the given principal.
name The name of the state definition.
policyName Name of the policy.
principal The principal which can be a certificate ARN or a Cognito ID.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_present(name, policyName, policyDocument, region=None, key=None, keyid=None, profile=None)
Ensure policy exists.
name The name of the state definition.
policyName Name of the policy.
policyDocument The JSON document that describes the policy. The length of the policyDocument must be a minimum length of 1, with a maximum length of 2048, excluding whitespace.
region Region to connect to.
key Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.thing_type_absent(name, thingTypeName, region=None, key=None, keyid=None, profile=None)

Ensure thing type with passed properties is absent.

New in version 2016.11.0.

name  The name of the state definition.
thingTypeName  Name of the thing type.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.thing_type_present(name, thingTypeName, thingTypeDescription, searchableAttributesList, region=None, key=None, keyid=None, profile=None)

Ensure thing type exists.

New in version 2016.11.0.

name  The name of the state definition
thingTypeName  Name of the thing type
thingTypeDescription  Description of the thing type
searchableAttributesList  List of string attributes that are searchable for the thing type
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key, keyid, or a pillar key (string) that contains a dict with region, key, and keyid

salt.states.boto_iot.topic_rule_absent(name, ruleName, region=None, key=None, keyid=None, profile=None)

Ensure topic rule with passed properties is absent.

name  The name of the state definition.
ruleName  Name of the policy.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.topic_rule_present(name, ruleName, sql, actions, description='', ruleDisabled=False, region=None, key=None, keyid=None, profile=None)

Ensure topic rule exists.

name  The name of the state definition
ruleName  Name of the rule.
sql  The SQL statement used to query the topic.
actions  The actions associated with the rule.
description  The description of the rule.
ruleDisabled  Specifies whether the rule is disabled.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
23.19.44 `salt.states.boto_kinesis`

Manage Kinesis Streams

New in version 2017.7.0.

Create and destroy Kinesis streams. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto3, which can be installed via package, or pip.

This module accepts explicit Kinesis credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
region: us-east-1
```

It’s also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure Kinesis stream does not exist:

```
boto_kinesis.absent:
  - name: new_stream
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  - region: us-east-1
```

Ensure Kinesis stream exists:

```
boto_kinesis.present:
  - name: new_stream
  - retention_hours: 168
  - enhanced_monitoring: ['ALL']
  - num_shards: 2
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  - region: us-east-1
```

`salt.states.boto_kinesis.absent(name, region=None, key=None, keyid=None, profile=None)`

Delete the kinesis stream, if it exists.

- `name` (string) Stream name
- `region` (string) Region to connect to.
- `key` (string) Secret key to be used.
- `keyid` (string) Access key to be used.
- `profile` (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_kinesis.present(name, retention_hours=None, enhanced_monitoring=None, num_shards=None, do_reshard=True, region=None, key=None, keyid=None, profile=None)

Ensure the kinesis stream is properly configured and scaled.

*name (string)* Stream name

*retention_hours (int)* Retain data for this many hours. AWS allows minimum 24 hours, maximum 168 hours.

*enhanced_monitoring (list of string)* Turn on enhanced monitoring for the specified shard-level metrics. Pass in ['ALL'] or True for all metrics, [] or False for no metrics. Turn on individual metrics by passing in a list: ['IncomingBytes', 'OutgoingBytes'] Note that if only some metrics are supplied, the remaining metrics will be turned off.

*num_shards (int)* Reshard stream (if necessary) to this number of shards ‼‼! Resharding is expensive! Each split or merge can take up to 30 seconds, and the reshard method balances the partition space evenly. Resharding from N to N+1 can require 2N operations. Resharding is much faster with powers of 2 (e.g. $2^N$ to $2^{N+1}$ )‼‼!

*do_reshard (boolean)* If set to False, this script will NEVER reshard the stream, regardless of other input. Useful for testing.

*region (string)* Region to connect to.

*key (string)* Secret key to be used.

*keyid (string)* Access key to be used.

*profile (dict)* A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.45 salt.states.boto_kms

Manage KMS keys, key policies and grants.

New in version 2015.8.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify *key*, *keyid* and *region* via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure mykey key exists:

```
boto_kms.key_present:
  - name: mykey
  - region: us-east-1
```

# Using a profile from pillars
Ensure mykey key exists:

(continues on next page)
salt.states.boto_kms.key_present:
- name: mykey
- region: us-east-1
- profile: myprofile

# Passing in a profile
Ensure mykey key exists:
boto_key.key_present:
- name: mykey
- region: us-east-1
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgwupUjasdfklkgjsdfjakghs

salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None,
grants=None, manage_grants=False, key_rotation=False,
enabled=True, region=None, key=None, keyid=None, profile=None)

Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is
enabled or disabled.
name Name of the key.
policy Key usage policy.
description Description of the key.
key_usage Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT,
    which is also the only supported option.
grants A list of grants to apply to the key. Not currently implemented.
manage_grants Whether or not to manage grants. False by default, which will not manage any grants.
key_rotation Whether or not key rotation is enabled for the key. False by default.
enabled Whether or not the key is enabled. True by default.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
    keyid.

23.19.46 salt.states.boto_lambda

Manage Lambda Functions

New in version 2016.3.0.

Create and destroy Lambda Functions. Be aware that this interacts with Amazon's services, and so may incur charges.

depends
  - boto
  - boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance
Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is neces-
sary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:
It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

### Ensure function exists:

```
boto_lambda.function_present:
  - FunctionName: myfunction
  - Runtime: python2.7
  - Role: iam_role_name
  - Handler: entry_function
  - ZipFile: code.zip
  - S3Bucket: bucketname
  - S3Key: keyname
  - S3ObjectVersion: version
  - Description: "My Lambda Function"
  - Timeout: 3
  - MemorySize: 128
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_lambda.alias_absent(name, FunctionName, Name, region=None, key=None, keyid=None, profile=None)

Ensure alias with passed properties is absent.

- **name** The name of the state definition.
- **FunctionName** Name of the function.
- **Name** Name of the alias.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.alias_present(name, FunctionName, Name, FunctionVersion, Description=", region=None, key=None, keyid=None, profile=None)

Ensure alias exists.

- **name** The name of the state definition.
- **FunctionName** Name of the function for which you want to create an alias.
- **Name** The name of the alias to be created.
- **FunctionVersion** Function version for which you are creating the alias.
- **Description** A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_lambda.event_source_mapping_absent(name, EventSourceArn, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping with passed properties is absent.

name The name of the state definition.
EventSourceArn ARN of the event source.
FunctionName Name of the lambda function.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.event_source_mapping_present(name, EventSourceArn, FunctionName, StartingPosition, Enabled=True, BatchSize=100, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping exists.

name The name of the state definition.
EventSourceArn The Amazon Resource Name (ARN) of the Amazon Kinesis or the Amazon DynamoDB stream that is the event source.
FunctionName The Lambda function to invoke when AWS Lambda detects an event on the stream.

You can specify an unqualified function name (for example, "Thumbnail") or you can specify Amazon Resource Name (ARN) of the function (for example, "arn:aws:lambda:us-west-2:account-id:function:ThumbNail"). AWS Lambda also allows you to specify only the account ID qualifier (for example, "account-id:Thumbnail"). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

StartingPosition The position in the stream where AWS Lambda should start reading. (TRIM_HORIZON | LATEST)
Enabled Indicates whether AWS Lambda should begin polling the event source. By default, Enabled is true.
BatchSize The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records. The default is 100 records.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.function_absent(name, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure function with passed properties is absent.

name The name of the state definition.
FunctionName Name of the function.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_lambda.function_present(name, FunctionName, Runtime, Role, Handler, ZipFile=None, S3Bucket=None, S3Key=None, S3ObjectVersion=None, Description='', Timeout=3, MemorySize=128, Permissions=None, RoleRetries=5, region=None, key=None, keyid=None, profile=None, VpcConfig=None, Environment=None)

Ensure function exists.

**name** The name of the state definition
**FunctionName** Name of the Function.
**Runtime** The Runtime environment for the function. One of 'nodejs', 'java8', or 'python2.7'
**Role** The name or ARN of the IAM role that the function assumes when it executes your function to access any other AWS resources.
**Handler** The function within your code that Lambda calls to begin execution. For Node.js it is the module-name.*export* value in your function. For Java, it can be package.classname::handler or package.classname.

**ZipFile** A path to a .zip file containing your deployment package. If this is specified, S3Bucket and S3Key must not be specified.
**S3Bucket** Amazon S3 bucket name where the .zip file containing your package is stored. If this is specified, S3Key must be specified and ZipFile must NOT be specified.
**S3Key** The Amazon S3 object (the deployment package) key name you want to upload. If this is specified, S3Key must be specified and ZipFile must NOT be specified.
**S3ObjectVersion** The version of S3 object to use. Optional, should only be specified if S3Bucket and S3Key are specified.

**Description** A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.

**Timeout** The function execution time at which Lambda should terminate this function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

**MemorySize** The amount of memory, in MB, your function is given. Lambda uses this memory size to infer the amount of CPU and memory allocated to your function. Your function use-case determines your CPU and memory requirements. For example, a database operation might need less memory compared to an image processing function. The default value is 128 MB. The value must be a multiple of 64 MB.

**VpcConfig** If your Lambda function accesses resources in a VPC, you must provide this parameter identifying the list of security group IDs/Names and subnet IDs/Name. These must all belong to the same VPC. This is a dict of the form:

```
VpcConfig:
    SecurityGroupNames:
    - mysecgroup1
    - mysecgroup2
    SecurityGroupIds:
    - sg-abcdef1234
    SubnetNames:
    - mysubnet1
    SubnetIds:
    - subnet-1234abcd
    - subnet-abcd1234
```

If VpcConfig is provided at all, you MUST pass at least one security group and one subnet.

**Permissions** A list of permission definitions to be added to the function’s policy

**RoleRetries** IAM Roles may take some time to propagate to all regions once created. During that time function creation may fail; this state will automatically retry this number of times. The default is 5.

**Environment** The parent object that contains your environment's configuration settings. This is a dictionary of the form:
New in version 2017.7.0.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.47 salt.states.boto_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon’s services, and so may incur charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn’t match. This is due to a limitation in Amazon’s launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that’s in use by an autoscale group can not be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
| asg.keyid | GKTADJGHEIQSXMKKRBJ08H |
| asg.key  | askdjghsdfjkghWupUjasdfklkdfklgjsdfjajkghs |
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
| myprofile |
| keyid     | GKTADJGHEIQSXMKKRBJ08H |
| key       | askdjghsdfjkghWupUjasdfklkdfklgjsdfjajkghs |
| region    | us-east-1 |
```

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

```
Ensure mylc exists:
   boto_lc.present:
     - name: mylc
     - image_id: ami-0b9c9f62
     - key_name: mykey
```

(continues on next page)
- **security_groups**:  
  - mygroup  
- **instance_type**: m1.small  
- **instance_monitoring**: true  
- **block_device_mappings**:  
  - '/dev/sda1':  
    - **volume_type**: 'io1'  
    - **iops**: 220  
    - **delete_on_termination**: true  
- **cloud_init**:  
  - **boothooks**:  
    - 'disable-master.sh': |  
      #!/bin/bash  
      echo "manual" > /etc/init/salt-master.override  
  - **scripts**:  
    - 'run_salt.sh': |  
      #!/bin/bash  
      add-apt-repository -y ppa:saltstack/salt  
      apt-get update  
      apt-get install -y salt-minion  
      salt-call state.highstate  
- **region**: us-east-1  
- **keyid**: GKTADJGHEIQSXMKKRBJ08H  
- **key**: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars.  
**Ensure mylc exists:**  
- **boto_lc.present**:  
  - **name**: mylc  
  - **image_id**: ami-0b9c9f62  
  - **profile**: myprofile

# Passing in a profile.  
**Ensure mylc exists:**  
- **boto_lc.present**:  
  - **name**: mylc  
  - **image_id**: ami-0b9c9f62  
  - **profile**:  
    - **keyid**: GKTADJGHEIQSXMKKRBJ08H  
    - **key**: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs  
  - **region**: us-east-1

`salt.states.boto_lc.absent(name, region=None, key=None, keyid=None, profile=None)`  
Ensure the named launch configuration is deleted.  
**name** Name of the launch configuration.  
**region** The region to connect to.  
**key** Secret key to be used.  
**keyid** Access key to be used.  
**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_lc.present(name, image_id, key_name=None, vpc_id=None, vpc_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, delete_on_termination=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, region=None, key=None, keyid=None, profile=None)

Ensure the launch configuration exists.

name Name of the launch configuration.

image_id AMI to use for instances. AMI must exist or creation of the launch configuration will fail.

key_name Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.

vpc_id The VPC id where the security groups are defined. Only necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_name.

vpc_name Name of the VPC where the security groups are defined. Only necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_id.

security_groups List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.

user_data The user data available to launched EC2 instances.

cloud_init A dict of cloud_init configuration. Currently supported keys: boothooks, scripts and cloud-config. Mutually exclusive with user_data.

instance_type The instance type. ex: m1.small.

kernel_id The kernel id for the instance.

ramdisk_id The RAM disk ID for the instance.

block_device_mappings A dict of block device mappings that contains a dict with volume_type, delete_on_termination, iops, size, encrypted, snapshot_id.

volume_type Indicates what volume type to use. Valid values are standard, io1, gp2. Default is standard.

delete_on_termination Whether the volume should be explicitly marked for deletion when its instance is terminated (True), or left around (False). If not provided, or None is explicitly passed, the default AWS behaviour is used, which is True for ROOT volumes of instances, and False for all others.

iops For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.

size Desired volume size (in GiB).

encrypted Indicates whether the volume should be encrypted. Encrypted EBS volumes must be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or an unencrypted volume from an encrypted snapshot.

instance_monitoring Whether instances in group are launched with detailed monitoring.

spot_price The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.

instance_profile_name The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.

ebs_optimized Specifies whether the instance is optimized for EBS I/O (true) or not (false).

associate_public_ip_address Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in an Amazon VPC.

region The region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
23.19.48 salt.states.boto_rds

Manage RDSs

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

| rds.keyid: GKTADJGHEIQSXMKKRBJ08H |
| rds.key: askdjghsdfjghWupUjasdfklgjsdfjajkghs |

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

| myprofile: |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjghWupUjasdfklgjsdfjajkghs |
| region: us-east-1 |

Ensure myrds RDS exists:

```python
boto_rds.present:
  - name: myrds
  - allocated_storage: 5
  - storage_type: standard
  - db_instance_class: db.t2.micro
  - engine: MySQL
  - master_username: myuser
  - master_user_password: mypass
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjghWupUjasdfklgjsdfjajkghs
  - tags:
    key: value
```

Ensure parameter group exists:

```python
create-parameter-group:
  - name: myparametergroup
  - db_parameter_group_family: mysql5.6
  - description: "parameter group family"
  - parameters:
    - binlog_cache_size: 32768
    - binlog_checksum: CRC32
  - region: eu-west-1
```

depends boto3

```python
salt.states.boto_rds.absent(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tag=None, wait_for_deletion=True, timeout=180, region=None, key=None, keyid=None, profile=None)
```

Ensure RDS instance is absent.

23.19. state modules
name  Name of the RDS instance.

skip_final_snapshot  Whether a final db snapshot is created before the instance is deleted. If True, no snapshot
            is created. If False, a snapshot is created before deleting the instance.

final_db_snapshot_identifier  If a final snapshot is requested, this is the identifier used for that snapshot.

tags  A dict of tags.

wait_for_deletion (bool)  Wait for the RDS instance to be deleted completely before finishing the state.

timeout (in seconds)  The amount of time that can pass before raising an Exception.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
            keyid.

salt.states.boto_rds.parameter_present
            (name, db_parameter_group_family, description, parameters=None, apply_method='pending-reboot',
                tags=None, region=None, key=None, keyid=None, profile=None)

Ensure DB parameter group exists and update parameters.

name  The name for the parameter group.

db_parameter_group_family  The DB parameter group family name. A DB parameter group can be associated
            with one and only one DB parameter group family, and can be applied only to a DB instance running a
            database engine and engine version compatible with that DB parameter group family.

description  Parameter group description.

parameters  The DB parameters that need to be changed of type dictionary.

apply_method  The apply-immediate method can be used only for dynamic parameters; the pending-reboot
            method can be used with MySQL and Oracle DB instances for either dynamic or static parameters. For
            Microsoft SQL Server DB instances, the pending-reboot method can be used only for static parameters.

tags  A dict of tags.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
            keyid.

salt.states.boto_rds.present
            (name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None,
                storage_type=None, db_security_groups=None, vpc_security_group_ids=None, vpc_security_groups=None,
                availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None,
                db_parameter_group_name=None, db_cluster_identifier=None, tde_credential_arn=None, tde_credential_password=None,
                storage_encrypted=None, kms_keyid=None, backup_retention_period=None, preferred_backup_window=None,
                port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None,
                iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None,
                copy_tags_to_snapshot=None, region=None, domain=None, key=None, keyid=None, monitoring_interval=None, monitoring_role_arn=None,
                domain_iam_role_name=None, promotion_tier=None, profile=None)

Ensure RDS instance exists.

name  Name of the RDS state definition.

allocated_storage  The amount of storage (in gigabytes) to be initially allocated for the database instance.
**db_instance_class** The compute and memory capacity of the Amazon RDS DB instance.

**engine** The name of the database engine to be used for this instance. Supported engine types are: MySQL, mariadb, oracle-se1, oracle-se, oracle-ee, sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web, postgres and aurora. For more information, please see the `engine` argument in the Boto3 RDS `create_db_instance` documentation.

**master_username** The name of master user for the client DB instance.

**master_user_password** The password for the master database user. Can be any printable ASCII character except "/", ",", or "/@".

**db_name** The meaning of this parameter differs according to the database engine you use. See the Boto3 RDS documentation to determine the appropriate value for your configuration. [https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance](https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance)

**storage_type** Specifies the storage type to be associated with the DB instance. Options are standard, gp2 and io1. If you specify io1, you must also include a value for the iops parameter.

**db_security_groups** A list of DB security groups to associate with this DB instance.

**vpc_security_group_ids** A list of EC2 VPC security group IDs to associate with this DB instance.

**availability_zone** The EC2 Availability Zone that the database instance will be created in.

**db_subnet_group_name** A DB subnet group to associate with this DB instance.

**preferred_maintenance_window** The weekly time range (in UTC) during which system maintenance can occur.

**db_parameter_group_name** A DB parameter group to associate with this DB instance.

**db_cluster_identifier** If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

**tde_credential_arn** The ARN from the Key Store with which the instance is associated for TDE encryption.

**tde_credential_password** The password to use for TDE encryption if an encryption key is not used.

**storage_encrypted** Specifies whether the DB instance is encrypted.

**kms_keyid** If storage_encrypted is true, the KMS key identifier for the encrypted DB instance.

**backup_retention_period** The number of days for which automated backups are retained.

**preferred_backup_window** The daily time range during which automated backups are created if automated backups are enabled.

**port** The port number on which the database accepts connections.

**multi_az** Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.

**engine_version** The version number of the database engine to use.

**auto_minor_version_upgrade** Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.

**license_model** License model information for this DB instance.

**iops** The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

**option_group_name** Indicates that the DB instance should be associated with the specified option group.

**character_set_name** For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.

**publicly_accessible** Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

**wait_status** Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up

**tags** A dict of tags.

**copy_tags_to_snapshot** Specifies whether tags are copied from the DB instance to snapshots of the DB instance.

**region** Region to connect to.

**domain** The identifier of the Active Directory Domain.

**key** AWS secret key to be used.

**keyid** AWS access key to be used.
monitoring_interval  The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB instance.

monitoring_role_arn  The ARN for the IAM role that permits RDS to send Enhanced Monitoring metrics to CloudWatch Logs.

domain_iam_role_name  Specify the name of the IAM role to be used when making API calls to the Directory Service.

promotion_tier  A value that specifies the order in which an Aurora Replica is promoted to the primary instance after a failure of the existing primary instance. For more information, see Fault Tolerance for an Aurora DB Cluster.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None, db_parameter_group_name=None)

Ensure RDS replica exists.

Ensure myrds replica RDS exists:
boto_rds.create_replica:
  - name: myreplica
  - source: mydb

salt.states.boto_rds.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
	salt.states.boto_rds.subnet_group_present(name, description, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure DB subnet group exists.

name  The name for the DB subnet group. This value is stored as a lowercase string.

subnet_ids  A list of the EC2 Subnet IDs for the DB subnet group. Either subnet_ids or subnet_names must be provided.

subnet_names  A list of The EC2 Subnet names for the DB subnet group. Either subnet_ids or subnet_names must be provided.

description  Subnet group description.

tags  A dict of tags.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.49 salt.states.boto_route53

Manage Route53 records

New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQXSMMKRBJ08H
route53.key: askdjghsdfjkgHUpUjasdfklgjsdfajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQXSMMKRBJ08H
  key: askdjghsdfjkgHUpUjasdfklgjsdfajkghs
  region: us-east-1
```

```
mycnamerecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
    - ttl: 60
    - record_type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQXSMMKRBJ08H
    - key: askdjghsdfjkgHUpUjasdfklgjsdfajkghs
```

```# Using a profile from pillars
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile: myprofile
```

```# Passing in a profile
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile:
        keyid: GKTADJGHEIQXSMMKRBJ08H
        key: askdjghsdfjkgHUpUjasdfklgjsdfajkghs
```

```salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)```

Ensure the Route53 record is deleted.

- `name` Name of the record.
- `zone` The zone to delete the record from.
- `record_type` The record type (A, NS, MX, TXT, etc.)
- `identifier` An identifier to match for deletion.
region  The region to connect to.
key   Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
        keyid.
wait_for_sync Wait for an INSYNC change status from Route53.
split_dns Route53 supports a public and private DNS zone with the same names.
private_zone If using split_dns, specify if this is the private zone.

salt.states.boto_route53.hosted_zone_absent(name, domain_name=None, region=None,
               key=None, keyid=None, profile=None)

Ensure the Route53 Hostes Zone described is absent
name The name of the state definition.
domain_name The FQDN (including final period) of the zone you wish absent. If not provided, the value of
name will be used.

salt.states.boto_route53.hosted_zone_present(name, domain_name=None, private_zone=False, caller_ref=None, com-
                                                ment='', vpc_id=None, vpc_name=None,
                                                vpc_region=None, region=None, key=None,
                                                keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes. Note that most things cannot be modified once a zone
is created - it must be deleted and re-spun to update these attributes:
• private_zone (AWS API limitation).
• comment (the appropriate call exists in the AWS API and in boto3, but has not, as of this writing, been
  added to boto2).
• vpc_id (same story - we really need to rewrite this module with boto3)
• vpc_name (really just a pointer to vpc_id anyway).
• vpc_region (again, supported in boto3 but not boto2).
If you need the ability to update these attributes, please use the newer boto3_route53 module instead.
name The name of the state definition.
domain_name The name of the domain. This must be fully-qualified, terminating with a period. This is the
name you have registered with your domain registrar. It is also the name you will delegate from your
registrar to the Amazon Route 53 delegation servers returned in response to this request. Defaults to
the value of name if not provided.
private_zone Set True if creating a private hosted zone.
caller_ref A unique string that identifies the request and that allows create_hosted_zone() calls to be retried
without the risk of executing the operation twice. This helps ensure idempotency across state calls, but
can cause issues if a zone is deleted and then an attempt is made to recreate it with the same caller_ref.
If not provided, a unique UUID will be generated at each state run, which avoids the risk of the above
(transient) error. This option is generally not needed. Maximum length of 128.
comment Any comments you want to include about the hosted zone.
vpc_id When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required.
        Exclusive with vpc_name. Ignored when creating a non-private zone.
vpc_name When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required.
        Exclusive with vpc_id. Ignored when creating a non-private zone.
vpc_region When creating a private hosted zone, the region of the associated VPC is required. If not provided,
an effort will be made to determine it from vpc_id or vpc_name, where possible. If this fails, you'll need
to provide an explicit value for this option. Ignored when creating a non-private zone.

salt.states.boto_route53.present(name, value, zone, record_type, ttl=None, identifier=None,
                                  region=None, key=None, keyid=None, profile=None,
                                  wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is present.
name Name of the record.
value
Value of the record. As a special case, you can pass in: `private:<Name tag>` to have the function autodetermine the private IP `public:<Name tag>` to have the function autodetermine the public IP.

- `zone` The zone to create the record in.
- `record_type` The record type (A, NS, MX, TXT, etc.)
- `ttl` The time to live for the record.
- `identifier` The unique identifier to use for this record.
- `region` The region to connect to.
- `key` Secret key to be used.
- `keyid` Access key to be used.
- `profile` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- `wait_for_sync` Wait for an INSYNC change status from Route53 before returning success.
- `split_dns` Route53 supports parallel public and private DNS zones with the same name.
- `private_zone` If using split_dns, specify if this is the private zone.

```python
salt.states.boto_route53.rr_absent(*args, **kwargs)
salt.states.boto_route53.rr_present(*args, **kwargs)
```

## 23.19.50 salt.states.boto_s3

Manage S3 Resources

New in version 2018.3.0.

Manage S3 resources. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  region: us-east-1
```

Ensure S3 object exists:

```python
boto_s3.object_present:
  - name: s3-bucket/s3-key
  - source: /path/to/local/file
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  - profile: my-profile
```

depends boto3
salt.states.boto_s3.object_present(name, source=None, hash_type=None, extra_args=None, extra_args_from_pillar='boto_s3_object_extra_args', region=None, key=None, keyid=None, profile=None)

Ensure object exists in S3.

- **name** The name of the state definition. This will be used to determine the location of the object in S3, by splitting on the first slash and using the first part as the bucket name and the remainder as the S3 key.
- **source** The source file to upload to S3, currently this only supports files hosted on the minion's local file system (starting with /).
- **hash_type** Hash algorithm to use to check that the object contents are correct. Defaults to the value of the hash_type config option.
- **extra_args** A dictionary of extra arguments to use when uploading the file. Note that these are only enforced if new objects are uploaded, and not modified on existing objects. The supported args are those in the ALLOWED_UPLOAD_ARGS list at http://boto3.readthedocs.io/en/latest/reference/customizations/s3.html. However, Note that the ‘ACL’, ‘GrantFullControl’, ‘GrantRead’, ‘GrantReadACP’, and ‘GrantWriteACL’ keys are currently not supported.
- **extra_args_from_pillar** Name of pillar dict that contains extra arguments. Extra arguments defined for this specific state will be merged over those from the pillar.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 23.19.51 salt.states.boto_s3_bucket

**Manage S3 Buckets**

New in version 2016.3.0.

Create and destroy S3 buckets. Be aware that this interacts with Amazon's services, and so may incur charges.

- **depends**
  - boto
  - boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```
Ensure bucket exists:

```python
boto_s3_bucket.present:
- Bucket: mybucket
- LocationConstraint: EU
- ACL:
  - GrantRead: "uri=http://acs.amazonaws.com/groups/global/AllUsers"
- CORSRules:
  - AllowedHeaders: []
  - AllowedMethods: ["GET"]
  - AllowedOrigins: ["*"]
  - ExposeHeaders: []
  - MaxAgeSeconds: 123
- LifecycleConfiguration:

- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

salt.states.boto_s3_bucket.absent(name, Bucket, Force=False, region=None, key=None, keyid=None, profile=None)

Ensure bucket with passed properties is absent.

name The name of the state definition.
Bucket Name of the bucket.
Force Empty the bucket first if necessary - Boolean.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_s3_bucket.present(name, Bucket, LocationConstraint=None, ACL=None, CORSRules=None, LifecycleConfiguration=None, Logging=None, NotificationConfiguration=None, Policy=None, Replication=None, RequestPayment=None, Tagging=None, Versioning=None, Website=None, region=None, key=None, keyid=None, profile=None)
Ensure bucket exists.

- **name**: The name of the state definition
- **Bucket Name of the bucket.**
- **LocationConstraint**: 'EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1'
- **ACL**: The permissions on a bucket using access control lists (ACL).
- **CORSRules**: The cors configuration for a bucket.
- **LifecycleConfiguration**: Lifecycle configuration for your bucket.
- **Logging**: The logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters.
- **NotificationConfiguration**: notifications of specified events for a bucket.
- **Policy**: Policy on the bucket.
- **Replication**: Replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB.
- **RequestPayment**: The request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download.
- **Tagging**: A dictionary of tags that should be set on the bucket.
- **Versioning**: The versioning state of the bucket.
- **Website**: The website configuration of the bucket.

**Region to connect to.**

- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 23.19.52 salt.states.boto_secgroup

**Manage Security Groups**

New in version 2014.7.0.

Create and destroy Security Groups. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
seigroup.keyid: GKTADJGHEIQSXMKKRBJ08H
seigroup.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure **myseigroup exists**:

- `boto_secgroup.present`

(continues on next page)
- name: mysecgroup
- description: My security group
- vpc_name: myvpc
- rules:
  - ip_protocol: tcp
    from_port: 80
    to_port: 80
    cidr_ip:
      - 10.0.0.0/8
      - 192.168.0.0/16
  - ip_protocol: tcp
    from_port: 8080
    to_port: 8090
    cidr_ip:
      - 10.0.0.0/8
      - 192.168.0.0/16
  - ip_protocol: icmp
    from_port: -1
    to_port: -1
    source_group_name: mysecgroup
  - ip_protocol: tcp
    from_port: 8080
    to_port: 8080
    source_group_name: MyOtherSecGroup
    source_group_name_vpc: MyPeeredVPC
- rules_egress:
  - ip_protocol: all
    from_port: -1
    to_port: -1
    cidr_ip:
      - 10.0.0.0/8
      - 192.168.0.0/16
- tags:
  SomeTag: 'My Tag Value'
  SomeOtherTag: 'Other Tag Value'
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - profile: myprofile

# Passing in a profile
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
      region: us-east-1
Note: When using the `profile` parameter and `region` is set outside of the profile group, region is ignored and a default region will be used.

If `region` is missing from the `profile` data set, `us-east-1` will be used as the default region.

salt.states.boto_secgroup.absent(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Ensure a security group with the specified name does not exist.

- **name**: Name of the security group.
- **vpc_id**: The ID of the VPC to remove the security group from, if any. Exclusive with `vpc_name`.
- **vpc_name**: The name of the VPC to remove the security group from, if any. Exclusive with `vpc_name`.

New in version 2016.3.0.

- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.

salt.states.boto_secgroup.present(name, description, vpc_id=None, vpc_name=None, rules=None, rules_egress=None, delete_ingress_rules=True, delete_egress_rules=True, region=None, key=None, keyid=None, profile=None, tags=None)

Ensure the security group exists with the specified rules.

- **name**: Name of the security group.
- **description**: A description of this security group.
- **vpc_id**: The ID of the VPC to create the security group in, if any. Exclusive with `vpc_name`.
- **vpc_name**: The name of the VPC to create the security group in, if any. Exclusive with `vpc_id`.

New in version 2016.3.0.

New in version 2015.8.2.

- **rules**: A list of ingress rule dicts. If not specified, `rules=None`, the ingress rules will be unmanaged. If set to an empty list, `[]`, then all ingress rules will be removed.
- **rules_egress**: A list of egress rule dicts. If not specified, `rules_egress=None`, the egress rules will be unmanaged. If set to an empty list, `[]`, then all egress rules will be removed.
- **delete_ingress_rules**: Some tools (EMR comes to mind) insist on adding rules on-the-fly, which salt will happily remove on the next run. Set this param to False to avoid deleting rules which were added outside of salt.
- **delete_egress_rules**: Some tools (EMR comes to mind) insist on adding rules on-the-fly, which salt will happily remove on the next run. Set this param to False to avoid deleting rules which were added outside of salt.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.
- **tags**: List of key:value pairs of tags to set on the security group.

New in version 2016.3.0.
23.19.53 salt.states.boto_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
   keyid: GKTADJGHEIQSXMKKRBJ08H
   key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs
   region: us-east-1
```

```python
mytopic:
   boto_sns.present:
      - region: us-east-1
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs

# Using a profile from pillars
mytopic:
   boto_sns.present:
      - region: us-east-1
      - profile: mysnsprofile

# Passing in a profile
mytopic:
   boto_sns.present:
      - region: us-east-1
      - profile:
         keyid: GKTADJGHEIQSXMKKRBJ08H
         key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs
```

```python
salt.states.boto_sns.absent(name, region=None, key=None, keyid=None, profile=None, unsubscribe=False)
```

Ensure the named sns topic is deleted.

- **name** Name of the SNS topic.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- **unsubscribe** If True, unsubscribe all subscriptions to the SNS topic before deleting the SNS topic

New in version 2016.11.0.
salt.states.boto_sns.present(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)

Ensure the SNS topic exists.

- **name** Name of the SNS topic.
- **subscriptions** List of SNS subscriptions.

Each subscription is a dictionary with a protocol and endpoint key:

```python
[
    {'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
    {'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'}
]
```

- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

23.19.54 salt.states.boto_sqs

Manage SQS Queues

New in version 2014.7.0.

Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```yaml
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

```yaml
myqueue:
    boto_sqs.present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
        - attributes:
            ReceiveMessageWaitTimeSeconds: 20
```

# Using a profile from pillars

```yaml
myqueue:
    boto_sqs.present:
        - region: us-east-1
```

(continues on next page)
- **profile**: mysqsprefile

```
# Passing in a profile
myqueue:
    boto_sqs.present:
        - region: us-east-1
        - profile:
            keyid: GKTADJGHEIQXSXMKKRB8H
            key: askdjghsdfjkghWupUjasdfkldfjklgjsdfjajkghs
```

```python
salt.states.boto_sqs.absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure the named sqs queue is deleted.

- **name**: Name of the SQS queue.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_sqs.present(name, attributes=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the SQS queue exists.

- **name**: Name of the SQS queue.
- **attributes**: A dict of key/value SQS attributes.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

## 23.19.55 salt.states.boto_vpc

**Manage VPCs**

New in version 2015.8.0.

```python
depends
    - boto >= 2.8.0
    - boto3 >= 1.2.6
```

Create and destroy VPCs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
vpc.keyid: GKTADJGHEIQXSXMKKRB8H
vpc.key: askdjghsdfjkghWupUjasdfkldfjklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:
Ensure VPC exists:
```yaml
boto_vpc.present:
  - name: myvpc
  - cidr_block: 10.10.11.0/24
  - dns_hostnames: True
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgghWupUjasdfsdfklgjsdfjajkgghs
```

Ensure subnet exists:
```yaml
boto_vpc.subnet_present:
  - name: mysubnet
  - vpc_id: vpc-123456
  - cidr_block: 10.0.0.0/16
  - region: us-east-1
  - profile: myprofile
```

```yaml
{% set profile = salt['pillar.get']('aws:region:us-east-1:profile') %}
```

Ensure internet gateway exists:
```yaml
boto_vpc.internet_gateway_present:
  - name: myigw
  - vpc_name: myvpc
  - profile: {{ profile }}
```

Ensure route table exists:
```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      instance_id: i-123456
    - subnet_names:
      - subnet1
      - subnet2
    - region: us-east-1
  - profile:
    - keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgghWupUjasdfsdfklgjsdfjajkgghs
```

New in version 2016.11.0.

Request, accept and delete VPC peering connections. VPC peering connections can be named allowing the name to be used throughout the state file. Following example shows how to request and accept a VPC peering connection.
accept the vpc peering connection:
  boto_vpc.accept_vpc_peering_connection:
  - conn_name: salt_vpc_peering
  - region: us-west-2
  - require:
    - boto_vpc: request a vpc peering connection

request a vpc peering connection:
  boto_vpc.request_vpc_peering_connection:
  - requester_vpc_id: vpc-4a3d522e
  - peer_vpc_id: vpc-ae81e9ca
  - region: us-west-2
  - conn_name: salt_vpc_peering

VPC peering connections need not be named. In this case the VPC peering connection ID should be used in the state file.

accept the vpc peering connection:
  boto_vpc.accept_vpc_peering_connection:
  - conn_id: pcx-1873c371
  - region: us-west-2

VPC peering connections can be deleted, as shown below.

delete a named vpc peering connection:
  boto_vpc.delete_vpc_peering_connection:
  - conn_name: salt_vpc_peering

Delete also accepts a VPC peering connection id.

delete a vpc peering connection by id:
  boto_vpc.delete_vpc_peering_connection:
  - conn_id: pcx-1873c371

salt.states.boto_vpc.absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
  Ensure VPC with passed properties is absent.
  name  Name of the VPC.
  tags  A list of tags. All tags must match.
  region  Region to connect to.
  key  Secret key to be used.
  keyid  Access key to be used.
  profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.accept_vpc_peering_connection(name=None, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)
  Accept a VPC pending requested peering connection between two VPCs.
  name  Name of this state
  conn_id  The connection ID to accept. Exclusive with conn_name. String type.
  conn_name  The name of the VPC peering connection to accept. Exclusive with conn_id. String type.
  region  Region to connect to.
  key  Secret key to be used.
  keyid  Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.11.0.

Example:

```python
boto_vpc.accept_vpc_peering_connection:
  - conn_name: salt_peering_connection
# usage with vpc peering connection id and region
boto_vpc.accept_vpc_peering_connection:
  - conn_id: pbx-1873d472
  - region: us-west-2
```

```python
salt.states.boto_vpc.delete_vpc_peering_connection(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)
```

name Name of the state
conn_id ID of the peering connection to delete. Exclusive with conn_name.
conn_name The name of the peering connection to delete. Exclusive with conn_id.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.11.0.

Example:

```python
deleate a vpc peering connection:
boto_vpc.delete_vpc_peering_connection:
  - region: us-west-2
  - conn_id: pcx-4613b12e
```

Connection name can be specified (instead of ID). Specifying both conn_name and conn_id will result in an error.

```python
deleate a vpc peering connection:
boto_vpc.delete_vpc_peering_connection:
  - conn_name: salt_vpc_peering
```

```python
salt.states.boto_vpc.dhcp_options_absent(name=None, dhcp_options_id=None, region=None, key=None, keyid=None, profile=None)
```

Ensure a set of DHCP options with the given settings exist.
name (string) Name of the DHCP options set.
dhcp_options_id (string) Id of the DHCP options set.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.3.0.
salt.states.boto_vpc.dhcp_options_present
(name, dhcp_options_id=None, vpc_name=None, vpc_id=None, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a set of DHCP options with the given settings exist. Note that the current implementation only SETS values during option set creation. It is unable to update option sets in place, and thus merely verifies the set exists via the given name and/or dhcp_options_id param.

name (string) Name of the DHCP options.
vpc_name (string) Name of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
vpc_id (string) Id of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
domain_name (string) Domain name to be associated with this option set.
domain_name_servers (list of strings) The IP address(es) of up to four domain name servers.
ntp_servers (list of strings) The IP address(es) of up to four desired NTP servers.
etbios_name_servers (list of strings) The IP address(es) of up to four NetBIOS name servers.
etbios_node_type (string) The NetBIOS node type (1, 2, 4, or 8). For more information about the allowed values, see RFC 2132. The recommended is 2 at this time (broadcast and multicast are currently not supported).
tags (dict of key: value pairs) A set of tags to be added.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.

salt.states.boto_vpc.internet_gateway_absent
(name, detach=False, region=None, key=None, keyid=None, profile=None)

Ensure the named internet gateway is absent.

name Name of the internet gateway.
detach First detach the internet gateway from a VPC, if attached.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.internet_gateway_present
(name, vpc_name=None, vpc_id=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure an internet gateway exists.

name Name of the internet gateway.
vpc_name Name of the VPC to which the internet gateway should be attached.
vpc_id Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id may be provided.
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.nat_gateway_absent(name=None, subnet_name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None, wait_for_delete_retries=0)

Ensure the nat gateway in the named subnet is absent.

This function requires boto3.

New in version 2016.11.0.

name Name of the state.
subnet_name Name of the subnet within which the nat gateway should exist
subnet_id Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_delete_retries NAT gateway may take some time to be go into deleted or failed state. During the deletion process, subsequent release of elastic IPs may fail; this state will automatically retry this number of times to ensure the NAT gateway is in deleted or failed state before proceeding. Default is set to 0 for backward compatibility.

salt.states.boto_vpc.nat_gateway_present(name, subnet_name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None, allocation_id=None)

Ensure a nat gateway exists within the specified subnet

This function requires boto3.

New in version 2016.11.0.

Example:

def boto_vpc.nat_gateway_present:
    - subnet_name: my-subnet

name Name of the state
subnet_name Name of the subnet within which the nat gateway should exist
subnet_id Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.
allocation_id If specified, the elastic IP address referenced by the ID is associated with the gateway. Otherwise, a new allocation_id is created and used.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.present(name, cidr_block, instance_tenancy=None, dns_support=None, dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure VPC exists.

name Name of the VPC.
cidr_block The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
instance_tenancy Instances launched in this VPC will be single-tenant or dedicated hardware.
dns_support Indicates whether the DNS resolution is supported for the VPC.
dns_hostnames Indicates whether the instances launched in the VPC get DNS hostnames.
tags  A list of tags.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_vpc.request_vpc_peering_connection(name, requester_vpc_id= None,
    requester_vpc_name= None,
    peer_vpc_id= None,
    peer_vpc_name= None,
    conn_name= None,
    peer_owner_id= None,
    region= None,  # key=None,
    keyid=None,  # profile=None)
```

name  Name of the state
requester_vpc_id  ID of the requesting VPC. Exclusive with requester_vpc_name. String type.
requester_vpc_name  Name tag of the requesting VPC. Exclusive with requester_vpc_id. String type.
peer_vpc_id  ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name. String type.
peer_vpc_name  Name tag of the VPC to create VPC peering connection with. This can only be a VPC in the same account. Exclusive with peer_vpc_id. String type.
conn_name  The (optional) name to use for this VPC peering connection. String type.
peer_owner_id  ID of the owner of the peer VPC. String type. If this isn't supplied AWS uses your account ID. Required if peering to a different account.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

Example:

```
request a vpc peering connection:
    boto_vpc.request_vpc_peering_connection:
        - requester_vpc_id: vpc-4b3522e
        - peer_vpc_id: vpc-ae83f9ca
        - conn_name: salt_peering_connection
```

```
salt.states.boto_vpc.route_table_absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure the named route table is absent.
name  Name of the route table.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_vpc.route_table_present(name, vpc_name=None, vpc_id=None,
    routes=None, subnet_ids=None, subnet_names=None, tags=None, region=None,
    key=None, keyid=None, profile=None)
```

Ensure route table with routes exists and is associated to a VPC.
This function requires boto3 to be installed if nat gateways are specified.
Example:

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      internet_gateway_name: InternetGateway
    - destination_cidr_block: 10.10.11.0/24
      instance_id: i-123456
    - destination_cidr_block: 10.10.12.0/24
      interface_id: eni-123456
    - destination_cidr_block: 10.10.13.0/24
      instance_name: mygatewayserver
    - subnet_names:
      - subnet1
      - subnet2
```

- **name** Name of the route table.
- **vpc_name** Name of the VPC with which the route table should be associated.
- **vpc_id** Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.
- **routes** A list of routes. Each route has a cidr and a target.
- **subnet_ids** A list of subnet ids to associate
- **subnet_names** A list of subnet names to associate
- **tags** A list of tags.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_vpc.subnet_absent**

```python
(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)
```

Ensure subnet with passed properties is absent.

- **name** Name of the subnet.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_vpc.subnet_present**

```python
(name, cidr_block, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None, route_table_id=None, route_table_name=None, auto_assign_public_ipv4=False)
```

Ensure a subnet exists.

- **name** Name of the subnet.
- **cidr_block** The range if IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
- **vpc_name** Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
- **vpc_id** Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
- **availability_zone** AZ in which the subnet should be placed.
- **tags** A list of tags.
- **route_table_id** A route table ID to explicitly associate the subnet with. If both route_table_id and
route_table_name are specified, route_table_id will take precedence.

New in version 2016.11.0.

**route_table_name** A route table name to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.

New in version 2016.11.0.

**region** Region to connect to.
**key** Secret key to be used.
**keyid** Access key to be used.
**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.vpc_peering_connection_absent(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)
salt.states.boto_vpc.vpc_peering_connection_present(name, requester_vpc_id=None, requester_vpc_name=None, peer_vpc_id=None, peer_vpc_name=None, conn_name=None, peer_owner_id=None, region=None, key=None, keyid=None, profile=None)
```

**name** Name of the state
**requester_vpc_id** ID of the requesting VPC. Exclusive with requester_vpc_name.
**requester_vpc_name** Name tag of the requesting VPC. Exclusive with requester_vpc_id.
**peer_vpc_id** ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name.
**peer_vpc_name** Name tag of the VPC to create VPC peering connection with. This can only be a VPC in the same account, else resolving it into a vpc ID will fail. Exclusive with peer_vpc_id.
**conn_name** The name to use for this VPC peering connection.
**peer_owner_id** ID of the owner of the peer VPC. Defaults to your account ID, so a value is required if peering with a VPC in a different account.
**region** Region to connect to.
**key** Secret key to be used.
**keyid** Access key to be used.
**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

**Example:**

```bash
effce peering twixt local vpc and the other guys:
  boto_vpc.vpc_peering_connection_present:
    - requester_vpc_name: my_local_vpc
    - peer_vpc_name: some_other_guys_vpc
    - conn_name: peering_from_here_to_there
    - peer_owner_id: 012345654321
```

```bash
```
23.19.56 salt.states.bower

Installation of Bower Packages

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:

```
npm:
  pkg.installed
git:
  pkg.installed
bower:
  npm.installed
  require:
    - pkg: npm
    - pkg: git
underscore:
  bower.installed:
    - dir: /path/to/project
    - require:
      - npm: bower
```

salt.states.bower.bootstrap(name, user=None)

Bootsraps a frontend distribution.

Will execute 'bower install' on the specified directory.

user The user to run Bower with

salt.states.bower.installed(name, dir, pkgs=None, user=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

```
underscore:
  bower.installed:
    - dir: /path/to/project
    - user: someuser
jquery#2.0:
  bower.installed:
    - dir: /path/to/project
```

name The package to install
dir The target directory in which to install the package
pkgs A list of packages to install with a single Bower invocation; specifying this argument will ignore the name argument
user The user to run Bower with
e env A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.

salt.states.bower.pruned(name, user=None, env=None)

New in version 2017.7.0.

Cleans up local bower_components directory.

Will execute 'bower prune' on the specified directory (param: name)

user The user to run Bower with
salt.states.bower.removed(name, dir, user=None)
Verify that the given package is not installed.
  dir  The target directory in which to install the package
  user  The user to run Bower with

23.19.57  salt.states.btrfs

  maintainer  Alberto Planas <aplanas@suse.com>
  maturity  new
  depends  None
  platform  Linux

salt.states.btrfs.properties(name, device, use_default=False, __dest=None, **properties)
Makes sure that a list of properties are set in a subvolume, file or device.
  name  Name of the object to change
  device  Device where the object lives, if None, the device will be in name
  use_default  If True, this subvolume will be resolved to the default subvolume assigned during the create operation
  properties  Dictionary of properties
  Valid properties are ‘ro’, ‘label’ or ‘compression’. Check the documentation to see where those properties are valid for each object.

salt.states.btrfs.subvolume_created(name, device, qgroupids=None, set_default=False, copy_on_write=True, force_set_default=True, __dest=None)
Makes sure that a btrfs subvolume is present.
  name  Name of the subvolume to add
  device  Device where to create the subvolume
  qgroupids  Add the newly created subcolume to a qgroup. This parameter is a list
  set_default  If True, this new subvolume will be set as default when mounted, unless subvol option in mount is used
  copy_on_write  If false, set the subvolume with chattr +C
  force_set_default  If false and the subvolume is already present, it will not force it as default if set_default is True

salt.states.btrfs.subvolume_deleted(name, device, commit=False, __dest=None)
Makes sure that a btrfs subvolume is removed.
  name  Name of the subvolume to remove
  device  Device where to remove the subvolume
  commit  Wait until the transaction is over

23.19.58  salt.states.cabal

Installation of Cabal Packages

New in version 2015.8.0.
These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides cabal (cabal-install in case of Debian based distributions). Example:

.. code-block:: yaml
cabal-install: pkg.installed

ShellCheck:

cabal.installed:

- require: - pkg: cabal-install

salt.states.cabal.installed(name, pkgs=None, user=None, install_global=False, env=None)
Verify that the given package is installed and is at the correct version (if specified).

salt.states.cabal.removed(name, user=None, env=None)
Verify that given package is not installed.

23.19.59 salt.states.ceph

Manage ceph with salt.
New in version 2016.11.0.

salt.states.ceph.quorum(name, **kwargs)
Quorum state
This state checks the mon daemons are in quorum. It does not alter the cluster but can be used in formula as a dependency for many cluster operations.

Example usage in sls file:

```
  quorum:
    sesceph.quorum:
      - require:
        - sesceph: mon_running
```

23.19.60 salt.states.chef

Execute Chef client runs

Run chef-client or chef-solo

```
my-chef-run:
  chef.client:
    - override-runlist: 'demo1,demo2'
    - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []
```

(continues on next page)
my-solo-run:
  chef.solo:
    - environment: dev

salt.states.chef.client(name, **kwargs)
  name Unique identifier for the state. Does not affect the Chef run.
  server The chef server URL
  client_key Set the client key file location
  config The configuration file to use
  config-file-jail Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside
  this path will be loaded).
  environment Set the Chef Environment on the node
  group Group to set privilege to
  json-attributes Load attributes from a JSON file or URL
  localmode Point chef-client at local repository if True
  log_level Set the log level (debug, info, warn, error, fatal)
  logfile Set the log file location
  node-name The node name for this client
  override-runlist Replace current run list with specified items for a single run
  pid Set the PID file location, defaults to /tmp/chef-client.pid
  run-lock-timeout Set maximum duration to wait for another client run to finish, default is indefinitely.
  runlist Permanently replace current run list with specified items
  user User to set privilege to
  validation_key Set the validation key file location, used for registering new clients

salt.states.chef.solo(name, **kwargs)
  name Unique identifier for the state. Does not affect the Chef run.
  config The configuration file to use
  environment Set the Chef Environment on the node
  group Group to set privilege to
  json-attributes Load attributes from a JSON file or URL
  log_level Set the log level (debug, info, warn, error, fatal)
  logfile Set the log file location
  node-name The node name for this client
  override-runlist Replace current run list with specified items for a single run
  recipe-url Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
  run-lock-timeout Set maximum duration to wait for another client run to finish, default is indefinitely.
  user User to set privilege to

23.19.61 salt.states.chocolatey

Manage Chocolatey package installs .. versionadded:: 2016.3.0

Note: Chocolatey pulls data from the Chocolatey internet database to determine current versions, find available
versions, etc. This is normally a slow operation and may be optimized by specifying a local, smaller chocolatey repo.

salt.states.chocolatey.installed(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None, allow_multiple=False, execution_timeout=None)

Installs a package if not already installed
Parameters
• **name** *(str)* -- The name of the package to be installed. Required.

• **version** *(str)* -- Install a specific version of the package. Defaults to latest version. If the version is different to the one installed then the specified version will be installed. Default is None.

• **source** *(str)* -- Chocolatey repository (directory, share or remote URL, feed). Defaults to the official Chocolatey feed. Default is None.

• **force** *(bool)* -- Reinstall the current version of an existing package. Do not use with **allow_multiple**. Default is False.

• **pre_versions** *(bool)* -- Include pre-release packages. Default is False.

• **install_args** *(str)* -- Install arguments you want to pass to the installation process, i.e product key or feature list. Default is None.

• **override_args** *(bool)* -- Set to True if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments. Default is False.

• **force_x86** *(bool)* -- Force x86 (32bit) installation on 64 bit systems. Default is False.

• **package_args** *(str)* -- Arguments you want to pass to the package. Default is None.

• **allow_multiple** *(bool)* -- Allow multiple versions of the package to be installed. Do not use with **force**. Does not work with all packages. Default is False.

New in version 2017.7.0.

• **execution_timeout** *(str)* -- Chocolatey execution timeout value you want to pass to the installation process. Default is None.

---

**Installs some package:**

```python
chocolatey.installed:
  - name: packagename
  - version: '12.04'
  - source: 'mychocolatey/source'
  - force: True
```

**salt.states.chocolatey.source_present** *(name, source_location, username=None, password=None, force=False)*

Instructs Chocolatey to add a source if not already present.

- **name** The name of the source to be added as a chocolatey repository.
- **source** Location of the source you want to work with.
- **username** Provide username for chocolatey sources that need authentication credentials.
- **password** Provide password for chocolatey sources that need authentication credentials.
- **force** Salt will not modify a existing repository with the same name. Set this option to true to update an existing repository.

**CLI Example:**

```python
add_some_source:
  chocolatey.source_present:
    - name: reponame
    - source: https://repo.example.com
    - username: myuser
    - password: mypassword
```

**salt.states.chocolatey.uninstalled** *(name, version=None, uninstall_args=None, override_args=False)*

Uninstalls a package

- **name** The name of the package to be uninstalled
- **version** Uninstalls a specific version of the package. Defaults to latest version installed.
uninstall_args A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list
override_args Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments

```
Removemypackage:
    chocolatey.uninstalled:
        - name: mypackage
        - version: '21.5'
```

salt.states.chocolatey.upgraded(name=None, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None)

Upgrades a package. Will install the package if not installed.
New in version 2018.3.0.
Parameters

- **name** (str) -- The name of the package to be installed. Required.
- **version** (str) -- Install a specific version of the package. Defaults to latest version. If the version is greater than the one installed then the specified version will be installed. Default is None.
- **source** (str) -- Chocolatey repository (directory, share or remote URL, feed). Defaults to the official Chocolatey feed. Default is None.
- **force** (bool) -- True will reinstall an existing package with the same version. Default is False.
- **pre_versions** (bool) -- True will include pre-release packages. Default is False.
- **install_args** (str) -- Install arguments you want to pass to the installation process, i.e product key or feature list. Default is None.
- **override_args** (bool) -- True will override the original install arguments (for the native installer) in the package and use those specified in install_args. False will append install_args to the end of the default arguments. Default is False.
- **force_x86** (bool) -- True forces 32bit installation on 64 bit systems. Default is False.
- **package_args** (str) -- Arguments you want to pass to the package. Default is None.

```
upgrade_some_package:
    chocolatey.upgraded:
        - name: packagename
        - version: '12.04'
        - source: 'mychocolatey/source'
```
23.19.62 salt.states.chronos_job

Configure Chronos jobs via a salt proxy.

```python
my_job:
    chronos_job.config:
        - config:
            schedule: "R//PT2S"
            command: "echo 'hi!'"
            owner: "me@example.com"
```

New in version 2015.8.2.

salt.states.chronos_job.absent(name)

Ensure that the chronos job with the given name is not present.

Parameters
- name: The name of the job

Returns
A standard Salt changes dictionary

salt.states.chronos_job.config(name, config)

Ensure that the chronos job with the given name is present and is configured to match the given config values.

Parameters
- name: The job name
- config: The configuration to apply (dict)

Returns
A standard Salt changes dictionary

23.19.63 salt.states.cimc

A state module to manage Cisco UCS chassis devices.

codeauthor Spencer Ervin <spencer ervin@hotmail.com>
maturity new
depends none
platform unix

About

This state module was designed to handle connections to a Cisco Unified Computing System (UCS) chassis. This module relies on the CIMC proxy module to interface with the device.

See also:

CIMC Proxy Module

salt.states.cimc.hostname(name, hostname=None)

Ensures that the hostname is set to the specified value.

New in version 2019.2.0.

Parameters
- name: The name of the module function to execute.
- hostname: The hostname of the server.

SLS Example:

```python
set_name:
    cimc.hostname:
        - hostname: foobar
```
salt.states.cimc.logging_levels(name, remote=None, local=None)

Ensures that the logging levels are set on the device. The logging levels must match the following options: emergency, alert, critical, error, warning, notice, informational, debug.

New in version 2019.2.0.

name: The name of the module function to execute.
remote(str): The logging level for SYSLOG logs.
local(str): The logging level for the local device.

SLS Example:

```
logging_levels:
    cimc.logging_levels:
        - remote: informational
        - local: notice
```

salt.states.cimc.ntp(name, servers)

Ensures that the NTP servers are configured. Servers are provided as an individual string or list format. Only four NTP servers will be reviewed. Any entries past four will be ignored.

name: The name of the module function to execute.

servers(str, list): The IP address or FQDN of the NTP servers.

SLS Example:

```
ntp_configuration_list:
    cimc.ntp:
        - servers:
            - foo.bar.com
            - 10.10.10.10

ntp_configuration_str:
    cimc.ntp:
        - servers: foo.bar.com
```

salt.states.cimc.power_configuration(name, policy=None, delayType=None, delay-Value=None)

Ensures that the power configuration is configured on the system. This is only available on some C-Series servers.

New in version 2019.2.0.

name: The name of the module function to execute.

policy(str): The action to be taken when chassis power is restored after an unexpected power loss. This can be one of the following:
  - reset: The server is allowed to boot up normally when power is restored. The server can restart immediately or, optionally, after a fixed or random delay.
  - stay-off: The server remains off until it is manually restarted.
  - last-state: The server restarts and the system attempts to restore any processes that were running before power was lost.

delayType(str): If the selected policy is reset, the restart can be delayed with this option. This can be one of the following:
  - fixed: The server restarts after a fixed delay.
  - random: The server restarts after a random delay.
delayValue(int): If a fixed delay is selected, once chassis power is restored and the Cisco IMC has finished rebooting, the system waits for the specified number of seconds before restarting the server. Enter an integer between 0 and 240.

SLS Example:

```yaml
reset_power:
  cimc.power_configuration:
    - policy: reset
    - delayType: fixed
    - delayValue: 0

power_off:
  cimc.power_configuration:
    - policy: stay-off
```

salt.states.cimc.syslog(name, primary=None, secondary=None)
Ensures that the syslog servers are set to the specified values. A value of None will be ignored.

name: The name of the module function to execute.

primary(str): The IP address or FQDN of the primary syslog server.

secondary(str): The IP address or FQDN of the secondary syslog server.

SLS Example:

```yaml
syslog_configuration:
  cimc.syslog:
    - primary: 10.10.10.10
    - secondary: foo.bar.com
```

salt.states.cimc.user(name, id='', user='', priv='', password='', status='active')
Ensures that a user is configured on the device. Due to being unable to verify the user password. This is a forced operation.

New in version 2019.2.0.

name: The name of the module function to execute.

id(int): The user ID slot on the device.

user(str): The username of the user.

priv(str): The privilege level of the user.

password(str): The password of the user.

status(str): The status of the user. Can be either active or inactive.

SLS Example:

```yaml
user_configuration:
  cimc.user:
    - id: 11
    - user: foo
    - priv: admin
    - password: mypassword
    - status: active
```
23.19.64 salt.states.cisconso

State module for Cisco NSO Proxy minions

New in version 2016.11.0.

For documentation on setting up the cisconso proxy minion look in the documentation for salt.proxy.cisconso.

salt.states.cisconso.value_present(name, datastore, path, config)

Ensure a specific value exists at a given path

Parameters

- name (str) -- The name for this rule
- datastore (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
- path (list, str OR tuple) -- The device path to set the value at, a list of element names in order, / separated
- config (dict) -- The new value at the given path

Examples:

```python
enable pap auth:
cisconso.config_present:
  - name: enable_pap_auth
  - datastore: running
  - path: devices/device/ex0/config/sys/interfaces/serial/ppp0/authentication
  - config:
    authentication:
      method: pap
      "list-name": foobar
```

23.19.65 salt.states.cloud

Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```python
my-ec2-instance:
  cloud.profile:
    my-ec2-config
```

salt.states.cloud.absent(name, onlyif=None, unless=None)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

- name The name of the instance to destroy
- onlyif Do run the state only if is unless succeed
- unless Do not run the state at least unless succeed

salt.states.cloud.present(name, cloud_provider, onlyif=None, unless=None, opts=None, **kwargs)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of
an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

name The name of the instance to create
cloud_provider The name of the cloud provider to use
onlyif Do run the state only if is unless succeed
unless Do not run the state at least unless succeed
opts Any extra opts that need to be used

salt.states.cloud.profile(name, profile, onlyif=None, unless=None, opts=None, **kwargs)
Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used
to create an instance using a profile, this state will not verify the state of any of those arguments on an
existing instance. Stateful properties of an instance should be configured using their own individual state
(i.e., cloud.tagged, cloud.untagged, etc).

name The name of the instance to create
profile The name of the cloud profile to use
onlyif Do run the state only if is unless succeed
unless Do not run the state at least unless succeed
kwargs Any profile override or addition
opts Any extra opts that need to be used

salt.states.cloud.volume_absent(name, provider=None, **kwargs)
Check that a block volume exists.

salt.states.cloud.volume_attached(name, server_name=None, provider=None, **kwargs)
Check if a block volume is attached.

salt.states.cloud.volume_detached(name, server_name=None, provider=None, **kwargs)
Check if a block volume is attached.

Returns True if server or Volume do not exist.

salt.states.cloud.volume_present(name, provider=None, **kwargs)
Check that a block volume exists.

23.19.66 salt.states.cmd

Execution of arbitrary commands

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under
certain circumstances.

A simple example to execute a command:

```
# Store the current date in a file
'date > /tmp/salt-run':
cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```
'!/var/log/messages/':
cmd.run:
  - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```

Only run if the file specified by creates does not exist, in this case touch /tmp/foo if it does not exist:
**touch /tmp/foo:**
```
cmd.run:
  - creates: /tmp/foo
```

`creates` also accepts a list of files, in which case this state will run if any of the files do not exist:
```
"echo 'foo' | tee /tmp/bar > /tmp/baz":
  cmd.run:
    - creates:
      - /tmp/bar
      - /tmp/baz
```

**Note:** The `creates` option was added to the `cmd` state in version 2014.7.0, and made a global requisite in 3001.

Sometimes when running a command that starts up a daemon, the init script doesn’t return properly which causes Salt to wait indefinitely for a response. In situations like this try the following:
```
run_installer:
  cmd.run:
    - name: /tmp/installer.bin > /dev/null 2>&1
```

Salt determines whether the `cmd` state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt’s state system. Therefore, by default, the `cmd` state assumes that any command execution results in a changed state.

This means that if a `cmd` state is watched by another state then the state that’s watching will always be executed due to the `changed` state in the `cmd` state.

**Using the "Stateful" Argument**

Many state functions in this module now also accept a `stateful` argument. If `stateful` is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. If there’s nothing in the stdout of the command, then assume no changes. Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of =).
2. If it’s JSON then it must be a JSON object (e.g., {}). If it’s key=value pairs then quoting may be used to include spaces. (Python’s shlex module is used to parse the key=value string)

Two special keys or attributes are recognized in the output:
```
changed: bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)
comment: str (i.e., any string)
```

So, only if `changed` is True then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.
3. If there's a comment then it will be used as the comment of the state.

Here's an example of how one might write a shell script for use with a stateful command:

```
#!/bin/bash
#
echo "Working hard..."

# writing the state line
echo # an empty line here so the next line will be the last.
echo "changed=yes comment='something has changed' whatever=123"
```

And an example SLS file using this module:

```
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful: True

Run only if myscript changed something:
  cmd.run:
    - name: echo hello
    - cwd: /
    - onchanges:
      - cmd: Run myscript
```

Note that if the second `cmd.run` state also specifies `stateful: True` it can then be watched by some other states as well.

4. The stateful argument can optionally include a test_name parameter.

This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.

New in version 2015.2.0.

```
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful: 
      - test_name: /path/to/myscript test

Run masterscript:
  cmd.script:
    - name: masterscript
    - source: salt://path/to/masterscript
    - cwd: /
    - stateful:
      - test_name: masterscript test
```
Should I use `cmd.run` or `cmd.wait`?

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to watch other states, and is executed when the state it is watching changes. Example:

```
[/usr/local/bin/postinstall.sh:]
  cmd.wait:
    - watch:
      - pkg: mycustompkg
    file.managed:
      - source: salt://utils/scripts/postinstall.sh
  mycustompkg:
    pkg.installed:
      - require:
        - file: /usr/local/bin/postinstall.sh
```

cmd.wait itself do not do anything; all functionality is inside its `mod_watch` function, which is called by `watch` on changes.

The preferred format is using the `onchanges Requisite`, which works on `cmd.run` as well as on any other state. The example would then look as follows:

```
[/usr/local/bin/postinstall.sh:]
  cmd.run:
    - onchanges:
      - pkg: mycustompkg
    file.managed:
      - source: salt://utils/scripts/postinstall.sh
  mycustompkg:
    pkg.installed:
      - require:
        - file: /usr/local/bin/postinstall.sh
```

How do I create an environment from a pillar map?

The map that comes from a pillar can be directly consumed by the `env` option! To use it, one may pass it like this. Example:

```
printenv:
  cmd.run:
    - env: {{ salt['pillar.get']['example:key'], {} }}
```

salt.states.cmd.call(name, func, args=(), kws=*, output_loglevel='debug', hide_output=False, use_vt=False, **kwargs)

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the `salt.renderers.pydsl` renderer.

In addition, the `stateful` argument has no effects here.
The return value of the invoked function will be interpreted as follows.

If it's a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as result in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```json
{
    'name': name,
    'changes': {'retval': result},
    'result': True if result is None else bool(result),
    'comment': result if isinstance(result, six.string_types) else ''
}
```

salt.states.cmd.mod_watch(name, **kwargs)

Execute a cmd function based on a watch call

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly.

Parameters for this function should be set by the state being triggered.

salt.states.cmd.run(name, cwd=None, root=None, runas=None, shell=None, env=None, prepend_path=None, stateful=False, umask=None, output_loglevel='debug', hide_output=False, timeout=None, ignore_timeout=False, use_vt=False, success_retcodes=None, **kwargs)

Run a command if certain circumstances are met. Use cmd.wait if you want to use the watch requisite.

- **name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.
- **cwd** The current working directory to execute the command in, defaults to /root
- **root** Path to the root of the jail to use. If this parameter is set, the command will run inside a chroot
- **runas** The user name to run the command as
- **shell** The shell to use for execution, defaults to the shell grain
- **env** A list of environment variables to be set prior to execution. Example:

```python
script-foo:
    cmd.run:
        - env:
            - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal $PATH:

```python
script-bar:
    cmd.run:
        - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
```
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

Note: When using environment variables on Window's, case-sensitivity matters, i.e. Window's uses Path as opposed to PATH for other systems.

prepend_path $PATH segment to prepend (trailing ': ' not necessary) to $PATH. This is an easier alternative to the Jinja workaround.

New in version 2018.3.0.

stateful The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

umask The umask (in octal) to use when running the command.

output_loglevel [debug] Control the loglevel at which the output from the command is logged to the minion log.

Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

hide_output [False] Suppress stdout and stderr in the state's results.

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

timeout If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

ignore_timeout Ignore the timeout of commands, which is useful for running nohup processes.

New in version 2015.8.0.

creates Only run if the file specified by creates do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

New in version 2014.7.0.

use_vt [False] Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

bg [False] If True, run command in background and do not await or deliver its results.

New in version 2016.3.6.

success_retcodes: This parameter will be allow a list of non-zero return codes that should be considered a success. If the return code returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 2019.2.0.

Note: cmd.run supports the usage of reload_modules. This functionality allows you to force Salt to reload all modules. You should only use reload_modules if your cmd.run does some sort of installation (such as pip), if you do not reload the modules future items in your state which rely on the software being installed will fail.
getpip:

```
    cmd.run:
        - name: /usr/bin/python /usr/local/sbin/get-pip.py
        - unless: which pip
        - require:
            - pkg: python
            - file: /usr/local/sbin/get-pip.py
        - reload_modules: True
```

salt.states.cmd.script(name, source=None, template=None, cwd=None, runas=None, password=None, shell=None, env=None, stateful=False, umask=None, timeout=None, use_vt=False, output_loglevel='debug', hide_output=False, defaults=None, context=None, success_retcodes=None, **kwargs)

Download a script and execute it with specified arguments.

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**name** Either "cmd arg1 arg2 arg3..." (cmd is not used) or a source "salt://..."

**cwd** The current working directory to execute the command in, defaults to /root

**runas** Specify an alternate user to run the command. The default behavior is to run as the user under which Salt is running. If running on a Windows minion you must also use the **password** argument, and the target user account must be in the Administrators group.

**password**

New in version 3000: Windows only. Required when specifying **runas**. This parameter will be ignored on non-Windows platforms.

**shell** The shell to use for execution. The default is set in grains['shell']

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
    cmd.script:
        - env:
            - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](https://github.com/saltstack/salt/issues/55080).

Variables as values are not evaluated. So $PATH in the following example is a literal '$PATH':

```
salt://scripts/bar.sh:
```

(continues on next page)
One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**Note:** When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses `Path` as opposed to `PATH` for other systems.

salt.states.cmd.wait(name, cwd=None, root=None, runas=None, shell=None, env=(), stateful=False, umask=None, output_loglevel='debug', hide_output=False, use_vt=False, success_retcodes=None, **kwargs)

Run the given command only if the watch statement calls it.

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

- **name**: The command to execute, remember that the command will execute with the path and permissions of the salt-minion.
- **cwd**: The current working directory to execute the command in, defaults to `/root`.
- **root**: Path to the root of the jail to use. If this parameter is set, the command will run inside a chroot.
- **runas**: The user name to run the command as.
- **shell**: The shell to use for execution, defaults to `/bin/sh`.
- **env**: A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `$PATH`:

```
script-bar:
  cmd.wait:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin' }}|join(':')
```

**Note:** When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses `Path` as opposed to `PATH` for other systems.

- **umask**: The umask (in octal) to use when running the command.
- **stateful**: The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.
- **creates**: Only run if the file specified by `creates` do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

New in version 2014.7.0.

- **output_loglevel**: `[debug] Control the loglevel at which the output from the command is logged to the minion log.`
Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

**hide_output** [False] Suppress stdout and stderr in the state’s results.

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**success_retcodes**: This parameter will be allow a list of non-zero return codes that should be considered a success. If the return code returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 2019.2.0.

salt.states.cmd.wait_call(name, func, args=(), kws=None, stateful=False, use_vt=False, output_loglevel='debug', hide_output=False, **kwargs)

salt.states.cmd.wait_script(name, source=None, template=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, use_vt=False, output_loglevel='debug', hide_output=False, **kwargs)

Download a script from a remote source and execute it only if a watch statement calls it.

**source** The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**cwd** The current working directory to execute the command in, defaults to /root

**runas** The user name to run the command as

**shell** The shell to use for execution, defaults to the shell grain

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
   cmd.wait_script:
    - env:
      - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
   cmd.wait_script:

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.
success_retcodes: This parameter will allow a list of non-zero return codes that should be considered a success. If the return code returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 2019.2.0.

23.19.67 salt.states.composer

Installation of Composer Packages

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

get-composer:
  cmd.run:
  - name: 'CURL=`which curl`; $CURL -ss https://getcomposer.org/installer | php'
  - unless: test -f /usr/local/bin/composer
  - cwd: /root/

install-composer:
  cmd.wait:
  - name: mv /root/composer.phar /usr/local/bin/composer
  - cwd: /root/
  - watch:
    - cmd: get-composer
/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true

salt.states.composer.installed(name, composer=Na as, php=None, user=None, prefer_source=Na as, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='~/root', always_check=True, env=None)

Verify that the correct versions of composer dependencies are present.

- name Directory location of the composer.json file.
- composer Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)
- php Location of the php executable to use with composer. (i.e. /usr/bin/php)
- user Which system user to run composer as.

New in version 2014.1.4.

- prefer_source --prefer-source option of composer.
- prefer_dist --prefer-dist option of composer.
- no_scripts --no-scripts option of composer.
- no_plugins --no-plugins option of composer.
- optimize --optimize-autoloader option of composer. Recommended for production.
- quiet --quiet option for composer. Whether or not to return output from composer.
- composer_home $COMPOSER_HOME environment variable
- always_check If True, always run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.
- env A list of environment variables to be set prior to execution.

salt.states.composer.update(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='~/root', env=None)

Composer update the directory to ensure we have the latest versions of all project dependencies.

- name Directory location of the composer.json file.
- composer Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)
- php Location of the php executable to use with composer. (i.e. /usr/bin/php)
- user Which system user to run composer as.

New in version 2014.1.4.

- prefer_source --prefer-source option of composer.
- prefer_dist --prefer-dist option of composer.
- no_scripts --no-scripts option of composer.
- no_plugins --no-plugins option of composer.
- optimize --optimize-autoloader option of composer. Recommended for production.
no_dev  --no-dev option for composer. Recommended for production.
quiet  --quiet option for composer. Whether or not to return output from composer.
composer_home  $COMPOSER_HOME environment variable
env  A list of environment variables to be set prior to execution.

23.19.68  salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- minute
- hour
- daymonth
- month
- dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

**Warning:** Any timing arguments not specified take a value of *.* This means that setting `hour` to 5, while not defining the `minute` param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!

Additionally, the default user for these states is `root`. Therefore, if the cron job is for another user, it is necessary to specify that user with the `user` parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```bash
date > /tmp/crontest:
  cron.present:
    - user: root
    - minute: 5
```

Is changed to this:

```bash
date > /tmp/crontest:
  cron.present:
    - user: root
    - minute: 7
    - hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```bash
date > /tmp/crontest:
  cron.present:
    - identifier: SUPERCRON
    - user: root
    - minute: 7
    - hour: 2
```
New in version 2014.1.2.

And, some months later, you modify it:

```yaml
superscript > /tmp/crontest:
  cron.present:
    - identifier: SUPERCRON
    - user: root
    - minute: 3
    - hour: 4
```

New in version 2014.1.2.

The old `date > /tmp/crontest` will be replaced by `superscript > /tmp/crontest`.

Additionally, Salt also supports running a cron every \( x \) minutes very similarly to the Unix convention of using \( */5 \) to have a job run every five minutes. In Salt, this looks like:

```yaml
date > /tmp/crontest:
  cron.present:
    - user: root
    - minute: '*/5'
```

The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```yaml
/path/to/cron/script:
  cron.present:
    - user: root
    - minute: random
    - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of \( * \) for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from \( * \) to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

Added the opportunity to set a job with a special keyword like `@reboot` or `@hourly`. Quotes must be used, otherwise PyYAML will strip the `@` sign.

```yaml
/path/to/cron/script:
  cron.present:
    - user: root
    - special: '@hourly'
```

The script will be executed every reboot if cron daemon support this option.

```yaml
/path/to/cron/otherscript:
  cron.absent:
    - user: root
    - special: '@daily'
```

This counter part definition will ensure that a job with a special keyword is not set.
**salt.states.cron.absent**(*name*, *user='root*', *identifier=False*, *special=None*, **kwargs*)

Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

- **name**: The command that should be absent in the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.
- **identifier**: Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name.
- **special**: The special keyword used in the job (e.g. @reboot, @hourly...). Quotes must be used, otherwise PyYAML will strip the '@' sign.

**salt.states.cron.env_absent**(*name*, *user='root'*)

Verifies that the specified environment variable is absent from the crontab for the specified user.

- **name**: The name of the environment variable to remove from the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.

**salt.states.cron.env_present**(*name*, *value=None*, *user='root'*)

Verifies that the specified environment variable is present in the crontab for the specified user.

- **name**: The name of the environment variable to set in the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.
- **value**: The value to set for the given environment variable.

**salt.states.cron.file**(*name*, *source_hash='', source_hash_name=None*, *user='root*', *template=None*, *context=None*, *replace=True*, *defaults=None*, *backup='', **kwargs*)

Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.

- **name**: The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

  If the file is hosted on a HTTP or FTP server then the `source_hash` argument is also required.

- **source_hash**: This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file: `md5=e138491e9d5b97023cea823fe17bac22`.

- **source_hash_name**: When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path `/tmp/foo.txt`, then the following line in a hash file would match:

  ```
  acbd18db4cc2f85cedef654fccc4a4d8   foo.txt
  ```

  However, sometimes a hash file will include multiple similar paths:

  ```
  37b51d194a7513e45b56f652f2d51f2   ./dir1/foo.txt
  acbd18db4cc2f85cedef654fccc4a4d8   ./dir2/foo.txt
  73feff4a4b7f6bb68e44cf984e5f6e88   ./dir3/foo.txt
  ```

  In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

  ```
  foo_crontab:
  
  cron.file:
  
  - name: https://mydomain.tld/dir2/foo.txt
  - source_hash: https://mydomain.tld/hashe
  - source_hash_name: ./dir2/foo.txt
  ```

  **Note**: This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example...
above, simply using foobar.txt would not match.

New in version 2016.3.5.

**user** The user to whom the crontab should be assigned. This defaults to root.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.

**context** Overrides default context variables passed to the template.

**replace** If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.

**defaults** Default context passed to the template.

**backup** Overrides the default backup mode for the user’s crontab.

```python
salt.states.cron.present(name='root', minute='*', hour='*', daymonth='*', month='*', dayweek='*', comment=None, commented=False, identifier=False, special=None)
```

Verifies that the specified cron job is present for the specified user. It is recommended to use identifier. Otherwise the cron job is installed twice if you change the name. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system’s documentation. Most Unix-like systems’ cron documentation can be found via the crontab man page: `man 5 crontab`.

**name** The command that should be executed by the cron job.

**user** The name of the user whose crontab needs to be modified, defaults to the root user

**minute** The information to be set into the minute section, this can be any string supported by your cron system's minute field. Default is *

**hour** The information to be set in the hour section. Default is *

**daymonth** The information to be set in the day of month section. Default is *

**month** The information to be set in the month section. Default is *

**dayweek** The information to be set in the day of week section. Default is *

**comment** User comment to be added on line previous the cron job

**commented** The cron job is set commented (prefixed with `#DISABLED#`). Defaults to False.

New in version 2016.3.0.

**identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name

**special** A special keyword to specify periodicity (eg. @reboot, @hourly…). Quotes must be used, otherwise PyYAML will strip the ‘@’ sign.

New in version 2016.3.0.

### 23.19.69 salt.states.cryptdev

**Opening of Encrypted Devices**

Ensure that an encrypted device is mapped with the `mapped` function:

```yaml
mappedname:
  cryptdev.mapped:
    - device: /dev/sdb1
    - keyfile: /etc/keyfile.key
    - opts:
      - size=256

swap:
  crypted.mapped:
    - device: /dev/sdx4
```

(continues on next page)
- **keyfile**: /dev/urandom
- **opts**: swap,cipher=aes-cbc-essiv:sha256,size=256

**mappedbyuuid:**
- **crypted.mapped:**
  - **device**: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
  - **keyfile**: /etc/keyfile.key
  - **config**: /etc/alternate-crypttab

New in version 2018.3.0.

**salt.states.cryptdev.mapped**(name, device, keyfile=None, opts=None, config='/etc/crypttab', persist=True, immediate=False, match_on='name')

Verify that a device is mapped

- **name**: The name under which the device is to be mapped
- **device**: The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314.
- **keyfile**: Either None if the password is to be entered manually on boot, or an absolute path to a keyfile. If the password is to be asked interactively, the mapping cannot be performed with immediate=True.
- **opts**: A list object of options or a comma delimited list
- **config**: Set an alternative location for the crypttab, if the map is persistent. Default is /etc/crypttab
- **persist**: Set if the map should be saved in the crypttab. Default is True
- **immediate**: Set if the device mapping should be executed immediately. Requires that the keyfile not be None, because the password cannot be asked interactively. Note that options are not passed through on the initial mapping. Default is False.
- **match_on**: A name or list of crypttab properties on which this state should be applied. Default is name, meaning that the line is matched only by the name parameter. If the desired configuration requires two devices mapped to the same name, supply a list of parameters to match on.

**salt.states.cryptdev.unmapped**(name, config='/etc/crypttab', persist=True, immediate=False)

Ensure that a device is unmapped

- **name**: The name to ensure is not mapped
- **config**: Set an alternative location for the crypttab, if the map is persistent. Default is /etc/crypttab
- **persist**: Set if the map should be removed from the crypttab. Default is True
- **immediate**: Set if the device should be unmapped immediately. Default is False.

### 23.19.70 salt.states.csf

CSF Ip tables management

- **depends**: csf utility

**configuration** See [http://download.configserver.com/csf/install.txt](http://download.configserver.com/csf/install.txt) for setup instructions.

**Simply allow/deny rules:**
- **csf.rule_present**: ip: 1.2.3.4
  - **method**: allow

**salt.states.csf.nics_skip**(name, nics, ipv6)

Alias for **csf.nics_skipped**

**salt.states.csf.nics_skipped**(name, nics, ipv6=False)
name Meaningless arg, but required for state.
nics A list of nics to skip.
ipv6 Boolean. Set to true if you want to skip the ipv6 interface. Default false (ipv4).

salt.states.csf.option_present(name, value, reload=False)
Ensure the state of a particular option/setting in csf.
name The option name in csf.conf
value The value it should be set to.
reload Boolean. If set to true, csf will be reloaded after.

salt.states.csf.ports_open(name, ports, proto='tcp', direction='in')
Ensure ports are open for a protocol, in a direction. e.g. - proto='tcp', direction='in' would set the values for
TCP_IN in the csf.conf file.
ports A list of ports that should be open.
proto The protocol. May be one of 'tcp', 'udp', 'tcp6', or 'udp6'.
direction Choose 'in', 'out', or both to indicate the port should be opened for inbound traffic, outbound traffic,
or both.

salt.states.csf.rule_absent(name, method, port=None, proto='tcp', direction='in', port_origin='d',
    ip_origin='s', ttl=None, reload=False)
Ensure iptable is not present.
name The ip address or CIDR for the rule.
method The type of rule. Either 'allow' or 'deny'.
port Optional port to be open or closed for the iptables rule.
proto The protocol. Either 'tcp', 'udp'. Only applicable if port is specified.
direction The direction of traffic to apply the rule to. Either 'in', or 'out'. Only applicable if port is specified.
port_origin Specifies either the source or destination port is relevant for this rule. Only applicable if port is
    specified. Either 's', or 'd'.
ip_origin Specifies whether the ip in this rule refers to the source or destination ip. Either 's', or 'd'. Only
    applicable if port is specified.
ttl How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny()’ are used.
reload Reload the csf service after applying this rule. Default false.

salt.states.csf.rule_present(name, method, port=None, proto='tcp', direction='in', port_origin='d',
    ip_origin='s', ttl=None, comment='', reload=False)
Ensure iptable rule exists.
name The ip address or CIDR for the rule.
method The type of rule. Either 'allow' or 'deny'.
port Optional port to be open or closed for the iptables rule.
proto The protocol. Either 'tcp', or 'udp'. Only applicable if port is specified.
direction The direction of traffic to apply the rule to. Either 'in', or 'out'. Only applicable if port is specified.
port_origin Specifies either the source or destination port is relevant for this rule. Only applicable if port is
    specified. Either 's', or 'd'.
ip_origin Specifies whether the ip in this rule refers to the source or destination ip. Either 's', or 'd'. Only
    applicable if port is specified.
ttl How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny()’ are used.
comment An optional comment to appear after the rule as a #comment .
reload Reload the csf service after applying this rule. Default false.

salt.states.csf.testing_off(name, reload=False)
Ensure testing mode is enabled in csf.
reload Reload CSF after changing the testing status. Default false.

salt.states.csf.testing_on(name, reload=False)
Ensure testing mode is enabled in csf.
reload Reload CSF after changing the testing status. Default false.
23.19.71 salt.states.cyg

Installation of Cygwin packages.

A state module to manage cygwin packages. Packages can be installed or removed.

dos2unix:
  cyg.installed

class salt.states.cyg.DictDiffer(current_dict, past_dict)

Calculate the difference between two dictionaries.

(1) items added
(2) items removed
(3) keys same in both but changed values
(4) keys same in both and unchanged values

added()
  Return a set of additions to past_dict.

changed()
  Return a set of the keys with changed values.

removed()
  Return a set of things removed from past_dict.

same()
  True if the two dicts are the same.

unchanged()
  Return a set of the keys with unchanged values.

salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)

Make sure that a package is installed.

name  The name of the package to install
cyg_arch  [x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64
mirrors  [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
  cyg.installed:
    - mirrors:
      - http://mirror/without/public/key: ""

salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)

Make sure that a package is not installed.

name  The name of the package to uninstall
cyg_arch  [x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64
mirrors  [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
  cyg.removed:
    - mirrors:
      - http://mirror/without/public/key: ""

salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)

Make sure all packages are up to date.
23.19.72 salt.states.ddns

Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates.

depends
- dnspython

Note: The dnspython module is required when managing DDNS using a TSIG key. If you are not using a TSIG key, DDNS is allowed by ACLs based on IP address and the dnspython module is not required.

Example:

```yaml
webserver:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/dnspy_tsig_key.txt
```

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)

Ensures that the named DNS record is absent.

name The host portion of the DNS record, e.g., ‘webserver’. Name and zone are concatenated when the entry is created unless name includes a trailing dot, so make sure that information is not duplicated in these two arguments.
zone The zone to check
data Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.
rdtype DNS resource type. If omitted, all types will be purged.
**kwargs Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname). Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the dnspython spec.

salt.states.ddns.present(name, zone, ttl, data=‘A’, **kwargs)

Ensures that the named DNS record is present with the given ttl.

name The host portion of the DNS record, e.g., ‘webserver’. Name and zone are concatenated when the entry is created unless name includes a trailing dot, so make sure that information is not duplicated in these two arguments.
zone The zone to check/update
ttl TTL for the record
**data**  Data for the DNS record. E.g., the IP address for an A record.

**rdtype**  DNS resource type. Default 'A'.

**kwargs**  Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).

Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the `<dnspython>` spec.

### 23.19.73  `salt.states.debconfmod`

**Management of debconf selections**

**depends**

- debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections prior to package installation.

**Available Functions**

The debconfmod state has two functions, the `set` and `set_file` functions.

**set**  Set debconf selections from the state itself.

**set_file**  Set debconf selections from a file.

<table>
<thead>
<tr>
<th>nullmailer-debconf:</th>
<th>ferm-debconf:</th>
</tr>
</thead>
<tbody>
<tr>
<td>debconf.set:</td>
<td>debconf.set:</td>
</tr>
<tr>
<td>- name: nullmailer</td>
<td>- name: ferm</td>
</tr>
<tr>
<td>- data:</td>
<td>- data:</td>
</tr>
<tr>
<td>&quot;shared/mailname&quot;:</td>
<td>&quot;ferm/enable&quot;:</td>
</tr>
<tr>
<td>{type: 'string',</td>
<td></td>
</tr>
<tr>
<td>value: 'server.domain.tld'}</td>
<td>{type: 'boolean', value: True}</td>
</tr>
<tr>
<td>&quot;nullmailer/relayhost&quot;:  {type: 'string', value: 'mail.domain.tld'}</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Due to how PyYAML imports nested dicts (see [here](#)), the values in the `data` dict must be indented four spaces instead of two.

If you’re setting debconf values that requires `dpkg-reconfigure`, you can use the `onchanges` requisite to reconfigure your package:

<table>
<thead>
<tr>
<th>set-default-shell:</th>
<th>reconfigure-dash:</th>
</tr>
</thead>
<tbody>
<tr>
<td>debconf.set:</td>
<td>cmd.run:</td>
</tr>
<tr>
<td>- name: dash</td>
<td>- name: dpkg-reconfigure -f noninteractive dash</td>
</tr>
<tr>
<td>- data:</td>
<td>- onchanges:</td>
</tr>
<tr>
<td>&quot;dash/sh&quot;: {type: 'boolean', value: False}</td>
<td>- debconf: set-default-shell</td>
</tr>
</tbody>
</table>

---

23.19.  state modules
Every time the `set-default-shell` state changes, the `reconfigure-dash` state will also run.

**Note:** For boolean types, the value should be `true` or `false`, not `'true'` or `'false'`.

salt.states.debconfmod.set(name, data, **kwargs)

Set debconf selections

```yaml
<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}
```

*name*: The package name to set answers for.
*data*: A set of questions/answers for debconf. Note that everything under this must be indented twice.
*question*: The question the is being preanswered
*type*: The type of question that is being asked (string, boolean, select, etc.)
*value*: The answer to the question

salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)

Set debconf selections from a file or a template

```yaml
<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections

<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections?saltenv=myenvironment

<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections.jinja2
    - template: jinja
    - context:
      some_value: "false"
```

*source*: The location of the file containing the package selections
*template* If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported
*context* Overrides default context variables passed to the template.
*defaults* Default context passed to the template.
23.19.74 salt.states.dellchassis

Manage chassis via Salt Proxies.

New in version 2015.8.2.

Below is an example state that sets basic parameters:

```yaml
my-dell-chassis:
dellchassis.chassis:
  - chassis_name: my-dell-chassis
  - datacenter: dc-1-us
  - location: my-location
  - mode: 2
  - idrac_launch: 1
  - slot_names:
    - server-1: my-slot-name
    - server-2: my-other-slot-name
  - blade_power_states:
    - server-1: on
    - server-2: off
    - server-3: powercycle
```

However, it is possible to place the entire set of chassis configuration data in pillar. Here's an example pillar structure:

```yaml
proxy:
  host: 10.27.20.18
  admin_username: root
  fallback_admin_username: root
  passwords:
    - super-secret
    - old-secret
  proxytype: fx2

chassis:
  name: fx2-1
  username: root
  password: saltstack1
  datacenter: london
  location: rack-1-shelf-3
  management_mode: 2
  idrac_launch: 0
  slot_names:
    - 'server-1': blade1
    - 'server-2': blade2

servers:
  server-1:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.132
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-2:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
```

(continues on next page)
And to go with it, here's an example state that pulls the data from the pillar stated above:

```python
{% set details = pillar.get('proxy:chassis', {}) %}
standup-step1:
dellchassis.chassis:
  - name: {{ details['name'] }}
  - location: {{ details['location'] }}
  - mode: {{ details['management_mode'] }}
  - idrac_launch: {{ details['idrac_launch'] }}
  - slot_names:
    {% for entry in details['slot_names'] %}
      - {{ next(iter(entry)) }}: {{ entry[next(iter(entry))] }}
    {% endfor %}
blade_powercycle:
dellchassis.chassis:
  - blade_power_states:
    - server-1: powercycle
    - server-2: powercycle
    - server-3: powercycle
    - server-4: powercycle

# Set idrac_passwords for blades. racadm needs them to be called 'server-x'
{% for k, v in details['servers'].iteritems() %}
  {{ k }}:
    - idrac_password: {{ v['idrac_password'] }}
{% endfor %}
```
# Set management ip addresses, passwords, and snmp strings for switches
{% for k, v in details['switches'].iteritems() %}
{{ k }}-switch-setup:
  dellchassis.switch:
  - name: {{ k }}
  - ip: {{ v['ip'] }}
  - netmask: {{ v['netmask'] }}
  - gateway: {{ v['gateway'] }}
  - password: {{ v['password'] }}
  - snmp: {{ v['snmp'] }}
{% endfor %}

Note: This state module relies on the dracr.py execution module, which runs racadm commands on the chassis, blades, etc. The racadm command runs very slowly and, depending on your state, the proxy minion return might timeout before the racadm commands have completed. If you are repeatedly seeing minions timeout after state calls, please use the -t CLI argument to increase the timeout variable.

For example:
salt '*' state.sls my-dell-chasis-state-name -t 60

Note: The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take minutes to execute.

salt.states.dellchassis.blade_idrac(name, idrac_password=None, idrac_ipmi=None, idrac_ip=None, idrac_netmask=None, idrac_gateway=None, idrac_dnsname=None, idrac_dhcp=None)

Set parameters for iDRAC in a blade.

Parameters

- **idrac_password** -- Password to use to connect to the iDRACs directly (idrac_ipmi and idrac_dnsname must be set directly on the iDRAC. They can't be set through the CMC. If this password is present, use it instead of the CMC password)
- **idrac_ipmi** -- Enable/Disable IPMI over LAN
- **idrac_ip** -- Set IP address for iDRAC
- **idrac_netmask** -- Set netmask for iDRAC
- **idrac_gateway** -- Set gateway for iDRAC
- **idrac_dhcp** -- Turn on DHCP for iDRAC (True turns on, False does nothing because setting a static IP will disable DHCP).

Returns A standard Salt changes dictionary

NOTE: If any of the IP address settings is configured, all of ip, netmask, and gateway must be present

salt.states.dellchassis.chassis(name, chassis_name=None, password=None, datacenter=None, location=None, mode=None, idrac_launch=None, slot_names=None, blade_power_states=None)

Manage a Dell Chassis.

**chassis_name** The name of the chassis.

**datacenter** The datacenter in which the chassis is located

**location** The location of the chassis.

**password** Password for the chassis. Note: If this password is set for the chassis, the current implementation of this state will set this password both on the chassis and the iDrac passwords on any configured blades.
If the password for the blades should be distinct, they should be set separately with the blade_idrac function.

**mode**  The management mode of the chassis. Viable options are:
- 0: None
- 1: Monitor
- 2: Manage and Monitor

**idrac_launch**  The iDRAC launch method of the chassis. Viable options are:
- 0: Disabled (launch iDRAC using IP address)
- 1: Enabled (launch iDRAC using DNS name)

**slot_names**  The names of the slots, provided as a list identified by their slot numbers.

**blade_power_states**  The power states of a blade server, provided as a list and identified by their server numbers. Viable options are:
- on: Ensure the blade server is powered on.
- off: Ensure the blade server is powered off.
- powercycle: Power cycle the blade server.

Example:

```yaml
my-dell-chassis:
dellchassis.chassis:
  -chassis_name: my-dell-chassis
  -location: my-location
  -datacenter: london
  -mode: 2
  -idrac_launch: 1
  -slot_names:
    -1: my-slot-name
    -2: my-other-slot-name
  -blade_power_states:
    -server-1: on
    -server-2: off
    -server-3: powercycle

salt.states.dellchassis.firmware_update(hosts=None, directory='')
State to update the firmware on host using the racadm command

firmwarefile  filename (string) starting with salt://
host  string representing the hostname supplied to the racadm command
directory  Directory name where firmwarefile will be downloaded

```yaml
dellchassis-firmware-update:
dellchassis.firmware_update:
  hosts:
    cmc:
      salt://firmware_cmc.exe
    server-1:
      salt://firmware.exe
directory: /opt/firmwares

salt.states.dellchassis.switch(name, ip=None, netmask=None, gateway=None, dhcp=None, password=None, snmp=None)
Manage switches in a Dell Chassis.

name  The switch designation (e.g. switch-1, switch-2)

ip  The Static IP Address of the switch

netmask  The netmask for the static IP

gateway  The gateway for the static IP

dhcp  True: Enable DHCP False: Do not change DHCP setup (disabling DHCP is automatic when a static IP is set)
password The access (root) password for the switch
snmp The SNMP community string for the switch

Example:

```yaml
my-dell-chassis:
  dellchassis.switch:
    - switch: switch-1
    - ip: 192.168.1.1
    - netmask: 255.255.255.0
    - gateway: 192.168.1.254
    - dhcp: True
    - password: secret
    - snmp: public
```

23.19.75 salt.states.disk

Disk monitoring state

Monitor the state of disk resources.

The `disk.status` function can be used to report that the used space of a filesystem is within the specified limits.

```yaml
used_space:
  disk.status:
    - name: /dev/xda1
    - maximum: 79%
    - minimum: 11%
```

It can be used with an `onfail` requisite, for example, to take additional action in response to or in preparation for other states.

```yaml
storage_threshold:
  disk.status:
    - name: /dev/xda1
    - maximum: 97%

clear_cache:
  cmd.run:
    - name: rm -r /var/cache/app
    - onfail:
      - disk: storage_threshold
```

To use kilobytes (KB) for `minimum` and `maximum` rather than percents, specify the `absolute` flag:

```yaml
used_space:
  disk.status:
    - name: /dev/xda1
    - minimum: 1024 KB
    - maximum: 1048576 KB
    - absolute: True
```

`salt.states.disk.status(name, maximum=None, minimum=None, absolute=False, free=False)`
Return the current disk usage stats for the named mount point

- **name** Disk mount or directory for which to check used space
- **maximum** The maximum disk utilization
- **minimum** The minimum disk utilization
absolute  By default, the utilization is measured in percentage. Set the absolute flag to use kilobytes.

    New in version 2016.11.0.

free  By default, minimum & maximum refer to the amount of used space. Set to True to evaluate the free space instead.

23.19.76 salt.states.docker_container

Management of Docker containers

New in version 2017.7.0.

    depends docker Python module

Note:  Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using pip.install:

    salt myminion pip.install docker

To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:

    salt myminion pip.uninstall docker-py
    salt myminion pip.install docker

These states were moved from the docker state module (formerly called dockerng) in the 2017.7.0 release. When running the docker_container.running state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is None. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.

Note:  To pull from a Docker registry, authentication must be configured. See here for more information on how to configure access to docker registries in Pillar data.

salt.states.docker_container.absent(name, force=False)

    Ensure that a container is absent
    name  Name of the container
    force  [False] Set to True to remove the container even if it is running

Usage Examples:

    mycontainer:
    - docker_container.absent

    multiple_containers:
    - docker_container.absent:
        - names:
            - foo
            - bar
            - baz

salt.states.docker_container.mod_watch(name, sfun=None, **kwargs)

    The docker_container watcher, called to invoke the watch command.
Note: This state exists to support special handling of the watch requisite. It should not be called directly.
Parameters for this function should be set by the state being triggered.

```
salt.states.docker_container.run(name, image=None, bg=False, failhard=True, replace=False,
    force=False, skip_translate=None, ignore_collisions=False, validate_ip_addrs=True,
    client_timeout=60, **kwargs)
```

New in version 2018.3.0.

Note: If no tag is specified in the image name, and nothing matching the specified image is pulled on the minion, the docker pull that retrieves the image will pull all tags for the image. A tag of latest is not implicit for the pull. For this reason, it is recommended to specify the image in repo:tag notation.

Like the cmd.run state, only for Docker. Does the equivalent of a docker run and returns information about the container that was created, as well as its output.

This state accepts the same arguments as docker_container.running, with the exception of watch_action, start, and shutdown_timeout (though the force argument has a different meaning in this state).

In addition, this state accepts the arguments from docker.logs, with the exception of follow, to control how logs are returned.

Additionally, the following arguments are supported:

creates A path or list of paths. Only run if one or more of the specified paths do not exist on the minion.

bg [False] If True, run container in background and do not await or deliver its results.

Note: This may not be useful in cases where other states depend on the results of this state. Also, the logs will be inaccessible once the container exits if auto_remove is set to True, so keep this in mind.

failhard [True] If True, the state will return a False result if the exit code of the container is non-zero. When this argument is set to False, the state will return a True result regardless of the container's exit code.

Note: This has no effect if bg is set to True.

replace [False] If True, and if the named container already exists, this will remove the existing container. The default behavior is to return a False result when the container already exists.

force [False] If True, and the named container already exists, and replace is also set to True, then the container will be forcibly removed. Otherwise, the state will not proceed and will return a False result.

CLI Examples:

```
salt myminion docker.run_container myuser/myimage command=/usr/local/bin/myscript. → sh
```

usage example

```
{% set pkg_version = salt.pillar.get('pkg_version', '1.0-1') %}
build_package:
    docker_container.run:
        - image: myuser/builder:latest
        - binds: /home/myuser/builds:/build_dir
        - command: /scripts/build.sh {{ pkg_version }}
```
- creates: /home/myuser/builds/myapp-{{ pkg_version }}.noarch.rpm
- replace: True
- networks:
  - mynet
- require:
  - docker_network: mynet

salt.states.docker_container.running(name, image=None, skip_translate=None, ignore_collisions=False, validate_ip_addrs=True, force=False, watch_action='force', start=True, shutdown_timeout=None, client_timeout=60, networks=None, **kwargs)

Ensure that a container with a specific configuration is present and running

**name** Name of the container

**image** Image to use for the container

**Note:** This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the `docker_image.present` state should be used to manage the image.

Changed in version 2018.3.0: If no tag is specified in the image name, and nothing matching the specified image is pulled on the minion, the `docker pull` that retrieves the image will pull all tags for the image. A tag of `latest` is no longer implicit for the pull. For this reason, it is recommended to specify the image in `repo:tag` notation.

**skip_translate** This function translates Salt CLI or SLS input into the format which `docker-py` expects. However, in the event that Salt’s translation logic fails (due to potential changes in the Docker Remote API, or to bugs in the translation code), this argument can be used to exert granular control over which arguments are translated and which are not.

Pass this argument as a comma-separated list (or Python list) of arguments, and translation for each passed argument name will be skipped. Alternatively, pass `True` and all translation will be skipped.

Skipping translation allows for arguments to be formatted directly in the format which `docker-py` expects. This allows for API changes and other issues to be more easily worked around. An example of using this option to skip translation would be:

For example, imagine that there is an issue with processing the `port_bindings` argument, and the following configuration no longer works as expected:

```yaml
mycontainer:
  docker_container.running:
    - image: 7.3.1611
    - port_bindings:
      - 10.2.9.10:8080:80
```

By using `skip_translate`, you can forego the input translation and configure the port binding in the format `docker-py` needs:

```yaml
mycontainer:
  docker_container.running:
    - image: 7.3.1611
    - skip_translate: port_bindings
    - port_bindings: {8080: [('10.2.9.10', 80)], '4193/udp': 9314}
```
See the following links for more information:
- docker-py Low-level API
- Docker Engine API

ignore_collisions [False] Since many of docker-py’s arguments differ in name from their CLI counterparts (with which most Docker users are more familiar), Salt detects usage of these and aliases them to the docker-py version of that argument so that both CLI and API versions of a given argument are supported. However, if both the alias and the docker-py version of the same argument (e.g. env and environment) are used, an error will be raised. Set this argument to True to suppress these errors and keep the docker-py version of the argument.

validate_ip_addrs [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False.

force [False] Set this parameter to True to force Salt to re-create the container irrespective of whether or not it is configured as desired.

watch_action [force] Control what type of action is taken when this state watches another state that has changes. The default action is force, which runs the state with force set to True, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage. For example:

```
mycontainer:
  docker_container.running:
    - image: busybox
    - watch_action: SIGHUP
    - watch:
      - file: some_file
```

Note: If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

start [True] Set to False to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the Django migrate and collectstatic commands. In instances such as this, the container only needs to be started the first time.

shutdown_timeout If the container needs to be replaced, the container will be stopped using docker.stop. If a shutdown_timeout is not set, and the container was created using stop_timeout, that timeout will be used. If neither of these values were set, then a timeout of 10 seconds will be used.

Changed in version 2017.7.0: This option was renamed from stop_timeout to shutdown_timeout to accommodate the stop_timeout container configuration setting.

client_timeout [60] Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

NETWORK MANAGEMENT

New in version 2018.3.0.

Changed in version 2019.2.0: If the networks option is used, any networks (including the default bridge network) which are not specified will be disconnected.
The `networks` argument can be used to ensure that a container is attached to one or more networks. Optionally, arguments can be passed to the networks. In the example below, `net1` is being configured with arguments, while `net2` and `bridge` are being configured without arguments:

```
foo:
  docker_container.running:
    - image: myuser/myimage:foo
    - networks:
      - net1:
        - aliases:
          - bar
          - baz
        - ipv4_address: 10.0.20.50
      - net2
      - bridge
    - require:
      - docker_network: net1
      - docker_network: net2
```

The supported arguments are the ones from the docker-py's `connect_container_to_network` function (other than `container` and `net_id`).

**Important:** Unlike with the arguments described in the CONTAINER CONFIGURATION PARAMETERS section below, these network configuration parameters are not translated at all. Consult the `connect_container_to_network` documentation for the correct type/format of data to pass.

To start a container with no network connectivity (only possible in 2019.2.0 and later) pass this option as an empty list. For example:

```
foo:
  docker_container.running:
    - image: myuser/myimage:foo
    - networks: []
```

**CONTAINER CONFIGURATION PARAMETERS**

*auto_remove (or rm)* [False] Enable auto-removal of the container on daemon side when the container’s process exits (analogous to running a docker container with `-r` on the CLI).

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - auto_remove: True
```

*binds* Files/directories to bind mount. Each bind mount should be passed in one of the following formats:

- `<host_path>:`:<container_path> - `host_path` is mounted within the container as `container_path` with read-write access.
- `<host_path>:`:<container_path>:<selinux_context> - `host_path` is mounted within the container as `container_path` with read-write access. Additionally, the specified selinux context will be set within the container.
- `<host_path>:`:<container_path>:<read_only> - `host_path` is mounted within the container as `container_path`, with the read-only or read-write setting explicitly defined.
- `<host_path>:`:<container_path>:<read_only>,<selinux_context> - `host_path` is mounted within the container as `container_path`, with the read-only or read-write setting explicitly defined. Additionally, the specified selinux context will be set within the container.
<read_only> can be either rw for read-write access, or ro for read-only access. When omitted, it is assumed to be read-write.

<selinux_context> can be z if the volume is shared between multiple containers, or Z if the volume should be private.

Note: When both <read_only> and <selinux_context> are specified, there must be a comma before <selinux_context>.

Binds can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds: /srv/www:/var/www:ro,/etc/foo.conf:/usr/local/etc/foo.conf:rw

foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds:
      - /srv/www:/var/www:ro
      - /home/myuser/conf/foo.conf:/etc/foo.conf:rw
```

However, in cases where both ro/rw and an selinux context are combined, the only option is to use a YAML list, like so:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds:
      - /srv/www:/var/www:ro,Z
      - /home/myuser/conf/foo.conf:/etc/foo.conf:Z
```

Since the second bind in the previous example is mounted read-write, the rw and comma can be dropped. For example:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds:
      - /srv/www:/var/www:ro,Z
      - /home/myuser/conf/foo.conf:Z
```

blkio_weight Block IO weight (relative weight), accepts a weight value between 10 and 1000.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - blkio_weight: 100
```

blkio_weight_device Block IO weight (relative device weight), specified as a list of expressions in the format PATH:RATE

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - blkio_weight_device: /dev/sda:100
```
cap_add List of capabilities to add within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cap_add: SYS_ADMIN, MKNOD
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cap_add:
      - SYS_ADMIN
      - MKNOD
```

Note: This option requires Docker 1.2.0 or newer.

cap_drop List of capabilities to drop within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cap_drop: SYS_ADMIN, MKNOD
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cap_drop:
      - SYS_ADMIN
      - MKNOD
```

Note: This option requires Docker 1.2.0 or newer.

command (or cmd) Command to run in the container

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - command: bash
```

cpuset_cpus (or cpuset) CPUs on which which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpuset_cpus: "0,1"
```

cpuset_mems Memory nodes on which which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of MEMs (e.g. 0,1). Only effective on NUMA systems.

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpuset_mems: "0,1"
```
cpu_group  The length of a CPU period in microseconds

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_group: 100000
```

cpu_period  Microseconds of CPU time that the container can get in a CPU period

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_period: 50000
```

cpu_shares  CPU shares (relative weight), specified as an integer between 2 and 1024.

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_shares: 512
```

detach  [False] If True, run the container’s command in the background (daemon mode)

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - detach: True
```

devices  List of host devices to expose within the container. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices: /dev/net/tun,/dev/xvda1:/dev/xvda1, /dev/xvdb1:/dev/xvdb1:r
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices:
      - /dev/net/tun
      - /dev/xvda1:/dev/xvda1
      - /dev/xvdb1:/dev/xvdb1:r
```

device_read_bps  Limit read rate (bytes per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is either an integer number of bytes, or a string ending in kb, mb, or gb. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps: /dev/sda:1mb,/dev/sdb:5mb
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps:
      - /dev/sda:1mb
      - /dev/sdb:5mb
```

device_read_iops  Limit read rate (I/O per second) from a device, specified as a list of expressions in the format PATH:RATE.
PATH:RATE, where RATE is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_iops: /dev/sda:1000, /dev/sdb:500
```

**device_write_bps** Limit write rate (bytes per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is either an integer number of bytes, or a string ending in kb, mb, or gb. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_bps: /dev/sda:1mb, /dev/sdb:5mb
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_bps:
        - /dev/sda:1mb
        - /dev/sdb:5mb
```

**device_write_iops** Limit write rate (I/O per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_iops: /dev/sda:1000, /dev/sdb:500
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_iops:
        - /dev/sda:1000
        - /dev/sdb:500
```

**dns** List of DNS nameservers. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns: 8.8.8.8, 8.8.4.4
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns: 8.8.8.8, 8.8.4.4
```

(continues on next page)
- **image**: bar/baz:latest
- **dns**:
  - 8.8.8.8
  - 8.8.4.4

**Note**: To skip IP address validation, use `validate_ip_addrs=False`

**dns_opt** Additional options to be added to the container’s `resolv.conf` file. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns_opt: ndots:9

foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns_opt:
      - ndots:9
```

**dns_search** List of DNS search domains. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns_search: foo1.domain.tld,foo2.domain.tld

foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns_search:
      - foo1.domain.tld
      - foo2.domain.tld
```

**domainname** The domain name to use for the container

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - domainname: domain.tld
```

**entrypoint** Entrypoint for the container

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - entrypoint: "mycmd --arg1 --arg2"
```

This argument can also be specified as a list:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - entrypoint:
```

(continues on next page)
environment  Either a list of variable/value mappings, or a list of strings in the format `VARNAME=value`. The below three examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment:
      - VAR1: value
      - VAR2: value

foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment: "VAR1=value,VAR2=value"

foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment:
      - VAR1=value
      - VAR2=value
```

eextra_hosts  Additional hosts to add to the container's `/etc/hosts` file. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts: web1:10.9.8.7,web2:10.9.8.8

foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts:
        - web1:10.9.8.7
        - web2:10.9.8.8
```

Note: To skip IP address validation, use `validate_ip_addrs=False`

Note: This option requires Docker 1.3.0 or newer.

group_add  List of additional group names and/or IDs that the container process will run as. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - group_add: web, network
```
hostname Hostname of the container. If not provided, the value passed as the container’s `name` will be used for the hostname.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - hostname: web1
```

**Warning:** hostname cannot be set if `network_mode` is set to host. The below example will result in an error:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - hostname: web1
    - network_mode: host
```

**interactive (or stdin_open)**  [False] Leave stdin open, even if not attached

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - interactive: True
```

**ipc_mode (or ipc)** Set the IPC mode for the container. The default behavior is to create a private IPC namespace for the container, but this option can be used to change that behavior:

- `container:<container_name_or_id>` reuses another container shared memory, semaphores and message queues
- `host`: use the host's shared memory, semaphores and message queues

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ipc_mode: container:foo

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ipc_mode: host
```

**Warning:** Using `host` gives the container full access to local shared memory and is therefore considered insecure.

**isolation** Specifies the type of isolation technology used by containers

```
foo:
  docker_container.running:
```

(continues on next page)
labels  Add metadata to the container. Labels can be set both with and without values, and labels with values can be passed either as key=value or key: value pairs. For example, while the below would be very confusing to read, it is technically valid, and demonstrates the different ways in which labels can be passed:

```
mynet:
  docker_network.present:
    - labels:
      - foo
      - bar=baz
      - hello: world
```

The labels can also simply be passed as a YAML dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```
foo:
  docker_network.present:
    - labels:
      foo: '
      bar: baz
      hello: world
```

Changed in version 2018.3.0: Methods for specifying labels can now be mixed. Earlier releases required either labels with or without values.

links  Link this container to another. Links can be specified as a list of mappings or a comma-separated or Python list of expressions in the format <container_name_or_id>:<link_alias>. The below three examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      - web1: link1
      - web2: link2
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links: web1:link1,web2:link2
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      - web1:link1
      - web2:link2
```

log_driver and log_opt  Set container’s logging driver and options to configure that driver. Requires Docker 1.6 or newer.
```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt:
      - syslog-address: tcp://192.168.0.42
      - syslog-facility: daemon
```

The `log_opt` can also be expressed as a comma-separated or YAML list of `key=value` pairs. The below two examples are equivalent to the above one:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt: "syslog-address=tcp://192.168.0.42,syslog-facility=daemon"
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt:
      - syslog-address=tcp://192.168.0.42
      - syslog-facility=daemon
```

**Note:** The logging driver feature was improved in Docker 1.13 introducing option name changes. Please see Docker's [Configure logging drivers](https://docs.docker.com/config/daemon/log_config/) documentation for more information.

`lxc_conf` Additional LXC configuration parameters to set before starting the container. Either a list of variable/value mappings, or a list of strings in the format `VARNAME=value`. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
      - lxc.utsname: docker
      - lxc.arch: x86_64
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf: lxc.utsname=docker,lxc.arch=x86_64
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
      - lxc.utsname=docker
      - lxc.arch=x86_64
```

**Note:** These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has been deprecated for some time.
mac_address  MAC address to use for the container. If not specified, a random MAC address will be used.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - mac_address: 01:23:45:67:89:0a
```

mem_limit (or memory)  [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. \(512\text{M}\), \(2\text{G}\), etc.). A value of 0 (the default) means no memory limit.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - mem_limit: 512M
```

mem_swappiness  Tune a container's memory swappiness behavior. Accepts an integer between 0 and 100.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - mem_swappiness: 60
```

memswap_limit (or memory_swap)  [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - memswap_limit: 1G
```

network_disabled  [False] If True, networking will be disabled within the container.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - network_disabled: True
```

network_mode  [bridge] One of the following:

- **bridge** - Creates a new network stack for the container on the docker bridge
- **none** - No networking (equivalent of the Docker CLI argument `--net=none`). Not to be confused with Python's `None`.
- **container:<name_or_id>** - Reuses another container's network stack
- **host** - Use the host's network stack inside the container

**Warning:** Using host mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - network_mode: "none"
```

```
foo:
    docker_container.running:
        - image: bar/baz:latest
        - network_mode: container:web1
```

oom_kill_disable  Whether to disable OOM killer
foo:
    docker_container.running:
    - image: bar/baz:latest
    - oom_kill_disable: False

oom_score_adj  An integer value containing the score given to the container in order to tune OOM killer preferences.

foo:
    docker_container.running:
    - image: bar/baz:latest
    - oom_score_adj: 500

pid_mode  Set to host to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

foo:
    docker_container.running:
    - image: bar/baz:latest
    - pid_mode: host

Note: This option requires Docker 1.5.0 or newer.

pids_limit  Set the container's PID limit. Set to -1 for unlimited.

foo:
    docker_container.running:
    - image: bar/baz:latest
    - pids_limit: 2000

port_bindings (or publish)  Bind exposed ports. Port bindings should be passed in the same way as the --publish argument to the docker run CLI command:

- ip:hostPort:containerPort - Bind a specific IP and port on the host to a specific port within the container.
- ip::containerPort - Bind a specific IP and an ephemeral port to a specific port within the container.
- hostPort:containerPort - Bind a specific port on all of the host's interfaces to a specific port within the container.
- containerPort - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or expressed as a YAML list, and port ranges can be defined using dashes. The below two examples are equivalent:

foo:
    docker_container.running:
    - image: bar/baz:latest
    - port_bindings: "4505-4506:14505-14506,2123:2123/udp,8080"

foo:
    docker_container.running:
    - image: bar/baz:latest
    - port_bindings:
      - 4505-4506:14505-14506
      - 2123:2123/udp
      - 8080
Note: When specifying a protocol, it must be passed in the containerPort value, as seen in the examples above.

ports A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports: 1111,2222/udp

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports:
      - 1111
      - 2222/udp
```

privileged [False] If True, runs the exec process with extended privileges

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - privileged: True
```

publish_all_ports (or publish_all) [False] Publish all ports to the host

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports: 8080
    - publish_all_ports: True
```

read_only [False] If True, mount the container’s root filesystem as read only

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - read_only: True
```

restart_policy (or restart) Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always, unless-stopped, or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always or unless-stopped restart policy.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - restart_policy: on-failure:5

bar:
  docker_container.running:
    - image: bar/baz:latest
    - restart_policy: always
```

security_opt (or security_opts): Security configuration for MLS systems such as SELinux and AppArmor. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
  docker_container.running:
  - image: bar/baz:latest
  - security_opt: apparmor:unconfined

foo:
  docker_container.running:
  - image: bar/baz:latest
  - security_opt:
    - apparmor:unconfined

**Important:** Some security options can contain commas. In these cases, this argument **must** be passed as a Python list, as splitting by comma will result in an invalid configuration.

**Note:** See the documentation for security_opt at [https://docs.docker.com/engine/reference/run/#security-configuration](https://docs.docker.com/engine/reference/run/#security-configuration)

**shm_size** Size of /dev/shm

foo:
  docker_container.running:
  - image: bar/baz:latest
  - shm_size: 128M

**stop_signal** Specify the signal docker will send to the container when stopping. Useful when running systemd as PID 1 inside the container.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - stop_signal: SIGRTMIN+3

**Note:** This option requires Docker 1.9.0 or newer and docker-py 1.7.0 or newer.

**stop_timeout** Timeout to stop the container, in seconds

foo:
  docker_container.running:
  - image: bar/baz:latest
  - stop_timeout: 5

**Note:** In releases prior to 2017.7.0, this option was not set in the container configuration, but rather this timeout was enforced only when shutting down an existing container to replace it. To remove the ambiguity, and to allow for the container to have a stop timeout set for it, the old stop_timeout argument has been renamed to shutdown_timeout, while stop_timeout now refers to the container’s configured stop timeout.

**storage_opt** Storage driver options for the container. Can be either a list of strings in the format `option=value`, or a list of mappings between option and value. The below three examples are equivalent:

---

23.19. state modules
foo:
    docker_container.running:
    - image: bar/baz:latest
    - storage_opt:
        - dm.basesize: 40G

foo:
    docker_container.running:
    - image: bar/baz:latest
    - storage_opt: dm.basesize=40G

sysctls (or sysctl) Set sysctl options for the container. Can be either a list of strings in the format `option=value`, or a list of mappings between option and value. The below three examples are equivalent:

foo:
    docker_container.running:
    - image: bar/baz:latest
    - sysctls:
        - fs.nr_open: 1048576
        - kernel.pid_max: 32768

foo:
    docker_container.running:
    - image: bar/baz:latest
    - sysctls: fs.nr_open=1048576,kernel.pid_max=32768

foo:
    docker_container.running:
    - image: bar/baz:latest
    - sysctls:
        - fs.nr_open=1048576
        - kernel.pid_max=32768

tmpfs A map of container directories which should be replaced by tmpfs mounts and their corresponding mount options.

foo:
    docker_container.running:
    - image: bar/baz:latest
    - tmpfs:
        - /run: rw,noexec,nosuid,size=65536k

tty [False] Attach TTYs

foo:
    docker_container.running:
    - image: bar/baz:latest
    - tty: True

ulimits List of ulimits. These limits should be passed in the format `<ulimit_name>::<soft_limit>::<hard_limit>`, with the hard limit being optional. Can be
expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits: nofile=1024:1024,nproc=60
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits:
      - nofile=1024:1024
      - nproc=60
```

**user** User under which to run exec process

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - user: foo
```

**userns_mode** (or **user_ns_mode**) Sets the user namespace mode, when the user namespace remapping option is enabled

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - userns_mode: host
```

**volumes** (or **volume**) List of directories to expose as volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes: /mnt/vol1,/mnt/vol2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes:
      - /mnt/vol1
      - /mnt/vol2
```

**volumes_from** Container names or IDs from which the container will get volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes_from: foo
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes_from:
      - foo
```

**volume_driver** sets the container's volume driver
foo:
  docker_container.running:
  - image: bar/baz:latest
  - volume_driver: foobar

working_dir (or workdir) Working directory inside the container

foo:
  docker_container.running:
  - image: bar/baz:latest
  - working_dir: /var/log/nginx

salt.states.docker_container.stopped:
(name=Name,  containers=None,  shutdown_timeout=None,  unpause=False,  error_on_absent=True, **kwargs)

Ensure that a container (or containers) is stopped
name Name or ID of the container
containers Run this state on more than one container at a time. The following two examples accomplish the
same thing:

stopped_containers:
  docker_container.stopped:
  - names:
    - foo
    - bar
    - baz

stopped_containers:
  docker_container.stopped:
  - containers:
    - foo
    - bar
    - baz

However, the second example will be a bit quicker since Salt will stop all specified containers in a single
run, rather than executing the state separately on each image (as it would in the first example).

shutdown_timeout Timeout for graceful shutdown of the container. If this timeout is exceeded, the con-
tainer will be killed. If this value is not passed, then the container's configured stop_timeout will
be observed. If stop_timeout was also unset on the container, then a timeout of 10 seconds will be
used.
unpause [False] Set to True to unpause any paused containers before stopping. If unset, then an error will
be raised for any container that was paused.
error_on_absent [True] By default, this state will return an error if any of the specified containers are absent.
Set this to False to suppress that error.

23.19.77 salt.states.docker_image

Management of Docker images
New in version 2017.7.0.

depends docker Python module

Note: Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and
releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using pip.install:
To upgrade from `docker-py` to `docker`, you must first uninstall `docker-py`, and then install `docker`:

```
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the `docker` state module (formerly called `dockerng`) in the 2017.7.0 release.

**Note:** To pull from a Docker registry, authentication must be configured. See [here](#) for more information on how to configure access to docker registries in Pillar data.

---

### `salt.states.docker_image.absent` (`name=None, images=None, force=False`)

Ensure that an image is absent from the Minion. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

- **images** Run this state on more than one image at a time. The following two examples accomplish the same thing:

  - `remove_images:
    docker_image.absent:
    - names:
      - busybox
      - centos:6
      - nginx`

  - `remove_images:
    docker_image.absent:
    - images:
      - busybox
      - centos:6
      - nginx`

However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

- **force** [False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

**Note:** This option can also be overridden by Pillar data. If the Minion has a pillar variable named `docker.running.force` which is set to True, it will turn on this option. This pillar variable can even be set at runtime. For example:

```
salt myminion state.sls docker_stuff pillar="{docker.force: True}"`
```

If this pillar variable is present and set to False, then it will turn off this option.

For more granular control, setting a pillar variable named `docker.force.image_name` will affect only the named image.

### `salt.states.docker_image.mod_watch` (`name, sfun=None, **kwargs`)

The docker_image watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly.
Parameters for this function should be set by the state being triggered.

```python
salt.states.docker_image.present(name, tag=None, build=None, load=None, force=False, insecure_registry=False, client_timeout=60, dockerfile=None, sls=None, base='opensuse/python', saltenv='base', pillar=None, **kwargs)
```

Changed in version 2018.3.0: The `tag` argument has been added. It is now required unless pulling from a registry.

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, loaded from a saved image, or built by running SLS files against a base image.

If none of the `build`, `load`, or `sls` arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless `force` is set to `True`. Here is an example of a state that will pull an image from the Docker Hub:

```yaml
myuser/myimage:
  docker_image.present:
    - tag: mytag
```

tag  Tag name for the image. Required when using `build`, `load`, or `sls` to create the image, but optional if pulling from a repository.

New in version 2018.3.0.

build  Path to directory on the Minion containing a Dockerfile

```yaml
myuser/myimage:
  docker_image.present:
    - build: /home/myuser/docker/myimage
    - tag: mytag
```

The image will be built using `docker.build` and the specified image name and tag will be applied to it.

New in version 2016.11.0.

Changed in version 2018.3.0: The `tag` must be manually specified using the `tag` argument.

load  Loads a tar archive created with `docker.save` (or the `docker save` Docker CLI command), and assigns it the specified repo and tag.

```yaml
myuser/myimage:
  docker_image.present:
    - load: salt://path/to/image.tar
    - tag: mytag
```

Changed in version 2018.3.0: The `tag` must be manually specified using the `tag` argument.

force  [False] Set this parameter to `True` to force Salt to pull/build/load the image even if it is already present.

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response from the API.

dockerfile  Allows for an alternative Dockerfile to be specified. Path to alternative Dockefile is relative to the build path for the Docker container.

New in version 2018.3.0.
Allow for building of image with `docker.sls_build` by specifying the SLS files with which to build. This can be a list or comma-separated string.

```yaml
myuser/myimage:
  docker_image.present:
    - tag: latest
    - sls:
        - webapp1
        - webapp2
    - base: centos
    - saltenv: base
```

New in version 2017.7.0.

Changed in version 2018.3.0: The `tag` must be manually specified using the `tag` argument.

**base** Base image with which to start `docker.sls_build`

New in version 2017.7.0.

**saltenv** Specify the environment from which to retrieve the SLS indicated by the `mods` parameter.

New in version 2017.7.0.

Changed in version 2018.3.0: Now uses the effective saltenv if not explicitly passed. In earlier versions, `base` was assumed as a default.

**pillarenv** Specify a Pillar environment to be used when applying states. This can also be set in the minion config file using the `pillarenv` option. When neither the `pillarenv` minion config option nor this CLI argument is used, all Pillar environments will be merged together.

New in version 2018.3.0.

**pillar** Custom Pillar values, passed as a dictionary of key-value pairs

Note: Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

New in version 2018.3.0.

### 23.19.78 salt.states.docker_network

Management of Docker networks

New in version 2017.7.0.

**depends** docker Python module

Note: Older releases of the Python bindings for Docker were called `docker-py` in PyPI. All releases of `docker`, and releases of `docker-py` >= 1.6.0 are supported. These python bindings can easily be installed using `pip.install`:

```
salt myminion pip.install docker
```

To upgrade from `docker-py` to `docker`, you must first uninstall `docker-py`, and then install `docker`:

```
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the `docker` state module (formerly called `dockerng`) in the 2017.7.0 release.
salt.states.docker_network.absent(name)
    Ensure that a network is absent.
    name  Name of the network
Usage Example:

    network_foo:
      docker_network.absent

salt.states.docker_network.present(name, skip_translate=None, ignore_collisions=False, validate_ip_addrs=True, containers=None, reconnect=True, **kwargs)

Changed in version 2018.3.0: Support added for network configuration options other than driver and driver_opts, as well as IPAM configuration.

Ensure that a network is present

Note: This state supports all arguments for network and IPAM pool configuration which are available for the release of docker-py installed on the minion. For that reason, the arguments described below in the NETWORK CONFIGURATION and IP ADDRESS MANAGEMENT (IPAM) sections may not accurately reflect what is available on the minion. The docker.get_client_args function can be used to check the available arguments for the installed version of docker-py (they are found in the network_config and ipam_config sections of the return data), but Salt will not prevent a user from attempting to use an argument which is unsupported in the release of Docker which is installed. In those cases, network creation be attempted but will fail.

name  Network name
skip_translate  This function translates Salt SLS input into the format which docker-py expects. However, in the event that Salt’s translation logic fails (due to potential changes in the Docker Remote API, or to bugs in the translation code), this argument can be used to exert granular control over which arguments are translated and which are not.

    Pass this argument as a comma-separated list (or Python list) of arguments, and translation for each passed argument name will be skipped. Alternatively, pass True and all translation will be skipped.

    Skipping translation allows for arguments to be formatted directly in the format which docker-py expects. This allows for API changes and other issues to be more easily worked around. See the following links for more information:
    • docker-py Low-level API
    • Docker Engine API
New in version 2018.3.0.

ignore_collisions  [False] Since many of docker-py’s arguments differ in name from their CLI counterparts (with which most Docker users are more familiar), Salt detects usage of these and aliases them to the docker-py version of that argument. However, if both the alias and the docker-py version of the same argument (e.g. options and driver_opts) are used, an error will be raised. Set this argument to True to suppress these errors and keep the docker-py version of the argument.

New in version 2018.3.0.

validate_ip_addrs  [True] For parameters which accept IP addresses/subnets as input, validation will be performed. To disable, set this to False.

New in version 2018.3.0.

containers  A list of containers which should be connected to this network.

Note: As of the 2018.3.0 release, this is not the recommended way of managing a container’s membership in a network, for a couple reasons:
1. It does not support setting static IPs, aliases, or links in the container's IP configuration.
2. If a `docker_container.running` state replaces a container, it will not be reconnected to the network until the `docker_network.present` state is run again. Since containers often have require requisites to ensure that the network is present, this means that the `docker_network.present` state ends up being run before the `docker_container.running`, leaving the container unattached at the end of the Salt run.

For these reasons, it is recommended to use `docker_container.running`'s network management support.

**reconnect** [True] If `containers` is not used, and the network is replaced, then Salt will keep track of the containers which were connected to the network and reconnect them to the network after it is replaced. Salt will first attempt to reconnect using the same IP the container had before the network was replaced. If that fails (for instance, if the network was replaced because the subnet was modified), then the container will be reconnected without an explicit IP address, and its IP will be assigned by Docker.

Set this option to `False` to keep Salt from trying to reconnect containers. This can be useful in some cases when managing static IPs in `docker_container.running`. For instance, if a network's subnet is modified, it is likely that the static IP will need to be updated in the `docker_container.running` state as well. When the network is replaced, the initial reconnect attempt would fail, and the container would be reconnected with an automatically-assigned IP address. Then, when the `docker_container.running` state executes, it would disconnect the network again and reconnect using the new static IP. Disabling the reconnect behavior in these cases would prevent the unnecessary extra reconnection.

New in version 2018.3.0.

**NETWORK CONFIGURATION ARGUMENTS**

**driver** Network driver

```yaml
mynet:
  docker_network.present:
    - driver: macvlan
```

**driver_opts (or driver_opt, or options)** Options for the network driver. Either a dictionary of option names and values or a Python list of strings in the format `varname=value`. The below three examples are equivalent:

```yaml
mynet:
  docker_network.present:
    - driver: macvlan
    - driver_opts: macvlan_mode=bridge,parent=eth0

mynet:
  docker_network.present:
    - driver: macvlan
    - driver_opts:
      - macvlan_mode=bridge
      - parent=eth0

mynet:
  docker_network.present:
    - driver: macvlan
    - driver_opts:
      - macvlan_mode: bridge
    - parent: eth0
```

The options can also simply be passed as a dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:
### mynet:
```yaml
  docker_network.present:  
    - driver: macvlan  
    - driver_opts:     
      macvlan_mode: bridge  
      parent: eth0  
```

**check_duplicate**  [True] If True, checks for networks with duplicate names. Since networks are primarily keyed based on a random ID and not on the name, and network name is strictly a user-friendly alias to the network which is uniquely identified using ID, there is no guaranteed way to check for duplicates. This option provides a best effort, checking for any networks which have the same name, but it is not guaranteed to catch all name collisions.

```yaml
mynet:  
  docker_network.present:  
    - check_duplicate: False  
```

**internal**  [False] If True, restricts external access to the network

```yaml
mynet:  
  docker_network.present:  
    - internal: True  
```

**labels**  Add metadata to the network. Labels can be set both with and without values, and labels with values can be passed either as `key=value` or `key: value` pairs. For example, while the below would be very confusing to read, it is technically valid, and demonstrates the different ways in which labels can be passed:

```yaml
mynet:  
  docker_network.present:  
    - labels:     
      - foo     
      - bar=baz  
      - hello: world  
```

The labels can also simply be passed as a YAML dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```yaml
foo:  
  docker_network.present:  
    - labels:     
      foo: 。 。  
      bar: baz  
      hello: world  
```

Changed in version 2018.3.0: Methods for specifying labels can now be mixed. Earlier releases required either labels with or without values.

**enable_ipv6 (or ipv6)**  [False] Enable IPv6 on the network

```yaml
mynet:  
  docker_network.present:  
    - enable_ipv6: True  
```

**Note:** While it should go without saying, this argument must be set to True to configure an IPv6 subnet. Also, if this option is turned on without an IPv6 subnet explicitly configured, you will get an error unless you have set up a fixed IPv6 subnet. Consult the Docker IPv6 docs for information on how to do this.
**attachable** [False] If True, and the network is in the global scope, non-service containers on worker nodes will be able to connect to the network.

```yaml
mynet:
  docker_network.present:
    - attachable: True
```

**Note:** This option cannot be reliably managed on CentOS 7. This is because while support for this option was added in API version 1.24, its value was not added to the inspect results until API version 1.26. The version of Docker which is available for CentOS 7 runs API version 1.24, meaning that while Salt can pass this argument to the API, it has no way of knowing the value of this config option in an existing Docker network.

**scope** Specify the network's scope (local, global or swarm)

```yaml
mynet:
  docker_network.present:
    - scope: local
```

**ingress** [False] If True, create an ingress network which provides the routing-mesh in swarm mode

```yaml
mynet:
  docker_network.present:
    - ingress: True
```

### IP ADDRESS MANAGEMENT (IPAM)

This state supports networks with either IPv4, or both IPv4 and IPv6. If configuring IPv4, then you can pass the IPAM pool arguments below as individual arguments. However, if configuring IPv4 and IPv6, the arguments must be passed as a list of dictionaries, in the ipam_pools argument (click here for some examples). These docs also have more information on these arguments.

#### IPAM ARGUMENTS

**ipam_driver** IPAM driver to use, if different from the default one

```yaml
mynet:
  docker_network.present:
    - ipam_driver: foo
```

**ipam_opts** Options for the IPAM driver. Either a dictionary of option names and values or a Python list of strings in the format `varname=value`. The below three examples are equivalent:

```yaml
mynet:
  docker_network.present:
    - ipam_driver: foo
    - ipam_opts: foo=bar,baz=qux
```

```yaml
mynet:
  docker_network.present:
    - ipam_driver: foo
    - ipam_opts: - foo=bar
    - baz=qux
```

```yaml
mynet:
  docker_network.present:
    - ipam_driver: foo
    - ipam_driver: foo
```

(continues on next page)
The options can also simply be passed as a dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```
mynet:
  docker_network.present:
    - ipam_driver: macvlan
    - ipam_opts:
      foo: bar
      baz: qux
```

### IPAM POOL ARGUMENTS

- **subnet** Subnet in CIDR format that represents a network segment
- **iprange (or ip_range)** Allocate container IP from a sub-range within the subnet

Subnet in CIDR format that represents a network segment

- **gateway** IPv4 or IPv6 gateway for the master subnet
- **aux_addresses (or aux_address)** A dictionary of mapping container names to IP addresses which should be allocated for them should they connect to the network. Either a dictionary of option names and values or a Python list of strings in the format `host=ipaddr`.

### IPAM CONFIGURATION EXAMPLES

Below is an example of an IPv4-only network (keep in mind that `subnet` is the only required argument).

```
mynet:
  docker_network.present:
    - subnet: 10.0.20.0/24
    - iprange: 10.0.20.128/25
    - gateway: 10.0.20.254
    - aux_addresses:
      foo.bar.tld: 10.0.20.50
      hello.world.tld: 10.0.20.51
```

**Note:** The `aux_addresses` can be passed differently, in the same way that `driver_opts` and `ipam_opts` can.

This same network could also be configured this way:

```
mynet:
  docker_network.present:
    - ipam_pools:
      - subnet: 10.0.20.0/24
      iprange: 10.0.20.128/25
      gateway: 10.0.20.254
      aux_addresses:
        foo.bar.tld: 10.0.20.50
        hello.world.tld: 10.0.20.51
```

Here is an example of a mixed IPv4/IPv6 subnet.

```
mynet:
  docker_network.present:
```

(continues on next page)
- **ipam_pools**:
  - **subnet**: 10.0.20.0/24
    - **gateway**: 10.0.20.1
  - **subnet**: fe3f:2180:26:1::/123
    - **gateway**: fe3f:2180:26:1::1

### 23.19.79 salt.states.docker_volume

Management of Docker volumes

New in version 2017.7.0.

```python
deps depend docker Python module
```

**Note:** Older releases of the Python bindings for Docker were called `docker-py` in PyPI. All releases of `docker`, and releases of `docker-py` >= 1.6.0 are supported. These python bindings can easily be installed using `pip`:

```bash
salt myminion pip.install docker
```

To upgrade from `docker-py` to `docker`, you must first uninstall `docker-py`, and then install `docker`:

```bash
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the `docker` state module (formerly called `dockerng`) in the 2017.7.0 release.

**salt.states.docker_volume.absent**(name, driver=``None``)

Ensure that a volume is absent.

New in version 2015.8.4.

Changed in version 2017.7.0: This state was renamed from `docker.volume_absent` to `docker_volume.absent`

*name* Name of the volume

Usage Examples:

```yaml
volume_foo:
  docker_volume.absent
```

**salt.states.docker_volume.present**(name, driver=``None``, driver_opts=``None``, force=``False``)

Ensure that a volume is present.

New in version 2015.8.4.

Changed in version 2015.8.6: This state no longer deletes and re-creates a volume if the existing volume's driver does not match the `driver` parameter (unless the `force` parameter is set to `True`).

Changed in version 2017.7.0: This state was renamed from `docker.volume_present` to `docker_volume.present`

*name* Name of the volume

*driver* Type of driver for that volume. If `None` and the volume does not yet exist, the volume will be created using Docker's default driver. If `None` and the volume does exist, this function does nothing, even if the existing volume's driver is not the Docker default driver. (To ensure that an existing volume's driver matches the Docker default, you must explicitly name Docker's default driver here.)

*driver_opts* Options for the volume driver
force [False] If the volume already exists but the existing volume’s driver does not match the driver specified by the driver parameter, this parameter controls whether the function errors out (if False) or deletes and re-creates the volume (if True).

Usage Examples:

```yaml
volume_foo:
  docker_volume.present

volume_bar:
  docker_volume.present
  - name: bar
  - driver: local
  - driver_opts:
    foo: bar

volume_bar:
  docker_volume.present
  - name: bar
  - driver: local
  - driver_opts:
    foo: bar
    option: value
```

### 23.19.80 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```yaml
damian:
  drac.present:
    - name: damian
    - password: secret
    - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```yaml
damian:
  drac.absent:
    - name: damian
```

Ensure DRAC network is in a consistent state

```yaml
my_network:
  drac.network:
    - ip: 10.225.108.29
    - netmask: 255.255.255.224
    - gateway: 10.225.108.1
```

**salt.states.drac.absent(name)**

Ensure a user does not exist on the Dell DRAC

name: The users username
salt.states.drac.network(ip, netmask, gateway)
Ensure the DRAC network settings are consistent

salt.states.drac.present(name, password, permission)
Ensure the user exists on the Dell DRAC
name: The users username
password: The password used to authenticate
permission: The permissions that should be assigned to a user

23.19.81 salt.states.dvs

Manage VMware distributed virtual switches (DVSs) and their distributed virtual portgroups (DVportgroups).

codeauthor Alexandru Bleotu <alexandru.bleotu@morganstaley.com>

Examples

Several settings can be changed for DVSs and DVportgroups. Here are two examples covering all of the settings. Fewer settings can be used

DVS

```
'name': 'dvs1',
'max_mtu': 1000,
'uplink_names': [
  'dvUplink1',
  'dvUplink2',
  'dvUplink3'
],
'capability': {
  'portgroup_operation_supported': false,
  'operation_supported': true,
  'port_operation_supported': false
},
'lacp_api_version': 'multipleLag',
'contact_email': 'foo@email.com',
'product_info': {
  'version': '6.0.0',
  'vendor': 'VMware, Inc.',
  'name': 'DVS'
},
'network_resource_management_enabled': true,
'contact_name': 'me@email.com',
'infrastructure_traffic_resource_pools': [
  {
    'reservation': 0,
    'limit': 1000,
    'share_level': 'high',
    'key': 'management',
    'num_shares': 100
  }
]```

(continues on next page)
},
{
    'reservation': 0,
    'limit': -1,
    'share_level': 'normal',
    'key': 'faultTolerance',
    'num_shares': 50
},
{
    'reservation': 0,
    'limit': 32000,
    'share_level': 'normal',
    'key': 'vmotion',
    'num_shares': 50
},
{
    'reservation': 10000,
    'limit': -1,
    'share_level': 'normal',
    'key': 'virtualMachine',
    'num_shares': 50
},
{
    'reservation': 0,
    'limit': -1,
    'share_level': 'custom',
    'key': 'iscsi',
    'num_shares': 75
},
{
    'reservation': 0,
    'limit': -1,
    'share_level': 'normal',
    'key': 'nfs',
    'num_shares': 50
},
{
    'reservation': 0,
    'limit': -1,
    'share_level': 'normal',
    'key': 'hbr',
    'num_shares': 50
},
{
    'reservation': 8750,
    'limit': 15000,
    'share_level': 'high',
    'key': 'vsan',
    'num_shares': 100
},
{
    'reservation': 0,
    'limit': -1,
    'share_level': 'normal',
    'key': 'vdp',
    'num_shares': 50
}(continues on next page)
Note: The mandatory attribute is: name.

Portgroup

```
'security_policy': {
    'allow_promiscuous': true,
    'mac_changes': false,
    'forged_transmits': true
},
'name': 'vmotion-v702',
'out_shaping': {
    'enabled': true,
    'average_bandwidth': 1500,
    'burst_size': 4096,
    'peak_bandwidth': 1500
},
'num_ports': 128,
'teaming': {
    'port_order': {
        'active': [
            'dvUplink2'
        ],
        'standby': [
            'dvUplink1'
        ]
    },
    'notify_switches': false,
    'reverse_policy': true,
    'rolling_order': false,
    'policy': 'failover_explicit',
    'failure_criteria': {
        'check_error_percent': true,
        'full_duplex': false,
        'check_duplex': false,
        'percentage': 50,
        'check_speed': 'minimum',
        'speed': 20,
        'check_beacon': true
    }
},
'type': 'earlyBinding',
'vlan_id': 100,
'description': 'Managed by Salt. Random settings.'
```

Note: The mandatory attributes are: name, type.
Dependencies

- pyVmomi Python Module

**pyVmomi**

PyVmomi can be installed via pip:

```bash
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```bash
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**salt.states.dvs.dvs_configured(name, dvs)**

Creates a DVS. Creates a new DVS, if it doesn't exist in the provided datacenter or reconfigures it if configured differently.

dvs DVS dict representations (see module sysdocs)

**salt.states.dvs.portgroups_configured(name, dvs, portgroups)**

Configures portgroups on a DVS.

Creates/updates/removes portgroups in a provided DVS

**salt.states.dvs.uplink_portgroup_configured(name, dvs, uplink_portgroup)**

Configures the uplink portgroup on a DVS. The state assumes there is only one uplink portgroup.

**salt.states.elasticsearch.alias_absent(name, index)**

Ensure that the index alias is absent.

**salt.states.elasticsearch.alias_present(name, index, definition=None)**

Ensure that the named index alias is present.

Example:

```
mytestalias:
  elasticsearch.alias_present:
    - index: testindex
    - definition:
      filter:
        term:
          user: kimchy
```

salt.states.elasticsearch.index_absent(name)
Ensure that the named index is absent.
name Name of the index to remove

salt.states.elasticsearch.index_present(name, definition=None)
Ensure that the named index is present.
name Name of the index to add
definition Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html

Example:

```
# Default settings
mytestindex:
  elasticsearch_index.present

# Extra settings
mytestindex2:
  elasticsearch_index.present:
    - definition:
      settings:
        index:
          number_of_shards: 10
```

salt.states.elasticsearch.index_template_absent(name)
Ensure that the named index template is absent.
name Name of the index to remove

salt.states.elasticsearch.index_template_present(name, definition, check_definition=False)
Ensure that the named index template is present.
name Name of the index to add
definition Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-templates.html
check_definition If the template already exists and the definition is up to date

Example:

```
mytestindex2_template:
  elasticsearch.index_template_present:
    - definition:
      template: logstash-*
      order: 1
      settings:
        number_of_shards: 1
```

salt.states.elasticsearch.pipeline_absent(name)
Ensure that the named pipeline is absent
name Name of the pipeline to remove

salt.states.elasticsearch.pipeline_present(name, definition)
Ensure that the named pipeline is present.
name Name of the index to add
definition Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/master/pipeline.html
Example:

```yaml
test_pipeline:
  elasticsearch.pipeline_present:
    - definition:
        description: example pipeline
        processors:
          - set:
              field: collector_timestamp_millis
              value: '[[ '{{' _ingest.timestamp{{' }} '}}' ]]
```

salt.states.elasticsearch.search_template_absent(name)
Ensure that the search template is absent
name Name of the search template to remove

salt.states.elasticsearch.search_template_present(name, definition)
Ensure that the named search template is present.
name Name of the search template to add
definition Required dict for creation parameters as per http://www.elastic.co/guide/en/elasticsearch/reference/current/search-template.html
Example:

```yaml
test_pipeline:
  elasticsearch.search_template_present:
    - definition:
        inline:
          size: 10
```

23.19.83 salt.states.elasticsearch_index

State module to manage Elasticsearch indices

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use elasticsearch state instead

salt.states.elasticsearch_index.absent(name)
Ensure that the named index is absent.
name Name of the index to remove

salt.states.elasticsearch_index.present(name, definition=None)
New in version 2015.8.0.
Changed in version 2017.3.0: Marked definition as optional.
Ensure that the named index is present.
name Name of the index to add
definition Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html
Example:
# Default settings
mytestindex:
  elasticsearch_index.present

# Extra settings
mytestindex2:
  elasticsearch_index.present:
    - definition:
      settings:
        index:
          number_of_shards: 10

## 23.19.84 salt.states.elasticsearch_index_template

State module to manage Elasticsearch index templates

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use elasticsearch state instead

salt.states.elasticsearch_index_template.absent(name)

 Ensure that the named index template is absent.

 name Name of the index to remove

salt.states.elasticsearch_index_template.present(name, definition)

 New in version 2015.8.0.

 Changed in version 2017.3.0: Marked definition as required.

 Ensure that the named index template is present.

 name Name of the index to add

 definition Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-templates.html

 Example:

mytestindex2_template:
  elasticsearch_index_template.present:
    - definition:
      template: logstash-**
      order: 1
      settings:
        number_of_shards: 1

## 23.19.85 salt.states.environ

Support for getting and setting the environment variables of the current salt process.

salt.states.environ.setenv(name, value, false_unsets=False, clear_all=False, update_minion=False, permanent=False)

 Set the salt process environment variables.

 name The environment key to set. Must be a string.

 value Either a string or dict. When string, it will be the value set for the environment key of ‘name’ above. When a dict, each key/value pair represents an environment variable to set.

 false_unsets If a key’s value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key’s value is False and false_unsets is not True, then the key’s value will be set to an empty string. Default: False
clear_all USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

update_minion If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

permanent On Windows minions this will set the environment variable in the registry so that it is always added as a environment variable when applications open. If you want to set the variable to HKLM instead of HKCU just pass in "HKLM" for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.

Example:

```python
a_string_env:
  environ.setenv:
    - name: foo
    - value: bar
    - update_minion: True

a_dict_env:
  environ.setenv:
    - name: does_not_matter
    - value:
      foo: bar
      baz: quux
```

### salt.states.eselect

Management of Gentoo configuration using eselect

A state module to manage Gentoo configuration via eselect

salt.states.eselect.set_(name, target, module_parameter=None, action_parameter=None)

Verify that the given module is set to the given target

- **name** The name of the module
- **target** The target to be set for this module
- **module_parameter** additional params passed to the defined module
- **action_parameter** additional params passed to the defined action

Example:

```python
profile:
  eselect.set:
    - target: hardened/linux/amd64
```
23.19.87 salt.states.esxcluster

Manage VMware ESXi Clusters.

Dependencies

- pyVmomi Python Module

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

salt.states.esxcluster.cluster_configured(name, cluster_config)

Configures a cluster. Creates a new cluster, if it doesn’t exist on the vCenter or reconfigures it if configured differently

Supported proxies: esxdatacenter, esxcluster

- **name** Name of the state. If the state is run in by an esxdatacenter proxy, it will be the name of the cluster.
- **cluster_config** Configuration applied to the cluster. Complex datastructure following the ESXClusterConfigSchema. Valid example is:

```
drs:
    default_vm_behavior: fullyAutomated
    enabled: true
    vmotion_rate: 3
ha:
    admission_control
    _enabled: false
    default_vm_settings:
        isolation_response: powerOff
        restart_priority: medium
    enabled: true
    hb_ds_candidate_policy: userSelectedDs
    host_monitoring: enabled
    options:
        - key: das.ignoreinsufficientbdatastore
          value: 'true'
    vm_monitoring: vmMonitoringDisabled
    vm_swap_placement: vmDirectory
```

(continues on next page)
vsan:
  auto_claim_storage: false
  compression_enabled: true
  dedup_enabled: true
  enabled: true

salt.states.esxcluster.licenses_configured(name, licenses=None)
  Configures licenses on the cluster entity
  Checks if each license exists on the server:
  • if it doesn't, it creates it
  Check if license is assigned to the cluster:
  • if it's not assigned to the cluster:
    – assign it to the cluster if there is space
    – error if there's no space
  • if it's assigned to the cluster nothing needs to be done

salt.states.esxcluster.vsan_datastore_configured(name, datastore_name)
  Configures the cluster's VSAN datastore
  WARNING: The VSAN datastore is created automatically after the first ESXi host is added to the cluster; the state assumes that the datastore exists and errors if it doesn't.

23.19.88 salt.states.esxdatacenter

Salt states to create and manage VMware vSphere datacenters (datacenters).
  
  codeauthor Alexandru Bleotu <alexandru.bleotu@morganstaley.com>

Dependencies

• pyVmomi Python Module

States

datacenter_configured

Makes sure a datacenter exists and is correctly configured.

If the state is run by an esxdatacenter minion, the name of the datacenter is retrieved from the proxy details, otherwise the datacenter has the same name as the state.

Supported proxies: esxdatacenter

Example:

1. Make sure that a datacenter named target_dc exists on the vCenter, using a esxdatacenter proxy:

Proxy minion configuration (connects passthrough to the vCenter):

    proxy:
      proxitype: esxdatacenter
datacenter: target_dc
vcenter: vcenter.fake.com
mechanism: sspi

(continues on next page)
State configuration:

```
domain: fake.com
principal: host
```

salt.states.esxdatacenter.datacenter_configured(name)

Makes sure a datacenter exists.

If the state is run by an esxdatacenter minion, the name of the datacenter is retrieved from the proxy details, otherwise the datacenter has the same name as the state.

Supported proxies: esxdatacenter

name: Datacenter name. Ignored if the proxytype is esxdatacenter.

23.19.89 salt.states.esxi

Manage VMware ESXi Hosts.

New in version 2015.8.4.

Dependencies

- pyVmomi Python Module
- ESXCLI

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.
ESXCLI

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host’s syslog configuration.

**Note:** Be aware that some functionality in this state module may depend on the type of license attached to the ESXi host.

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The `ntpd` service is restricted to an Enterprise Plus license, while `ssh` is available via the Standard license.

Please see the [vSphere Comparison](#) page for more information.

About

This state module was written to be used in conjunction with Salt’s ESXi *Proxy Minion*. For a tutorial on how to use Salt’s ESXi Proxy Minion, please refer to the [ESXi Proxy Minion Tutorial](#) for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

`salt.states.esxi.coredump_configured(name, enabled, dump_ip, host_vnic='vmk0', dump_port=6500)`

Ensures a host’s core dump configuration.

- **name** Name of the state.
- **enabled** Sets whether or not ESXi core dump collection should be enabled. This is a boolean value set to `True` or `False` to enable or disable core dumps.
  
  Note that ESXi requires that the core dump must be enabled before any other parameters may be set. This also affects the `changes` results in the state return dictionary. If `enabled` is `False`, we can’t obtain any previous settings to compare other state variables, resulting in many old references returning `None`.

  Once `enabled` is `True` the `changes` dictionary comparisons will be more accurate. This is due to the way the system coredump network configuration command returns data.

- **dump_ip** The IP address of host that will accept the dump.
- **host_vnic** Host VNic port through which to communicate. Defaults to `vmk0`.
- **dump_port** TCP port to use for the dump. Defaults to `6500`.

Example:

```
configure-host-coredump:
  esxi.coredump_configured:
    - enabled: True
    - dump_ip: 'my-coredump-ip.example.com'
```
salt.states.esxi.diskgroups_configured(name, diskgroups, erase_disks=False)

Configures the disk groups to use for vsan.

This function will do the following:
1. Check whether or not all disks in the diskgroup spec exist, and raises and errors if they do not.
2. Create diskgroups with the correct disk configurations if diskgroup (identified by the cache disk canonical name) doesn't exist
3. Adds extra capacity disks to the existing diskgroup

Example:

```yaml
{
    'cache_scsi_addr': 'vmhba1:C0:T0:L0',
    'capacity_scsi_addrs': [
        'vmhba2:C0:T0:L0',
        'vmhba3:C0:T0:L0',
        'vmhba4:C0:T0:L0',
    ]
}
```

**name**  Mandatory state name

**diskgroups**  Disk group representation containing scsi disk addresses. Scsi addresses are expected for disks in the diskgroup:

**erase_disks**  Specifies whether to erase all partitions on all disks member of the disk group before the disk group is created. Default value is False.

salt.states.esxi.host_cache_configured(name, enabled, datastore, swap_size='100%',
                                         dedicated_backing_disk=False,
                                         erase_backing_disk=False)

Configures the host cache used for swapping.

It will do the following:
1. Checks if backing disk exists
2. Creates the VMFS datastore if doesn't exist (datastore partition will be created and use the entire disk)
3. Raises an error if dedicated_backing_disk is True and partitions already exist on the backing disk
4. Configures host_cache to use a portion of the datastore for caching (either a specific size or a percentage of the datastore)

Examples

**Percentage swap size (can't be 100%)**

```yaml
{
    'enabled': true,
    'datastore': {
        'backing_disk_scsi_addr': 'vmhba0:C0:T0:L0',
        'vmfs_version': 5,
        'name': 'hostcache'
    }
    'dedicated_backing_disk': false
    'swap_size': '98%',
}
```

**Fixed sized swap size**

```yaml
{
    'enabled': true,
    'datastore': {
        'backing_disk_scsi_addr': 'vmhba0:C0:T0:L0',
    }
    'dedicated_backing_disk': true
    'swap_size': '100%',
    'name': 'hostcache'
}
```
'vmfs_version': 5,
'name': 'hostcache'
}
'dedicated_backing_disk': true
'swap_size': '10GiB',
}

name  Mandatory state name.
enabled Specifies whether the host cache is enabled.
datastore Specifies the host cache datastore.
swap_size Specifies the size of the host cache swap. Can be a percentage or a value in GiB. Default value is 100%.
dedicated_backing_disk Specifies whether the backing disk is dedicated to the host cache which means it must have no other partitions. Default is False.
erase_backing_disk Specifies whether to erase all partitions on the backing disk before the datastore is created. Default value is False.

salt.states.esxi.ntp_configured(name, service_running, ntp_servers=None, service_policy=None, service_restart=False, update_datetime=False)
Ensures a host's NTP server configuration such as setting NTP servers, ensuring the NTP daemon is running or stopped, or restarting the NTP daemon for the ESXi host.

name  Name of the state.
service_running Ensures the running state of the ntp daemon for the host. Boolean value where True indicates that ntpd should be running and False indicates that it should be stopped.
ntp_servers A list of servers that should be added to the ESXi host's NTP configuration.
service_policy The policy to set for the NTP service.

Note: When setting the service policy to off or on, you must quote the setting. If you don't, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

service_restart If set to True, the ntp daemon will be restarted, regardless of its previous running state. Default is False.
update_datetime If set to True, the date/time on the given host will be updated to UTC. Default setting is False. This option should be used with caution since network delays and execution delays can result in time skews.

Example:

```
configure-host-ntp:
esxi.ntp_configured:
  - service_running: True
  - ntp_servers:
    - 192.174.1.100
    - 192.174.1.200
  - service_policy: 'on'
  - service_restart: True
```

salt.states.esxi.password_present(name, password)
Ensures the given password is set on the ESXi host. Passwords cannot be obtained from host, so if a password is set in this state, the vsphere.update_host_password function will always run (except when using test=True functionality) and the state's changes dictionary will always be populated.

The username for which the password will change is the same username that is used to authenticate against the ESXi host via the Proxy Minion. For example, if the pillar definition for the proxy username is defined as root, then the username that the password will be updated for via this state is root.

3658 Chapter 23. Salt Module Reference
name Name of the state.

password The new password to change on the host.

Example:

```yaml
configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'
```

salt.states.esxi.ssh_configured(name, service_running, ssh_key=None, ssh_key_file=None, service_policy=None, service_restart=False, certificate_verify=None)

Manage the SSH configuration for a host including whether or not SSH is running or the presence of a given SSH key. Note: Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

name Name of the state.

service_running Ensures whether or not the SSH service should be running on a host. Represented as a boolean value where True indicates that SSH should be running and False indicates that SSH should stopped.

In order to update SSH keys, the SSH service must be running.

ssh_key Public SSH key to added to the authorized_keys file on the ESXi host. You can use ssh_key or ssh_key_file, but not both.

ssh_key_file File containing the public SSH key to be added to the authorized_keys file on the ESXi host. You can use ssh_key_file or ssh_key, but not both.

service_policy The policy to set for the NTP service.

Note: When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

service_restart If set to True, the SSH service will be restarted, regardless of its previous running state. Default is False.

certificate_verify If set to True, the SSL connection must present a valid certificate. Default is True.

Example:

```yaml
configure-host-ssh:
  esxi.ssh_configured:
    - service_running: True
    - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
    - service_policy: 'on'
    - service_restart: True
    - certificate_verify: True
```

salt.states.esxi.syslog_configured(name, syslog_configs, firewall=True, reset_service=True, reset_syslog_config=False, reset_configs=None)

Ensures the specified syslog configuration parameters. By default, this state will reset the syslog service after any new or changed parameters are set successfully.

name Name of the state.

syslog_configs Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--) )

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size, and default-timeout.

Each syslog_config option also needs a configuration value to set. For example, loghost requires URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas.
firewall  Enable the firewall rule set for syslog. Defaults to True.
reset_service  After a successful parameter set, reset the service. Defaults to True.
reset_syslog_config  Resets the syslog service to its default settings. Defaults to False. If set to True, default settings defined by the list of syslog configs in reset_configs will be reset before running any other syslog settings.
reset_configs  A comma-delimited list of parameters to reset. Only runs if reset_syslog_config is set to True. If reset_syslog_config is set to True, but no syslog configs are listed in reset_configs, then reset_configs will be set to all by default.

See syslog_configs parameter above for a list of valid options.

Example:

```
configure-host-syslog:
esxi.syslog_configured:
  - syslog_configs:
    default-timeout: 120
    firewall: True
    reset_service: True
    reset_syslog_config: True
    reset_configs: loghost,default-timeout
```

salt.states.esxi.vmotion_configured(name, enabled, device=’vmk0’)
Configures a host’s VMotion properties such as enabling VMotion and setting the device VirtualNic that VMotion will use.

name  Name of the state.
enabled  Ensures whether or not VMotion should be enabled on a host as a boolean value where True indicates that VMotion should be enabled and False indicates that VMotion should be disabled.
device  The device that uniquely identifies the VirtualNic that will be used for VMotion for the host. Defaults to vmk0.

Example:

```
configure-vmotion:
esxi.vmotion_configured:
  - enabled: True
  - device: sample-device
```

salt.states.esxi.vsan_configured(name, enabled, add_disks_to_vsan=False)
Configures a host’s VSAN properties such as enabling or disabling VSAN, or adding VSAN-eligible disks to the VSAN system for the host.

name  Name of the state.
enabled  Ensures whether or not VSAN should be enabled on a host as a boolean value where True indicates that VSAN should be enabled and False indicates that VSAN should be disabled.
add_disks_to_vsan  If set to True, any VSAN-eligible disks for the given host will be added to the host’s VSAN system. Default is False.

Example:

```
configure-host-vsan:
esxi.vsan_configured:
  - enabled: True
  - add_disks_to_vsan: True
```
23.19.90 salt.states.esxvm

Salt state to create, update VMware ESXi Virtual Machines.

Dependencies

- pyVmomi
- jsonschema

States

vm_configured

Enforces correct virtual machine configuration. Creates, updates and registers a virtual machine.

This state identifies the action which should be taken for the virtual machine and applies that action via the create, update, register state functions.

Supported proxies: esxvm

Example:

1. Get the virtual machine my_vm status with an esxvm proxy:

Proxy minion configuration for esxvm proxy:

```yaml
proxy:
  proxitype: esxvm
  datacenter: my_dc
  vcenter: vcenter.fake.com
  mechanism: sspi
  domain: fake.com
  principal: host
```

State configuration:

```yaml
myvm_state:
  esxvm.vm_configured:
    - vm_name: my_vm
    - cpu: {{ {'count': 4, 'cores_per_socket': 2} }}
    - memory: {{ {'size': 16384, 'unit': 'MB'} }}
    - image: rhel7_64Guest
    - version: vmx-12
    - interfaces: {{ {}:
        'adapter': 'Network adapter 1',
        'name': 'my_pg1',
        'switch_type': 'distributed',
        'adapter_type': 'vmxnet3',
        'mac': '00:50:56:00:01:02',
        'connectable': { 'start_connected': true, 'allow_guest_control': true, 'connected': true},
        { 'adapter': 'Network adapter 2',
          'name': 'my_pg2',
          'switch_type': 'distributed',
```

(continues on next page)
adapter_type': 'vmxnet3',
'mac': '00:50:56:00:01:03',
'connectable': { 'start_connected': true,
  'allow_guest_control': true,
  'connected': true}}}

- disks: {{ [ {
  'adapter': 'Hard disk 1',
  'unit': 'MB',
  'size': 51200,
  'filename': 'my_vm/sda.vmdk',
  'datastore': 'my_datastore',
  'address': '0:0',
  'thin_provision': true,
  'eagerly_scrub': false,
  'controller': 'SCSI controller 0'},
  { 'adapter': 'Hard disk 2',
    'unit': 'MB',
    'size': 10240,
    'filename': 'my_vm/sdb.vmdk',
    'datastore': 'my_datastore',
    'address': '0:1',
    'thin_provision': true,
    'eagerly_scrub': false,
    'controller': 'SCSI controller 0'}
]
- scsi_devices: {{ [ {
  'adapter': 'SCSI controller 0',
  'type': 'paravirtual',
  'bus_sharing': 'no_sharing',
  'bus_number': 0}
]
- serial_ports: {{ [ {
  'adapter': 'Serial port 1',
  'type': 'network',
  'yield': false,
  'backing': {
    'uri': 'my_uri',
    'direction': 'server',
    'filename': 'my_file'},
  'connectable': {
    'start_connected': true,
    'allow_guest_control': true,
    'connected': true}}
]
- datacenter: {{ 'my_dc' }}
- datastore: 'my_datastore'
- placement: {{ {'cluster': 'my_cluster'} }}
- cd_dvd_drives: {{ [] }}
- advanced_configs: {{ {'my_param': '1'}}
- template: false
- tools: false
- power_on: false
- deploy: false
vm_updated

Updates a virtual machine to a given configuration.

vm_created

Creates a virtual machine with a given configuration.

vm_registered

Registers a virtual machine with its configuration file path.

Dependencies

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==6.0.0.2016.4
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against. To be able to connect through SSPI you must use pyvmomi 6.0.0.2016.4 or above. The ESXVM State Module was tested with this version.

About

This state module was written to be used in conjunction with Salt's ESXi Proxy Minion. For a tutorial on how to use Salt's ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

```
salt.states.esxvm.vm_cloned(name)
```

Clones a virtual machine from a template virtual machine if it doesn't exist and a template is defined.

```
salt.states.esxvm.vm_configured(name, vm_name, cpu, memory, image, version, interfaces, disks, scsi_devices, serial_ports, datacenter, datastore, placement, cd_dvd_drives=None, sata_controllers=None, advanced_configs=None, template=None, tools=True, power_on=False, deploy=False)
```

Selects the correct operation to be executed on a virtual machine, non-existing machines will be created,
existing ones will be updated if the config differs.

```python
class salt.states.esxvm.vm_created:
    def __init__(self, name, vm_name, cpu, memory, image, version, interfaces, disks, scsi_devices, serial_ports, datacenter, datastore, placement, ide_controllers=None, sata_controllers=None, cd_dvd_drives=None, advanced_configs=None, power_on=False):
        # Create a virtual machine with the given properties if it doesn't exist.
```

```python
class salt.states.esxvm.vm_registered:
    def __init__(self, vm_name, datacenter, placement, vm_file, power_on=False):
        # Registers a virtual machine if the machine files are available on the main datastore.
```

```python
class salt.states.esxvm.vm_updated:
    def __init__(self, name, vm_name, cpu, memory, image, version, interfaces, disks, scsi_devices, serial_ports, datacenter, datastore, ide_controllers=None, sata_controllers=None, cd_dvd_drives=None, advanced_configs=None, power_on=False):
        # Updates a virtual machine configuration if there is a difference between the given and deployed configuration.
```

### 23.19.91 salt.states.etcd_mod

**Manage etcd Keys**

New in version 2015.8.0.

```text
depends
- python-etcd
```

This state module supports setting and removing keys from etcd.

**Configuration**

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```ini
my_etcd_config:
etcd.host: 127.0.0.1
etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```ini
etcd.host: 127.0.0.1
etcd.port: 4001
```

**Note:** The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

Etcd profile configuration can be overridden using following arguments: `host`, `port`, `username`, `password`, `ca`, `client_key` and `client_cert`.

```ini
my-value:
etcd.set:
- name: /path/to/key
```

(continues on next page)
Available Functions

- **set**
  This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

```yaml
/foo/bar/baz:
  etcd.set:
    - value: foo
      - profile: my_etcd_config
```

- **wait_set**
  Performs the same functionality as `set` but only if a watch requisite is True.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_set:
    - value: foo
      - profile: my_etcd_config
      - watch:
        - file: /some/file.txt
```

- **rm**
  This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

```yaml
/foo/bar/baz:
  etcd.rm:
    - profile: my_etcd_config
```

- **wait_rm**
  Performs the same functionality as `rm` but only if a watch requisite is True.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```
salt.states.etcd_mod.directory(name, profile=None, **kwargs)
Create a directory in etcd.

- **name**: The etcd directory name, for example: /foo/bar/baz.
- **profile**: Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```yaml
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

salt.states.etcd_mod.mod_watch(name, **kwargs)
The etcd watcher, called to invoke the watch command. When called, execute a etcd function based on a watch call requisite.

**Note**: This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.etcd_mod.rm(name, recurse=False, profile=None, **kwargs)
Deletes a key from etcd

- **name**: The etcd key name to remove, for example /foo/bar/baz.
- **recurse**: Optional, defaults to False. If True performs a recursive delete.
- **profile**: Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```yaml
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

salt.states.etcd_mod.set_(name, value, profile=None, **kwargs)
Set a key in etcd

- **name**: The etcd key name, for example: /foo/bar/baz.
- **value**: The value the key should contain.
- **profile**: Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```yaml
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None, **kwargs)
Deletes a key from etcd only if the watch statement calls it. This function is also aliased as wait_rm.

- **name**: The etcd key name to remove, for example /foo/bar/baz.
- **recurse**: Optional, defaults to False. If True performs a recursive delete, see: https://python-etcd.readthedocs.io/en/latest/#delete-a-key.
- **profile**: Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```yaml
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

salt.states.etcd_mod.wait_set(name, value, profile=None, **kwargs)
Set a key in etcd only if the watch statement calls it. This function is also aliased as wait_set.

- **name**: The etcd key name, for example: /foo/bar/baz.
value  The value the key should contain.
profile  The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to None.

```yaml
my_etd_config:
etcd.host: 127.0.0.1
etcd.port: 4001
```

23.19.92  salt.states.ethtool

Configuration of network device
New in version 2016.11.0.

codeauthor  Krzysztof Pawlowski  <msciciel@msciciel.eu>
maturity  new
depends  python-ethtool
platform  linux

```yaml
eth0:
ethtool.coalesce:
  - name: eth0
  - rx_usecs: 24
  - tx_usecs: 48

eth0:
ethtool.ring:
  - name: eth0
  - rx: 1024
  - tx: 1024

eth0:
ethtool.offload:
  - name: eth0
  - tcp_segmentation_offload: on
```

salt.states.ethtool.coalesce(name, **kwargs)
Manage coalescing settings of network device
name  Interface name to apply coalescing settings

```yaml
eth0:
ethtool.coalesce:
  - name: eth0
  - adaptive_rx: on
  - adaptive_tx: on
  - rx_usecs: 24
  - rx_frame: 0
  - rx_usecs_irq: 0
  - rx_frames_irq: 0
  - tx_usecs: 48
  - tx_frames: 0
  - tx_usecs_irq: 0
  - tx_frames_irq: 0
  - stats_block_usecs: 0
  - pkt_rate_low: 0
```

(continues on next page)
- rx_usecs_low: 0
- rx_frames_low: 0
- tx_usecs_low: 0
- tx_frames_low: 0
- rx_usecs_high: 0
- rx_frames_high: 0
- tx_usecs_high: 0
- tx_frames_high: 0
- sample_interval: 0

salt.states.ethtool.offload(name, **kwargs)
Manage protocol offload and other features of network device
name Interface name to apply coalescing settings

eth0:
    ethtool.offload:
        - name: eth0
        - tcp_segmentation_offload: on

salt.states.ethtool.ring(name, **kwargs)
Manage rx/tx ring parameters of network device
Use 'max' word to set with factory maximum
name Interface name to apply ring parameters

eth0:
    ethtool.ring:
        - name: eth0
        - rx: 1024
        - rx_mini: 0
        - rx_jumbo: 0
        - tx: max

23.19.93 salt.states.event
Send events through Salt’s event system during state runs

salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, show_changed=True, **kwargs)
Send an event to the Salt Master
New in version 2014.7.0.
Accepts the same arguments as the event.send execution module of the same name, with the additional argument:

Parameters show_changed -- If True, state will show as changed with the data argument as the change value. If False, shows as unchanged.

Example:

# ...snip bunch of states above

mycompany/mystaterun/status/update:
    event.send:
        - data:
23.19.94 **salt.states.file**

Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed.

Regular files can be enforced with the **file.managed** state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of **file.managed** which makes use of the jinja templating system would look like this:

```
# Stand up a new web server.
apache:
pkg:
  - installed
  - name: httpd
service:
  - running
  - enable: True
  - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
event:
  - wait
  - name: mycompany/loadbalancer/pool/update
  - data:
    new_web_server_ip: {{ grains['ipv4'] | first() }}
  - watch:
    - pkg: apache
```

```
/etc/http/conf/http.conf:
file.managed:
  - source: salt://apache/http.conf
  - user: root
  - group: root
  - mode: 644
  - attrs: ai
  - template: jinja
  - defaults:
    custom_var: "default value"
    other_var: 123
{% if grains['os'] == 'Ubuntu' %}
  - context:
```

(continues on next page)
It is also possible to use the `py renderer` as a templating option. The template would be a Python script which would need to contain a function called `run()`, which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

```python
def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context])  # Arguments as globals
    return '\n\n'.join(lines)
```

Note: The `defaults` and `context` arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. More information.

If using a template, any user-defined template variables in the file defined in `source` must be passed in using the `defaults` and/or `context` arguments. The general best practice is to place default values in `defaults`, with conditional overrides going into `context`, as seen above.

The template will receive a variable `custom_var`, which would be accessed in the template using `{{ custom_var }}`. If the operating system is Ubuntu, the value of the variable `custom_var` would be `override`, otherwise it is the default default value.

The `source` parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here's an example:

```
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf
      - salt://foo.conf.fallback
      - user: foo
      - group: users
      - mode: 644
      - attrs: i
      - backup: minion
```

Note: Salt supports backing up managed files via the `backup` option. For more details on this functionality please review the `backup_mode documentation`.

The `source` parameter can also specify a file in another Salt environment. In this example `foo.conf` in the `dev` environment will be used instead.

```
/etc/foo.conf:
  file.managed:
    - source:
      - 'salt://foo.conf?saltenv=dev'
      - user: foo
      - group: users
      - mode: '0644'
      - attrs: i
```
Warning: When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

The names parameter, which is part of the state compiler, can be used to expand the contents of a single state declaration into multiple, single state declarations. Each item in the names list receives its own individual state name and is converted into its own low-data structure. This is a convenient way to manage several files with similar attributes.

```yaml
salt_master_conf:
  file.managed:
    - user: root
    - group: root
    - mode: '0644'
    - names:
      - /etc/salt/master.d/master.conf:
        - source: salt://saltmaster/master.conf
      - /etc/salt/minion.d/minion-99.conf:
        - source: salt://saltmaster/minion.conf
```

Note: There is more documentation about this feature in the Names declaration section of the Highstate docs.

Special files can be managed via the mknod function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and FIFO pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions. In most cases the creation of some special files require root permissions on the minion. This would require that the minion to be run as the root user. Here is an example of a character device:

```
/var/named/chroot/dev/random:
  file.mknod:
    - ntype: c
    - major: 1
    - minor: 8
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
```

(continues on next page)
Directories can be managed via the `directory` function. This function can create and enforce the permissions on a directory. A directory statement will look like this:

```
/srv/stuff/substuf:
    file.directory:
        - user: fred
        - group: users
        - mode: 755
        - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can do so by adding a `recurse` directive:

```
/srv/stuff/substuf:
    file.directory:
        - user: fred
        - group: users
        - mode: 755
        - makedirs: True
        - recurse:
            - user
            - group
            - mode
```

As a default, `mode` will resolve to `dir_mode` and `file_mode`, to specify both directory and file permissions, use this form:

```
/srv/stuff/substuf:
    file.directory:
        - user: fred
        - group: users
        - file_mode: 744
        - dir_mode: 755
        - makedirs: True
        - recurse:
            - user
            - group
            - mode
```

Symlinks can be easily created; the symlink function is very simple and only takes a few arguments:

```
/etc/grub.conf:
    file.symlink:
        - target: /boot/grub/grub.conf
```

Recursive directory management can also be set via the `recurse` function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using `recurse` would look something like this:

```
/opt/code/flask:
    file.recurse:
        - source: salt://code/flask
        - include_empty: True
```
A more complex recurse example:

```{%
set site_user = 'testuser' %}
{%
set site_name = 'test_site' %}
{%
set project_name = 'test_proj' %}
{%
set sites_dir = 'test_dir' %}
%
```

django-project:

```ini
file.recurse:
    - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
    - user: {{ site_user }}
    - dir_mode: 2775
    - file_mode: '0644'
    - template: jinja
    - source: salt://project/templates_dir
    - include_empty: True
```

Retention scheduling can be applied to manage contents of backup directories. For example:

```ini
/var/backups/example_directory:
file.retenion_schedule:
    - strftime_format: example_name_%Y%m%dT%H%M%S.tar.bz2
    - retain:
        most_recent: 5
        first_of_hour: 4
        first_of_day: 14
        first_of_week: 6
        first_of_month: 6
        first_of_year: all
```

salt.states.file.absent(name, **kwargs)

Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module. If a directory is supplied, it will be recursively deleted.

name The path which should be deleted

salt.states.file.accumulated(name, filename, text, **kwargs)

Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

name Accumulator name
filenameFilename which would receive this accumulator (see file.managed state documentation about name)
text String or list for adding in accumulator
require_in / watch_in One of them required for sure we fill up accumulator before we manage the file. Probably the same as filename

Example:

Given the following:

```ini
animals_doing_things:
file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: 'jumps over the lazy dog.'
    - require_in:
        - file: animal_file

animal_file:
file.managed:
    - name: /tmp/animal_file.txt
```

(continues on next page)
One might write a template for `animal_file.txt` like the following:

```
The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{% for animal %}
→animal }{% endfor %}
```

Collectively, the above states and template file will produce:

```
The quick brown fox jumps over the lazy dog.
```

Multiple accumulators can be "chained" together.

**Note:** The 'accumulator' data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

---

**salt.states.file.append**

```
Ensure that some text appears at the end of a file.
```

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

- **name** The location of the file to append to.
- **text** The text to be appended, which can be a single string or a list of strings.
- **makedirs** If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.
- **source** A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

- **source_hash**
  This can be one of the following:
  1. a source hash string
  2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

---

3674 Chapter 23. Salt Module Reference
See the `source_hash` parameter description for `file.managed` function for more details and examples.

**template** The named templating engine will be used to render the appended-to file. Defaults to `jinja`. The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the `source_hashes` argument is also required.

**source_hashes** A list of source_hashes corresponding to the sources list specified in the sources argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

**ignore_whitespace** New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to `False` if you want to change this behavior.

Multi-line example:

```
/etc/motd:
 file.append:
  - text:
    Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
    - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
 file.append:
  - text:
    - Trust no one unless you have eaten much salt with him.
    - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
 file:
  - append
  - template: jinja
  - sources:
    - salt://motd/devops-messages.tmpl
    - salt://motd/hr-messages.tmpl
    - salt://motd/general-messages.tmpl
```

New in version 0.9.5.

```
salt.states.file.blockreplace(name, marker_start="#-- start managed zone --#", marker_end="#- end managed zone --#", source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content="", append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True, append_newline=None, insert_before_match=None, insert_after_match=None)
```

Maintain an edit in a file in a zone delimited by two line markers
New in version 2014.1.0.

Changed in version 2017.7.5, 2018.3.1: append_newline argument added. Additionally, to improve idempotence, if the string represented by marker_end is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove append_newline: False from the SLS and have the block properly replaced if the end of the content block is immediately followed by the marker_end (i.e. no newline before the marker).

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits.

Note: This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

Additionally, you can use `file.accumulated` and target this state. All accumulated data dictionaries' content will be added in the content block.

**name** Filesstem path to the file to be edited

**marker_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker_end** The line content identifying the end of the content block. As of versions 2017.7.5 and 2018.3.1, everything up to the text matching the marker will be replaced, so it's important to ensure that your marker includes the beginning of the text you wish to replace.

**content** The content to be used between the two lines identified by marker_start and marker_end

**source** The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```
file_override_example:
  file.blockreplace:
    - name: /etc/example.conf
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

```
<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
</table>
```

(continues on next page)
sha512 128
sha384 96
sha256 64
sha224 56
sha1 40
md5 32

See the source_hash parameter description for file.managed function for more details and examples.

**template** [jinja] Templating engine to be used to render the downloaded file. The following engines are supported:
- cheetah
- genshi
- jinja
- mako
- py
- wempy

**context** Overrides default context variables passed to the template

**defaults** Default context passed to the template

**append_if_not_found** [False] If markers are not found and this option is set to True, the content block will be appended to the file.

**prepend_if_not_found** [False] If markers are not found and this option is set to True, the content block will be prepended to the file.

**insert_before_match** If markers are not found, this parameter can be set to a regex which will insert the block before the first found occurrence in the file.

New in version 3001.

**insert_after_match** If markers are not found, this parameter can be set to a regex which will insert the block after the first found occurrence in the file.

New in version 3001.

**backup** The file extension to use for a backup of the file if any edit is made. Set this to False to skip making a backup.

**dry_run** [False] If True, do not make any edits to the file and simply return the changes that would be made.

**show_changes** [True] Controls how changes are presented. If True, the Changes section of the state return will contain a unified diff of the changes made. If False, then it will contain a boolean (True if any changes were made, otherwise False).

**append_newline** Controls whether or not a newline is appended to the content block. If the value of this argument is True then a newline will be added to the content block. If it is False, then a newline will not be added to the content block. If it is unspecified, then a newline will only be added to the content block if it does not already end in a newline.

New in version 2017.7.5, 2018.3.1.

Example of usage with an accumulator and with a variable:

```
{% set myvar = 42 %}
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
      marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-
      marker_end: "# END managed zone {{ myvar }} --"
      content: 'First line of content'
      append_if_not_found: True
      backup: '.bak'
```
Salt Documentation, Release 3003.1

(continued from previous page)

```python
- show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
      - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
      text 3
text 4
    - require_in:
      - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

salt.states.file.cached(name, source_hash='', source_hash_name=None, skip_verify=False, saltenv='base')

New in version 2017.7.3.

Ensures that a file is saved to the minion's cache. This state is primarily invoked by other states to ensure that we do not re-download a source file if we do not need to.

**name** The URL of the file to be cached. To cache a file from an environment other than base, either use the saltenv argument or include the saltenv in the URL (e.g. `salt://path/to/file.conf?saltenv=dev`).

**source_hash** See the documentation for this same argument in the file.managed state.

**source_hash_name** See the documentation for this same argument in the file.managed state.

**skip_verify** See the documentation for this same argument in the file.managed state.

**Note:** Setting this to True will result in a copy of the file being downloaded from a remote (http(s), ftp,
etc.) source each time the state is run.

```
saltenv
```

Used to specify the environment from which to download a file from the Salt fileserver (i.e. those with `salt://` URL).

This state will in most cases not be useful in SLS files, but it is useful when writing a state or remote-execution module that needs to make sure that a file at a given URL has been downloaded to the cachedir. One example of this is in the `archive.extracted` state:

```
result = __states__['file.cached'](source_match,
source_hash=source_hash,
source_hash_name=source_hash_name,
skip_verify=skip_verify,
saltenv=__env__)
```

This will return a dictionary containing the state's return data, including a `result` key which will state whether or not the state was successful. Note that this will not catch exceptions, so it is best used within a `try/except`.

Once this state has been run from within another state or remote-execution module, the actual location of the cached file can be obtained using `cp.is_cached`:

```
cached = __salt__['cp.is_cached'](source_match, saltenv=__env__)
```

This function will return the cached path of the file, or an empty string if the file is not present in the minion cache.

```
salt.states.file.comment(name, regex, char='#', backup=':bak')
```

Comment out specified lines in a file.

- **name** The full path to the file to be edited
- **regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing `^` or `$` characters outside the parenthesis (e.g., the pattern `^foo$` will be rewritten as `^(foo)$`)

Note that you _need_ the leading `^`, otherwise each time you run `highstate`, another comment char will be inserted.

- **char** [#] The character to be inserted at the beginning of a line in order to comment it out
- **backup** [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:

```
/etc/fstab:
file.comment:
  - regex: ^bind 127.0.0.1
```

New in version 0.9.5.

```
salt.states.file.copy_(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, subdir=False, **kwargs)
```

If the file defined by the `source` option exists on the minion, copy it to the named path. The file will not be overwritten if it already exists, unless the `force` option is set to `True`.

**Note:** This state only copies files from one location on a minion to another location on the same minion. For
copying files from the master, use a `file.managed` state.

**name**  The location of the file to copy to

**source**  The location of the file to copy to the location specified with name

**force**  If the target location is present then the file will not be moved, specify "force: True" to overwrite the target file

**makedirs**  If the target subdirectories don’t exist create them

**preserve**  New in version 2015.5.0.

Set `preserve: True` to preserve user/group ownership and mode after copying. Default is `False`.  If `preserve` is set to `True`, then user/group/mode attributes will be ignored.

**user**  New in version 2015.5.0.

The user to own the copied file, this defaults to the user salt is running as on the minion. If `preserve` is set to `True`, then this will be ignored

**group**  New in version 2015.5.0.

The group to own the copied file, this defaults to the group salt is running as on the minion. If `preserve` is set to `True` or on Windows this will be ignored

**mode**  New in version 2015.5.0.

The permissions to set on the copied file, aka 644, '0775', '4664'. If `preserve` is set to `True`, then this will be ignored. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**subdir**  New in version 2015.5.0.

If the name is a directory then place the file inside the named directory

**Note:**  The copy function accepts paths that are local to the Salt minion. This function does not support salt://, http://, or the other additional file paths that are supported by `states.file.managed` and `states.file.recurse`.

**Usage:**

```python
# Use 'copy', not 'copy_'
/etc/example.conf:
  file.copy:
    - source: /tmp/example.conf
```

**salt.states.file.decode**(name, encoded_data=None, contents_pillar=None, encoding_type='base64', checksum='md5')

Decode an encoded file and write it to disk

New in version 2016.3.0.

**name**  Path of the file to be written.

**encoded_data**  The encoded file. Either this option or `contents_pillar` must be specified.

**contents_pillar**  A Pillar path to the encoded file. Uses the same path syntax as `pillar.get`. The `hashutil.base64_encodefile` function can load encoded content into Pillar. Either this option or `encoded_data` must be specified.

**encoding_type**  [base64] The type of encoding.

**checksum**  [md5] The hashing algorithm to use to generate checksums. Wraps the `hashutil.digest` execution function.

**Usage:**
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - contents_pillar: mypillar:thefile

# or
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      Z2V0IHNhbHRlZAo=

Be careful with multi-line strings that the YAML indentation is correct. E.g.,

```yaml
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      {{ salt.pillar.get('path:to:data') | indent(8) }}
```

salt.states.file.directory(name, user=None, group=None, recurse=None, max_depth=None, dir_mode=None, file_mode=None, makedirs=False, clean=False, require=None, exclude_pat=None, follow_symlinks=False, force=False, backupname=None, allow_symlink=True, children_only=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False, **kwargs)

Ensure that a named directory is present and has the right perms
name  The location to create or manage a directory, as an absolute path
user  The user to own the directory; this defaults to the user salt is running as on the minion
group The group ownership set for the directory; this defaults to the group salt is running as on the minion.
On Windows, this is ignored
recurse Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left unchanged respectively. directories will be left unchanged respectively. If silent is defined, individual file/directory change notifications will be suppressed.

Example:

```yaml
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
      - group
      - mode
```

Leave files or directories unchanged:
New in version 2015.5.0.

**max_depth** Limit the recursion depth. The default is no limit=None. ‘max_depth’ and ‘clean’ are mutually exclusive.

New in version 2016.11.0.

**dir_mode / mode** The permissions mode to set any directories created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**file_mode** The permissions mode to set any files created if ‘mode’ is run in ‘recurse’. This defaults to dir_mode. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**makedirs** If the directory is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean** Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required. ‘clean’ and ‘max_depth’ are mutually exclusive.

**require** Require other resources such as packages or files

**exclude** When ‘clean’ is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks** [False] If the desired path is a symlink (or recurse is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

Changed in version 3001.1: If set to False symlinks permissions are ignored on Linux systems because it does not support permissions modification. Symlinks permissions are always 0o777 on Linux.

**force** If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname** If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink** [True] If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

**children_only** [False] If children_only is True the base of a path is excluded when performing a recursive operation. In case of /path/to/base, base will be ignored while all of /path/to/base/* are still operated on.
**win_owner** [None] The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.

**win_perms** [None] A dictionary containing permissions to grant and their propagation. For example:

```yaml
{ 'Administrators': {'perms': 'full_control', 'applies_to': 'this_folder_only'}}
```

Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to is optional and defaults to this_folder_subfolder_files.

New in version 2017.7.0.

**win_deny_perms** [None] A dictionary containing permissions to deny and their propagation. For example:

```yaml
{ 'Administrators': {'perms': 'full_control', 'applies_to': 'this_folder_only'}}
```

Can be a single basic perm or a list of advanced perms.

New in version 2017.7.0.

**win_inheritance** [True] True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

**win_perms_reset** [False] If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

New in version 2018.3.0.

Here’s an example using the above win_* parameters:

```yaml
create_config_dir:  
file.directory:  
  - name: 'C:\config'  
  - win_owner: Administrators  
  - win_perms:  
    # Basic Permissions  
    dev_ops:  
      perms: full_control  
    # List of advanced permissions  
    appuser:  
      perms:  
        - read_attributes  
        - read_ea  
        - create_folders  
        - read_permissions  
        applies_to: this_folder_only  
    joe_snuffy:  
      perms: read  
      applies_to: this_folder_files  
  - win_deny_perms:  
    fred_snuffy:  
      perms: full_control  
  - win_inheritance: False
```

**salt.states.file.exists**(name, **kwargs)

Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt’s purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

This function does not create the file if it doesn’t exist, it will return an error.

name Absolute path which must exist

**salt.states.file.hardlink**(name, target, force=False, makedirs=False, user=None, group=None, 
`dir_mode=None`, **kwargs)

Create a hard link If the file already exists and is a hard link pointing to any location other than the specified target, the hard link will be replaced. If the hard link is a regular file or directory then the state will return False. If the regular file is desired to be replaced with a hard link pass force: True
**name**  The location of the hard link to create
**target**  The location that the hard link points to
**force**  If the name of the hard link exists and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the hard link file will be deleted to make room for the hard link, unless backupname is set, when it will be renamed
**makedirs**  If the location of the hard link does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory
**user**  The user to own any directories made if makedirs is set to true. This defaults to the user salt is running as on the minion
**group**  The group ownership set on any directories made if makedirs is set to true. This defaults to the group salt is running as on the minion. On Windows, this is ignored

salt.states.file.value

Key/Value based editing of a file.

New in version 3001.

This function differs from `file.replace` in that it is able to search for keys, followed by a customizable separator, and replace the value with the given value. Should the value be the same as the one already in the file, no changes will be made.

Either supply both `key` and `value` parameters, or supply a dictionary with key / value pairs. It is an error to supply both.
**name**  Name of the file to search/replace in.
**key**  Key to search for when ensuring a value. Use in combination with a `value` parameter.
**value**  Value to set for a given key. Use in combination with a `key` parameter.
**key_values**  Dictionary of key / value pairs to search for and ensure values for. Used to specify multiple key / values at once.
**separator**  `"="` Separator which separates key from value.
**append_if_not_found**  [False] Append the key/value to the end of the file if not found. Note that this takes precedence over `prepend_if_not_found`.
**prepend_if_not_found**  [False] Prepend the key/value to the beginning of the file if not found. Note that `append_if_not_found` takes precedence.
**search_only**  [False] Show a diff of the resulting removals and inserts.
**show_changes**  [True] Show a diff of the resulting removals and inserts.
**ignore_if_missing**  [False] Return with success even if the file is not found (or not readable).
**count**  [1] Number of occurrences to allow (and correct), default is 1. Set to -1 to replace all, or set to 0 to remove all lines with this key regardless of its value.

**Note:** Any additional occurrences after `count` are removed. A count of -1 will only replace all occurrences that are currently uncommented already. Lines commented out will be left alone.

**uncomment**  [None] Disregard and remove supplied leading characters when finding keys. When set to None, lines that are commented out are left for what they are.

**Note:** The argument to `uncomment` is not a prefix string. Rather, it is a set of characters, each of which are stripped.

**key_ignore_case**  [False] Keys are matched case insensitively. When a value is changed the matched key is kept as-is.
value_ignore_case  [False] Values are checked case insensitively, trying to set e.g. 'Yes' while the current value is 'yes', will not result in changes when value_ignore_case is set to True.

An example of using file.keyvalue to ensure sshd does not allow for root to login with a password and at the same time setting the login-gracetime to 1 minute and disabling all forwarding:

```python
sshd_config_harden:
    file.keyvalue:
      name: /etc/ssh/sshd_config
      key_values:
        permitrootlogin: 'without-password'
        LoginGraceTime: '1m'
        DisableForwarding: 'yes'
      separator: '
      uncomment: '# '
      key_ignore_case: True
      append_if_not_found: True
```

The same example, except for only ensuring PermitRootLogin is set correctly. Thus being able to use the shorthand key and value parameters instead of key_values.

```python
sshd_config_harden:
    file.keyvalue:
      name: /etc/ssh/sshd_config
      key: PermitRootLogin
      value: without-password
      separator: '
      uncomment: '# '
      key_ignore_case: True
      append_if_not_found: True
```

Note: Notice how the key is not matched case-sensitively, this way it will correctly identify both 'PermitRootLogin' as well as 'permitrootlogin'.

saltstates.file.line(name, content=None, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True, create=False, user=None, group=None, file_mode=None)

Line-focused editing of a file.

New in version 2015.8.0.

Note: file.line exists for historic reasons, and is not generally recommended. It has a lot of quirks. You may find file.replace to be more suitable.

file.line is most useful if you have single lines in a file, potentially a config file, that you would like to manage. It can remove, add, and replace lines.

name  Filesystem path to the file to be edited.
content  Content of the line. Allowed to be empty if mode=delete.
match  Match the target line for an action by a fragment of a string or regular expression.

If neither before nor after are provided, and match is also None, match falls back to the content value.

mode  Defines how to edit a line. One of the following options is required:
  • ensure  If line does not exist, it will be added. If before and after are specified either zero lines, or lines that contain the content line are allowed to be in between before and
after. If there are lines, and none of them match then it will produce an error.

- **replace** If line already exists, it will be replaced.
- **delete** Delete the line, if found.
- **insert** Nearly identical to **ensure**. If a line does not exist, it will be added.

The differences are that multiple (and non-matching) lines are allowed between **before** and **after**, if they are specified. The line will always be inserted right before **before**. **insert** also allows the use of **location** to specify that the line should be added at the beginning or end of the file.

**Note:** If **mode=insert** is used, at least one of the following options must also be defined: **location**, **before**, or **after**. If **location** is used, it takes precedence over the other two options.

**location** In **mode=insert** only, whether to place the **content** at the beginning or end of a the file. If **location** is provided, **before** and **after** are ignored. Valid locations:
- **start** Place the content at the beginning of the file.
- **end** Place the content at the end of the file.

**before** Regular expression or an exact case-sensitive fragment of the string. Will be tried as both a regex and a part of the line. Must match exactly one line in the file. This value is only used in **ensure** and **insert** modes. The content will be inserted just before this line, matching its indent unless **indent=False**.

**after** Regular expression or an exact case-sensitive fragment of the string. Will be tried as both a regex and a part of the line. Must match exactly one line in the file. This value is only used in **ensure** and **insert** modes. The content will be inserted directly after this line, unless **before** is also provided. If **before** is not matched, indentation will match this line, unless **indent=False**.

**show_changes** Output a unified diff of the old file and the new file. If **False** return a boolean if any changes were made. Default is True

**Note:** Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

**backup** Create a backup of the original file with the extension: "Year-Month-Day-Hour-Minutes-Seconds".

**quiet** Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.

**indent** Keep indentation with the previous line. This option is not considered when the **delete** mode is specified. Default is True.

**create** Create an empty file if doesn’t exist.

New in version 2016.11.0.

**user** The user to own the file, this defaults to the user salt is running as on the minion.

New in version 2016.11.0.

**group** The group ownership set for the file, this defaults to the group salt is running as on the minion On Windows, this is ignored.

New in version 2016.11.0.

**file_mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

New in version 2016.11.0.

If an equal sign (=) appears in an argument to a Salt command, it is interpreted as a keyword argument in the format of key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
update_config:
  file.line:
    - name: /etc/myconfig.conf
```

(continues on next page)
- **mode**: ensure
- **content**: my key = my value
- **before**: somekey.*?

Examples:
Here's a simple config file.

```yaml
[some_config]
# Some config file
# this line will go away
here=False
away=True
goodbye=away
```

And an sls file:

```yaml
remove_lines:
    file.line:
    - name: /some/file.conf
      mode: delete
      match: away
```

This will produce:

```yaml
[some_config]
# Some config file
here=False
away=True
goodbye=away
```

If that state is executed 2 more times, this will be the result:

```yaml
[some_config]
# Some config file
here=False
```

Given that original file with this state:

```yaml
replace_things:
    file.line:
    - name: /some/file.conf
      mode: replace
      match: away
      content: here
```

Three passes will this state will result in this file:

```yaml
[some_config]
# Some config file
here
here=False
```
Each pass replacing the first line found. Given this file:

```bash
insert after me
something
insert before me
```

The following state:

```yaml
insert_a_line:
  file_line:
    - name: /some/file.txt
    - mode: insert
    - after: insert after me
    - before: insert before me
    - content: thrice
```

If this state is executed 3 times, the result will be:

```bash
insert after me
something
thrice
thrice
thrice
insert before me
```

If the mode is ensure instead, it will fail each time. To succeed, we need to remove the incorrect line between before and after:

```bash
insert after me
insert before me
```

With an ensure mode, this will insert `thrice` the first time and make no changes for subsequent calls. For something simple this is fine, but if you have instead blocks like this:

```bash
Begin SomeBlock
  foo = bar
End

Begin AnotherBlock
  another = value
End
```

And given this state:

```yaml
ensure_someblock:
  file_line:
    - name: /some/file.conf
    - mode: ensure
    - after: Begin SomeBlock
    - before: End
    - content: this = should be my content
```
This will fail because there are multiple End lines. Without that problem, it still would fail because there is a non-matching line, \texttt{foo = bar}. Ensure only allows either zero, or the matching line present to be present in between before and after.

\begin{verbatim}
salt.states.file.managed(name, source=None, source_hash='',
keep_source=True, user=None, group=None, mode=None, attrs=None,
template=None, makedirs=False, dir_mode=None, context=None, replace=True, defaults=None, backup='', show_changes=True, create=True,
contents=None, tmp_dir='', tmp_ext='', contents_pillar=None, contents_grains=None, contents_delimiter=':',
encoding=None, encoding_errors='strict', allow_empty=True, follow_symlinks=True, check_cmd=None, skip_verify=False, selinux=None,
win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False, verify_ssl=True,
**kwargs)
\end{verbatim}

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

name The location of the file to manage, as an absolute path.

source The source file to download to the minion, this source file can be hosted on either the salt master server (salt://), the salt minion local file system (/), or on an HTTP or FTP server (http(s)://, ftp://).

Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed. If source is left blank or None, please also set replaced to False to make your intention explicit.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored. Source list functionality only supports local files and remote files hosted on the salt master server or retrievable via HTTP, HTTPS, or FTP.

\begin{verbatim}
file_override_example:
    file.managed:
        - source:
          - salt://file_that_does_not_exist
          - salt://file_that_exists
\end{verbatim}

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

\begin{verbatim}
<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
</tbody>
</table>
\end{verbatim}

(continues on next page)
Using a Source Hash File  The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
               src-0.7.3.tar.gz
    source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
               tomdroid-src-0.7.3.hash
```

The following lines are all supported formats:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0d8ebbdcc8de71b1d5c8bc06a /
/etc/resolv.conf
ead4b23703509d37c4a90e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

Inserting the Source Hash in the SLS Data

The source_hash can be specified as a simple checksum, like so:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
               src-0.7.3.tar.gz
    source_hash: 79eef25f9b0b2c642c62b7f737d4f53f
```

Note: Releases prior to 2016.11.0 must also include the hash type, like in the below example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
               src-0.7.3.tar.gz
    source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

Known issues: If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    - source_hash_name: tomdroid-src-0.7.3.tar.gz/+md5

source_hash_name When source_hash refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path /tmp/foo.txt, then the following line in a hash file would match:

<table>
<thead>
<tr>
<th>sha256</th>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>acbd18db4cc2f85cedef654fccc4a4d8</td>
<td>foo.txt</td>
</tr>
</tbody>
</table>

However, sometimes a hash file will include multiple similar paths:

<table>
<thead>
<tr>
<th>sha256</th>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>37b51d194a7513e45b56f6524f2d51f2</td>
<td>./dir1/foo.txt</td>
</tr>
<tr>
<td>acbd18db4cc2f85cedef654fccc4a4d8</td>
<td>./dir2/foo.txt</td>
</tr>
<tr>
<td>73feffa4b7f6bb68e44cf984c85f6e88</td>
<td>./dir3/foo.txt</td>
</tr>
</tbody>
</table>

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
/tmp/foo.txt:
  file.managed:
    - source: https://mydomain.tld/dir2/foo.txt
    - source_hash: https://mydomain.tld/hashes
    - source_hash_name: ./dir2/foo.txt
```

Note: This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using foo.txt would not match.

New in version 2016.3.5.

keep_source [True] Set to False to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

user The user to own the file, this defaults to the user salt is running as on the minion.

group The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored.

mode The permissions to set on this file, e.g. 644, 0775, or 4664.

The default mode for new files and directories corresponds to the umask of the salt process. The mode of existing files and directories will only be changed if mode is specified.

Note: This option is not supported on Windows.

Changed in version 2016.11.0: This option can be set to keep, and Salt will keep the mode from the Salt fileserver. This is only supported when the source URL begins with salt://, or for files local to the minion. Because the source option cannot be used with any of the contents options, setting the mode to keep is also incompatible with the contents options.
Note: keep does not work with salt-ssh.

As a consequence of how the files are transferred to the minion, and the inability to connect back to the master with salt-ssh, salt is unable to stat the file as it exists on the fileserver and thus cannot mirror the mode on the salt-ssh minion

Note: This option is not supported on Windows.

New in version 2018.3.0.

**template** If this setting is applied, the named templating engine will be used to render the downloaded file.

The following templates are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

**makedirs** [False] If set to True, then the parent directories will be created to facilitate the creation of the named file. If False, and the parent directory of the destination file doesn’t exist, the state will fail.

**dir_mode** If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**replace** [True] If set to False and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**backup** Overrides the default backup mode for this specific file. See backup_mode documentation for more details.

**show_changes** Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

**create** [True] If set to False, then the file will only be managed if the file already exists on the system.

**contents** Specify the contents of the file. Cannot be used in combination with source. Ignores hashes and does not use a templating engine.

This value can be either a single string, a multiline YAML string or a list of strings. If a list of strings, then the strings will be joined together with newlines in the resulting file. For example, the below two example states would result in identical file contents:

```yaml
/path/to/file1:
  file.managed:
    - contents:
      - This is line 1
      - This is line 2

/path/to/file2:
  file.managed:
    - contents:
```

(continues on next page)
contents_pillar  New in version 0.17.0.

Changed in version 2016.11.0: contents_pillar can also be a list, and the pillars will be concatenated together to form one file.

Operates like contents, but draws from a value stored in pillar, using the pillar path syntax used in pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

For example, the following could be used to deploy an SSH private key:

```
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - attrs: a
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate /home/deployer/.ssh/id_rsa with the contents of pillar['userdata']['deployer']['id_rsa']. An example of this pillar setup would be like so:

```
userdata:
  deployer:
    id_rsa: |
    -----BEGIN RSA PRIVATE KEY-----
    MIIEowIBAAKCAQEAoQiwO3JhBquPAalQF9qP1llZNXVjYMIswrMe2HcWUVBgh+vY
    U7sCwx/dH6+VvNwmCoqmNnP+8gTPKGl1vgAObJAnMT623dMXjVKwnEag2PRJIXy
    B/HaAre9euNiY3LvIzBTWRSfetF+rvWvIKVBPvWlgGrfgz70m0pxux+UyFbAGLin+
    GpxzZAmAFpZw45sShlRuisXXZj/shQb8p9M5e04Z3rjCPIcXI
    -----END RSA PRIVATE KEY-----
```

Note: The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

To avoid the hassle of creating an indented multiline YAML string, the file_tree external pillar can be used instead. However, this will not work for binary files in Salt releases before 2015.8.4.

contents_grains  New in version 2014.7.0.

Operates like contents, but draws from a value stored in grains, using the grains path syntax used in grains.get. This functionality works similarly to contents_pillar, but with grains.

For example, the following could be used to deploy a "message of the day" file:

```
write_motd:
  file.managed:
    - name: /etc/motd
    - contents_grains: motd
```

This would populate /etc/motd file with the contents of the motd grain. The motd grain is not a default grain, and would need to be set prior to running the state:
contentsnewline [True] New in version 2014.7.0.

Changed in version 2015.8.4: This option is now ignored if the contents being deployed contain binary data.

If True, files managed using contents, contents_pillar, or contents_grains will have a newline added to the end of the file if one is not present. Setting this option to False will ensure the final line, or entry, does not contain a new line. If the last line, or entry in the file does contain a new line already, this option will not remove it.

contents_delimiter New in version 2015.8.4.

Can be used to specify an alternate delimiter for contents_pillar or contents_grains. This delimiter will be passed through to pillar.get or grains.get when retrieving the contents.

coding If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See https://docs.python.org/3/library/codecs.html#standard-encodings for the list of available encodings.

New in version 2017.7.0.

coding_errors ['strict'] Error encoding scheme. Default is `strict`. See https://docs.python.org/2/library/codecs.html#codec-base-classes for the list of available schemes.

New in version 2017.7.0.

If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

check_cmd New in version 2014.7.0.

The specified command will be run with an appended argument of a temporary file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

For example, the following could be used to verify sudoers before making changes:

```
/etc/sudoers:
    file.managed:
      - user: root
      - group: root
      - mode: 0440
      - attrs: i
      - source: salt://sudoers/files/sudoers.jinja
      - template: jinja
      - check_cmd: /usr/sbin/visudo -c -f
```

NOTE: This check_cmd functions differently than the requisite check_cmd.

tmp_dir Directory for temp file created by check_cmd. Useful for checkers dependent on config file location (e.g. daemons restricted to their own config directories by an apparmor profile).

```
/etc/dhcp/dhcpd.conf:
    file.managed:
      - user: root
      - group: root
      - mode: 0755
```
(continues on next page)
- **tmp_dir**: '/etc/dhcp'
- **contents**: '# Managed by Salt'
- **check_cmd**: dhcppd -t -cf

**tmp_ext** Suffix for temp file created by `check_cmd`. Useful for checkers dependent on config file extension (e.g. the init-checkconf upstart config checker).

```
/etc/init/test.conf:
  file.managed:
    - **user**: root
    - **group**: root
    - **mode**: 0440
    - **tmp_ext**: '.conf'
    - **contents**:   
      - 'description "Salt Minion"'
      - 'start on started mountall'
      - 'stop on shutdown'
      - 'respawn'
      - 'exec salt-minion'
    - **check_cmd**: init-checkconf -f
```

**skip_verify** [False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the `source_hash` argument will be ignored.

New in version 2016.3.0.

**selinux** [None] Allows setting the selinux user, role, type, and range of a managed file

```
/tmp/selinux.test
  file.managed:
    - **user**: root
    - **selinux**: 
      - **seuser**: system_u
      - **serole**: object_r
      - **setype**: system_conf_t
      - **serange**: s0
```

New in version 3000.

**win_owner** [None] The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.

**win_perms** [None] A dictionary containing permissions to grant and their propagation. For example:

```
{ 'Administrators': { 'perms': 'full_control' } }
```

Can be a single basic perm or a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

New in version 2017.7.0.

**win_deny_perms** [None] A dictionary containing permissions to deny and their propagation. For example:

```
{ 'Administrators': { 'perms': 'full_control' } }
```

Can be a single basic perm or a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

New in version 2017.7.0.

**win_inheritance** [True] True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

**win_perms_reset** [False] If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

New in version 2018.3.0.

Here's an example using the above `win_*` parameters:
create_config_file:
    file.managed:
        - name: C:\config\settings.cfg
        - source: salt://settings.cfg
        - win_owner: Administrators
        - win_perms:
            # Basic Permissions
            dev_ops:
                perms: full_control
            # List of advanced permissions
            appuser:
                perms:
                    - read_attributes
                    - read_ea
                    - create_folders
                    - read_permissions
            joe_snuffy:
                perms: read
        - win_deny_perms:
            fred_snuffy:
                perms: full_control
        - win_inheritance: False

verify_ssl If False, remote https file sources (https://) and source_hash will not attempt to validate the servers certificate. Default is True.

New in version 3002.

salt.states.file.missing(name, **kwargs)
Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.
name Absolute path which must NOT exist

salt.states.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')
Create a special file similar to the 'nix mknod command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of 'nix mknod. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.
name name of the file
ntype node type 'p' (fifo pipe), 'c' (character device), or 'b' (block device)
major major number of the device does not apply to a fifo pipe
minor minor number of the device does not apply to a fifo pipe
user owning user of the device/pipe
group owning group of the device/pipe
mode permissions on the device/pipe
Usage:
/dev/chr:
    file.mknod:
        - ntype: c
        - major: 180
        - minor: 31
        - user: root
(continues on next page)
New in version 0.17.0.

salt.states.file.mod_beacon(name, **kwargs)
Create a beacon to monitor a file based on a beacon state argument.

**Note:** This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)
Execute the check_cmd logic.
Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True

salt.states.file.not_cached(name, saltenv='base')
New in version 2017.7.3.
Ensures that a file is not present in the minion's cache, deleting it if found. This state is primarily invoked by other states to ensure that a fresh copy is fetched.

**name** The URL of the file to be removed from cache. To remove a file from cache in an environment other than base, either use the saltenv argument or include the saltenv in the URL (e.g. salt://path/to/file.conf?saltenv=dev).

**Note:** A list of URLs is not supported, this must be a single URL. If a local file is passed here, the state will take no action.

saltenv Used to specify the environment from which to download a file from the Salt files server (i.e. those with salt:// URL).

salt.states.file.patch(name, source=None, source_hash=None, source_hash_name=None, skip_verify=False, template=None, context=None, defaults=None, options='', reject_file=None, strip=None, saltenv=None, **kwargs)
Ensure that a patch has been applied to the specified file or directory

Changed in version 2019.2.0: The hash and dry_run_first options are now ignored, as the logic which determines whether or not the patch has already been applied no longer requires them. Additionally, this state now supports patch files that modify more than one file. To use these sort of patches, specify a directory (and, if necessary, the strip option) instead of a file.
Note: A suitable patch executable must be available on the minion. Also, keep in mind that the pre-check this state does to determine whether or not changes need to be made will create a temp file and send all patch output to that file. This means that, in the event that the patch would not have applied cleanly, the comment included in the state results will reference a temp file that will no longer exist once the state finishes running.

**name** The file or directory to which the patch should be applied

**source** The patch file to apply

  Changed in version 2019.2.0: The source can now be from any file source supported by Salt (salt://, http://, https://, ftp://, etc.). Templating is also now supported.

**source_hash** Works the same way as in `file.managed`

  New in version 2019.2.0.

**source_hash_name** Works the same way as in `file.managed`

  New in version 2019.2.0.

**skip_verify** Works the same way as in `file.managed`

  New in version 2019.2.0.

**template** Works the same way as in `file.managed`

  New in version 2019.2.0.

**context** Works the same way as in `file.managed`

  New in version 2019.2.0.

**defaults** Works the same way as in `file.managed`

  New in version 2019.2.0.

**options** Extra options to pass to patch. This should not be necessary in most cases.

Note: For best results, short opts should be separate from one another. The -- and -r, and -o options are used internally by this state and cannot be used here. Additionally, instead of using -pN or --strip=N, use the `strip` option documented below.

**reject_file** If specified, any rejected hunks will be written to this file. If not specified, then they will be written to a temp file which will be deleted when the state finishes running.

Important: The parent directory must exist. Also, this will overwrite the file if it is already present.

**strip** Number of directories to strip from paths in the patch file. For example, using the below SLS would instruct Salt to use -p1 when applying the patch:

```
/etc/myfile.conf:
  file.patch:
    - source: salt://myfile.patch
    - strip: 1
```

New in version 2019.2.0: In previous versions, -p1 would need to be passed as part of the options value.

**saltenv** Specify the environment from which to retrieve the patch file indicated by the `source` parameter. If not provided, this defaults to the environment from which the state is being executed.
Salt Documentation, Release 3003.1

Note: Ignored when the patch file is from a non-salt:// source.

Usage:

```
# Equivalent to ``patch --forward /opt/myfile.txt myfile.patch``

/oju/myfile.txt:
  file.patch:
    - source: salt://myfile.patch
```

salt.states.file.prepend

Ensure that some text appears at the beginning of a file.

The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

- **name** The location of the file to append to.
- **text** The text to be appended, which can be a single string or a list of strings.
- **makedirs** If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.
- **source** A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

- **source_hash**
  - This can be one of the following:
    1. a source hash string
    2. the URI of a file that contains source hash strings

  The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

```
<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>
```

See the source_hash parameter description for file.managed function for more details and examples.

- **template** The named templating engine will be used to render the appended-to file. Defaults to jinja. The following templates are supported:
  - cheetah
  - genshi
  - jinja
  - mako
  - py
**wempy**

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the source_hashes argument is also required.

**source_hashes** A list of source_hashes corresponding to the sources list specified in the sources argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

**ignore_whitespace** New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to False if you want to change this behavior.

Multi-line example:

```
/etc/motd:
  file.prepend:
    - text: |
      Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
      ~ Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.prepend:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Optionally, require the text to appear exactly as specified (order and position). Combine with multi-line or multiple lines of input.

```
/etc/motd:
  file.prepend:
    - header: True
    - text:
      - This will be the very first line in the file.
      - The 2nd line, regardless of duplicates elsewhere in the file.
      - These will be written anew if they do not appear verbatim.
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - prepend
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 2014.7.0.

salt.states.file.recurse(name, source, keep_source=True, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, replace=True, defaults=None, include_empty=False, backup='', include_pat=None, exclude_pat=None, maxdepth=None, keep_symlinks=False, force_symlinks=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, **kwargs)
Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

**name**  
The directory to set the recursion in

**source**  
The source directory, this directory is located on the salt master file server and is specified with the `salt://` protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**keep_source**  
[True] Set to False to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

**clean**  
Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**  
Require other resources such as packages or files

**user**  
The user to own the directory. This defaults to the user salt is running as on the minion

**group**  
The group ownership set for the directory. This defaults to the group salt is running as on the minion. On Windows, this is ignored

**dir_mode**  
The permissions mode to set on any directories created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**Note:** This option is **not** supported on Windows.

**file_mode**  
The permissions mode to set on any files created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**Note:** This option is **not** supported on Windows.

Changed in version 2016.11.0: This option can be set to `keep`, and Salt will keep the mode from the Salt fileserver. This is only supported when the source URL begins with `salt://`, or for files local to the minion. Because the `source` option cannot be used with any of the `contents` options, setting the mode to `keep` is also incompatible with the `contents` options.

**sym_mode**  
The permissions mode to set on any symlink created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**Note:** This option is **not** supported on Windows.

**template**  
If this setting is applied, the named templating engine will be used to render the downloaded file.

The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**Note:** The template option is required when recursively applying templates.
replace [True] If set to False and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

context Overrides default context variables passed to the template.

defaults Default context passed to the template.

include_empty Set this to True if empty directories should also be created (default is False)

backup Overrides the default backup mode for all replaced files. See backup_mode documentation for more details.

include_pat When copying, include only this pattern, or list of patterns, from the source. Default is glob match; if prefixed with 'E@', then regexp match. Example:

| include_pat: hello* | : glob matches 'hello01', 'hello02' |
| - include_pat: E@hello | : regexp matches 'otherhello', 'hello01' |

Changed in version 3001: List patterns are now supported

- include_pat: hello01
- hello02

exclude_pat Exclude this pattern, or list of patterns, from the source when copying. If both include_pat and exclude_pat are supplied, then it will apply conditions cumulatively. i.e. first select based on include_pat, and then within that result apply exclude_pat.

Also, when 'clean=True', exclude this pattern from the removal list and preserve in the destination. Example:

| exclude_pat: APPDATA* | : glob matches APPDATA.01, APPDATA.02,.. for exclusion |
| - exclude_pat: E@(APPDATA)|(TEMPDATA) | : regexp matches APPDATA or TEMPDATA for exclusion |

Changed in version 3001: List patterns are now supported

- exclude_pat: APPDATA.01
- APPDATA.02

maxdepth When copying, only copy paths which are of depth maxdepth from the source path. Example:

| maxdepth: 0 | : Only include files located in the source directory |
| - maxdepth: 1 | : Only include files located in the source or immediate subdirectories |

keep_symlinks Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to rsync, then set this to True.

force_symlinks Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

win_owner [None] The owner of the symlink and directories if makedirs is True. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.7.

win_perms [None] A dictionary containing permissions to grant

New in version 2017.7.7.

win_deny_perms [None] A dictionary containing permissions to deny
New in version 2017.7.7.

**win_inheritance** [None] True to inherit permissions from parent, otherwise False

New in version 2017.7.7.

**salt.states.file.rename** *(name, source, force=False, makedirs=False, **kwargs)*

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

- **name** The location of the file to rename to
- **source** The location of the file to move to the location specified with name
- **force** If the target location is present then the file will not be moved, specify "force: True" to overwrite the target file
- **makedirs** If the target subdirectories don't exist create them

New in version 0.17.0.

**salt.states.file.replace** *(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', show_changes=True, ignore_if_missing=False, backslash_literal=False, **kwargs)*

Maintain an edit in a file.

- **name** Filesystem path to the file to be edited. If a symlink is specified, it will be resolved to its target.
- **pattern** A regular expression, to be matched using Python's `re.search()`.

**Note:** If you need to match a literal string that contains regex special characters, you may want to use salt's custom Jinja filter, `regex_escape`.

```python
{{ 'http://example.com?foo=bar%20baz' | regex_escape }}
```

- **repl** The replacement text
- **count** Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.
- **flags** A list of flags defined in the `re` module documentation from the Python standard library. Each list item should be a string that will correlate to the human-friendly flag name. E.g., `['IGNORECASE', 'MULTILINE']`. Optionally, flags may be an int, with a value corresponding to the XOR () of all the desired flags. Defaults to 8 (which equates to `['MULTILINE']`).

**Note:** `file.replace` reads the entire file as a string to support multiline regex patterns. Therefore, when using anchors such as ^ or $ in the pattern, those anchors may be relative to the line OR relative to the file. The default for `file.replace` is to treat anchors as relative to the line, which is implemented by setting the default value of `flags` to `['MULTILINE']`. When overriding the default value for `flags`, if 'MULTILINE' is not present then anchors will be relative to the file. If the desired behavior is for anchors to be relative to the line, then simply add 'MULTILINE' to the list of flags.

- **bufsize** How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.

- **append_if_not_found** [False] If set to `True`, and pattern is not found, then the content will be appended to the file.

New in version 2014.7.0.

- **prepend_if_not_found** [False] If set to `True` and pattern is not found, then the content will be prepended to the file.

New in version 2014.7.0.

- **not_found_content** Content to use for append/prepend if not found. If `None` (default), uses `repl`. Useful when `repl` uses references to group in pattern.
New in version 2014.7.0.

**backup** The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**show_changes** `[True]` Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Returns a boolean or a string.

**ignore_if_missing** `[False]` New in version 2016.3.4.

Controls what to do if the file is missing. If set to `False`, the state will display an error raised by the execution module. If set to `True`, the state will simply report no changes.

**backslash_literal** `[False]` New in version 2016.11.7.

Interpret backslashes as literal backslashes for the repl and not escape characters. This will help when using append/prepend so that the backslashes are not interpreted for the repl on the second run of the state.

For complex regex patterns, it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML’s multiline string syntax.

```yaml
complex_search_and_replace:
  file.replace:
    # <...snip...>
    - pattern: |
        CentOS \(2.6.32[^\n]+\n\s+root[^\n]+\n\)+
```

**Note:** When using YAML multiline string syntax in `pattern:`, make sure to also use that syntax in the `repl: part, or you might loose line feeds.

When regex capture groups are used in `pattern:`, their captured value is available for reuse in the `repl: part as a backreference (ex. `\1`).

```yaml
add_login_group_to_winbind_ssh_access_list:
  file.replace:
    - name: '/etc/security/pam_winbind.conf'
    - pattern: '^(require_membership_of = )(.*)$'
    - repl: '\1\2,append-new-group-to-line'
```

**Note:** The `file.replace` state uses Python’s `re` module. For more advanced options, see [https://docs.python.org/2/library/re.html](https://docs.python.org/2/library/re.html)

**salt.states.file.retention_schedule**(name, retain, strftime_format=None, timezone=None)

Apply retention scheduling to backup storage directory.

New in version 2016.11.0.

**Parameters**

- **name** -- The filesystem path to the directory containing backups to be managed.
- **retain** -- Delete the backups, except for the ones we want to keep. The N below should be an integer but may also be the special value of `all`, which keeps all files matching the criteria. All of the retain options default to `None`, which means to not keep files based on this criteria.
  - **most_recent** N Keep the most recent N files.
  - **first_of_hour** N For the last N hours from now, keep the first file after the hour.
  - **first_of_day** N For the last N days from now, keep the first file after midnight. See also `timezone`.
  - **first_of_week** N For the last N weeks from now, keep the first file after Sunday midnight.
Salt Documentation, Release 3003.1

first_of_month N  For the last N months from now, keep the first file after the start of the month.

first_of_year N   For the last N years from now, keep the first file after the start of the year.

- **strptime_format** -- A python strftime format string used to first match the file-names of backups and then parse the filename to determine the datetime of the file. https://docs.python.org/2/library/datetime.html#datetime.datetime.strptime

Defaults to None, which considers all files in the directory to be backups eligible for deletion and uses os.path.getmtime() to determine the datetime.

- **timezone** -- The timezone to use when determining midnight. This is only used when datetime is pulled from os.path.getmtime(). Defaults to None which uses the timezone from the locale.

Usage example:

```
/var/backups/example_directory:
file.retention_schedule:
  - retain:
    most_recent: 5
    first_of_hour: 4
    first_of_day: 7
    first_of_week: 6  # Not Implemented yet.
    first_of_month: 6
    first_of_year: all
    - strptime_format: example_name_%Y%m%dT%H%M%S.tar.bz2
    - timezone: None
```

salt.states.file.serialize(name, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, backup='', makedirs=False, show_changes=True, create=True, merge_if_exists=False, encoding=None, encoding_errors='strict', serializer=None, serializer_opts=None, deserializer_opts=None, **kwargs)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

- **name** The location of the file to create
- **dataset** The dataset that will be serialized
- **dataset_pillar** Operates like dataset, but draws from a value stored in pillar, using the pillar path syntax used in pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version 2015.8.0.

- **serializer (or formatter)** Write the data as this format. See the list of `serializer modules` for supported output formats.

  Changed in version 3002: serializer argument added as an alternative to formatter. Both are accepted, but using both will result in an error.

- **encoding** If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See https://docs.python.org/3/library/codecs.html#standard-encodings for the list of available encodings.

  New in version 2017.7.0.

- **encoding_errors** ['strict'] Error encoding scheme. Default is `'strict'`. See https://docs.python.org/2/library/codecs.html#codec-base-classes for the list of available schemes.

  New in version 2017.7.0.

- **user** The user to own the directory, this defaults to the user salt is running as on the minion

- **group** The group ownership set for the directory, this defaults to the group salt is running as on the minion

- **mode** The permissions to set on this file, e.g. 644, 0775, or 4664.

23.19. state modules 3705
The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**Note:** This option is not supported on Windows.

**backup** Overrides the default backup mode for this specific file.

**mkdirs** Create parent directories for destination file.

New in version 2014.1.3.

**show_changes** Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made.

**create** Default is True, if create is set to False then the file will only be managed if the file already exists on the system.

**merge_if_exists** Default is False, if `merge_if_exists` is True then the existing file will be parsed and the dataset passed in will be merged with the existing content.

New in version 2014.7.0.

**serializer_opts** Pass through options to serializer. For example:

```yaml
/etc/dummy/package.yaml
file.serialize:
  - serializer: yaml
  - serializer_opts:
    - explicit_start: True
    - default_flow_style: True
    - indent: 4
```

The valid opts are the additional opts (i.e. not the data being serialized) for the function used to serialize the data. Documentation for the these functions can be found in the list below:

- For `yaml`: `yaml.dump()`
- For `json`: `json.dumps()`
- For `python`: `pprint.pformat()`
- For `msgpack`: Run `python -c 'import msgpack; help(msgpack.Packer)'` to see the available options (`encoding`, `unicode_errors`, etc.)

**deserializer_opts** Like **serializer_opts** above, but only used when merging with an existing file (i.e. when `merge_if_exists` is set to `True`).

The options specified here will be passed to the deserializer to load the existing data, before merging with the specified data and re-serializing.

```yaml
/etc/dummy/package.yaml
file.serialize:
  - serializer: yaml
  - serializer_opts:
    - explicit_start: True
    - default_flow_style: True
    - indent: 4
  - deserializer_opts:
    - encoding: latin-1
    - merge_if_exists: True
```

The valid opts are the additional opts (i.e. not the data being deserialized) for the function used to deserialize the data. Documentation for the these functions can be found in the list below:

- For `yaml`: `yaml.load()`
- For `json`: `json.loads()`

However, note that not all arguments are supported. For example, when deserializing JSON, arguments like `parse_float` and `parse_int` which accept a callable object cannot be handled in an SLS file.
New in version 2019.2.0.

For example, this state:

```json
/etc/dummy/package.json:
  file.serialize:
    - dataset:
      name: naive
      description: A package using naive versioning
      author: A confused individual <iam@confused.com>
      dependencies:
        express: '>= 1.2.0'
        optimist: '>= 0.1.0'
      engine: node 0.4.1
    - serializer: json
```

will manage the file `/etc/dummy/package.json`:

```json
{
    "author": "A confused individual <iam@confused.com>",
    "dependencies": {
        "express": ">= 1.2.0",
        "optimist": ">= 0.1.0"
    },
    "description": "A package using naive versioning",
    "engine": "node 0.4.1",
    "name": "naive"
}
```

salt.states.file.shortcut(name, target, arguments=None, working_dir=None, description=None, icon_location=None, force=False, backupname=None, makedirs=False, user=None, **kwargs)

Create a Windows shortcut

If the file already exists and is a shortcut pointing to any location other than the specified target, the shortcut will be replaced. If it is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a shortcut pass force: True, if it is to be renamed, pass a backupname.

name The location of the shortcut to create. Must end with either ".lnk" or ".url"
target The location that the shortcut points to
arguments Any arguments to pass in the shortcut
working_dir Working directory in which to execute target
description Description to set on shortcut
icon_location Location of shortcut’s icon
force If the name of the shortcut exists and is not a file and force is set to False, the state will fail. If force is set to True, the link or directory in the way of the shortcut file will be deleted to make room for the shortcut, unless backupname is set, when it will be renamed
backupname If the name of the shortcut exists and is not a file, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.
makedirs If the location of the shortcut does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory. Setting this to True will also create the parent for backupname if necessary.
user The user to own the file, this defaults to the user salt is running as on the minion

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.
salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=None, **kwargs)

Create a symbolic link (symlink, soft link)

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If an entry with the same name exists then the state will return False. If the existing entry is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

**name** The location of the symlink to create

**target** The location that the symlink points to

**force** If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the existing entry in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed

Changed in version 3000: Force will now remove all types of existing file system entries, not just files, directories and symlinks.

**backupname** If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first. An absolute path OR a basename file/directory name must be provided. The latter will be placed relative to the symlink destination's parent directory.

**makedirs** If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

**user** The user to own the file, this defaults to the user salt is running as on the minion

**group** The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**win_owner** [None] The owner of the symlink and directories if makedirs is True. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.7.

**win_perms** [None] A dictionary containing permissions to grant

New in version 2017.7.7.

**win_deny_perms** [None] A dictionary containing permissions to deny

New in version 2017.7.7.

**win_inheritance** [None] True to inherit permissions from parent, otherwise False

New in version 2017.7.7.

salt.states.file.tidied(name, age=0, matches=None, rmdirs=False, size=0, **kwargs)

Remove unwanted files based on specific criteria. Multiple criteria are OR’d together, so a file that is too large but is not old enough will still get tidied.

If neither age nor size is given all files which match a pattern in matches will be removed.

**name** The directory tree that should be tidied

**age** Maximum age in days after which files are considered for removal

**matches** List of regular expressions to restrict what gets removed. Default: [“”]

**rmdirs** Whether or not it's allowed to remove directories

**size** Maximum allowed file size. Files greater or equal to this size are removed. Doesn't apply to directories or symbolic links

```
cleanup:
  file.tidied:
    - name: /tmp/salt_test
```

(continues on next page)
- `rmdirs`: True
- `matches`:
  - foo
  - b.*r

salt.states.file.touch(name, atime=None, mtime=None, makedirs=False)
Replicate the ‘nix “touch” command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don’t care about atime or mtime, you should use file.managed instead, as it is more feature-complete. (Just leave out the source/template/contents arguments, and it will just create the file and/or check its permissions, without messing with contents)

name name of the file
atime atime of the file
mtime mtime of the file
makedirs whether we should create the parent directory/directories in order to touch the file

Usage:
```
/var/log/httpd/logrotate.empty:
file.touch
```
New in version 0.9.5.

salt.states.file.uncomment(name, regex, char='#', backup='.bak')
Uncomment specified commented lines in a file

name The full path to the file to be edited
regex A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between comment() and uncomment()). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend ‘^[ t]’)
char [#] The character to remove in order to uncomment a line
backup [.bak] The file will be backed up before edit with this file extension;

Warning: This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:
```
/etc/adduser.conf:
file.uncomment:
  - regex: EXTRA_GROUPS
```
New in version 0.9.5.
23.19.95 salt.states.firewall

State to check firewall configurations

New in version 2016.3.0.

```python
salt.states.firewall.check(name, port=None, **kwargs)
```

Checks if there is an open connection from the minion to the defined host on a specific port.

- `name` host name or ip address to test connection to
- `port` The port to test the connection on
- `kwargs` Additional parameters, parameters allowed are: `proto` (tcp or udp) `family` (ipv4 or ipv6) `timeout`

```python
testgoogle:
  firewall.check:
    - name: 'google.com'
    - port: 80
    - proto: 'tcp'
```

23.19.96 salt.states.firewalld

Management of firewalld

New in version 2015.8.0.

The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp. It will be applied permanently and directly before restart/reload.

```yaml
public:
  firewalld.present:
    - name: public
    - block_icmp:
      - echo-reply
      - echo-request
    - default: False
    - masquerade: True
    - ports:
      - 22/tcp
      - 25/tcp
```

The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```yaml
my_zone:
  firewalld.present:
    - name: public
    - masquerade: True
    - port_fwd:
      - 22:2222:tcp
      - 80:443:tcp:192.168.0.1
```

The following example binds the public zone to interface eth0 and to all packets coming from the 192.168.1.0/24 subnet. It also removes the zone from all other interfaces or sources.
Here, we define a new service that encompasses TCP ports 4505 4506:

```yaml
public:
  firewalld.present:
    - name: public
    - interfaces:
        - eth0
    - sources:
        - 192.168.1.0/24
```

To make this new service available in a zone, the following can be used, which would allow access to the salt master from the 10.0.0.0/8 subnet:

```yaml
saltzone:
  firewalld.present:
    - name: saltzone
    - services:
        - saltmaster
    - sources:
        - 10.0.0.0/8
```

The `salt.states.firewalld.ForwardingMapping(srcport, destport, protocol, destaddr)` class represents a port forwarding statement mapping a local port to a remote port for a specific protocol (TCP or UDP).

```python
todict()
```

Returns a pretty dictionary meant for command line output.

The `salt.states.firewalld.present(name, block_icmp=None, prune_block_icmp=False, default=None, masquerade=False, ports=None, prune_ports=False, port_fwd=None, prune_port_fwd=False, services=None, prune_services=False, interfaces=None, prune_interfaces=False, sources=None, prune_sources=False, rich_rules=None, prune_rich_rules=False)` function ensures a zone has specific attributes.

- **name**: The zone to modify.
- **default** [None] Set this zone as the default zone if True.
- **masquerade** [False] Enable or disable masquerade for a zone.
- **block_icmp** [None] List of ICMP types to block in the zone.
- **prune_block_icmp** [False] If True, remove all but the specified block_icmp from the zone.
- **ports** [None] List of ports to add to the zone.
- **prune_ports** [False] If True, remove all but the specified ports from the zone.
- **port_fwd** [None] List of port forwards to add to the zone.
- **prune_port_fwd** [False] If True, remove all but the specified port_fwd from the zone.
- **services** [None] List of services to add to the zone.
- **prune_services** [False] If True, remove all but the specified services from the zone. 
- **interfaces** [None] List of interfaces to add to the zone.
- **prune_interfaces** [False] If True, remove all but the specified interfaces from the zone.
- **sources** [None] List of sources to add to the zone.
prune_sources [False] If True, remove all but the specified sources from the zone.
rich_rules [None] List of rich rules to add to the zone.
prune_rich_rules [False] If True, remove all but the specified rich rules from the zone.

salt.states.firewalld.service(name, ports=None, protocols=None)
Ensure the service exists and encompasses the specified ports and protocols.
New in version 2016.11.0.

23.19.97 salt.states.gem

Installation of Ruby modules packaged as gems

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

addressable:
  gem.installed:
    - user: rvm
    - ruby: jruby@jgemset

salt.states.gem.installed(name, ruby=None, gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None, source=None)
Make sure that a gem is installed.
  name The name of the gem to install
  ruby: None Only for RVM or rbenv installations: the ruby version and gemset to target.
  gem_bin: None Custom gem command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.
  user: None The user under which to run the gem command

New in version 0.17.0.
  version [None] Specify the version to install for the gem. Doesn't play nice with multiple gems at once
  rdoc [False] Generate RDoc documentation for the gem(s).
  ri [False] Generate RI documentation for the gem(s).
  pre_releases [False] Install pre-release version of gem(s) if available.
  proxy [None] Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]
  source [None] Use the specified HTTP gem source server to download gem. Format: http://hostname[:port]

salt.states.gem.removed(name, ruby=None, user=None, gem_bin=None)
Make sure that a gem is not installed.
  name The name of the gem to uninstall
  gem_bin [None] Full path to gem binary to use.
  ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
  user: None The user under which to run the gem command

New in version 0.17.0.

salt.states.gem.sources_add(name, ruby=None, user=None)
Make sure that a gem source is added.
  name The URL of the gem source to be added
  ruby: None For RVM or rbenv installations: the ruby version and gemset to target.
  user: None The user under which to run the gem command

New in version 0.17.0.

salt.states.gem.sources_remove(name, ruby=None, user=None)
Make sure that a gem source is removed.
name  The URL of the gem source to be removed
ruby: None  For RVM or rbenv installations: the ruby version and gemset to target.
user: None  The user under which to run the gem command

New in version 0.17.0.

23.19.98  salt.states.git

States to manage git repositories and git configuration

Important:  Before using git over ssh, make sure your remote host fingerprint exists in your ~/.ssh/known_hosts file.

Changed in version 2015.8.8: This state module now requires git 1.6.5 (released 10 October 2009) or newer.

salt.states.git.cloned(name, target, branch=None, user=None, password=None, identity=None, https_user=None, https_pass=None, output_encoding=None)

New in version 2018.3.3,2019.2.0.

Ensure that a repository has been cloned to the specified target directory. If not, clone that repository. No fetches will be performed once cloned.

name  Address of the remote repository
target  Name of the target directory where repository should be cloned
branch  Remote branch to check out. If unspecified, the default branch (i.e. the one to the remote HEAD points) will be checked out.

Note:  The local branch name will match the remote branch name. If the branch name is changed, then that branch will be checked out locally, but keep in mind that remote repository will not be fetched. If your use case requires that you keep the clone up to date with the remote repository, then consider using git.latest.

user  User under which to run git commands. By default, commands are run by the user under which the minion is running.
password  Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.
identity  Path to a private key to use for ssh URLs. Works the same way as in git.latest, see that state's documentation for more information.
https_user  HTTP Basic Auth username for HTTPS (only) clones
https_pass  HTTP Basic Auth password for HTTPS (only) clones
output_encoding  Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

Note:  This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

salt.states.git.config_set(name, value=None, multivar=None, repo=None, user=None, password=None, output_encoding=None, **kwargs)

New in version 2014.7.0.

Changed in version 2015.8.0: Renamed from git.config to git.config_set. For earlier versions, use git.config.

Ensure that a config value is set to the desired value(s)
**name** Name of the git config value to set
**value** Set a single value for the config item
**multivar** Set multiple values for the config item

---

**Note:** The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

---

New in version 2015.8.0.

**repo** Location of the git repository for which the config value should be set. Required unless `global` is set to `True`.

**user** User under which to run git commands. By default, the commands are run by the user under which the minion is running.

**password**
Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**global** [False] If `True`, this will set a global git config option

**output_encoding** Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

---

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

---

New in version 2018.3.1.

Local Config Example:

```bash
# Single value
mylocalrepo:
git.config_set:
  - name: user.email
  - value: foo@bar.net
  - repo: /path/to/repo

# Multiple values
mylocalrepo:
git.config_set:
  - name: mysection.myattribute
    - multivar:
      - foo
      - bar
      - baz
  - repo: /path/to/repo
```

Global Config Example (User `foo`):

```bash
mylocalrepo:
git.config_set:
  - name: user.name
  - value: Foo Bar
  - user: foo
  - global: True
```

```
salt.states.git.config_unset(name, value_regex=None, repo=None, user=None, password=None, output_encoding=None, **kwargs)
```
New in version 2015.8.0.

Ensure that the named config key is not present

name  The name of the configuration key to unset. This value can be a regex, but the regex must match the entire key name. For example, `foo\.` would not match all keys in the `foo` section, it would be necessary to use `foo\..+` to do so.

value_regex  Regex indicating the values to unset for the matching key(s)

**Note:** This option behaves differently depending on whether or not `all` is set to `True`. If it is, then all values matching the regex will be deleted (this is the only way to delete multiple values from a multivar). If `all` is set to `False`, then this state will fail if the regex matches more than one value in a multivar.

**all**  [False]  If `True`, unset all matches

**repo**  Location of the git repository for which the config value should be set. Required unless `global` is set to `True`.

**user**  User under which to run git commands. By default, commands are run by the user under which the minion is running.

**password**  
Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**global**  [False]  If `True`, this will set a global git config option

**output_encoding**  Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:**  This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

**Examples:**

```yaml
# Value matching 'baz'
mylocalrepo:
    git.config_unset:
    - name: foo.bar
    - value_regex: 'baz'
    - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
    git.config_unset:
    - name: foo.bar
    - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
    git.config_unset:
    - name: 'foo\..+'
    - all: True

# Ensure that global config value is unset
mylocalrepo:
    git.config_unset:
    - name: foo.bar
    - global: True
```
salt.states.git.detached(name, rev, target, remote='origin', user=None, password=None, force_clone=False, force_checkout=False, fetch_remote=True, hard_reset=False, submodules=False, identity=None, https_user=None, https_pass=None, output_encoding=None, **kwargs)

New in version 2016.3.0.

Make sure a repository is cloned to the given target directory and is a detached HEAD checkout of the commit ID resolved from rev.

name Address of the remote repository.
rev The branch, tag, or commit ID to checkout after clone. If a branch or tag is specified it will be resolved to a commit ID and checked out.
target Name of the target directory where repository is about to be cloned.
remote [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.
user User under which to run git commands. By default, commands are run by the user under which the minion is running.
password Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

force_clone [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.
force_checkout [False] When checking out the revision ID, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.
fetch_remote [True] If False a fetch will not be performed and only local refs will be reachable.
hard_reset [False] If True a hard reset will be performed before the checkout and any uncommitted modifications to the working directory will be discarded. Untracked files will remain in place.

Note: Changes resulting from a hard reset will not trigger requisites.

submodules [False] Update submodules
identity A path on the minion (or a SaltStack fileserver URL, e.g. salt://path/to/identity_file) to a private key to use for SSH authentication.
https_user HTTP Basic Auth username for HTTPS (only) clones
https_pass HTTP Basic Auth password for HTTPS (only) clones
output_encoding Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

Note: This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

salt.states.git.latest(name, target, rev='HEAD', branch=None, user=None, password=None, update_head=True, force_checkout=False, force_clone=False, force_fetch=False, force_reset=False, submodules=False, bare=False, mirror=False, remote='origin', fetch_tags=True, sync_tags=True, depth=None, identity=None, https_user=None, https_pass=None, refspec_branch='', refspec_tag='', output_encoding=None, **kwargs)

Make sure the repository is cloned to the given directory and is up-to-date.

name Address of the remote repository, as passed to git clone
Note: From the Git documentation, there are two URL formats supported for SSH authentication. The below two examples are equivalent:

```
# ssh:// URL
ssh://user@server/project.git

# SCP-like syntax
user@server:project.git
```

A common mistake is to use an ssh:// URL, but with a colon after the domain instead of a slash. This is invalid syntax in Git, and will therefore not work in Salt. When in doubt, confirm that a git clone works for the URL before using it in Salt.

It has been reported by some users that SCP-like syntax is incompatible with git repos hosted on Atlassian Stash/BitBucket Server. In these cases, it may be necessary to use ssh:// URLs for SSH authentication.

**rev** [HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to `<remote>/<rev>`, unless rev refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If rev is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.

Changed in version 2015.8.0: If not specified, **rev** now defaults to the remote repository's HEAD.

**target** Name of the target directory where repository is about to be cloned

**branch** Name of the local branch into which to checkout the specified rev. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.

New in version 2015.8.0.

Note: If this argument is not specified, this means that Salt will not change the local branch if the repository is reset to another branch/tag/SHA1. For example, assume that the following state was run initially:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
```

This would have cloned the HEAD of that repo (since a **rev** wasn't specified), and because **branch** is not specified, the branch in the local clone at `/var/www/foo` would be whatever the default branch is on the remote repository (usually master, but not always). Now, assume that it becomes necessary to switch this checkout to the dev branch. This would require **rev** to be set, and probably would also require **force_reset** to be enabled:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - force_reset: True
```

The result of this state would be to perform a hard-reset to `origin/dev`. Since **branch** was not specified though, while `/var/www/foo` would reflect the contents of the remote repo's dev branch,
the local branch would still remain whatever it was when it was cloned. To make the local branch match the remote one, set `branch` as well, like so:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - branch: dev
    - force_reset: True
```

This may seem redundant, but Salt tries to support a wide variety of use cases, and doing it this way allows for the use case where the local branch doesn’t need to be strictly managed.

**user** Local system user under which to run git commands. By default, commands are run by the user under which the minion is running.

**Note:** This is not to be confused with the username for http(s)/SSH authentication.

- **user** Local system user under which to run git commands. By default, commands are run by the user under which the minion is running.

  **Note:** This is not to be confused with the username for http(s)/SSH authentication.

- **password** Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.4.

- **update_head** [True] If set to `False`, then the remote repository will be fetched (if necessary) to ensure that the commit to which `rev` points exists in the local checkout, but no changes will be made to the local HEAD.

  New in version 2015.8.3.

- **force_checkout** [False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to `True` to discard unwritten changes when checking out.

- **force_clone** [False] If the `target` directory exists and is not a git repository, then this state will fail. Set this argument to `True` to remove the contents of the target directory and clone the repo into it.

- **force_fetch** [False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to `True` to force the fetch even if it is a non-fast-forward update.

  New in version 2015.8.0.

- **force_reset** [False] If the update is not a fast-forward, this state will fail. Set this argument to `True` to force a hard-reset to the remote revision in these cases.

  Changed in version 2019.2.0: This option can now be set to `remote-changes`, which will instruct Salt not to discard local changes if the repo is up-to-date with the remote repository.

- **submodules** [False] Update submodules on clone or branch change

- **bare** [False] Set to `True` if the repository is to be a bare clone of the remote repository.

- **mirror** Set to `True` if the repository is to be a mirror of the remote repository. This implies that `bare` set to `True`, and thus is incompatible with `rev`.

- **remote** [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

- **fetch_tags** [True] If `True`, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

- **sync_tags** [True] If `True`, then Salt will delete tags which exist in the local clone but are not found on the remote repository.

  New in version 2018.3.4.
depth  Defines depth in history when git a clone is needed in order to ensure latest. E.g. depth: 1 is useful when deploying from a repository with a long history. Use rev to specify branch or tag. This is not compatible with revision IDs.

Changed in version 2019.2.0: This option now supports tags as well as branches, on Git 1.8.0 and newer.

identity  Path to a private key to use for ssh URLs. This can be either a single string, or a list of strings. For example:

```
# Single key
git@github.com:user/repo.git:
  git.latest:
    - user: deployer
    - identity: /home/deployer/.ssh/id_rsa

# Two keys

git@github.com:user/repo.git:
  git.latest:
    - user: deployer
    - identity:
        - /home/deployer/.ssh/id_rsa
        - /home/deployer/.ssh/id_rsa_alternate
```

If multiple keys are specified, they will be tried one-by-one in order for each git command which needs to authenticate.

Warning: Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.

Changed in version 2016.3.0: Key can now be specified as a SaltStack fileserver URL (e.g. salt:// path/to/identity_file).

https_user  HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

https_pass  HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

refspec_branch  [*] A glob expression defining which branches to retrieve when fetching. See git-fetch(1) for more information on how refspecs work.

New in version 2017.7.0.

refspec_tag  [*] A glob expression defining which tags to retrieve when fetching. See git-fetch(1) for more information on how refspecs work.

New in version 2017.7.0.

output_encoding  Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

Note: This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.
Note: Clashing ID declarations can be avoided when including different branches from the same git repository in the same SLS file by using the `name` argument. The example below checks out the `gh-pages` and `gh-pages-prod` branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts` ssh key required to perform the git checkout.

Also, it has been reported that the SCP-like syntax for

```
    gitlab.example.com:
    ssh_known_hosts:
    - present
    - user: root
    - enc: ecdsa

    git-website-staging:
    git.latest:
    - name: git@gitlab.example.com:user/website.git
    - rev: gh-pages
    - target: /usr/share/nginx/staging
    - identity: /root/.ssh/website_id_rsa
    - require:
      - pkg: git
      - ssh_known_hosts: gitlab.example.com

    git-website-staging:
    git.latest:
    - name: git@gitlab.example.com:user/website.git
    - rev: gh-pages
    - target: /usr/share/nginx/staging
    - identity: salt://website/id_rsa
    - require:
      - pkg: git
      - ssh_known_hosts: gitlab.example.com

    git-website-prod:
    git.latest:
    - name: git@gitlab.example.com:user/website.git
    - rev: gh-pages-prod
    - target: /usr/share/nginx/prod
    - identity: /root/.ssh/website_id_rsa
    - require:
      - pkg: git
      - ssh_known_hosts: gitlab.example.com
```

Ensure that a repository exists in the given directory

```
salt.states.git.present(name, force=False, bare=True, template=None, separate_git_dir=None, shared=None, user=None, password=None, output_encoding=None)
```

Ensure that a repository exists in the given directory

**Warning:** If the minion has Git 2.5 or later installed, `name` points to a worktree, and `force` is set to `True`, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

**name** Path to the directory

Changed in version 2015.8.0: This path must now be absolute

**force** [False] If `True`, and if `name` points to an existing directory which does not contain a git repository,
then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

**bare** [True] If True, and a repository must be initialized, then the repository will be a bare repository.

**Note:** This differs from the default behavior of `git.init`, make sure to set this value to `False` if a bare repo is not desired.

**template** If a new repository is initialized, this argument will specify an alternate template directory.

New in version 2015.8.0.

**separate_git_dir** If a new repository is initialized, this argument will specify an alternate $GIT_DIR

New in version 2015.8.0.

**shared** Set sharing permissions on git repo. See `git-init(1)` for more details.

New in version 2015.8.0.

**user** User under which to run git commands. By default, commands are run by the user under which the minion is running.

New in version 0.17.0.

**password** Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**output_encoding** Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

---

### 23.19.99 salt.states.github

Github User State Module

New in version 2016.3.0.

This state is used to ensure presence of users in the Organization.

```python
# ensure user test is present in github
salt.states.github.present:
    github.present:
        - name: 'Example TestUser1'
        - email: example@domain.com
        - username: 'gitexample'
```

```python
# ensure user test is absent in github
salt.states.github.absent(name, profile='github', **kwargs)
    Ensure a github user is absent
```

The following parameters are required:
name Github handle of the user in organization

```
salt.states.github.present(name, profile='github', **kwargs)
```

Ensure a user is present

```
ensure user test is present in github:
  github.present:
    - name: 'gitexample'
```

The following parameters are required:

- name This is the github handle of the user in the organization

```
salt.states.github.repo_absent(name, profile='github', **kwargs)
```

Ensure a repo is absent.

Example:

```
ensure repo test is absent in github:
  github.repo_absent:
    - name: 'test'
```

The following parameters are required:

- name This is the name of the repository in the organization.

New in version 2016.11.0.

```
salt.states.github.repo_present(name, description=None, homepage=None, private=None, has_issues=None, has_wiki=None, has_downloads=None, auto_init=False, gitignore_template=None, license_template=None, teams=None, profile='github', **kwargs)
```

Ensure a repository is present

- name This is the name of the repository.
- description The description of the repository.
- homepage The URL with more information about the repository.
- private The visiblity of the repository. Note that private repositories require a paid GitHub account.
- has_issues Whether to enable issues for this repository.
- has_wiki Whether to enable the wiki for this repository.
- has_downloads Whether to enable downloads for this repository.
- auto_init Whether to create an initial commit with an empty README.
- gitignore_template The desired language or platform for a .gitignore, e.g "Haskell".
- license_template The desired LICENSE template to apply, e.g "mit" or "mozilla".
- teams The teams for which this repo should belong to, specified as a dict of team name to permission ('pull', 'push' or 'admin').

New in version 2017.7.0.

Example:

```
Ensure repo my-repo is present in github:
  github.repo_present:
    - name: 'my-repo'
    - description: 'My very important repository'
```

New in version 2016.11.0.

```
salt.states.github.team_absent(name, profile='github', **kwargs)
```

Ensure a team is absent.

Example:
The following parameters are required:

- **name**: This is the name of the team in the organization.

New in version 2016.11.0.

```python
ensure team test is present in github:
    github.team_absent:
        - name: 'test'
```

**salt.states.github.team_present**

```python
class team_present:
    def __init__(self, name, description=None, repo_names=None, privacy='secret',
                 permission='pull', members=None, enforce_mfa=False,
                 no_mfa_grace_seconds=0, profile='github', **kwargs):

    Ensure a team is present
    name: This is the name of the team in the organization.
    description: The description of the team.
    repo_names: The names of repositories to add the team to.
    privacy: The level of privacy for the team, can be 'secret' or 'closed'. Defaults to secret.
    permission: The default permission for new repositories added to the team, can be 'pull', 'push' or 'admin'. Defaults to pull.
    members: The members belonging to the team, specified as a dict of member name to optional configuration. Options include 'enforce_mfa_from' and 'mfa_exempt'.
    enforce_mfa: Whether to enforce MFA requirements on members of the team. If True then all members without mfa_exempt: True configured will be removed from the team. Note that no_mfa_grace_seconds may be set to allow members a grace period.
    no_mfa_grace_seconds: The number of seconds of grace time that a member will have to enable MFA before being removed from the team. The grace period will begin from enforce_mfa_from on the member configuration, which defaults to 1970/01/01.

Example:

```python
Ensure team test is present in github:
    github.team_present:
        - name: 'test'
        - members:
            user1: {}
            user2: {}  # user2 is not explicitly listed

Ensure team test_mfa is present in github:
    github.team_present:
        - name: 'test_mfa'
        - members:
            user1:
                enforce_mfa_from: 2016/06/15
                enforce_mfa: True
```

New in version 2016.11.0.

### 23.19.100 salt.states.glance_image

**Management of OpenStack Glance Images**

New in version 2018.3.0.

- **depends**: shade
- **configuration**: See `salt.modules.glanceng` for setup instructions

Example States
### create image:
```
<table>
<thead>
<tr>
<th>Glance Image Present</th>
</tr>
</thead>
<tbody>
<tr>
<td>- name: cirros</td>
</tr>
<tr>
<td>- filename: cirros.raw</td>
</tr>
<tr>
<td>- image_format: raw</td>
</tr>
</tbody>
</table>
```

### delete image:
```
<table>
<thead>
<tr>
<th>Glance Image Absent</th>
</tr>
</thead>
<tbody>
<tr>
<td>- name: cirros</td>
</tr>
</tbody>
</table>
```

```python
salt.states.glance_image.absent(name, auth=None)

Ensure image does not exist
  - name Name of the image
```

```python
salt.states.glance_image.present(name, auth=None, **kwargs)

Ensure image exists and is up-to-date
  - name Name of the image
  - enabled Boolean to control if image is enabled
  - description An arbitrary description of the image
```

### 23.19.101 salt.states.glassfish

Manage Glassfish/Payara server . . . versionadded:: 2016.11.0

Management of glassfish using its RESTful API You can setup connection parameters like this

```yaml
- server:
  - ssl: true
  - url: localhost
  - port: 4848
  - user: admin
  - password: changeit
```

```python
salt.states.glassfish.connection_factory_absent(name, both=True, server=None)

Ensures the transaction factory is absent.
  - name Name of the connection factory
  - both Delete both the pool and the resource, defaults to true
```

```python
salt.states.glassfish.connection_factory_present(name, restype='connection_factory',
  description='', enabled=True,
  min_size=1, max_size=250, resize_quantity=2, idle_timeout=300,
  wait_timeout=60, reconnect_on_failure=False, transaction_support='',
  connection_validation=False, server=None)

Ensures that the Connection Factory is present
  - name Name of the connection factory
  - restype Type of the connection factory, can be either connection_factory, queue_connection_factory' or 'topic_connection_factory, defaults to connection_factory
  - description Description of the connection factory
  - enabled Is the connection factory enabled? defaults to true
  - min_size Minimum and initial number of connections in the pool, defaults to 1
  - max_size Maximum number of connections that can be created in the pool, defaults to 250
  - resize_quantity Number of connections to be removed when idle_timeout expires, defaults to 2
idle_timeout  Maximum time a connection can remain idle in the pool, in seconds, defaults to 300
wait_timeout  Maximum time a caller can wait before timeout, in seconds, defaults to 60
reconnect_on_failure  Close all connections and reconnect on failure (or reconnect only when used), defaults to false
transaction_support  Level of transaction support, can be either XATransaction, LocalTransaction or NoTransaction
connection_validation  Connection validation is required, defaults to false

salt.states.glassfish.destination_absent(name, server=None)
Ensures that the JMS Destination doesn't exists
name  Name of the JMS Destination

salt.states.glassfish.destination_present(name, physical, restype='queue', description='', enabled=True, server=None)
Ensures that the JMS Destination Resource (queue or topic) is present
name  The JMS Queue/Topic name
physical  The Physical destination name
restype  The JMS Destination resource type, either queue or topic, defaults is queue
description  A description of the resource
enabled  Defaults to True

salt.states.glassfish.jdbc_datasource_absent(name, both=True, server=None)
Ensures the JDBC Datasource doesn't exists
name  Name of the datasource
both  Delete both the pool and the resource, defaults to true

salt.states.glassfish.jdbc_datasource_present(name, description='', enabled=True, restype='datasource', vendor='mysql', sql_url='', sql_user='', sql_password='', min_size=8, max_size=32, resize_quantity=2, idle_timeout=300, wait_timeout=60, non_transactional=False, transaction_isolation='', isolation_guaranteed=True, server=None)
Ensures that the JDBC Datasource exists
name  Name of the datasource
description  Description of the datasource
enabled  Is the datasource enabled? defaults to true
restype  Resource type, can be datasource, xa_datasource, connection_pool_datasource or driver, defaults to datasource
vendor  SQL Server type, currently supports mysql, postgresql and mssql, defaults to mysql
sql_url  URL of the server in jdbc form
sql_user  Username for the server
sql_password  Password for that username
min_size  Minimum and initial number of connections in the pool, defaults to 8
max_size  Maximum number of connections that can be created in the pool, defaults to 32
resize_quantity  Number of connections to be removed when idle_timeout expires, defaults to 2
idle_timeout  Maximum time a connection can remain idle in the pool, in seconds, defaults to 300
wait_timeout  Maximum time a caller can wait before timeout, in seconds, defaults to 60
non_transactional  Return non-transactional connections
transaction_isolation  Defaults to the JDBC driver default
isolation_guaranteed  All connections use the same isolation level

salt.states.glassfish.system_properties_absent(name, server=None)
Ensures that the system property doesn't exists
name  Name of the system property
**salt.states.glassfish.system_properties_present***(server=None, **kwargs)***

Ensures that the system properties are present

**Properties** The system properties

### 23.19.102 salt.states.glusterfs

Manage GlusterFS pool.

**salt.states.glusterfs.add_volume_bricks**(name, bricks)

Add brick(s) to an existing volume

- **name** Volume name
- **bricks** List of bricks to add to the volume

```yaml
myvolume:
  glusterfs.add_volume_bricks:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.add_volume_bricks:
    - name: volume2
      bricks:
        - host1:/srv/gluster/drive2
        - host2:/srv/gluster/drive3
```

**salt.states.glusterfs.max_op_version**(name)

New in version 2019.2.0.

Add brick(s) to an existing volume

- **name** Volume name

```yaml
myvolume:
  glusterfs.max_op_version:
    name: volume1
    version: 30707
```

**salt.states.glusterfs.op_version**(name, version)

New in version 2019.2.0.

Add brick(s) to an existing volume

- **name** Volume name
- **version** Version to which the cluster.op-version should be set

```yaml
myvolume:
  glusterfs.op_version:
    name: volume1
    version: 30707
```

**salt.states.glusterfs.peered**(name)

Check if node is peered.

- **name** The remote host with which to peer.

```yaml
peer-cluster:
  glusterfs.peered:
    - name: two
```

(continues on next page)
peer-clusters:
glusterfs.peered:
  - names:
    - one
    - two
    - three
    - four

salt.states.glusterfs.started(name)
Check if volume has been started
name name of the volume

mycluster:
glusterfs.started: []

salt.states.glusterfs.volume_present(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False, arbiter=False)
Ensure that the volume exists
name name of the volume
bricks list of brick paths
replica replica count for volume
arbiter use every third brick as arbiter (metadata only)

New in version 2019.2.0.
start ensure that the volume is also started

myvolume:
glusterfs.volume_present:
  - bricks:
    - host1:/srv/gluster/drive1
    - host2:/srv/gluster/drive2

Replicated Volume:
glusterfs.volume_present:
  - name: volume2
  - bricks:
    - host1:/srv/gluster/drive2
    - host2:/srv/gluster/drive3
  - replica: 2
  - start: True

Replicated Volume with arbiter brick:
glusterfs.volume_present:
  - name: volume3
  - bricks:
    - host1:/srv/gluster/drive2
    - host2:/srv/gluster/drive3
    - host3:/srv/gluster/drive4
  - replica: 3
  - arbiter: True
  - start: True
23.19.103  salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

```python
class localdesktop_wm_prefs:
    def __init__(self, user=None):
        self.gnomedesktop_wm_preferences = {
            'user': user
        }

class localdesktop_lockdown:
    def __init__(self, user=None):
        self.gnomedesktop_lockdown = {
            'user': user
        }

class localdesktop_interface:
    def __init__(self, user=None):
        self.gnomedesktop_interface = {
            'user': user
        }
```

salt.states.gnomedesktop.desktop_interface(name=None, user=None, automatic_mnemonics=None, buttons_have_icons=None, can_change_accels=None, clock_format=None, clock_show_date=None, clock_show_seconds=None, cursor_blink=None, cursor_blink_time=None, cursor_blink_timeout=None, cursor_size=None, cursor_theme=None, document_font_name=None, enable_animations=None, font_name=None, gtk_color_palette=None, gtk_color_scheme=None, gtk_im_module=None, gtk_im_preedit_style=None, gtk_im_status_style=None, gtk_key_theme=None, gtk_theme=None, gtk_timeout_initial=None, gtk_timeout_repeat=None, icon_theme=None, menubar_accel=None, menubar_detachable=None, menus_have_icons=None, menus_have_tearoff=None, monospace_font_name=None, show_input_method_menu=None, show_unicode_menu=None, text_scaling_factor=None, toolbar_detachable=None, toolbar_icons_size=None, toolbar_style=None, toolkit_accessibility=None, **kwargs)

desktop_interface: sets values in the org.gnome.desktop.interface schema
salt.states.gnomedesktop.desktop_lockdown(name, user=None, disable_application_handlers=None, disable_command_line=None, disable_lock_screen=None, disable_log_out=None, disable_print_setup=None, disable_printing=None, disable_save_to_disk=None, disable_user_switching=None, user_administration_disabled=None, **kwargs)

desktop_lockdown: sets values in the org.gnome.desktop.lockdown schema

salt.states.gnomedesktop.wm_preferences(name, user=None, action_double_click_titlebar=None, action_middle_click_titlebar=None, action_right_click_titlebar=None, application_based=None, audible_bell=None, auto_raise=None, auto_raise_delay=None, button_layout=None, disable_workarounds=None, focus_mode=None, focus_new_windows=None, mouse_button_modifier=None, num_workspaces=None, raise_on_click=None, resize_with_right_button=None, theme=None, titlebar_font=None, titlebar_uses_system_font=None, visual_bell=None, visual_bell_type=None, workspace_names=None, **kwargs)

wm_preferences: sets values in the org.gnome.desktop.wm.preferences schema

23.19.104 salt.states.gpg

Management of the GPG keychains

New in version 2016.3.0.

salt.states.gpg.absent(name, keys=None, user=None, gnupghome=None, **kwargs)

Ensure GPG public key is absent in keychain

name The unique name or keyid for the GPG public key.
keys The keyid or keyids to add to the GPG keychain.
user Remove GPG keys from the specified user's keychain

salt.states.gpg.present(name, keys=None, user=None, keyserver=None, gnupghome=None, trust=None, **kwargs)

Ensure GPG public key is present in keychain

name The unique name or keyid for the GPG public key.
keys The keyid or keyids to add to the GPG keychain.
user Add GPG keys to the specified user's keychain
keyserver The keyserver to retrieve the keys from.

23.19. state modules
23.19.105 salt.states.grafana

Manage Grafana Dashboards

This module uses **elasticsearch**, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

```yaml
mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash
```

**# Basic usage (uses default pillar profile key 'grafana')**

Ensure `myservice` dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows_from_pillar:
    - systemhealth
    - requests
```

**# Passing hosts in**

Ensure `myservice` dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows:
    - collapse: false
      editable: true
      height: 150px
      title: System Health
      panels:
        - aliasColors: {}
          id: 200000
          annotate:
            enable: false
          bars: false
          datasource: null
          editable: true
          error: false
          fill: 7
          grid:
            leftMax: 100
            leftMin: null
            rightMax: null
            rightMin: null
            threshold1: 60
            threshold1Color: rgb(216, 27, 27)
            threshold2: null
            threshold2Color: rgba(234, 112, 112, 0.22)
          leftYAxisLabel: ''
          legend:
            avg: false
            current: false
            max: false
            min: false
```

(continues on next page)

  - collapse: false
    enable: true
    notice: false
    now: true
    refresh_intervals:
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

**salt.states.grafana.dashboard_absent**(name, hosts=None, profile='grafana')

Ensure the named grafana dashboard is deleted.

- **name** Name of the grafana dashboard.
- **profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

**salt.states.grafana.dashboard_present**(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.
name  Name of the grafana dashboard.
dashboard  A dict that defines a dashboard that should be managed.
dashboard_from_pillar  A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
rows  A list of grafana rows.
rows_from_pillar  A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
profile  A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

23.19.106  salt.states.grafana4_dashboard

Manage Grafana v4.0 Dashboards

New in version 2017.7.0.

configuration  This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_user: admin
  grafana_password: admin
  grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_token: token
  grafana_timeout: 3
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```
Ensure minimum dashboard is managed:
grafana4_dashboard.present:
  - name: insightful-dashboard
  - base_dashboards_from_pillar:
    - default_dashboard
  - base_rows_from_pillar:
    - default_row
  - base_panels_from_pillar:
    - default_panel
  - dashboard:
    rows:
      - title: Usage
        panels:
          - targets:
            - target: alias(constantLine(50), 'max')
        title: Imaginary
        type: graph

salt.states.grafana4_dashboard.absent(name, orgname=None, profile='grafana')

Ensure the named grafana dashboard is absent.
```
name Name of the grafana dashboard.
orgname Name of the organization in which the dashboard should be present.
profile Configuration profile used to connect to the Grafana instance. Default is ‘grafana’.
salt.states.grafana4_dashboard.present(name, base_dashboards_from_pillar=None, base_panels_from_pillar=None, base_rows_from_pillar=None, dashboard=None, orgname=None, profile=’grafana’)

Ensure the grafana dashboard exists and is managed.
name Name of the grafana dashboard.
base_dashboards_from_pillar A pillar key that contains a list of dashboards to inherit from
base_panels_from_pillar A pillar key that contains a list of panels to inherit from
base_rows_from_pillar A pillar key that contains a list of rows to inherit from
dashboard A dict that defines a dashboard that should be managed.
orgname Name of the organization in which the dashboard should be present.
profile Configuration profile used to connect to the Grafana instance. Default is ‘grafana’.

23.19.107 salt.states.grafana4_datasource

Manage Grafana v4.0 data sources
New in version 2017.7.0.
configuration This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the ‘grafana’ key by default, if defined.

Example configuration using basic authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_user: admin
  grafana_password: admin
  grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_token: token
  grafana_timeout: 3
```

The behavior of this module is to create data sources if they do not exists, and to update data sources if the already exists.

Ensure influxdb data source is present:

```
grafana4_datasource.present:
  name: influxdb
  type: influxdb
  url: http://localhost:8086
  access: proxy
  basic_auth: true
  basic_auth_user: myuser
  basic_auth_password: mypass
  is_default: true
```
salt.states.grafana4_datasource.absent(name, orgname=None, profile=’grafana’)

Ensure that a data source is present.
name Name of the data source to remove.
orgname Name of the organization from which the data source should be absent.
profile Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

```
salt.states.grafana4_datasource.present(name, type, url, access=None, user=None, password=None, database=None, basic_auth=None, basic_auth_user=None, basic_auth_password=None, tls_auth=None, json_data=None, is_default=None, with_credentials=None, type_logo_url=None, orgname=None, profile='grafana')
```

Ensure that a data source is present.
name Name of the data source.
type Type of the datasource ('graphite', 'influxdb' etc.).
access Use proxy or direct. Default: proxy
url The URL to the data source API.
user Optional - user to authenticate with the data source.
password Optional - password to authenticate with the data source.
database Optional - database to use with the data source.
basic_auth Optional - set to True to use HTTP basic auth to authenticate with the data source.
basic_auth_user Optional - HTTP basic auth username.
basic_auth_password Optional - HTTP basic auth password.
json_data Optional - additional json data to post (eg. "timeInterval").
is_default Optional - set data source as default.
with_credentials Optional - Whether credentials such as cookies or auth headers should be sent with cross-site requests.
type_logo_url Optional - Logo to use for this datasource.
orgname Name of the organization in which the data source should be present.
profile Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

23.19.108 salt.states.grafana4_org

Manage Grafana v4.0 orgs

New in version 2017.7.0.

configuration This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```
grafana:
grafana_url: http://grafana.localhost
grafana_user: admin
grafana_password: admin
grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
grafana_url: http://grafana.localhost
grafana_token: token
grafana_timeout: 3
```

Ensure foobar org is present:
```
grafana4_org.present:
```
(continues on next page)
- **name**: foobar
- **theme**: ""
- **home_dashboard_id**: 0
- **timezone**: "utc"
- **address1**: ""
- **address2**: ""
- **city**: ""
- **zip_code**: ""
- **state**: ""
- **country**: ""

salt.states.grafana4_org.absent(name, profile='grafana')

Ensure that a org is present.

- **name**: Name of the org to remove.
- **profile**: Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

salt.states.grafana4_org.present(name, users=None, theme=None, home_dashboard_id=None, timezone=None, address1=None, address2=None, city=None, zip_code=None, address_state=None, country=None, profile='grafana')

Ensure that an organization is present.

- **name**: Name of the org.
- **users**: Optional - Dict of user/role associated with the org. Example:

```python
table
<table>
<thead>
<tr>
<th>users:</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo: Viewer</td>
</tr>
<tr>
<td>bar: Editor</td>
</tr>
</tbody>
</table>
```

- **theme**: Optional - Selected theme for the org.
- **home_dashboard_id**: Optional - Home dashboard for the org.
- **timezone**: Optional - Timezone for the org (one of: "browser", "utc", or "").
- **address1**: Optional - address1 of the org.
- **address2**: Optional - address2 of the org.
- **city**: Optional - city of the org.
- **zip_code**: Optional - zip_code of the org.
- **address_state**: Optional - state of the org.
- **country**: Optional - country of the org.
- **profile**: Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

### 23.19.109 salt.states.grafana4_user

Manage Grafana v4.0 users

New in version 2017.7.0.

- **configuration**: This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```yaml
grafana:
  grafana_url: http://grafana.localhost
  grafana_user: admin
  grafana_password: admin
  grafana_timeout: 3
```
Example configuration using token based authentication:

```yaml
grafana:
  grafana_url: http://grafana.localhost
  grafana_token: token
  grafana_timeout: 3
```

Ensure foobar user is present:

```yaml
grafana4_user.present:
  - name: foobar
  - password: mypass
  - email: "foobart@localhost"
  - fullname: Foo Bar
  - is_admin: true
```

```yaml
salt.states.grafana4_user.absent(name, profile='grafana')
```

Ensure that a user is present.

```yaml
salt.states.grafana4_user.present(name, password, email, is_admin=False, fullname=None, theme=None, profile='grafana')
```

23.19.110 salt.states.grafana_dashboard

Manage Grafana v2.0 Dashboards

New in version 2016.3.0.

```yaml
grafana:
  grafana_timeout: 3
  grafana_token: qwertyuiop
  grafana_url: 'https://url.com'
```

Ensure minimum dashboard is managed:

```yaml
grafana_dashboard.present:
  - name: insightful-dashboard
    base_dashboards_from_pillar:
      - default_dashboard
    base_rows_from_pillar:
      - default_row
    base_panels_from_pillar:
      - default_panel
    dashboard:
      rows:
        - title: Usage
          panels:
            - targets:
```

(continues on next page)
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```python
salt.states.grafana_dashboard.absent(name, profile='grafana')
```

Ensure the named grafana dashboard is absent.

- **name**: Name of the grafana dashboard.
- **profile**: A pillar key or dict that contains grafana information

```python
salt.states.grafana_dashboard.present(name, base_dashboards_from_pillar=None, base_panels_from_pillar=None, base_rows_from_pillar=None, dashboard=None, profile='grafana')
```

Ensure the grafana dashboard exists and is managed.

- **name**: Name of the grafana dashboard.
- **base_dashboards_from_pillar**: A pillar key that contains a list of dashboards to inherit from
- **base_panels_from_pillar**: A pillar key that contains a list of panels to inherit from
- **base_rows_from_pillar**: A pillar key that contains a list of rows to inherit from
- **dashboard**: A dict that defines a dashboard that should be managed.
- **profile**: A pillar key or dict that contains grafana information

### 23.19.111 salt.states.grafana_datasource

Manage Grafana v2.0 data sources

New in version 2016.3.0.

```yaml
grafana:
  grafana_timeout: 3
  grafana_token: qwertyuiop
  grafana_url: 'https://url.com'
```

Ensure influxdb data source is present:

```python
salt.states.grafana_datasource.present:
  - name: influxdb
  - type: influxdb
  - url: http://localhost:8086
  - access: proxy
  - basic_auth: true
  - basic_auth_user: myuser
  - basic_auth_password: mypass
  - is_default: true
```

```python
salt.states.grafana_datasource.absent(name, profile='grafana')
```

 Ensure that a data source is present.

- **name**: Name of the data source to remove.

```python
salt.states.grafana_datasource.present(name, type, url, access='proxy', user='', password='', database='', basic_auth=False, basic_auth_user='', basic_auth_password='', is_default=False, json_data=None, profile='grafana')
```

Ensure that a data source is present.
**name**  Name of the data source.
**type**  Which type of data source it is (‘graphite’, ‘influxdb’ etc.).
**url**  The URL to the data source API.
**user**  Optional - user to authenticate with the data source
**password**  Optional - password to authenticate with the data source
**basic_auth**  Optional - set to True to use HTTP basic auth to authenticate with the data source.
**basic_auth_user**  Optional - HTTP basic auth username.
**basic_auth_password**  Optional - HTTP basic auth password.
**is_default**  Default: False

### 23.19.112 salt.states.grains

**Manage grains on the minion**

This state allows for grains to be set. Grains set or altered with this module are stored in the 'grains' file on the minions, By default, this file is located at: `/etc/salt/grains`

**Note:** This does NOT override any grains set in the minion config file.

#### salt.states.grains.absent

*New in version 2014.7.0.*

Delete a grain from the grains config file

**name**  The grain name

**destructive**  If destructive is True, delete the entire grain. If destructive is False, set the grain’s value to None. Defaults to False.

**force**  If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False

**delimiter**  A delimiter different from the default can be provided.

*New in version 2015.8.2.*

**delimiter**  A delimiter different from the default can be provided.

*New in version 2015.8.2.*

*Changed in version 2015.8.2.*

This state now support nested grains and complex values. It is also more conservative: if a grain has a value that is a list or a dict, it will not be removed unless the `force` parameter is True.

#### salt.states.grains.append

*New in version 2014.7.0.*

Append a value to a list in the grains config file. The grain that is being appended to (name) must exist before the new value can be added.

**name**  The grain name

**value**  The value to append

**convert**  If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

**delimiter**  A delimiter different from the default can be provided.

*New in version 2015.8.2.*
```python
grain_name:
    grains.append:
        - value: to_be_appended
```

salt.states.grains.exists(name, delimiter=":")

Ensure that a grain is set

- **name**: The grain name
- **delimiter**: A delimiter different from the default can be provided.

Check whether a grain exists. Does not attempt to check or set the value.

salt.states.grains.list_absent(name, value, delimiter=":")

Delete a value from a grain formed as a list.

- New in version 2014.1.0.
- **name**: The grain name.
- **value**: The value to delete from the grain list.
- **delimiter**: A delimiter different from the default : can be provided.

New in version 2015.8.2.

The grain should be list type

```yaml
roles:
    grains.list_absent:
        - value: db
```

For multiple grains, the syntax looks like:

```yaml
roles:
    grains.list_absent:
        - value:
            - web
            - dev
```

salt.states.grains.list_present(name, value, delimiter=":")

New in version 2014.1.0.

Ensure the value is present in the list-type grain. Note: If the grain that is provided in name is not present on the system, this new grain will be created with the corresponding provided value.

- **name**: The grain name.
- **value**: The value is present in the list type grain.
- **delimiter**: A delimiter different from the default : can be provided.

New in version 2015.8.2.

The grain should be list type

```yaml
roles:
    grains.list_present:
        - value: web
```

For multiple grains, the syntax looks like:

```yaml
roles:
    grains.list_present:
        - value:
            - web
            - dev
```
salt.states.grains.make_hashable(list_grain, result=None)

Ensure that a list grain is hashable.

list_grain The list grain that should be hashable
result This function is recursive, so it must be possible to use a sublist as parameter to the function. Should not be used by a caller outside of the function.

Make it possible to compare two list grains to each other if the list contains complex objects.

salt.states.grains.present(name, value, delimiter=':', force=False)

Ensure that a grain is set

Changed in version 2015.8.2.
name The grain name
value The value to set on the grain
force If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False

New in version 2015.8.2.
delimiter A delimiter different from the default can be provided.

New in version 2015.8.2.
It is now capable to set a grain to a complex value (i.e. lists and dicts) and supports nested grains as well.

If the grain does not yet exist, a new grain is set to the given value. For a nested grain, the necessary keys are created if they don't exist. If a given key is an existing value, it will be converted, but an existing value different from the given key will fail the state.

If the grain with the given name exists, its value is updated to the new value unless its existing or provided value is complex (list or dict). Use force: True to overwrite.

```yaml
cheese:
  grains.present:
    - value: edam

nested_grain_with_complex_value:
  grains.present:
    - name: icinga:Apache SSL
    - value:
      - command: check_https
      - params: -H localhost -p 443 -S

with,a,custom,delimiter:
  grains.present:
    - value: yay
    - delimiter: ', '
```

23.19.113 salt.states.group

Management of user groups

The group module is used to create and manage group settings, groups can be either present or absent. User/Group names can be passed to the adduser, deluser, and members parameters. adduser and deluser can be used together but not with members.

In Windows, if no domain is specified in the user or group name (i.e. DOMAIN\username) the module will assume a local user or group.
cheese:
  group.present:
    - gid: 7648
    - system: True
    - addusers:
      - user1
      - users2
    - delusers:
      - foo

cheese:
  group.present:
    - gid: 7648
    - system: True
    - members:
      - foo
      - bar
      - user1
      - user2

salt.states.group.absent(name)
Ensure that the named group is absent

Parameters
  name (str) -- The name of the group to remove

Example:

# Removes the local group `db_admin`

db_admin:
  group.absent

salt.states.group.present(name, gid=None, system=False, addusers=None, delusers=None, members=None)
Ensure that a group is present

Parameters
  • name (str) -- The name of the group to manage
  • gid (str) -- The group id to assign to the named group; if left empty, then the next available group id will be assigned. Ignored on Windows
  • system (bool) -- Whether or not the named group is a system group. This is essentially the '-r' option of 'groupadd'. Ignored on Windows
  • addusers (list) -- List of additional users to be added as a group members. Cannot conflict with names in delusers. Cannot be used in conjunction with members.
  • delusers (list) -- Ensure these user are removed from the group membership. Cannot conflict with names in addusers. Cannot be used in conjunction with members.
  • members (list) -- Replace existing group members with a list of new members. Cannot be used in conjunction with addusers or delusers.

Example:

# Adds DOMAIN\db_admins and Administrators to the local db_admin group
# Removes Users

db_admin:
  group.present:
    - addusers:
      - DOMAIN\db_admins
      - Administrators
    - delusers:
      - Users

(continues on next page)
## Ensures only DOMAIN\domain_admins and the local Administrator are members of the local Administrators group. All other users are removed

Administrators:

```yaml
- members:
  - DOMAIN\domain_admins
  - Administrator
```

### 23.19.114 salt.states.heat

**Management of Heat**

New in version 2017.7.0.

```
depends
  - heat Python module
configuration
  See salt.modules.heat for setup instructions.
```

The heat module is used to create, show, list and delete Heat stacks. Stack can be set as either absent or deploy.

```
heat.deployed:
  - name:
  - template: #Required
  - environment:
  - params: {}
  - poll: 5
  - rollback: False
  - timeout: 60

heat.absent:
  - name:
  - poll: 5
```

#### mysql:

```
heat.deployed:
  - template: salt://templates/mysql.heat.yaml
  - params: image: Debian 7
  - rollback: True
```

New in version 2017.7.5,2018.3.1: The spelling mistake in parameter enviroment was corrected to environment. The enviroment spelling mistake has been removed in Salt 3000.

```python
salt.states.heat.absent(name, poll=5, timeout=60, profile=None)
```

Ensure that the named stack is absent

- **name**: The name of the stack to remove
- **poll**: Poll(in sec.) and report events until stack complete
- **timeout**: Stack creation timeout in minutes
- **profile**: Profile to use
salt.states.heat.deployed(name, template=None, environment=None, params=None, poll=5, rollback=False, timeout=60, update=False, profile=None, **connection_args)

Deploy stack with the specified properties
name The name of the stack
template File of template
environment File of environment
params Parameter dict used to create the stack
poll Poll (in sec.) and report events until stack complete
rollback Enable rollback on create failure
timeout Stack creation timeout in minutes
profile Profile to use

New in version 2017.7.5, 2018.3.1: The spelling mistake in parameter environment was corrected to environment. The environment spelling mistake has been removed in Salt 3000.

23.19.115 salt.states.helm

salt.states.helm.release_absent(name, namespace=None, flags=None, kvflags=None)

Make sure the release name is absent.
name (string) The release name to uninstall.
namespace (string) The namespace scope for this request.
flags (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

```
helm_release_is_absent:
  helm.release_absent:
    - name: release_name

# In dry-run mode.
helm_release_is_absent_dry-run:
  helm.release_absent:
    - name: release_name
    - flags:
      - dry-run
```

salt.states.helm.release_present(name, chart, values=None, version=None, namespace=None, set=None, flags=None, kvflags=None)

Make sure the release name is present.
name (string) The release name to install.
chart (string) The chart to install.
values (string) Absolute path to the values.yaml file.
version (string) The exact chart version to install. If this is not specified, the latest version is installed.
namespace (string) The namespace scope for this request.
set (string or list) Set a values on the command line.
flags (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

```
helm_release_is_present:
  helm.release_present:
    - name: release_name
    - chart: repo/chart

# In dry-run mode.
```
helm_release_is_present_dry-run:
  helm.release_present:
    - name: release_name
    - chart: repo/chart
    - flags:
      - dry-run

# With values.yaml file.

helm_release_is_present_values:
  helm.release_present:
    - name: release_name
    - chart: repo/chart
    - kvflags:
      values: /path/to/values.yaml

salt.states.helm.repo_managed(name, present=None, absent=None, prune=False, repo_update=False, namespace=None, flags=None, kvflags=None)

Make sure the repository is updated.

name (string) Not used.
present (list) List of repository to be present. It's a list of dict: [{'name': 'local_name', 'url': 'repository_url'}]
absent (list) List of local name repository to be absent.
prune (boolean - default: False) If True, all repository already present but not in the present list would be removed.
repo_update (boolean - default: False) If True, the Helm repository is updated after a repository add or remove.
namespace (string) The namespace scope for this request.
flags (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

helm_repository_is_managed:
  helm.repo_managed:
    - present:
      - name: local_name_1
      - url: repository_url
    - absent:
      - local_name_2

salt.states.helm.repo_updated(name, namespace=None, flags=None, kvflags=None)

Make sure the repository is updated. To execute after a repository changes.

name (string) Not used.
namespace (string) The namespace scope for this request.
flags (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

helm_repository_is_updated:
  helm.repo_updated
23.19.116  salt.states.hg

**Interaction with Mercurial repositories**

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known_hosts, and the remote host has this host’s public key.

```bash
https://bitbucket.org/example_user/example_repo:
   hg.latest:
       - rev: tip
       - target: /tmp/example_repo
```

salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False, update_head=True)

  Make sure the repository is cloned to the given directory and is up to date
  name Address of the remote repository as passed to "hg clone"
  rev The remote branch, tag, or revision hash to clone/pull
  target Target destination directory path on minion to clone into
  clean Force a clean update with -C (Default: False)
  user Name of the user performing repository management operations

  New in version 0.17.0.

  identity Private SSH key on the minion server for authentication (ssh://)

  New in version 2015.5.0.

  force Force hg to clone into pre-existing directories (deletes contents)

  opts Include additional arguments and options to the hg command line

  update_head Should we update the head if new changes are found? Defaults to True

  New in version 2017.7.0.

23.19.117  salt.states.highstate_doc

To be used with processors in module highstate_doc.

salt.states.highstate_doc.note(name, source=None, contents=None, **kwargs)

  Add content to a document generated using highstate_doc.render.

  This state does not preform any tasks on the host. It only is used in highstate_doc lowstate processors to include extra documents.

```yaml
{{sls}} example note:
   highstate_doc.note:
       - name: example note
       - require_in:
           - pkg: somepackage
       - contents: |
           example `highstate_doc.note`
             ------------------
           This state does not do anything to the system! It is only used by a rendered file.
           .. this message appare above the `pkg: somepackage` state.
       - source: salt://{{tpldir}}/also_include_a_file.md
```

(continues on next page)
23.19.118  salt.states.host

Management of addresses and names in hosts file

The /etc/hosts file can be managed to contain definitions for specific hosts:

```yaml
salt-master:
  host.present:
    - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```yaml
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
```

**Note:** Changing the `names` in `host.present` does not cause an update to remove the old entry.

```yaml
server1:
  host.present:
    - ip: 192.168.0.42
    - ip: 192.168.0.43
    - ip: 192.168.0.44
    - names:
      - server1
```

You can replace all existing names for a particular IP address:

```yaml
127.0.1.1:
  host.only:
    - hostnames:
      - foo.example.com
      - foo
```

Or delete all existing names for an address:

```yaml
203.0.113.25:
  host.only:
    - hostnames: []
```

You can also include comments:
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
    - comment: A very important comment

salt.states.host.absent(name, ip)
Ensure that the named host is absent
name The host to remove
ip The ip addr(s) of the host to remove

salt.states.host.only(name, hostnames)
Ensure that only the given hostnames are associated with the given IP address.
New in version 2016.3.0.
name The IP address to associate with the given hostnames.
hostnames Either a single hostname or a list of hostnames to associate with the given IP address in the given order. Any other hostname associated with the IP address is removed. If no hostnames are specified, all hostnames associated with the given IP address are removed.

salt.states.host.present(name, ip, comment='', clean=False)
Ensures that the named host is present with the given ip
name The host to assign an ip to
ip The ip addr(s) to apply to the host. Can be a single IP or a list of IP addresses.
comment A comment to include for the host entry
New in version 3001.
clean Remove any entries which don’t match those configured in the ip option. Default is False.
New in version 2018.3.4.

23.19.119 salt.states.http

HTTP monitoring states
Perform an HTTP query and statefully return the result
New in version 2015.5.0.

salt.states.http.query(name, match=None, match_type='string', status=None, status_type='string', wait_for=None, **kwargs)
Perform an HTTP query and statefully return the result

Passes through all the parameters described in the utilities.http.query function:
name The name of the query.
match Specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text.
match_type Specifies the type of pattern matching to use on match. Default is string, but can also be set to pcre to use regular expression matching if a more complex pattern matching is required.

Note: Despite the name of match_type for this argument, this setting actually uses Python’s re.search() function rather than Python’s re.match() function.

status The status code for a URL for which to be checked. Can be used instead of or in addition to the match setting. This can be passed as an individual status code or a list of status codes.
**status_type**  Specifies the type of pattern matching to use for status. Default is `string`, but can also be set to `pcre` to use regular expression matching if a more complex pattern matching is required. Additionally, if a list of strings representing statuses is given, the type `list` can be used.

New in version 3000.

**Note:** Despite the name of `match_type` for this argument, this setting actually uses Python's `re.search()` function rather than Python's `re.match()` function.

If both `match` and `status` options are set, both settings will be checked. However, note that if only one option is `True` and the other is `False`, then `False` will be returned. If this case is reached, the comments in the return data will contain troubleshooting information.

For more information about the `http.query` state, refer to the [HTTP Tutorial](http://docs.saltstack.com/en/latest/environments/http/).

```python
query_example:
    http.query:
        - name: 'http://example.com/
        - status: 200

query_example2:
    http.query:
        - name: 'http://example.com/
        - status:
            - 200
            - 201
        - status_type: list
```

```
salt.states.http.wait_for_successful_query(name, wait_for=300, **kwargs)
    Like query but, repeat and wait until match/match_type or status is fulfilled. State returns result from last query state in case of success or if no successful query was made within wait_for timeout.
    name  The name of the query.
    wait_for  Total time to wait for requests that succeed.
    request_interval  Optional interval to delay requests by N seconds to reduce the number of requests sent.

    **Note:** All other arguments are passed to the http.query state.
```

### 23.19.120 salt.states.icinga2

**Icinga2 state**

New in version 2017.7.0.

```
depends
    - Icinga2 Python module
```

**configuration**  See `salt.modules.icinga2` for setup instructions.

The icinga2 module is used to execute commands. Its output may be stored in a file or in a grain.

```
command_id:
    icinga2.generate_ticket:
        - name: domain.tld
        - output: "/tmp/query_id.txt"
```
salt.states.icinga2.generate_cert(name)
   Generate an icinga2 certificate and key on the client.
   name  The domain name for which this certificate and key will be generated

salt.states.icinga2.generate_ticket(name, output=None, grain=None, key=None, overwrite=True)
   Generate an icinga2 ticket on the master.
   name  The domain name for which this ticket will be generated
   output grain: output in a grain other: the file to store results None: output to the result comment (default)
   grain: grain to store the output (need output=grain)
   key: the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
   overwrite: The file or grain will be overwritten if it already exists (default)

salt.states.icinga2.node_setup(name, master, ticket)
   Setup the icinga2 node.
   name  The domain name for which this certificate will be saved
   master Icinga2 master node for which this certificate will be saved
   ticket Authentication ticket generated on icinga2 master

salt.states.icinga2.request_cert(name, master, ticket, port='5665')
   Request CA certificate from master icinga2 node.
   name  The domain name for which this certificate will be saved
   master Icinga2 master node for which this certificate will be saved
   ticket Authentication ticket generated on icinga2 master
   port  Icinga2 port, defaults to 5665

salt.states.icinga2.save_cert(name, master)
   Save the certificate on master icinga2 node.
   name  The domain name for which this certificate will be saved
   master Icinga2 master node for which this certificate will be saved

23.19.121 salt.states.idem

Idem Support

This state provides access to idem states

New in version 3002.

salt.states.idem.state(name, sls, acct_file=None, acct_key=None, acct_profile=None, cache_dir=None, render=None, runtime=None, source_dir=None, test=False)
   Execute an idem sls file through a salt state
   sls  A list of idem sls files or sources
   acct_file Path to the acct file used in generating idem ctx parameters. Defaults to the value in the ACCT_FILE environment variable.
   acct_key  Key used to decrypt the acct file. Defaults to the value in the ACCT_KEY environment variable.
   acct_profile Name of the profile to add to idem’s ctx.acct parameter Defaults to the value in the ACCT_PROFILE environment variable.
   cache_dir The location to use for the cache directory
   render  The render pipe to use, this allows for the language to be specified (jinja|yaml)
   runtime Select which execution runtime to use (serial|parallel)
   source_dir  The directory containing sls files

cheese:
   idem.state: (continues on next page)
- runtime: parallel
- sls:
  - idem_state.sls
  - sls_source

Maturity  new
Depends  acct, pop, pop-config, idem
Platform  all

23.19.122 salt.states.ifttt

Trigger an event in IFTTT

This state is useful for trigging events in IFTTT.
New in version 2015.8.0.

```yaml
ifttt-event:
  ifttt.trigger_event:
    - event: TestEvent
    - value1: 'This state was executed successfully.'
    - value2: 'Another value we can send.'
    - value3: 'A third value we can send.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```yaml
ifttt: secret_key: bzMRb-KKIAaNOWkEEw792J7El-B3z7muhdhlbYblJn4V6
```

```python
salt.states.ifttt.trigger_event(name, event, value1=None, value2=None, value3=None)
Trigger an event in IFTTT
```

```yaml
ifttt-event:
  ifttt.trigger_event:
    - event: TestEvent
    - value1: 'A value that we want to send.'
    - value2: 'A second value that we want to send.'
    - value3: 'A third value that we want to send.'
```

The following parameters are required:

- **name**  The unique name for this event.
- **event**  The name of the event to trigger in IFTTT.

The following parameters are optional:

- **value1**  One of the values that we can send to IFTTT.
- **value2**  One of the values that we can send to IFTTT.
- **value3**  One of the values that we can send to IFTTT.
Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: path, mask, and cmd. The user whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the path declaration is the unique factor, so if an existing cron that looks like this:

```
Watch for modifications in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
    - cmd: 'echo "$$ $@"'
```

Is changed to this:

```
Watch for modifications and access in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
      - IN_ACCESS
    - cmd: 'echo "$$ $@"'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

```
salt.states.incron.absent(name, path, mask, cmd, user='root')
```

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.

- **name**: Unique comment describing the entry
- **path**: The path that should be watched
- **user**: The name of the user who's crontab needs to be modified, defaults to the root user
- **mask**: The mask of events that should be monitored for
- **cmd**: The cmd that should be executed

```
salt.states.incron.present(name, path, mask, cmd, user='root')
```

Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: `man 5 incrontab`.

- **name**: Unique comment describing the entry
- **path**: The path that should be watched
- **user**: The name of the user who's crontab needs to be modified, defaults to the root user
- **mask**: The mask of events that should be monitored for
- **cmd**: The cmd that should be executed
23.19.124 salt.states.influxdb08_database

Management of Influxdb 0.8 databases

(compatible with InfluxDB version 0.5-0.8)

New in version 2014.7.0.

salt.states.influxdb08_database.absent(name, user=None, password=None, host=None, port=None)

Ensure that the named database is absent
- name: The name of the database to remove
- user: The user to connect as (must be able to remove the database)
- password: The password of the user
- host: The host to connect to
- port: The port to connect to

salt.states.influxdb08_database.present(name, user=None, password=None, host=None, port=None)

Ensure that the named database is present
- name: The name of the database to create
- user: The user to connect as (must be able to remove the database)
- password: The password of the user
- host: The host to connect to
- port: The port to connect to

23.19.125 salt.states.influxdb08_user

Management of InfluxDB 0.8 users

(compatible with InfluxDB version 0.5-0.8)

New in version 2014.7.0.

salt.states.influxdb08_user.absent(name, database=None, user=None, password=None, host=None, port=None)

Ensure that the named cluster admin or database user is absent.
- name: The name of the user to remove
- database: The database to remove the user from
- user: The user to connect as (must be able to remove the user)
- password: The password of the user
- host: The host to connect to
- port: The port to connect to

salt.states.influxdb08_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)

Ensure that the cluster admin or database user is present.
- name: The name of the user to manage
- passwd: The password of the user
- database: The database to create the user in
- user: The user to connect as (must be able to create the user)
- password: The password of the user
- host: The host to connect to
- port: The port to connect to
23.19.126 salt.states.influxdb_continuous_query

Management of Influxdb continuous queries

New in version 2017.7.0.

(saline with InfluxDB version 0.9+)

salt.states.influxdb_continuous_query.absent(name, database, **client_args)
Ensure that given continuous query is absent.
name Name of the continuous query to remove.
database Name of the database that the continuous query was defined on.
salt.states.influxdb_continuous_query.present(name, database, query, resample_time=None, coverage_period=None, **client_args)
Ensure that given continuous query is present.
name Name of the continuous query to create.
database Database to create continuous query on.
query The query content
resample_time [None] Duration between continuous query resampling.
coverage_period [None] Duration specifying time period per sample.

23.19.127 salt.states.influxdb_database

Management of Influxdb databases

(saline with InfluxDB version 0.9+)

salt.states.influxdb_database.absent(name, **client_args)
Ensure that given database is absent.
name Name of the database to remove.
salt.states.influxdb_database.present(name, **client_args)
Ensure that given database is present.
name Name of the database to create.

23.19.128 salt.states.influxdb_retention_policy

Management of Influxdb retention policies

New in version 2017.7.0.

(saline with InfluxDB version 0.9+)

salt.states.influxdb_retention_policy.absent(name, database, **client_args)
Ensure that given retention policy is absent.
name Name of the retention policy to remove.
database Name of the database that the retention policy was defined on.
salt.states.influxdb_retention_policy.convert_duration(duration)
Convert the a duration string into XXhYYmZZs format
duration Duration to convert
Returns: duration_string String representation of duration in XXhYYmZZs format
salt.states.influxdb_retention_policy.present(name, database, duration='7d', replication=1, default=False, **client_args)

Ensure that given retention policy is present.
- name Name of the retention policy to create.
- database Database to create retention policy on.

23.19.129 salt.states.influxdb_user

Management of InfluxDB users

(compatible with InfluxDB version 0.9+)

salt.states.influxdb_user.absent(name, **client_args)

Ensure that given user is absent.
- name The name of the user to manage

salt.states.influxdb_user.present(name, passwd, admin=False, grants=None, **client_args)

Ensure that given user is present.
- name Name of the user to manage
- passwd Password of the user
- admin [False] Whether the user should have cluster administration privileges or not.
- grants Optional - Dict of database:privilege items associated with the user. Example:
  - grants: foo_db: read bar_db: all

Example:

```yaml
example user present in influxdb:
  influxdb_user.present:
    - name: example
    - passwd: somepassword
    - admin: False
    - grants:
        foo_db: read
        bar_db: all
```

23.19.130 salt.states.infoblox_a

Infoblox A record management.

functions accept api_opts:
- api_verifyssl: verify SSL [default to True or pillar value]
- api_url: server to connect to [default to pillar value]
- api_username: [default to pillar value]
- api_password: [default to pillar value]

salt.states.infoblox_a.absent(name=None, ipv4addr=None, **api_opts)

Ensure infoblox A record is removed.

State example:

```yaml
infoblox_a.absent:
  - name: example-ha-0.domain.com

infoblox_a.absent:
  - name: 127.0.23.23
```

23.19. state modules
salt.states.infoblox_a.present(name=None, ipv4addr=None, data=None, ensure_data=True, **api_opts)

Ensure infoblox A record.

When you wish to update a hostname ensure name is set to the hostname of the current record. You can give a new name in the data.name.

State example:

```yaml
infoblox_a.present:
  - name: example-ha-0.domain.com
  - data:
    name: example-ha-0.domain.com
    ipv4addr: 123.0.31.2
    view: Internal
```

23.19.131 salt.states.infoblox_cname

Infoblox CNAME management.

functions accept api_opts:

- api_verifyssl: verify SSL [default to True or pillar value]
- api_url: server to connect to [default to pillar value]
- api_username: [default to pillar value]
- api_password: [default to pillar value]

salt.states.infoblox_cname.absent(name=None, canonical=None, **api_opts)

Ensure the CNAME with the given name or canonical name is removed

salt.states.infoblox_cname.present(name=None, data=None, ensure_data=True, **api_opts)

Ensure the CNAME with the given data is present.

name CNAME of record

data raw CNAME api data see: https://INFOBLOX/wapidoc

State example:

```yaml
infoblox_cname.present:
  - name: example-ha-0.domain.com
  - data:
    name: example-ha-0.domain.com
    canonical: example.domain.com
    zone: example.com
    view: Internal
    comment: Example comment

infoblox_cname.present:
  - name: example-ha-0.domain.com
  - data:
    name: example-ha-0.domain.com
    canonical: example.domain.com
    zone: example.com
    view: Internal
    comment: Example comment
  - api_url: https://INFOBLOX/wapi/v1.2.1
  - api_username: username
  - api_password: passwd
```
23.19.132 salt.states.infoblox_host_record

Infoblox host record management.

functions accept api_opts:

  api_verifyssl: verify SSL [default to True or pillar value]
  api_url: server to connect to [default to pillar value]
  api_username: [default to pillar value]
  api_password: [default to pillar value]

salt.states.infoblox_host_record.absent(name=None, ipv4addr=None, mac=None, **api_opts)

Ensure the host with the given Name ipv4addr or mac is removed.

State example:

```yaml
infoblox_host_record.absent:
  - name: hostname.of.record.to.remove
infoblox_host_record.absent:
  - name:
    - ipv4addr: 192.168.0.1
infoblox_host_record.absent:
  - name:
    - mac: 12:02:12:31:23:43
```

salt.states.infoblox_host_record.present(name=None, data=None, ensure_data=True, **api_opts)

This will ensure that a host with the provided name exists. This will try to ensure that the state of the host matches the given data. If the host is not found then one will be created.

When trying to update a hostname ensure `name` is set to the hostname of the current record. You can give a new name in the `data.name`.

Avoid race conditions, use `func:nextavailableip`:

- `func:nextavailableip:network/ZG54dfgsrDFEFsfslAzA:10.0.0.0/8/default`
- `func:nextavailableip:10.0.0.0/8`
- `func:nextavailableip:10.0.0.0/8,externalconfigure_for_dns`
- `func:nextavailableip:10.0.0.3-10.0.0.10`

State Example:

```yaml
# this would update `original_hostname.example.ca` to changed `data`
infoblox_host_record.present:
  - name: original_hostname.example.ca
  - data: {"namhostname.example.cae": 'hostname.example.ca',
    'aliases': ['hostname.math.example.ca'],
    'extattrs': [{'Business Contact': {'value': 'EXAMPLE@example.ca'}},
    'ipv4addr': [{'configure_for_dhcp': True,
    'ipv4addr': 'func:nextavailableip:129.97.139.0/24',
    'mac': '00:50:56:84:6e:ae'],
    'ipv6addrs': []},
```
23.19.133 salt.states.infoblox_range

Infoblox host record management.

functions accept api_opts:

api_verifyssl: verify SSL [default to True or pillar value] api_url: server to connect to [default to pillar value] api_username: [default to pillar value] api_password: [default to pillar value]

```
salt.states.infoblox_range.absent(name=None, start_addr=None, end_addr=None, data=None, **api_opts)
```

Ensure the range is removed

Supplying the end of the range is optional.

State example:

```
infoblox_range.absent:
  - name: 'vlan10'

infoblox_range.absent:
  - name:
    - start_addr: 127.0.1.20
```

```
salt.states.infoblox_range.present(name=None, start_addr=None, end_addr=None, data=None, **api_opts)
```

Ensure range record is present.

infoblox_range.present: start_addr: '129.97.150.160', end_addr: '129.97.150.170',

Verbose state example:

```
infoblox_range.present:
  data: {
    'always_update_dns': False,
    'authority': False,
    'comment': 'range of IP addresses used for salt.. was used for ghost images deployment',
    'ddns_generate_hostname': True,
    'deny_all_clients': False,
    'deny_bootp': False,
    'disable': False,
    'email_list': [],
    'enable_ddns': False,
    'enable_dhcp_thresholds': False,

- sections:
  - test
  - test1

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

salt.states.ini_manage.sections_present(name, sections=None, separator='=')

/home/saltminion/api-paste.ini:
insections_present:
- separator: '=
- sections:
  - section_one
  - section_two

This will only create empty sections. To also create options, use options_present state
options present in file and not specified in sections will be deleted changes dict will contain the sections that changed
23.19.135 salt.states.ipmi

Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None

ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword

salt.states.ipmi.boot_device(name='default', **kwargs)
  Request power state change
  name = default
  • network -- Request network boot
  • hd -- Boot from hard drive
  • safe -- Boot from hard drive, requesting 'safe mode'
  • optical -- boot from CD/DVD/BD drive
  • setup -- Boot into setup utility
  • default -- remove any IPMI directed boot device request

kwargs
  • api_host=localhost
  • api_user=admin
  • api_pass=
  • api_port=623
  • api_kg=None

salt.states.ipmi.power(name='power_on', wait=300, **kwargs)
  Request power state change
  name
  Ensure power state one of:
  • power_on -- system turn on
  • power_off -- system turn off (without waiting for OS)
  • shutdown -- request OS proper shutdown
  • reset -- reset (without waiting for OS)
  • boot -- If system is off, then 'on', else 'reset'

wait  wait X seconds for the job to complete before forcing. (defaults to 300 seconds)
salt.states.ipmi.user_absent(name, channel=14, **kwargs)
Remove user Delete all user (uid) records having the matching name.

name string name of user to delete
channel channel to remove user access from defaults to 14 for auto.

kwargs

salt.states.ipmi.user_present(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
Ensure IPMI user and user privileges.

name name of user (limit 16 bytes)
uid user id number (1 to 7)
password user password (limit 16 bytes)
channel ipmi channel defaults to 14 for auto
callback User Restricted to Callback

False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.

True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they ‘call in’ to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

link_auth User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

ipmi_msg User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, ‘IPMI Messaging’ refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.)

23.19.136  salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

```python
setname:
    ipset.set_present:
        - set_type: bitmap:ip
        - range: 192.168.0.0/16
        - comment: True

setname:
    ipset.set_absent:
        - set_type: bitmap:ip
        - range: 192.168.0.0/16
        - comment: True

setname_ENTRIES:
    ipset.present:
        - set_name: setname
        - entry: 192.168.0.3
        - comment: Hello
        - require:
            - ipset: baz

setname_ENTRIES:
    ipset.present:
        - set_name: setname
        - entry:
            - 192.168.0.3
            - 192.168.1.3
        - comment: Hello
        - require:
            - ipset: baz

setname_ENTRIES:
    ipset.absent:
        - set_name: setname
        - entry:
            - 192.168.0.3
            - 192.168.1.3
        - comment: Hello
        - require:
            - ipset: baz

setname:
    ipset.flush:

salt.states.ipset.absent(name=None, entries=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Remove a entry or entries from a chain

ame  A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

family  Network family, ipv4 or ipv6.

salt.states.ipset.flush(name, family='ipv4', **kwargs)
```
New in version 2014.7.0.

Flush current ipset set
family Networking family, either ipv4 or ipv6

call set

salt.states.ipset.present(name, entry=None, family='ipv4', **kwargs)
New in version 2014.7.0.

Append an entry to a set
name A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
entry A single entry to add to a set or a list of entries to add to a set
family Network family, ipv4 or ipv6.

call set

salt.states.ipset.set_absent(name, family='ipv4', **kwargs)
New in version 2014.7.0.

Verify the set is absent.
family Networking family, either ipv4 or ipv6

call set

salt.states.ipset.set_present(name, set_type, family='ipv4', **kwargs)
New in version 2014.7.0.

Verify the set exists.
name A user-defined set name.
set_type The type for the set.
family Network family, either ipv4 or ipv6

23.19.137 salt.states.iptables

Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```
httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - connstate: NEW
      - dport: 80
      - protocol: tcp
      - sport: 1025:65535
      - save: True

httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - state
      - comment
      - comment: "Allow HTTP"
    - connstate: NEW
    - dport: 80
```

(continues on next page)
- **protocol**: tcp
- **sport**: 1025:65535
- **save**: True

**httpd**:

```yaml
iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - source: '127.0.0.1'
  - dport: 80
  - protocol: tcp
  - sport: 1025:65535
  - save: True

.. Invert Rule

**httpd**:

```yaml
iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - source: '!127.0.0.1'
  - dport: 80
  - protocol: tcp
  - sport: 1025:65535
  - save: True
```

**httpd**:

```yaml
iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - source: 'not 127.0.0.1'
  - dport: 80
  - protocol: tcp
  - sport: 1025:65535
  - save: True
```

**httpd**:

```yaml
iptables.append:
  - table: filter
```
- **family**: ipv6
- **chain**: INPUT
- **jump**: ACCEPT
- **match**: state
- **connstate**: NEW
- **dport**: 80
- **protocol**: tcp
- **sport**: 1025:65535
- **save**: True

**httpd**:

```yaml
iptables.append:
  - table: filter
    - family: ipv4
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dports:
      - 80
      - 443
    - protocol: tcp
    - sport: 1025:65535
    - save: True
```

**httpd**:  

```yaml
iptables.insert:
  - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True
```

**httpd**:  

```yaml
iptables.insert:
  - position: 1
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True
```

**httpd**:  

```yaml
iptables.delete:
  - table: filter
  - chain: INPUT
```

(continues on next page)
- jump: ACCEPT
  - match: state
  - connstate: NEW
  - dport: 80
  - protocol: tcp
  - sport: 1025:65535
  - save: True

httpd:
  - iptables.delete:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True

httpd:
  - iptables.delete:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True

default to accept:
  - iptables.set_policy:
    - chain: INPUT
    - policy: ACCEPT

Note: Whereas iptables will accept -p, --proto[c[o[l]]] as synonyms of --protocol, if --proto appears in an iptables command after the appearance of -m policy, it is interpreted as the --proto option of the policy extension (see the iptables-extensions(8) man page).

Example rules for IPSec policy:

accept.esp_in:
  - iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - source: 10.20.0.0/24
    - destination: 10.10.0.0/24
    - in-interface: eth0
    - match: policy

(continues on next page)
```yaml
- dir: in
- pol: ipsec
- reqid: 1
- proto: esp

accept_esp_forward_in:
iptables.append:
  - use:
    - iptables: accept_esp_in
  - chain: FORWARD

accept_esp_out:
iptables.append:
  - table: filter
  - chain: OUTPUT
  - jump: ACCEPT
  - source: 10.10.0.0/24
  - destination: 10.20.0.0/24
  - out-interface: eth0
  - match: policy
  - dir: out
  - pol: ipsec
  - reqid: 1
  - proto: esp

accept_esp_forward_out:
iptables.append:
  - use:
    - iptables: accept_esp_out
  - chain: FORWARD
```

**Note:** Various functions of the `iptables` module use the `--check` option. If the version of `iptables` on the target system does not include this option, an alternate version of this check will be performed using the output of `iptables-save`. This may have unintended consequences on legacy releases of `iptables`.

### `salt.states.iptables.append`

New in version 0.17.0.

Add a rule to the end of the specified chain.

- **name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
- **table** The table that owns the chain which should be modified
- **family** Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for `iptables`, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

Jump options that doesn’t take arguments should be passed in with an empty string.

### `salt.states.iptables.chain_absent`

New in version 2014.1.0.

Verify the chain is absent.

- **name** The chain to remove
- **table** The table to remove the chain from
- **family** Networking family, either ipv4 or ipv6

### `salt.states.iptables.chain_present`

New in version 2014.1.0.
Verify the chain is exist.

**name**  A user-defined chain name.
**table**  The table to own the chain.
**family**  Networking family, either ipv4 or ipv6

```
salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Delete a rule to a chain

**name**  A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
**table**  The table that owns the chain that should be modified
**family**  Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

```
salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Flush current iptables state

**table**  The table that owns the chain that should be modified
**family**  Networking family, either ipv4 or ipv6

```
salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Insert a rule into a chain

**name**  A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
**table**  The table that owns the chain that should be modified
**family**  Networking family, either ipv4 or ipv6
**position**  The numerical representation of where the rule should be inserted into the chain. Note that -1 is not a supported position value.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

```
salt.states.iptables.mod_aggregate(low, chunks, running)
```

The mod_aggregate function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

```
salt.states.iptables.set_policy(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Sets the default policy for iptables firewall tables

**table**  The table that owns the chain that should be modified
**family**  Networking family, either ipv4 or ipv6
**policy**  The requested table policy
Salt Documentation, Release 3003.1

23.19.138 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses the jboss-cli.sh script from a JBoss or Wildfly installation and parses its output to determine the execution result.

In order to run each state, a jboss_config dictionary with the following properties must be passed:

```yaml
jboss:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

If the controller doesn't require a password, then the cli_user and cli_password parameters are optional.

Since same dictionary with configuration will be used in all the states, it may be more convenient to move JBoss configuration and other properties to the pillar.

Example of application deployment from local filesystem:

```yaml
application_deployed:
  jboss7.deployed:
    - salt_source: '/tmp/webapp.war'
    - jboss_config: {{ pillar['jboss'] }}
```

For the sake of brevity, examples for each state assume that jboss_config is contained in the pillar.

**salt.states.jboss7.bindings_exist**(*name, jboss_config, bindings, profile=None*)

Ensures that given JNDI binding are present on the server. If a binding doesn't exist on the server it will be created. If it already exists its value will be changed.

- **jboss_config**: Dict with connection properties (see state description)
- **bindings**: Dict with bindings to set.
- **profile**: The profile name (domain mode only)

Example:

```yaml
jndi_entries_created:
  jboss7.bindings_exist:
    - bindings:
        'java:global/sampleapp/environment': 'DEV'
        'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.
      properties'
    - jboss_config: {{ pillar['jboss'] }}
```

**salt.states.jboss7.datasource_exists**(*name, jboss_config, datasource_properties, recreate=False, profile=None*)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn't exist, it is created, otherwise only the properties that are different will be updated.

- **name**: Datasource property name
- **jboss_config**: Dict with connection properties (see state description)
- **datasource_properties**: Dict with datasource properties
- **recreate**: [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not me possible to remove it.
- **profile**: [None] The profile name for this datasource (domain mode only)

Example:
**sampleDS:**

```yaml
jboss7.datasource_exists:
  - recreate: False
  - datasource_properties:
    driver-name: mysql
    connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
    jndi-name: 'java:jboss/datasources/sampleDS'
    user-name: sampleuser
    password: secret
    min-pool-size: 3
    use-java-context: True
    jboss_config: {{ pillar['jbosss'] }}
  - profile: full-ha
```

**salt.states.jboss7.deployed** *(name, jboss_config, salt_source=None)*

Ensures that the given application is deployed on server.

- **jboss_config:** Dict with connection properties (see state description)
- **salt_source:**
  - *How to find the artifact to be deployed.*
  - **target_file:** Where to look in the minion’s file system for the artifact to be deployed (e.g. `/tmp/application-web-0.39.war`). When source is specified, also specifies where to save the retrieved file.
  - **source:** (optional) File on salt master (e.g. `salt://application-web-0.39.war`). If absent, no files will be retrieved and the artifact in target_file will be used for the deployment.
  - **undeploy:** (optional) Regular expression to match against existing deployments. When present, if there is a deployment that matches the regular expression, it will be undeployed before the new artifact is deployed.
  - **undeploy_force:** (optional) If True, the artifact will be undeployed although it has not changed.

**Examples:**

Deployment of a file from minion’s local file system:

```yaml
application_deployed:
  jboss7.deployed:
    - salt_source: 
      target_file: '/tmp/webapp.war'
    - jboss_config: {{ pillar['jbosss'] }}
```

It is assumed that `/tmp/webapp.war` was made available by some other means. No applications will be undeployed; if an existing deployment that shares that name exists, then it will be replaced with the updated version.

Deployment of a file from the Salt master’s file system:

```yaml
application_deployed:
  jboss7.deployed:
    - source: salt://application-web-0.39.war
      target_file: '/tmp/application-web-0.39.war'
      undeploy: 'application-web-.*'
    - jboss_config: {{ pillar['jbosss'] }}
```

Here, application-web-0.39.war file is downloaded from Salt file system to `/tmp/application-web-0.39.war` file on minion. Existing deployments are checked if any of them matches ‘application-web-.*’ regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.
If the source parameter of salt_source is specified, it can use any protocol that the file states use. This includes not only downloading from the master but also HTTP, HTTPS, FTP, Amazon S3, and OpenStack Swift.

**salt.states.jboss7.reloaded**(name, jboss_config, timeout=60, interval=5)

Reloads configuration of jboss server.

- **jboss_config**: Dict with connection properties (see state description)
- **timeout**: Time to wait until jboss is back in running state. Default timeout is 60s.
- **interval**: Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:
- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloads configuration
- Waits for server to reload and be in running state

Example:

```
configuration_reloaded:
    jboss7.reloaded:
        - jboss_config: {{ pillar['jboss'] }}
```

### 23.19.139 salt.states.jenkins

**Management of Jenkins**

New in version 2016.3.0.

salt.states.jenkins.absent**(name, **kwargs)**

Ensure the job is absent from the Jenkins configured jobs

- **name**: The name of the Jenkins job to remove

salt.states.jenkins.present**(name, config=None, **kwargs)**

Ensure the job is present in the Jenkins configured jobs

- **name**: The unique name for the Jenkins job
- **config**: The Salt URL for the file to use for configuring the job

### 23.19.140 salt.states.junos

**State modules to interact with Junos devices.**

- **maturity**: new
- **dependencies**: junos-eznc, jxmlease

**Note**: Those who wish to use junos-eznc (PyEZ) version >= 2.1.0, must use the latest salt code from github until the next release.

Refer to junos for information on connecting to junos proxy.

salt.states.junos.cli**(name, **kwargs)**

Executes the CLI commands and reuturns the text output.
show version:
    junos.cli:
        - format: xml

get software version of device:
    junos.cli:
        - name: show version
        - format: text
        - dest: /home/user/show_version.log

Parameters

- Required --
  - name: The command that need to be executed on Junos CLI. (default = None)

- Optional --
  - kwargs: Keyworded arguments which can be provided like-
    - format: Format in which to get the CLI output. (text or xml, default = 'text')
    - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - dest: The destination file where the CLI output can be stored. (default = None)

salt.states.junos.commit(name, **kwargs)
Commit the changes loaded into the candidate configuration.

commit the changes:
    junos.commit:
        - confirm: 10

Parameters

Optional --
- kwargs: Keyworded arguments which can be provided like-
  - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
  - comment: Provide a comment to the commit. (default = None)
  - confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be roll backed in the given time unless the commit is confirmed.
  - sync: On dual control plane systems, requests that the candidate configuration on one control plane be copied to the other control plane, checked for correct syntax, and committed on both Routing Engines. (default = False)
  - force_sync: On dual control plane systems, force the candidate configuration on one control plane to be copied to the other control plane.
  - full: When set to True requires all the daemons to check and evaluate the new configuration.
  - detail: When true return commit detail.

salt.states.junos.commit_check(name)
Perform a commit check on the configuration.

perform commit check:
    junos.commit_check

salt.states.junos.diff(name, d_id=0, **kwargs)
Changed in version 3001.

Gets the difference between the candidate and the current configuration.
get the diff:
  junos.diff:
    - d_id: 10

Parameters Optional --
  • d_id: The rollback diff id (d_id) value [0-49]. (default = 0)

salt.states.junos.file_copy(name, dest=None, **kwargs)
Copies the file from the local device to the junos device.

/home/m2/info.txt:
  junos.file_copy:
    - dest: info_copy.txt

Parameters Required --
  • name: The source path where the file is kept.
  • dest: The destination path where the file will be copied.

salt.states.junos.get_table(name, table, table_file, **kwargs)
New in version 3001.
Retrieve data from a Junos device using Tables/Views

get route details:
  junos.get_table:
    - table: RouteTable
    - table_file: routes.yml

get interface details:
  junos.get_table:
    - table: EthPortTable
    - table_file: ethport.yml
    - table_args:
      interface_name: ge-0/0/0

name (required) task definition
table (required) Name of PyEZ Table
file YAML file that has the table specified in table parameter
path: Path of location of the YAML file. defaults to op directory in jnpr.junos.op
target: if command need to run on FPC, can specify fpc target
key: To overwrite key provided in YAML
key_items: To select only given key items
filters: To select only filter for the dictionary from columns
template_args: key/value pair which should render Jinja template command

salt.states.junos.install_config(name, **kwargs)
Loads and commits the configuration provided.

Install the mentioned config:
  junos.install_config:
    - name: salt://configs/interface.set
    - timeout: 100
    - diffs_file: '/var/log/diff'

Install the mentioned config:
  junos.install_config:
    - path: salt://configs/interface.set
name  Path where the configuration/template file is present. If the file has a *.conf extension, the content is treated as text format. If the file has a *.xml extension, the content is treated as XML format. If the file has a *.set extension, the content is treated as Junos OS set commands

template_vars  The dictionary of data for the jinja variables present in the jinja template

timeout  [30]  Set NETCONF RPC timeout. Can be used for commands which take a while to execute.

overwrite  [False]  Set to True if you want this file is to completely replace the configuration file. Sets action to override

Note:  This option cannot be used if format is "set".

merge  [False]  If set to True will set the load-config action to merge. the default load-config action is 'replace' for xml/json/text config

comment  Provide a comment to the commit. (default = None)

confirm  Provide time in minutes for commit confirmation. If this option is specified, the commit will be rolled back in the given time unless the commit is confirmed.

diffs_file  Path to the file where the diff (difference in old configuration and the committed configuration) will be stored.

Note:  The file will be stored on the proxy minion. To push the files to the master use cp.push.

salt.states.junos.install_os(name,**kwargs)
Installs the given image on the device. After the installation is complete the device is rebooted, if reboot=True is given as a keyworded argument.

salt://images/junos_image.tgz:
  junos.install_os:
  - timeout: 100
  - reboot: True

Parameters
  - Required --
    - name:  Path where the image file is present on the proxy minion.
  - Optional --
    - kwargs:  keyworded arguments to be given such as timeout, reboot etc
      - timeout:  Set NETCONF RPC timeout. Can be used to RPCs which take a while to execute. (default = 30 seconds)
      - reboot:  Whether to reboot after installation (default = False)
      - no_copy:  When True the software package will not be SCP’d to the device. (default = False)

salt.states.junos.load(name,**kwargs)
Loads the configuration provided onto the junos device.

Install the mentioned config:
  junos.load:
  - name:  salt://configs/interface.set
Install the mentioned config:

```bash
junos.load:
  - name: salt://configs/interface.set
  - template_vars:
    interface_name: lo0
    description: Creating interface via SaltStack.
```

Sample template:

```bash
set interfaces {{ interface_name }} unit 0
```

**name** Path where the configuration/template file is present. If the file has a `.conf` extension, the content is treated as text format. If the file has a `.xml` extension, the content is treated as XML format. If the file has a `.set` extension, the content is treated as Junos OS `set` commands.

**overwrite** [False] Set to `True` if you want this file is to completely replace the configuration file.

Note: This option cannot be used if `format` is "set".

**merge** [False] If set to `True` will set the load-config action to merge. the default load-config action is 'replace' for xml/json/text config

**update** [False] Compare a complete loaded configuration against the candidate configuration. For each hierarchy level or configuration object that is different in the two configurations, the version in the loaded configuration replaces the version in the candidate configuration. When the configuration is later committed, only system processes that are affected by the changed configuration elements parse the new configuration. This action is supported from PyEZ 2.1 (default = False)

**template_vars** Variables to be passed into the template processing engine in addition to those present in `__pillar__`, `__opts__`, `__grains__`, etc. You may reference these variables in your template like so: `{{ template_vars["var_name"] }}`

### salt.states.junos.lock(name)
Attempts an exclusive lock on the candidate configuration. This is a non-blocking call.

Note: Any user who wishes to use lock, must necessarily unlock the configuration too. Ensure `unlock` is called in the same orchestration run in which the lock is called.

### salt.states.junos.resultdecorator(function)

### salt.states.junos.rollback(name, d_id, **kwargs)
Rollbacks the committed changes.

#### Parameters
**Optional** --
- id:
- d_id: The rollback id value [0-49]. (default = 0) (this variable cannot be named `id`, it conflicts with the state compiler's internal id)
- **kwargs**: Keyworded arguments which can be provided like-
  - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
- comment: Provide a comment to the commit. (default = None)
- confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbaked in the given time unless the commit is confirmed.
- diffs_file: Path to the file where any diffs will be written. (default = None)

```python
salt.states.junos.rpc(name, dest=None, format='xml', args=None, **kwargs)
```

Executes the given rpc. The returned data can be stored in a file by specifying the destination path with dest as an argument.

```python
get-interface-information:
  junos.rpc:
    - dest: /home/user/rpc.log
    - interface_name: lo0

fetch interface information with terse:
  junos.rpc:
    - name: get-interface-information
    - terse: True
```

**Parameters**

- **Required**
  - name: The rpc to be executed. (default = None)

- **Optional**
  - dest: Destination file where the rpc output is stored. (default = None) Note that the file will be stored on the proxy minion. To push the files to the master use the salt's following execution module: `cp.push`
  - format: The format in which the rpc reply must be stored in file specified in the dest (used only when dest is specified) (default = xml)
  - kwargs: Keyworded arguments taken by rpc call like-
    * timeout: 30 Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default= 30 seconds)
    * filter: Only to be used with 'get-config' rpc to get specific configuration.
    * terse: Amount of information you want.
    * interface_name: Name of the interface whose information you want.

```python
salt.states.junos.set_hostname(name, **kwargs)
```

Changes the hostname of the device.

```python
device_name:
  junos.set_hostname:
    - comment: "Host-name set via saltstack."
```

**Parameters**

- **Required**
  - name: The name to be set. (default = None)

- **Optional**
  - kwargs: Keyworded arguments which can be provided like-
    * timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    * comment: Provide a comment to the commit. (default = None)
    * confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbaked in the given time unless the commit is confirmed.
salt.states.junos.shutdown(name, **kwargs)
Shuts down the device.

```python
shut the device:
junos.shutdown:
  - in_min: 10
```

Parameters Optional --
- kwargs:
  - reboot: Whether to reboot instead of shutdown. (default=False)
  - at: Specify time for reboot. (To be used only if reboot=yes)
  - in_min: Specify delay in minutes for shutdown

salt.states.junos.unlock(name)
Unlocks the candidate configuration.

```python
unlock the config:
junos.unlock
```

salt.states.junos.zeroize(name)
Resets the device to default factory settings.

```python
reset my device:
junos.zeroize
```

name: can be anything

23.19.141 salt.states.kapacitor

Kapacitor state module.

configuration This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```python
kapacitor.unsafe_ssl: 'false'
kapacitor.protocol: 'http'
kapacitor.host: 'localhost'
kapacitor.port: 9092
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

New in version 2016.11.0.

salt.states.kapacitor.task_absent(name)
Ensure that a task is absent from Kapacitor.

name Name of the task.

salt.states.kapacitor.task_present(name, tick_script, task_type='stream', database=None, retention_policy='default', enable=True, dbrps=None)
Ensure that a task is present and up-to-date in Kapacitor.

name Name of the task.
tick_script Path to the TICK script for the task. Can be a salt:// source.
task_type Task type. Defaults to 'stream'
dbrps A list of databases and retention policies in "dbname","rpname" format to fetch data from. For backward compatibility, the value of 'database' and 'retention_policy' will be merged as part of dbrps.

New in version 2019.2.0.
database  Which database to fetch data from. Defaults to None, which will use the default database in InfluxDB.
retention_policy  Which retention policy to fetch data from. Defaults to 'default'.
enable  Whether to enable the task or not. Defaults to True.

23.19.142  salt.states.kernelpkg

Manage kernel packages and active kernel version

Example state to install the latest kernel from package repositories:

```
install-latest-kernel:
    kernelpkg.latest_installed: []
```

Example state to boot the system if a new kernel has been installed:

```
boot-latest-kernel:
    kernelpkg.latest_active:
        - at_time: 1
```

Example state chaining the install and reboot operations:

```
install-latest-kernel:
    kernelpkg.latest_installed: []

boot-latest-kernel:
    kernelpkg.latest_active:
        - at_time: 1
        - onchanges:
            - kernelpkg: install-latest-kernel
```

Chaining can also be achieved using wait/listen requisites:

```
install-latest-kernel:
    kernelpkg.latest_installed: []

boot-latest-kernel:
    kernelpkg.latest_wait:
        - at_time: 1
        - listen:
            - kernelpkg: install-latest-kernel
```

`salt.states.kernelpkg.latest_active(name, at_time=None, **kwargs)`

Initiate a reboot if the running kernel is not the latest one installed.

Note:  This state does not install any patches. It only compares the running kernel version number to other kernel versions also installed in the system. If the running version is not the latest one installed, this state will reboot the system.

See `kernelpkg.upgrade` and `latest_installed()` for ways to install new kernel packages.

This module does not attempt to understand or manage boot loader configurations it is possible to have a new kernel installed, but a boot loader configuration that will never activate it. For this reason, it would not be advisable to schedule this state to run automatically.

Because this state function may cause the system to reboot, it may be preferable to move it to the very end of the state run. See `latest_wait()` for a waitable state that can be called with the `listen` requisite.
**name**  Arbitrary name for the state. Does not affect behavior.

**at_time**  The wait time in minutes before the system will be rebooted.

```
salt.states.kernelpkg.latest_installed(name, **kwargs)
```
Ensure that the latest version of the kernel available in the repositories is installed.

**Note:** This state only installs the kernel, but does not activate it. The new kernel should become active at the next reboot. See `kernelpkg.needs_reboot` for details on how to detect this condition, and `latest_active()` to initialize a reboot when needed.

```
salt.states.kernelpkg.latest_wait(name, at_time=None, **kwargs)
```
Initiate a reboot if the running kernel is not the latest one installed. This is the waitable version of `latest_active()` and will not take any action unless triggered by a watch or listen requisite.

**Note:** Because this state function may cause the system to reboot, it may be preferable to move it to the very end of the state run using `listen` or `listen_in` requisites.

```
system-up-to-date:
  pkg.uptodate:
    - refresh: true

boot-latest-kernel:
  kernelpkg.latest_wait:
    - at_time: 1
    - listen:
      - pkg: system-up-to-date
```

```
salt.states.kernelpkg.mod_watch(name, sfun, **kwargs)
```
Execute a kernelpkg state based on a watch or listen call

---

### 23.19.143  `salt.states.keyboard`

**Management of keyboard layouts**

The keyboard layout can be managed for the system:

```
salt.states.keyboard.system(name)
```
Set the keyboard layout for the system

**name**  The keyboard layout to use

Or it can be managed for XOrg:

```
salt.states.keyboard.xorg
```

---

---
salt.states.keyboard.xorg(name)
   Set the keyboard layout for XOrg
   layout  The keyboard layout to use

23.19.144  salt.states.keystone

Management of Keystone users

   depends
      • keystoneclient Python module

   configuration  See salt.modules.keystone for setup instructions.

Keystone tenants:
   keystone.tenant_present:
      - names:
        - admin
        - demo
        - service

Keystone roles:
   keystone.role_present:
      - names:
        - admin
        - Member

admin:
   keystone.user_present:
      - password: R00T_4CC3SS
      - email: admin@domain.com
      - roles:
        - admin  # tenants
          - admin  # roles
        - service:
          - admin
          - Member
        - require:
          - keystone: Keystone tenants
          - keystone: Keystone roles

nova:
   keystone.user_present:
      - password: '$up3rn0v4'
      - email: nova@domain.com
      - tenant: service
      - roles:
        - service:
          - admin
        - require:
          - keystone: Keystone tenants
          - keystone: Keystone roles

demo:
   keystone.user_present:
      - password: 'd3m0n$strati0n'
      - email: demo@domain.com
- tenant: demo
  roles:
    demo:
      - Member
  require:
    - keystone: Keystone tenants
    - keystone: Keystone roles

**nova service:**

```
keystone.service_present:
  - name: nova
  - service_type: compute
  - description: OpenStack Compute Service
```

salt.states.keystone.endpoint_absent(name, region=None, profile=None, interface=None, **connection_args)

Ensure that the endpoint for a service doesn't exist in Keystone catalog

- name The name of the service whose endpoints should not exist
- region (optional) The region of the endpoint. Defaults to RegionOne.
- interface The interface type, which describes the visibility of the endpoint. (for V3 API)

salt.states.keystone.endpoint_present(name, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, url=None, interface=None, **connection_args)

Ensure the specified endpoints exists for service

- name The Service name
- publicurl The public url of service endpoint (for V2 API)
- internalurl The internal url of service endpoint (for V2 API)
- adminurl The admin url of the service endpoint (for V2 API)
- region The region of the endpoint
- url The endpoint URL (for V3 API)
- interface The interface type, which describes the visibility of the endpoint. (for V3 API)

salt.states.keystone.project_absent(name, profile=None, **connection_args)

Ensure that the keystone project is absent. Alias for tenant_absent from V2 API to fulfill V3 API naming convention.

New in version 2016.11.0.

- name The name of the project that should not exist

```
delete_nova:
  keystone.project_absent:
    - name: nova
```

salt.states.keystone.project_present(name, description=None, enabled=True, profile=None, **connection_args)

Ensures that the keystone project exists Alias for tenant_present from V2 API to fulfill V3 API naming convention.

New in version 2016.11.0.

- name The name of the project to manage
- description The description to use for this project
- enabled Availability state for this project

```
nova:
  keystone.project_present:
```

(continues on next page)
- `enabled`: True
- `description`: 'Nova Compute Service'

salt.states.keystone.role_absent(name, profile=None, **connection_args)
   Ensure that the keystone role is absent.
   name The name of the role that should not exist

salt.states.keystone.role_present(name, profile=None, **connection_args)
   Ensures that the keystone role exists
   name The name of the role that should be present

salt.states.keystone.service_absent(name, profile=None, **connection_args)
   Ensure that the service doesn't exist in Keystone catalog
   name The name of the service that should not exist

salt.states.keystone.service_present(name, service_type, description=None, profile=None, **connection_args)
   Ensure service present in Keystone catalog
   name The name of the service
   service_type The type of Openstack Service
   description (optional) Description of the service

salt.states.keystone.tenant_absent(name, profile=None, **connection_args)
   Ensure that the keystone tenant is absent.
   name The name of the tenant that should not exist

salt.states.keystone.tenant_present(name, description=None, enabled=True, profile=None, **connection_args)
   Ensures that the keystone tenant exists
   name The name of the tenant to manage
   description The description to use for this tenant
   enabled Availability state for this tenant

salt.states.keystone.user_absent(name, profile=None, **connection_args)
   Ensure that the keystone user is absent.
   name The name of the user that should not exist

salt.states.keystone.user_present(name, password, email, tenant=None, enabled=True, roles=None, profile=None, password_reset=True, project=None, **connection_args)
   Ensure that the keystone user is present with the specified properties.
   name The name of the user to manage
   password The password to use for this user.

   Note: If the user already exists and a different password was set for the user than the one specified here, the password for the user will be updated. Please set the `password_reset` option to `False` if this is not the desired behavior.

   password_reset Whether or not to reset password after initial set. Defaults to `True`.
   email The email address for this user
   tenant The tenant (name) for this user
   project The project (name) for this user (overrides tenant in api v3)
   enabled Availability state for this user
   roles The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.
roles:
  admin:  # tenant
    - admin  # role
  service:
    - admin
    - Member

23.19.145 salt.states.keystone_domain

Management of OpenStack Keystone Domains

New in version 2018.3.0.

depends shade

configuration see salt.modules.keystoneng for setup instructions

Example States

```yaml
create_domain:
  keystone_domain.present:
    - name: domain1

create_domain_with_optional_params:
  keystone_domain.present:
    - name: domain1
    - enabled: False
    - description: 'my domain'

delete_domain:
  keystone_domain.absent:
    - name: domain1
```

salt.states.keystone_domain.absent(name, auth=None)
  Ensure domain does not exist
  name Name of the domain

salt.states.keystone_domain.present(name, auth=None, **kwargs)
  Ensure domain exists and is up-to-date
  name Name of the domain
  enabled Boolean to control if domain is enabled
  description An arbitrary description of the domain

23.19.146 salt.states.keystone_endpoint

Management of OpenStack Keystone Endpoints

New in version 2018.3.0.

depends shade

configuration see salt.modules.keystoneng for setup instructions

Example States
create endpoint:
  keystone_endpoint.present:
    - name: public
    - url: https://example.org:9292
    - region: RegionOne
    - service_name: glance

destroy endpoint:
  keystone_endpoint.absent:
    - name: public
    - url: https://example.org:9292
    - region: RegionOne
    - service_name: glance

create multiple endpoints:
  keystone_endpoint.absent:
    - names:
      - public
      - admin
      - internal
    - url: https://example.org:9292
    - region: RegionOne
    - service_name: glance

salt.states.keystone_endpoint.absent(name, service_name, auth=None, **kwargs)
Ensure an endpoint does not exists
  name  Interface name
  url  URL of the endpoint
  service_name  Service name or ID
  region  The region name to assign the endpoint

salt.states.keystone_endpoint.present(name, service_name, auth=None, **kwargs)
Ensure an endpoint exists and is up-to-date
  name  Interface name
  url  URL of the endpoint
  service_name  Service name or ID
  region  The region name to assign the endpoint
  enabled  Boolean to control if endpoint is enabled

23.19.147 salt.states.keystone_group

Management of OpenStack Keystone Groups

New in version 2018.3.0.

depends  shade

configuration  see salt.modules.keystoneng for setup instructions

Example States

create group:
  keystone_group.present:
    - name: group1

delete group:
keystone_group.absent:
  - name: group1

create group with optional params:
keystone_group.present:
  - name: group1
  - domain: domain1
  - description: 'my group'

salt.states.keystone_group.absent(name, auth=None, **kwargs)
Ensure group does not exist
name Name of the group
domain The name or id of the domain

calendar

salt.states.keystone_group.present(name, auth=None, **kwargs)
Ensure an group exists and is up-to-date
name Name of the group
domain The name or id of the domain
description An arbitrary description of the group

23.19.148 salt.states.keystone_project

Management of OpenStack Keystone Projects

New in version 2018.3.0.

depends shade
configuration see salt.modules.keystoneng for setup instructions

Example States

create project:
keystone_project.present:
  - name: project1

delete project:
keystone_project.absent:
  - name: project1

create project with optional params:
keystone_project.present:
  - name: project1
  - domain: domain1
  - enabled: False
  - description: 'my project'

salt.states.keystone_project.absent(name, auth=None, **kwargs)
Ensure a project does not exist
name Name of the project
domain The name or id of the domain

calendar

salt.states.keystone_project.present(name, auth=None, **kwargs)
Ensure a project exists and is up-to-date
name Name of the project
domain The name or id of the domain

3786 Chapter 23. Salt Module Reference
**description**  An arbitrary description of the project

### 23.19.149 salt.states.keystone_role

**Management of OpenStack Keystone Roles**

New in version 2018.3.0.

**depends** shade

**configuration** see `salt.modules.keystoneng` for setup instructions

**Example States**

```yaml
create role:
  keystone_role.present:
    - name: role1

delete role:
  keystone_role.absent:
    - name: role1

create role with optional params:
  keystone_role.present:
    - name: role1
    - description: 'my group'
```

```python
salt.states.keystone_role.absent(name, auth=None, **kwargs)
Ensure role does not exist
  name Name of the role

salt.states.keystone_role.present(name, auth=None, **kwargs)
Ensure an role exists
  name Name of the role
  description An arbitrary description of the role
```

### 23.19.150 salt.states.keystone_role_grant

**Management of OpenStack Keystone Role Grants**

New in version 2018.3.0.

**depends** shade

**configuration** see `salt.modules.keystoneng` for setup instructions

**Example States**

```yaml
create group:
  keystone_group.present:
    - name: group1

delete group:
  keystone_group.absent:
    - name: group1

create group with optional params:
```

(continues on next page)
```python
keystone_group.present:
- name: group1
- domain: domain1
- description: 'my group'
```
salt.states.keystone_role_grant.absent(name, auth=None, **kwargs)
salt.states.keystone_role_grant.present(name, auth=None, **kwargs)

23.19.151 salt.states.keystone_service

Management of OpenStack Keystone Services

New in version 2018.3.0.

depends shade
configuration see salt.modules.keystoneng for setup instructions

Example States

```yaml
create service:
  keystone_service.present:
  - name: glance
  - type: image

delete service:
  keystone_service.absent:
  - name: glance

create service with optional params:
  keystone_service.present:
  - name: glance
  - type: image
  - enabled: False
  - description: 'OpenStack Image'
```
salt.states.keystone_service.absent(name, auth=None)
  Ensure service does not exist
name Name of the service
salt.states.keystone_service.present(name, auth=None, **kwargs)
  Ensure an service exists and is up-to-date
name Name of the group
type Service type
enabled Boolean to control if service is enabled
description An arbitrary description of the service
23.19.152 salt.states.keystone_user

Management of OpenStack Keystone Users

New in version 2018.3.0.

depends shade

collection see salt.modules.keystoneng for setup instructions

Example States

<table>
<thead>
<tr>
<th>create user:</th>
<th>keystone_user.present:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- name: user1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>delete user:</th>
<th>keystone_user.absent:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- name: user1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>create user with optional params:</th>
<th>keystone_user.present:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- name: user1</td>
</tr>
<tr>
<td></td>
<td>- domain: domain1</td>
</tr>
<tr>
<td></td>
<td>- enabled: False</td>
</tr>
<tr>
<td></td>
<td>- password: password123</td>
</tr>
<tr>
<td></td>
<td>- email: &quot;<a href="mailto:user1@example.org">user1@example.org</a>&quot;</td>
</tr>
<tr>
<td></td>
<td>- description: 'my user'</td>
</tr>
</tbody>
</table>

salt.states.keystone_user.absent(name, auth=None, **kwargs)
Ensure user does not exists
name Name of the user
domain The name or id of the domain

salt.states.keystone_user.present(name, auth=None, **kwargs)
Ensure domain exists and is up-to-date
name Name of the domain
domain The name or id of the domain
enabled Boolean to control if domain is enabled
description An arbitrary description of the domain
password The user password
e-mail The users email address

23.19.153 salt.states.keystore

State management of a java keystore

salt.states.keystore.managed(name, passphrase, entries, force_remove=False)
Create or manage a java keystore.
nname The path to the keystore file
passphrase The password to the keystore
entries A list containing an alias, certificate, and optional private_key. The certificate and private_key can be a file or a string

```
- entries:
  - alias: hostname2
```
force_remove If True will cause the state to remove any entries found in the keystore which are not defined in the state. The default is False.

Example

```python
define_keystore:
    keystore.managed:
        - name: /path/to/keystore
        - passphrase: changeit
        - force_remove: True
        - entries:
            - alias: hostname1
              certificate: /path/to/cert.crt
            - alias: remotehost
              certificate: /path/to/cert2.crt
              private_key: /path/to/key2.key
            - alias: pillarhost
              certificate: {{ salt.pillar.get('path/to/cert') }}
```

23.19.154 salt.states.kmod

Loading and unloading of kernel modules

The Kernel modules on a system can be managed cleanly with the kmod state module:

```python
add_kvm:
    kmod.present:
        - name: kvm_amd
remove_beep:
    kmod.absent:
        - name: pcspkr
```

Multiple modules can be specified for both kmod.present and kmod.absent.

```python
add_sound:
    kmod.present:
        - mods:
            - snd_hda_codec_hdmi
            - snd_hda_codec
            - snd_hwdep
            - snd_hda_core
            - snd_pcm
            - snd_timer
            - snd
```

`salt.states.kmod.absent(name, persist=False, comment=True, mods=None)`

Verify that the named kernel module is not loaded
name The name of the kernel module to verify is not loaded
persist Remove module from /etc/modules
comment Comment out module in /etc/modules rather than remove it
mods A list of modules to verify are unloaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.

salt.states.kmod.present(name, persist=False, mods=None)
Ensure that the specified kernel module is loaded
name The name of the kernel module to verify is loaded
persist Also add module to /etc/modules
mods A list of modules to verify are loaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.

23.19.155 salt.states.kubernetes

Manage kubernetes resources as salt states

NOTE: This module requires the proper pillar values set. See salt.modules.kubernetesmod for more information.

**Warning:** Configuration options will change in 2019.2.0.

The kubernetes module is used to manage different kubernetes resources.

---

my-nginx:
  kubernetes.deployment_present:
    - namespace: default
      metadata:
        app: frontend

```

New in version 2017.7.0.

**salt.states.kubernetes.configmap_absent**(name, namespace=’default’, **kwargs)
Ensures that the named configmap is absent from the given namespace.

- **name**: The name of the configmap
- **namespace**: The namespace holding the configmap. The ‘default’ one is going to be used unless a different one is specified.

**salt.states.kubernetes.configmap_present**(name, namespace=’default’, data=None, source=None, template=None, **kwargs)
Ensures that the named configmap is present inside of the specified namespace with the given data. If the configmap exists it will be replaced.

- **name**: The name of the configmap.
- **namespace**: The namespace holding the configmap. The ‘default’ one is going to be used unless a different one is specified.
- **data**: The dictionary holding the configmaps.
- **source**: A file containing the data of the configmap in plain format.
- **template**: Template engine to be used to render the source file.

**salt.states.kubernetes.deployment_absent**(name, namespace=’default’, **kwargs)
Ensures that the named deployment is absent from the given namespace.

- **name**: The name of the deployment
namespace The name of the namespace

salt.states.kubernetes.deployment_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)

Ensures that the named deployment is present inside of the specified namespace with the given metadata and spec. If the deployment exists it will be replaced.

name The name of the deployment.
namespace The namespace holding the deployment. The 'default' one is going to be used unless a different one is specified.
metadata The metadata of the deployment object.
spec The spec of the deployment object.
source A file containing the definition of the deployment (metadata and spec) in the official kubernetes format.
template Template engine to be used to render the source file.

salt.states.kubernetes.namespace_absent(name, **kwargs)

Ensures that the named namespace is absent.

name The name of the namespace

salt.states.kubernetes.namespace_present(name, **kwargs)

Ensures that the named namespace is present.

name The name of the namespace

salt.states.kubernetes.node_label_absent(name, node, **kwargs)

Ensures that the named label is absent from the node.

name The name of the label
node The name of the node

salt.states.kubernetes.node_label_folder_absent(name, node, **kwargs)

Ensures the label folder doesn't exist on the specified node.

name The name of label folder
node The name of the node

salt.states.kubernetes.node_label_present(name, node, value, **kwargs)

Ensures that the named label is set on the named node with the given value. If the label exists it will be replaced.

name The name of the label.
value Value of the label.
node Node to change.

salt.states.kubernetes.pod_absent(name, namespace='default', **kwargs)

Ensures that the named pod is absent from the given namespace.

name The name of the pod
namespace The name of the namespace

salt.states.kubernetes.pod_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)

Ensures that the named pod is present inside of the specified namespace with the given metadata and spec. If the pod exists it will be replaced.

name The name of the pod.
namespace The namespace holding the pod. The 'default' one is going to be used unless a different one is specified.
metadata The metadata of the pod object.
spec The spec of the pod object.
source A file containing the definition of the pod (metadata and spec) in the official kubernetes format.
template Template engine to be used to render the source file.

salt.states.kubernetes.secret_absent(name, namespace='default', **kwargs)

Ensures that the named secret is absent from the given namespace.

name The name of the secret
namespace The name of the namespace

salt.states.kubernetes.secret_present(name, namespace='default', data=None, source=None, template=None, **kwargs)
Ensures that the named secret is present inside of the specified namespace with the given data. If the secret exists it will be replaced.

- name: The name of the secret.
- namespace: The namespace holding the secret. The 'default' one is going to be used unless a different one is specified.
- data: The dictionary holding the secrets.
- source: A file containing the data of the secret in plain format.
- template: Template engine to be used to render the source file.

salt.states.kubernetes.service_absent(name, namespace='default', **kwargs)
Ensures that the named service is absent from the given namespace.

- name: The name of the service
- namespace: The name of the namespace

salt.states.kubernetes.service_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)
Ensures that the named service is present inside of the specified namespace with the given metadata and spec. If the deployment exists it will be replaced.

- name: The name of the service.
- namespace: The namespace holding the service. The 'default' one is going to be used unless a different one is specified.
- metadata: The metadata of the service object.
- spec: The spec of the service object.
- source: A file containing the definition of the service (metadata and spec) in the official kubernetes format.
- template: Template engine to be used to render the source file.

23.19.156 salt.states.layman

Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

sunrise:
  layman.present

salt.states.layman.absent(name)
Verify that the overlay is absent

- name: The name of the overlay to delete

salt.states.layman.present(name)
Verify that the overlay is present

- name: The name of the overlay to add
23.19.157  salt.states.ldap

Manage entries in an LDAP database

New in version 2016.3.0.

The salt.states.ldap state module allows you to manage LDAP entries and their attributes.

salt.states.ldap.managed(name, entries, connect_spec=None)

Ensure the existence (or not) of LDAP entries and their attributes

Example:

```
ldapi:///:
  ldap.managed:
    - connect_spec:
      bind:
        method: sasl
      entries:
        # make sure the entry doesn't exist
        - cn=foo,ou=users,dc=example,dc=com:
          delete_others: True
        # make sure the entry exists with only the specified attribute values
        - cn=admin,dc=example,dc=com:
          replace:
            cn:
              admin
            description:
              LDAP administrator
            objectClass:
              simpleSecurityObject
              organizationalRole
            userPassword:
              {{pillar.ldap_admin_password}}
            # make sure the entry exists, its olcRootDN attribute has only the specified value, the olcRootDN attribute doesn't exist, and all other attributes are ignored
            - 'olcDatabase={1}hdb,cn=config':
              replace:
                olcRootDN:
                  cn=admin,dc=example,dc=com
                # the admin entry has its own password attribute
                olcRootPW: []
            # note the use of 'default'. also note how you don't have to use list syntax if there is only one attribute value
            - cn=foo,ou=users,dc=example,dc=com:
              delete_others: True
              default:
                userPassword: changeme
                shadowLastChange: 0
```
```yaml
# keep sshPublicKey if present, but don't create # the attribute if it is missing
sshPublicKey: []

- replace:
  - cn: foo
  - uid: foo
  - uidNumber: 1000
  - gidNumber: 1000
  - gecos: Foo Bar
  - givenName: Foo
  - sn: Bar
  - homeDirectory: /home/foo
  - loginShell: /bin/bash

objectClass:
  - inetOrgPerson
  - posixAccount
  - top
  - ldapPublicKey
  - shadowAccount
```

### Parameters

- **name** -- The URL of the LDAP server. This is ignored if `connect_spec` is either a connection object or a dict with a 'url' entry.
- **entries** -- A description of the desired state of zero or more LDAP entries.

*entries* is an iterable of dicts. Each of these dict's keys are the distinguished names (DNs) of LDAP entries to manage. Each of these dicts is processed in order. A later dict can reference an LDAP entry that was already mentioned in an earlier dict, which makes it possible for later dicts to enhance or alter the desired state of an LDAP entry.

The DNs are mapped to a description of the LDAP entry's desired state. These LDAP entry descriptions are themselves iterables of dicts. Each dict in the iterable is processed in order. They contain directives controlling the entry's state. The key names the directive type and the value is state information for the directive. The specific structure of the state information depends on the directive type.

The structure of *entries* looks like this:

```yaml
[{dn1: [[directive1: directive1_state, directive2: directive2_state], {directive3: directive3_state}]},
 {dn2: [[directive4: directive4_state, directive5: directive5_state}]},
 {dn3: [[directive6: directive6_state]]}]
```

These are the directives:

- **'delete_others'** Boolean indicating whether to delete attributes not mentioned in this dict or any of the other directive dicts for this DN. Defaults to False.

  If you don't want to delete an attribute if present, but you also don't want to add it if it is missing or modify it if it is present, you can use either the 'default' directive or the 'add' directive with an empty value list.

- **'default'** A dict mapping an attribute name to an iterable of default values for that attribute. If the attribute already exists, it is left alone. If not, it is created using the given list of values.
An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- 'add' Attribute values to add to the entry. This is a dict mapping an attribute name to an iterable of values to add.

An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- 'delete' Attribute values to remove from the entry. This is a dict mapping an attribute name to an iterable of values to delete from the attribute. If the iterable is empty, all of the attribute's values are deleted.

- 'replace' Attributes to replace. This is a dict mapping an attribute name to an iterable of values. Any existing values for the attribute are deleted, then the given values are added. The iterable may be empty.

In the above directives, the iterables of attribute values may instead be None, in which case an empty list is used, or a scalar such as a string or number, in which case a new list containing the scalar is used.

Note that if all attribute values are removed from an entry, the entire entry is deleted.

- connect_spec -- See the description of the connect_spec parameter of the ldap3.connect function in the ldap3 execution module. If this is a dict and the 'url' entry is not specified, the 'url' entry is set to the value of the name parameter.

Returns

A dict with the following keys:

- 'name' This is the same object passed to the name parameter.

- 'changes' This is a dict describing the changes made (or, in test mode, the changes that would have been attempted). If no changes were made (or no changes would have been attempted), then this dict is empty. Only successful changes are included.

Each key is a DN of an entry that was changed (or would have been changed). Entries that were not changed (or would not have been changed) are not included. The value is a dict with two keys:

- 'old' The state of the entry before modification. If the entry did not previously exist, this key maps to None. Otherwise, the value is a dict mapping each of the old entry's attributes to a list of its values before any modifications were made. Unchanged attributes are excluded from this dict.

- 'new' The state of the entry after modification. If the entry was deleted, this key maps to None. Otherwise, the value is a dict mapping each of the entry's attributes to a list of its values after the modifications were made. Unchanged attributes are excluded from this dict.

Example 'changes' dict where a new entry was created with a single attribute containing two values:

```python
{'dn1': {'old': None,
         'new': {'attr1': ['val1', 'val2']}}}
```

Example 'changes' dict where a new attribute was added to an existing entry:

```python
{'dn1': {'old': {},
         'new': {'attr2': ['val3']}}}
```
'result' One of the following values:
- True if no changes were necessary or if all changes were applied successfully.
- False if at least one change was unable to be applied.
- None if changes would be applied but it is in test mode.

23.19.158 salt.states.libcloud_dns

Manage DNS records and zones using libcloud

codeauthor Anthony Shaw <anthonyshaw@apache.org>

New in version 2016.11.0.

Create and delete DNS records or zones through Libcloud. Libcloud’s DNS system supports over 20 DNS providers including Amazon, Google, GoDaddy, Softlayer

This module uses libcloud, which can be installed via package, or pip.

configuration This module uses a configuration profile for one or multiple DNS providers

```yaml
libcloud_dns:
  profile1:
    driver: godaddy
    key: 2orgk34kgk34g
  profile2:
    driver: route53
    key: blah
    secret: blah
```

Example:

```yaml
my-zone:
  libcloud_dns.zone_present:
    - name: mywebsite.com
    - profile: profile1

my-website:
  libcloud_dns.record_present:
    - name: www
    - zone: mywebsite.com
    - type: A
    - data: 12.34.32.3
    - profile: profile1
    - require:
      - libcloud_dns: my-zone

depends apache-libcloud

salt.states.libcloud_dns.record_absent(name, zone, type, data, profile)
Ensures a record is absent.

Parameters
- name (str) -- Record name without the domain name (e.g. www). Note: If you want to create a record for a base domain name, you should specify empty string ("") for this argument.
- zone (str) -- Zone where the requested record is created, the domain name
- type (str) -- DNS record type (A, AAAA, ...).
- data (str) -- Data for the record (depends on the record type).
- profile (str) -- The profile key
salt.states.libcloud_dns.record_present(name, zone, type, data, profile)

Ensures a record is present.

Parameters

- **name**(str) -- Record name without the domain name (e.g. www). Note: If you want to create a record for a base domain name, you should specify empty string (""") for this argument.
- **zone**(str) -- Zone where the requested record is created, the domain name
- **type**(str) -- DNS record type (A, AAAA, ...).
- **data**(str) -- Data for the record (depends on the record type).
- **profile**(str) -- The profile key

salt.states.libcloud_dns.state_result(result, message, name, changes=None)

salt.states.libcloud_dns.zone_absent(domain, profile)

Ensures a record is absent.

Parameters

- **domain**(str) -- Zone name, i.e. the domain name
- **profile**(str) -- The profile key

salt.states.libcloud_dns.zone_present(domain, type, profile)

Ensures a record is present.

Parameters

- **domain**(str) -- Zone name, i.e. the domain name
- **type**(str) -- Zone type (master / slave), defaults to master
- **profile**(str) -- The profile key

23.19.159 salt.states.libcloud_loadbalancer

Apache Libcloud Load Balancer State

Manage load balancers using libcloud

codeauthor Anthony Shaw <anthonyshaw@apache.org>

Apache Libcloud load balancer management for a full list of supported clouds, see [http://libcloud.readthedocs.io/en/latest/loadbalancer/supported_providers.html](http://libcloud.readthedocs.io/en/latest/loadbalancer/supported_providers.html)

Clouds include Amazon ELB, ALB, Google, Aliyun, CloudStack, Softlayer

New in version 2018.3.0.

configuration This module uses a configuration profile for one or multiple Cloud providers

```
libcloud_loadbalancer:
  profile_test1:
    driver: gce
    key: G00G0123456789ABCXYZ
    secret: mysecret
  profile_test2:
    driver: alb
    key: 12345
    secret: mysecret
```

Example:

Using States to deploy a load balancer with extended arguments to specify region
lb_test:
  libcloud_loadbalancer.balancer_present:
    - name: example
    - port: 80
    - protocol: http
    - profile: google
    - ex_region: us-east1

depends apache-libcloud

salt.states.libcloud_loadbalancer.balancer_absent(name, profile, **libcloud_kwargs)
Ensures a load balancer is absent.
Parameters
  • name (str) -- Load Balancer name
  • profile (str) -- The profile key

salt.states.libcloud_loadbalancer.balancer_present(name, port, protocol, profile, algorithm=None, members=None, **libcloud_kwargs)
Ensures a load balancer is present.
Parameters
  • name (str) -- Load Balancer name
  • port (str) -- Port the load balancer should listen on, defaults to 80
  • protocol (str) -- Loadbalancer protocol, defaults to http.
  • profile (str) -- The profile key
  • algorithm (str) -- Load balancing algorithm, defaults to ROUND_ROBIN. See Algorithm type in Libcloud documentation for a full listing.
  • members (list of dict (ip, port)) -- An optional list of members to create on deployment

salt.states.libcloud_loadbalancer.member_absent(ip, port, balancer_id, profile, **libcloud_kwargs)
Ensure a load balancer member is absent, based on IP and Port
Parameters
  • ip (str) -- IP address for the member
  • port (int) -- Port for the member
  • balancer_id (str) -- id of a load balancer you want to detach the member from
  • profile (str) -- The profile key

salt.states.libcloud_loadbalancer.member_present(ip, port, balancer_id, profile, **libcloud_kwargs)
Ensure a load balancer member is present
Parameters
  • ip (str) -- IP address for the new member
  • port (int) -- Port for the new member
  • balancer_id (str) -- id of a load balancer you want to attach the member to
  • profile (str) -- The profile key

salt.states.libcloud_loadbalancer.state_result(result, message, name, changes=None)
23.19.160  salt.states.libcloud_storage

Apache Libcloud Storage State

Manage cloud storage using libcloud

   codeauthor  Anthony  Shaw  <anthonyshaw@apache.org>

Apache Libcloud Storage (object/blob) management for a full list of supported clouds, see http://libcloud.readthedocs.io/en/latest/storage/supported_providers.html

Clouds include Amazon S3, Google Storage, Aliyun, Azure Blobs, Ceph, OpenStack swift

New in version 2018.3.0.

   configuration  This module uses a configuration profile for one or multiple Storage providers

<table>
<thead>
<tr>
<th>libcloud_storage:</th>
</tr>
</thead>
<tbody>
<tr>
<td>profile_test1:</td>
</tr>
<tr>
<td>driver: google_storage</td>
</tr>
<tr>
<td>key: GOOG0123456789ABCXYZ</td>
</tr>
<tr>
<td>secret: mysecret</td>
</tr>
<tr>
<td>profile_test2:</td>
</tr>
<tr>
<td>driver: s3</td>
</tr>
<tr>
<td>key: 12345</td>
</tr>
<tr>
<td>secret: mysecret</td>
</tr>
</tbody>
</table>

Examples

Creating a container and uploading a file

   web_things:
   |   libcloud_storage.container_present: |
   |   name: my_container_name |
   |   profile: profile1 |
   |   libcloud_storage.object_present: |
   |   name: my_file.jpg |
   |   container: my_container_name |
   |   path: /path/to/local/file.jpg |
   |   profile: profile1 |

Downloading a file

This example will download the file from the remote cloud and keep it locally

   web_things:
   |   libcloud_storage.file_present: |
   |   name: my_file.jpg |
   |   container: my_container_name |
   |   path: /path/to/local/file.jpg |
   |   profile: profile1 |

   depends  apache-libcloud

salt.states.libcloud_storage.container_absent(name, profile)

Ensures a container is absent.
Parameters

- name (str) -- Container name
- profile (str) -- The profile key

`salt.states.libcloud_storage.container_present(name, profile)`
Ensures a container is present.

Parameters

- name (str) -- Container name
- profile (str) -- The profile key

`salt.states.libcloud_storage.file_present(container, name, path, profile, overwrite_existing=False)`
Ensures a object is downloaded locally.

Parameters

- container (str) -- Container name
- name (str) -- Object name in cloud
- path (str) -- Local path to file
- profile (str) -- The profile key
- overwrite_existing (bool) -- Replace if already exists

`salt.states.libcloud_storage.object_absent(container, name, profile)`
Ensures a object is absent.

Parameters

- container (str) -- Container name
- name (str) -- Object name in cloud
- profile (str) -- The profile key

`salt.states.libcloud_storage.object_present(container, name, path, profile)`
Ensures a object is present.

Parameters

- container (str) -- Container name
- name (str) -- Object name in cloud
- path (str) -- Local path to file
- profile (str) -- The profile key

`salt.states.libcloud_storage.state_result(result, message, name, changes)`

23.19.161 salt.states.linux_acl

Linux File Access Control Lists

The Linux ACL state module requires the `getfacl` and `setfacl` binaries.

Ensure a Linux ACL is present

```
root:
  acl_present:
    - name: /root
    - acl_type: user
    - acl_name: damian
    - perms: rwx
```

Ensure a Linux ACL does not exist

```
root:
  acl_absent:
    - name: /root
```
(continues on next page)
- **acl_type**: user
- **acl_name**: damian
- **perms**: rwx

Ensure a Linux ACL list is present

```yaml
root:
  acl.list_present:
    - name: /root
    - acl_type: user
    - acl_names:
      - damian
      - homer
    - perms: rwx
```

Ensure a Linux ACL list does not exist

```yaml
root:
  acl.list_absent:
    - name: /root
    - acl_type: user
    - acl_names:
      - damian
      - homer
    - perms: rwx
```

salt.states.linux_acl.absent(name, acl_type, acl_name='', perms='', recurse=False)
Ensure a Linux ACL does not exist

- **name** The acl path
- **acl_type** The type of the acl is used for, it can be 'user' or 'group'
- **acl_name** The user or group
- **perms** Remove the permissions eg.: rwx
- **recurse** Set the permissions recursive in the path

salt.states.linux_acl.list_absent(name, acl_type, acl_names=None, recurse=False)
Ensure a Linux ACL list does not exist

- **name** The acl path
- **acl_type** The type of the acl is used for, it can be 'user' or 'group'
- **acl_names** The list of users or groups
- **perms** Remove the permissions eg.: rwx
- **recurse** Set the permissions recursive in the path

salt.states.linux_acl.list_present(name, acl_type, acl_names=None, perms='', recurse=False, force=False)
Ensure a Linux ACL list is present

- **name** The acl path
- **acl_type** The type of the acl is used for it can be 'user' or 'group'
- **acl_names** The list of users or groups
- **perms** Set the permissions eg.: rwx
- **recurse** Set the permissions recursive in the path
- **force** Wipe out old permissions and ensure only the new permissions are set
salt.states.linux_acl.present(name, acl_type, acl_name='', perms='', recurse=False, force=False)

Ensure a Linux ACL is present
- **name**: The acl path
- **acl_type**: The type of the acl is used for it can be 'user' or 'group'
- **acl_name**: The user or group
- **perms**: Set the permissions eg.: rwx
- **recurse**: Set the permissions recursive in the path
- **force**: Wipe out old permissions and ensure only the new permissions are set

23.19.162  salt.states.locale

Management of languages/locales

Manage the available locales and the system default:

```
us_locale:
  locale.present:
    - name: en_US.UTF-8

default_locale:
  locale.system:
    - name: en_US.UTF-8
    - require:
      - locale: us_locale
```

salt.states.locale.present(name)

Generate a locale if it is not present

New in version 2014.7.0.
- **name**: The name of the locale to be present. Some distributions require the charmap to be specified as part of the locale at this point.

salt.states.locale.system(name)

Set the locale for the system
- **name**: The name of the locale to use

23.19.163  salt.states.logadm

Management of logs using Solaris logadm.

- **maintainer**: Jorge Schrauwen <sjorge@blackdot.be>
- **maturity**: new
- **depends**: salt.modulus.logadm
- **platform**: Oracle Solaris, Sun Solaris, illumos

New in version 2017.7.0.

```
.. note::
    TODO
```

salt.states.logadm.remove(name, log_file=None)

Remove a log from the logadm configuration
- **name**: [string] entryname
- **log_file**: [string] (optional) log file path
Note: If log_file is specified it will be used instead of the entry name.

```
salt.states.logadm.rotate(name, **kwargs)

Add a log to the logadm configuration
name [string] alias for entryname
kwargs [boolean|str|int] optional additional flags and parameters
```

23.19.164 salt.states.logrotate

Module for managing logrotate.

New in version 2017.7.0.

```
salt.states.logrotate.set_(name, key, value, setting=None, conf_file='/etc/logrotate.conf')

Set a new value for a specific configuration line.
Parameters
• key (str) -- The command or block to configure.
• value (str) -- The command value or command of the block specified by the key parameter.
• setting (str) -- The command value for the command specified by the value parameter.
• conf_file (str) -- The logrotate configuration file.
```

Example of usage with only the required arguments:
```
logrotate-rotate:
logrotate.set:
  - key: rotate
  - value: 2
```

Example of usage specifying all available arguments:
```
logrotate-wtmp-rotate:
logrotate.set:
  - key: /var/log/wtmp
  - value: rotate
  - setting: 2
  - conf_file: /etc/logrotate.conf
```

23.19.165 salt.states.loop

Loop state

Allows for looping over execution modules.

New in version 2017.7.0.

In both examples below, the execution module function boto_elb.get_instance_health returns a list of dicts. The condition checks the state-key of the first dict in the returned list and compares its value to the string InService.
```
wait_for_service_to_be_healthy:
  loop.until:
    - name: boto_elb.get_instance_health
    - condition: m_ret[0]['state'] == 'InService'
```
(continues on next page)
(continued from previous page)

- **period**: 5
- **timeout**: 20
- **m_args**:  
  - `{{ elb }}`
- **m_kwargs**:  
  - **keyid**: `{{ access_key }}`
  - **key**: `{{ secret_key }}`
  - **instances**: `"{{ instance }}"`

**Warning**: This state allows arbitrary python code to be executed through the condition parameter which is literally evaluated within the state. Please use caution.

Changed in version 3000.

A version that does not use eval is now available. It uses either the python `operator` to compare the result of the function called in `name`, which can be one of the following: `lt`, `le`, `eq` (default), `ne`, `ge`, `gt`. Alternatively, `compare_operator` can be filled with a function from an execution module in `__salt__` or `__utils__` like the example below. The function `data.subdict_match` checks if the `expected` expression matches the data returned by calling the name function (with passed `args` and `kwargs`).

Wait for service to be healthy:

```python
salt.states.loop.until_no_eval:
  - **name**: `boto_elb.get_instance_health`
  - **expected**: `'0:state:InService'`
  - **compare_operator**: `data.subdict_match`
  - **period**: 5
  - **timeout**: 20
  - **args**:  
    - `{{ elb }}`
  - **kwargs**:  
    - **keyid**: `{{ access_key }}`
    - **key**: `{{ secret_key }}`
    - **instances**: `"{{ instance }}"`
```

**salt.states.loop.until**

```python
(name, m_args=None, m_kwargs=None, condition=None, period=1, timeout=60)
```

Loop over an execution module until a condition is met.

**Parameters**

- **name** *(str)* -- The name of the execution module
- **m_args** *(list)* -- The execution module's positional arguments
- **m_kwargs** *(dict)* -- The execution module's keyword arguments
- **condition** *(str)* -- The condition which must be met for the loop to break. This should contain `m_ret` which is the return from the execution module.
- **period** *(int or float)* -- The number of seconds to wait between executions
- **timeout** *(int or float)* -- The timeout in seconds

**salt.states.loop.until_no_eval**

```python
(name, expected, compare_operator='eq', timeout=60, period=1, init_wait=0, args=None, kwags=None)
```

Generic waiter state that waits for a specific salt function to produce an expected result. The state fails if the function does not exist or raises an exception, or does not produce the expected result within the allotted retries.

**Parameters**

- **name** *(str)* -- Name of the module function to call
- **expected** -- Expected return value. This can be almost anything.
- **compare_operator** *(str)* -- Operator to use to compare the result of the module function call with the expected value. This can be anything present in __salt__ or __utils__. Will be called with 2 args: result, expected.
- **timeout** *(int or float)* -- Abort after this amount of seconds (excluding init_wait).
- **period** *(int or float)* -- Time (in seconds) to wait between attempts.
- **init_wait** *(int or float)* -- Time (in seconds) to wait before trying anything.
- **args** *(list)* -- Args to pass to the salt module function.
- **kwargs** *(dict)* -- Kwargs to pass to the salt module function.

New in version 3000.

### 23.19.166 salt.states.lvm

Management of Linux logical volumes

A state module to manage LVMs

```
/dev/sda:
  lvm.pv_present

my_vg:
  lvm.vg_present:
    - devices: /dev/sda

lvroot:
  lvm.lv_present:
    - vgname: my_vg
    - size: 10G
    - stripes: 5
    - stripesize: 8K

salt.states.lvm.lv_absent(name, vgname=None)
  Remove a given existing Logical Volume from a named existing volume group
  name The Logical Volume to remove
  vgname The name of the Volume Group on which the Logical Volume resides

salt.states.lvm.lv_present(name, vgname=None, size=None, extents=None, snapshot=None, pv='', thinvolume=False, thinpool=False, force=False, resizefs=False, **kwargs)
  Ensure that a Logical Volume is present, creating it if absent.
  name The name of the Logical Volume
  vgname The name of the Volume Group on which the Logical Volume resides
  size The size of the Logical Volume in megabytes, or use a suffix such as S, M, G, T, P for 512 byte sectors, megabytes, gigabytes or terabytes respectively. The suffix is case insensitive.
  extents The number of logical extents allocated to the Logical Volume It can be a percentage allowed by lvcreate’s syntax, in this case it will set the Logical Volume initial size and won’t be resized.
  snapshot The name of the snapshot
  pv The Physical Volume to use
  kwargs Any supported options to lvcreate. See linux_lvm for more details.
```

New in version 2016.11.0.

- **thinvolume** Logical Volume is thinly provisioned
- **thinpool** Logical Volume is a thin pool
  New in version 2018.3.0.
- **force** Assume yes to all prompts
  New in version 3002.0.

23.19. state modules 3807
resizefs Use fsadm to resize the logical volume filesystem if needed

salt.states.lvm.pv_absent(name)
Ensure that a Physical Device is not being used by lvm
name The device name to initialize.

salt.states.lvm.pv_present(name, **kwargs)
Set a Physical Device to be used as an LVM Physical Volume
name The device name to initialize.
kwarg Any supported options to pvcreate. See linux_lvm for more details.

salt.states.lvm.vg_absent(name)
Remove an LVM volume group
name The volume group to remove

salt.states.lvm.vg_present(name, devices=None, **kwargs)
Create an LVM Volume Group
name The Volume Group name to create
devices A list of devices that will be added to the Volume Group
kwarg Any supported options to vgcreate. See linux_lvm for more details.

23.19.167 salt.states.lvs_server

Management of LVS (Linux Virtual Server) Real Server

salt.states.lvs_server.absent(name, protocol=None, service_address=None, server_address=None)
Ensure the LVS Real Server in specified service is absent.
name The name of the LVS server.
protocol The service protocol (only support tcp, udp and fwmark service).
service_address The LVS service address.
server_address The LVS real server address.

salt.states.lvs_server.present(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)
Ensure that the named service is present.
name The LVS server name
protocol The service protocol
service_address The LVS service address
server_address The real server address.
packet_forward_method The LVS packet forwarding method (dr for direct routing, tunnel for tunneling, nat for network access translation).
weight The capacity of a server relative to the others in the pool.

lvsrs:
lvs_server.present:
  - protocol: tcp
  - service_address: 1.1.1.1:80
  - server_address: 192.168.0.11:8080
  - packet_forward_method: dr
  - weight: 10
23.19.168 salt.states.lvs_service

Management of LVS (Linux Virtual Server) Service

salt.states.lvs_service.absent(name, protocol=None, service_address=None)
   Ensure the LVS service is absent.
   name  The name of the LVS service
   protocol  The service protocol
   service_address  The LVS service address

salt.states.lvs_service.present(name, protocol=None, service_address=None, scheduler='wlc')
   Ensure that the named service is present.
   name  The LVS service name
   protocol  The service protocol
   service_address  The LVS service address
   scheduler  Algorithm for allocating TCP connections and UDP datagrams to real servers.

   lvstest:
      lvs_service.present:
         - service_address: 1.1.1.1:80
         - protocol: tcp
         - scheduler: rr

23.19.169 salt.states.lxc

Manage Linux Containers

salt.states.lxc.absent(name, stop=False, path=None)
   Ensure a container is not present, destroying it if present
   name  Name of the container to destroy
   stop  stop before destroying default: false
   New in version 2015.5.2.
   path  path to the container parent default: /var/lib/lxc (system default)
   New in version 2015.8.0.

   web01:
      lxc.absent

salt.states.lxc.edited_conf(name, lxc_conf=None, lxc_conf_unset=None)

   Warning: This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface).
   Issue #35523 was opened to track the addition of a suitable replacement or fix.

   Edit LXC configuration options
   Deprecated since version 2015.5.0.
   path  path to the container parent default: /var/lib/lxc (system default)
   New in version 2015.8.0.
setconf:
  lxc.edited_conf:
    - name: ubuntu
    - lxc_conf:
      - network.ipv4.ip: 10.0.3.6
    - lxc_conf_unset:
      - lxc.utsname

salt.states.lxc.frozen(name, start=True, path=None)
New in version 2015.5.0.

Ensure that a container is frozen

**Note:** This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use `lxc.present`.

**name** The name of the container

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**start** [True] Start container first, if necessary. If `False`, then this state will fail if the container is not running.

```yaml
web01:
  lxc.frozen
web02:
  lxc.frozen:
    - start: False
```

salt.states.lxc.present(name, running=None, clone_from=None, snapshot=False, profile=None, network_profile=None, template=None, options=None, image=None, config=None, fstype=None, size=None, backing=None, vgname=None, lvname=None, thinpool=None, path=None)

Changed in version 2015.8.0: The `lxc.created` state has been renamed to `lxc.present`, and the `lxc.cloned` state has been merged into this state.

Create the named container if it does not exist

**name** The name of the container to be created

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**running** [False]

- If `True`, ensure that the container is running
- If `False`, ensure that the container is stopped
- If `None`, do nothing with regards to the running state of the container

New in version 2015.8.0.

**clone_from** Create named container as a clone of the specified container

**snapshot** [False] Use Copy On Write snapshots (LVM). Only supported with `clone_from`.

**profile** Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below.

**network_profile** Network Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below.

New in version 2015.5.2.

Container Creation Arguments
**template**  The template to use. For example, `ubuntu` or `fedora`. For a full list of available templates, check out the `lxc.templates` function.

Conflicts with the `image` argument.

**Note:** The `download` template requires the following three parameters to be defined in `options`:
- `dist` - The name of the distribution
- `release` - Release name/version
- `arch` - Architecture of the container

The available images can be listed using the `lxc.images` function.

**options**
New in version 2015.5.0.

Template-specific options to pass to the `lxc-create` command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```
web01:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64
```

Remember to double-indent the options, due to how `PyYAML` works.

For available template options, refer to the `lxc` template scripts which are usually located under `/usr/share/lxc/templates`, or run `lxc-create -t <template> -h`.

**image**  A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing**  The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`

**fstype**  Filesystem type to use on LVM logical volume

**size**  Size of the volume to create. Only applicable if `backing` is set to `lvm`

**vgname**  [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`

**lvname**  Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`

**thinpool**  Name of a pool volume that will be used for thin-provisioning this container. Only applicable if `backing` is set to `lvm`

**salt.states.lxc.running**(name, restart=False, path=None)

Changed in version 2015.5.0: The `lxc.started` state has been renamed to `lxc.running`

Ensure that a container is running

**Note:** This state does not enforce the existence of the named container, it just starts the container if it is not running. To ensure that the named container exists, use `lxc.present`.

**name**  The name of the container

**path**  path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

**restart**  [False] Restart container if it is already running
salt.states.lxc.set_pass(name, **kwargs)

Deprecated since version 2015.5.0.

This state function has been disabled, as it did not conform to design guidelines. Specifically, due to the fact that lxc.set_password uses chpasswd(8) to set the password, there was no method to make this action idempotent (in other words, the password would be changed every time). This makes this state redundant, since the following state will do the same thing:

```yaml
setpass:
  module.run:
    - name: set_pass
    - m_name: root
    - password: secret
```

salt.states.lxc.stopped(name, kill=False, path=None)

Ensure that a container is stopped

Note: This state does not enforce the existence of the named container, it just stops the container if it running or frozen. To ensure that the named container exists, use lxc.present, or use the lxc.absent state to ensure that the container does not exist.

- name The name of the container
- path path to the container parent default: /var/lib/lxc (system default)
- kill [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

New in version 2015.8.0.

New in version 2015.5.0.

```yaml
web01:
  lxc.stopped
```

23.19.170 salt.states.lxd

Manage LXD profiles.

New in version 2019.2.0.

- maintainer René Jochum <rene@jochums.at>
- maturity new
- depends python-pylxd
- platform Linux

salt.states.lxd.authenticate(name, remote_addr, password, cert, key, verify_cert=True)

Authenticate with a remote peer.

- remote_addr An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
password : The PaSsW0rD

cert : PEM Formatted SSL Zertifikate.
Examples: /root/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: /root/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
name: Ignore this. This is just here for salt.

salt.states.lxd.config_managed(name, value, force_password=False)
Manage a LXD Server config setting.
name : The name of the config key.
value : Its value.
force_password [False] Set this to True if you want to set the password on every run.
As we can’t retrieve the password from LXD we can’t check if the current one is the same as the given one.

salt.states.lxd.init(name, storage_backend='dir', trust_password=None, network_address=None, network_port=None, storage_create_device=None, storage_create_loop=None, storage_pool=None, done_file='%SALT_CONFIG_DIR%/lxd_initialized')
Initializes the LXD Daemon, as LXD doesn’t tell if its initialized we touch the done_file and check if it exist.
This can only be called once per host unless you remove the done_file.
name : Ignore this. This is just here for salt.
storage_backend : Storage backend to use (zfs or dir, default: dir)
trust_password : Password required to add new clients
network_address [None] Address to bind LXD to (default: none)
network_port [None] Port to bind LXD to (Default: 8443)
storage_create_device [None] Setup device based storage using this DEVICE
storage_create_loop [None] Setup loop based storage with this SIZE in GB
storage_pool [None] Storage pool to use or create
done_file : Path where we check that this method has been called, as it can run only once and there’s currently no way to ask LXD if init has been called.

23.19.171 salt.states.lxd_container
Manage LXD containers.
New in version 2019.2.0.

maintainer René Jochum <rene@jochums.at>
maturity new
depends python-pylxd
platform Linux

salt.states.lxd_container.absent(name, stop=False, remote_addr=None, cert=None, key=None, verify_cert=True)
Ensure a LXD container is not present, destroying it if present
name : The name of the container to destroy
stop : stop before destroying default: false
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key: PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.frozen(name, start=True, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is frozen, start and freeze it if start is true
name : The name of the container to freeze
start : start and freeze it
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.migrated(name, remote_addr, cert, key, verify_cert, src_remote_addr, stop_and_start=False, src_cert=None, src_key=None, src_verify_cert=None)

Ensure a container is migrated to another host
If the container is running, it either must be shut down first (use stop_and_start=True) or criu must be installed on the source and destination machines.

For this operation both certs need to be authenticated, use lxd.authenticate <salt.states.lxd.authenticate to authenticate your cert(s).
name : The container to migrate
remote_addr : An URL to the destination remote Server
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
src_remote_addr : An URL to the source remote Server
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
stop_and_start: Stop before migrating and start after
src_cert : PEM Formatted SSL Zertifikate, if None we copy "cert"
Examples: ~/.config/lxc/client.crt
src_key : PEM Formatted SSL Key, if None we copy "key"
Examples: ~/.config/lxc/client.key
src_verify_cert : Wherever to verify the cert, if None we copy "verify_cert"

salt.states.lxd_container.present(name, running=None, source=None, profiles=None, config=None, devices=None, architecture='x86_64', ephemeral=False, restart_on_change=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Create the named container if it does not exist
name The name of the container to be created
running [None]
  • If True, ensure that the container is running
  • If False, ensure that the container is stopped
• If None, do nothing with regards to the running state of the container

source  [None] Can be either a string containing an image alias:

"xenial/amd64"

or an dict with type "image" with alias:

{"type": "image",
"alias": "xenial/amd64"}

or image with "fingerprint":

{"type": "image",
"fingerprint": "SHA-256"}

or image with "properties":

{"type": "image",
"properties": {
  "os": "ubuntu",
  "release": "14.04",
  "architecture": "x86_64"
}}

or none:

{"type": "none"}

or copy:

{"type": "copy",
"source": "my-old-container"}

profiles  [["default"] List of profiles to apply on this container

config : A config dict or None (None = unset).

Can also be a list:

[{
    'key': 'boot.autostart', 'value': 1},
{
    'key': 'security.privileged', 'value': '1'}]

devices : A device dict or None (None = unset).

architecture  ['x86_64'] Can be one of the following:

• unknown
• i686
• x86_64
• armv7l
• aarch64
• ppc
• ppc64
• ppc64le
• s390x

ephemeral  [False] Destroy this container after stop?

restart_on_change  [False] Restart the container when we detect changes on the config or its devices?

remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!

Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.

Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key

verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.running(name, restart=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is running and restart it if restart is True

name : The name of the container to start/restart.
restart : restart the container if it is already started.
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.stopped(name, kill=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is stopped, kill it if kill is true else stop it

name : The name of the container to stop
kill : kill if true
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

23.19.172 salt.states.lxd_image

Manage LXD images.
New in version 2019.2.0.

maintainer René Jochum <rene@jochums.at>
maturity new
depends python-pylxd
platform Linux

salt.states.lxd_image.absent(name, remote_addr=None, cert=None, key=None, verify_cert=True)

name : An alias or fingerprint of the image to check and delete.
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
salt.states.lxd_image.present(name, source, aliases=None, public=None, auto_update=None, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure an image exists, copy it else from source

name : An alias of the image, this is used to check if the image exists and it will be added as alias to the image on copy/create.
source : Source dict.

For an LXD to LXD copy:

```python
source:
  type: lxd
  name: ubuntu/xenial/amd64 # This can also be a fingerprint.
  remote_addr: https://images.linuxcontainers.org:8443
  cert: ~/.config/lxd/client.crt
  key: ~/.config/lxd/client.key
  verify_cert: False
```

From file:

```python
source:
  type: file
  filename: salt://lxd/files/busybox.tar.xz
  saltenv: base
```

From simplestreams:

```python
source:
  type: simplestreams
  server: https://cloud-images.ubuntu.com/releases
  name: xenial/amd64
```

From an URL:

```python
source:
  type: url
  url: https://dl.stgraber.org/lxd
```

aliases : List of aliases to append, can be empty.

public :
  Make this image public available on this instance? None on source_type LXD means copy source
  None on source_type file means False

auto_update :
  Try to auto-update from the original source? None on source_type LXD means copy source
  source_type file does not have auto-update.

remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
  Examples: https://myserver.lan:8443 /var/lib/mysocket.sock

cert : PEM Formatted SSL Zertifikate.
  Examples: ~/.config/lxc/client.crt

key : PEM Formatted SSL Key.
  Examples: ~/.config/lxc/client.key

verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
23.19.173 salt.states.lxd_profile

Manage LXD profiles.

New in version 2019.2.0.

maintainer René Jochum <rene@jochums.at>
maturity new
depends python-pylxd
platform Linux

salt.states.lxd_profile.absent(name, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD profile is not present, removing it if present.
name : The name of the profile to remove.
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it
off as LXD normally uses self-signed certificates.
See the requests-docs for the SSL stuff.

salt.states.lxd_profile.present(name, description=None, config=None, devices=None, remote_addr=None, cert=None, key=None, verify_cert=True)

Creates or updates LXD profiles
name : The name of the profile to create/update
description : A description string
config : A config dict or None (None = unset).
Can also be a list:
[[‘key’: ‘boot.autostart’, ‘value’: 1}], {‘key’: ‘security.privileged’, ‘value’: ‘1’}]
devices : A device dict or None (None = unset).
remote_addr : An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples: https://myserver.lan:8443 /var/lib/mysocket.sock
cert : PEM Formatted SSL Zertifikate.
Examples: ~/.config/lxc/client.crt
key : PEM Formatted SSL Key.
Examples: ~/.config/lxc/client.key
verify_cert [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it
off as LXD normally uses self-signed certificates.
See the lxd-docs for the details about the config and devices dicts. See the requests-docs for the SSL stuff.
23.19.174 salt.states.mac_assistive

Allows you to manage assistive access on macOS minions with 10.9+

Install, enable and disable assistive access on macOS minions

```bash
/usr/bin/osascript:
  assistive.installed:
    - enabled: True
```

```python
salt.states.mac_assistive.installed(name, enabled=True)
  Make sure that we have the given bundle ID or path to command installed in the assistive access panel.
  name: The bundle ID or path to command
  enabled: Should assistive access be enabled on this application?
```

23.19.175 salt.states.mac_keychain

Installing of certificates to the keychain

Install certificates to the macOS keychain

```bash
/mnt/test.p12:
  keychain.installed:
    - password: test123
```

```python
salt.states.mac_keychain.default_keychain(name, domain='user', user=None)
  Set the default keychain to use
  name: The chain in which to use as the default
  domain: The domain to use valid values are user|system|common|dynamic, the default is user
  user: The user to run as

salt.states.mac_keychain.installed(name, password, keychain='/Library/Keychains/System.keychain', **kwargs)
  Install a p12 certificate file into the macOS keychain
  name: The certificate to install
  password: The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section
  keychain: The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain
  allow_any: Allow any application to access the imported certificate without warning
  keychain_password: If your keychain is likely to be locked pass the password and it will be unlocked before running the import

salt.states.mac_keychain.uninstalled(name, password, keychain='/Library/Keychains/System.keychain', keychain_password=None)
  Uninstall a p12 certificate file from the macOS keychain
  name: The certificate to uninstall, this can be a path for a .p12 or the friendly name
  password: The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section
  cert_name: The friendly name of the certificate, this can be used instead of giving a certificate
  keychain: The keychain to remove the certificate from, this defaults to /Library/Keychains/System.keychain
  keychain_password: If your keychain is likely to be locked pass the password and it will be unlocked before running the import
23.19.176 salt.states.mac_xattr

Allows you to manage extended attributes on files or directories

Install, enable and disable assistive access on macOS minions

```
/path/to/file:
  xattr.exists:
    - attributes:
      - com.file.attr=test
      - com.apple.quarantine=0x00001111
```

salt.states.mac_xattr.delete(name, attributes)
Make sure the given attributes are deleted from the file/directory
- name The path to the file/directory
- attributes The attributes that should be removed from the file/directory, this is accepted as an array.

salt.states.mac_xattr.exists(name, attributes)
Make sure the given attributes exist on the file/directory
- name The path to the file/directory
- attributes The attributes that should exist on the file/directory, this is accepted as an array, with key and value split with an equals sign, if you want to specify a hex value then add 0x to the beginning of the value.

23.19.177 salt.states.macdefaults

Writing/reading defaults from a macOS minion

salt.states.macdefaults.absent(name, domain, user=None)
Make sure the defaults value is absent
- name The key of the given domain to remove
- domain The name of the domain to remove from
- user The user to write the defaults to

salt.states.macdefaults.write(name, domain, value, vtype='string', user=None)
Write a default to the system
- name The key of the given domain to write to
- domain The name of the domain to write to
- value The value to write to the given key
- vtype The type of value to be written, valid types are string, data, int[eger], float, bool[ean], date, array, array-add, dict, dict-add
- user The user to write the defaults to

23.19.178 salt.states.macpackage

Installing of mac pkg files

Install any kind of pkg, dmg or app file on macOS:

```
/mnt/test.pkg:
  macpackage.installed:
    - store: True

/mnt/test.dmg:
```

(continues on next page)
Salt Documentation, Release 3003.1

macpackage.installed:
  - dmg: True

/mnt/xcode.dmg:
macpackage.installed:
  - dmg: True
  - app: True
  - target: /Applications/Xcode.app
  - version_check: xcodebuild -version=Xcode 7.1\n.*7B91b

salt.states.macpackage.installed(name, target='LocalSystem', dmg=False, store=False, app=False, mpkg=False, force=False, allow_untrusted=False, version_check=None)

Install a Mac OS Package from a pkg or dmg file, if given a dmg file it will first be mounted in a temporary location
name The pkg or dmg file to install
target The location in which to install the package. This can be a path or LocalSystem
dmg Is the given file a dmg file?
store Should the pkg be installed as if it was from the Mac OS Store?
app Is the file a .app? If so then we'll just copy that to /Applications/ or the given target
mpkg Is the file a .mpkg? If so then we'll check all of the .pkg files found are installed
force Force the package to be installed even if its already been found installed
allow_untrusted Allow the installation of untrusted packages
version_check The command and version that we want to check against, the version number can use regex.

version_check: python --version_check=2.7.[0-9]

23.19.179 salt.states.makeconf

Management of Gentoo make.conf

A state module to manage Gentoo's make.conf file

makeopts:
  makeconf.present:
    - value: '-j3'

salt.states.makeconf.absent(name)
  Verify that the variable is not in the make.conf
name The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case

salt.states.makeconf.present(name, value=None, contains=None, excludes=None)
  Verify that the variable is in the make.conf and has the provided settings. If value is set, contains and excludes will be ignored.
name The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
value Enforce that the value of the variable is set to the provided value
contains Enforce that the value of the variable contains the provided value
excludes Enforce that the value of the variable does not contain the provided value.
23.19.180 salt.states.marathon_app

Configure Marathon apps via a salt proxy.

```yaml
my_app:
  marathon_app.config:
    - config:
        cmd: "while [ true ]; do echo 'Hello Marathon'; sleep 5; done"
        cpus: 0.1
        mem: 10
        instances: 3
```

New in version 2015.8.2.

salt.states.marathon_app.absent(name)

Ensure that the marathon app with the given id is not present.

Parameters name -- The app name/id

Returns A standard Salt changes dictionary

salt.states.marathon_app.config(name, config)

Ensure that the marathon app with the given id is present and is configured to match the given config values.

Parameters

- name -- The app name/id
- config -- The configuration to apply (dict)

Returns A standard Salt changes dictionary

salt.states.marathon_app.running(name, restart=False, force=True)

Ensure that the marathon app with the given id is present and restart if set.

Parameters

- name -- The app name/id
- restart -- Restart the app
- force -- Override the current deployment

Returns A standard Salt changes dictionary

23.19.181 salt.states.mdadm_raid

Managing software RAID with mdadm

depends mdadm

A state module for creating or destroying software RAID devices.

```
/dev/md0:
  raid.present:
    - level: 5
    - devices:
      - /dev/xvdd
      - /dev/xvde
      - /dev/xvdf
    - chunk: 256
    - run: True
```

salt.states.mdadm_raid.absent(name)

Verify that the raid is absent

name The name of raid device to be destroyed
salt.states.mdadm_raid.present(name, level, devices, **kwargs)

Verify that the raid is present.

Changed in version 2014.7.0.

- **name**  The name of raid device to be created
- **level**  The RAID level to use when creating the raid.
- **devices**  A list of devices used to build the array.
- **kwargs**  Optional arguments to be passed to mdadm.

Example:

```
/dev/md0:
raid:
  - absent

salt.states.memcached.absent(name, value=None, host='127.0.0.1', port=11211, time=0)

Ensure that a memcached key is not present.

- **name**  The key
- **value**  [None] If specified, only ensure that the key is absent if it matches the specified value.
- **host**  The memcached server IP address
- **port**  The memcached server port

```

```
foo:
  memcached.absent

bar:
  memcached.absent:
    - host: 10.0.0.1
```

salt.states.memcached.managed(name, value=None, host='127.0.0.1', port=11211, time=0, min_compress_len=0)

Manage a memcached key.

- **name**  The key to manage
- **value**  The value to set for that key
- **host**  The memcached server IP address
- **port**  The memcached server port

```
foo:
  memcached.managed:
    - value: bar
```
23.19.183 salt.states.modjk

State to control Apache modjk

```
salt.states.modjk.worker_activated(name, workers=None, profile='default')
```
Activate all the workers in the modjk load balancer

Example:

```
loadbalancer:
    modjk.worker_activated:
        - workers:
            - app1
            - app2
```

```
salt.states.modjk.worker_disabled(name, workers=None, profile='default')
```
Disable all the workers in the modjk load balancer

Example:

```
loadbalancer:
    modjk.worker_disabled:
        - workers:
            - app1
            - app2
```

```
salt.states.modjk.worker_recover(name, workers=None, profile='default')
```
Recover all the workers in the modjk load balancer

Example:

```
loadbalancer:
    modjk.worker_recover:
        - workers:
            - app1
            - app2
```

```
salt.states.modjk.worker_stopped(name, workers=None, profile='default')
```
Stop all the workers in the modjk load balancer

Example:

```
loadbalancer:
    modjk.worker_stopped:
        - workers:
            - app1
            - app2
```

23.19.184 salt.states.modjk_worker

Manage modjk workers

Send commands to a modjk load balancer via the peer system.

This module can be used with the prereq requisite to remove/add the worker from the load balancer before deploying/restarting service.

Mandatory Settings:
- The minion needs to have permission to publish the `modjk.*` functions (see here for information on configuring peer publishing permissions)

- The modjk load balancer must be configured as stated in the `modjk` execution module [documentation](#)

```python
salt.states.modjk_worker.activate(name, lbn, target, profile='default', tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Activate the named worker from the lbn load balancers at the targeted minions.

Example:

```python
disable-before-deploy:
  modjk_worker.activate:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain
```

```python
salt.states.modjk_worker.disable(name, lbn, target, profile='default', tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:

```python
disable-before-deploy:
  modjk_worker.disable:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain
```

```python
salt.states.modjk_worker.stop(name, lbn, target, profile='default', tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Stop the named worker from the lbn load balancers at the targeted minions. The worker won’t get any traffic from the lbn.

Example:

```python
disable-before-deploy:
  modjk_worker.stop:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain
```
23.19.185  salt.states.module

Execution of Salt modules from within states

Note: There are two styles of calling module.run. The legacy style will no longer be available starting in the 3005 release. To opt-in early to the new style you must add the following to your /etc/salt/minion config file:

```yaml
use_superseded:
  - module.run
```

With module.run these states allow individual execution module calls to be made via states. Here's a contrived example, to show you how it's done:

```yaml
# New Style
test.random_hash:
  module.run:
    - test.random_hash:
      - size: 42
      - hash_type: sha256

# Legacy Style
test.random_hash:
  module.run:
    - size: 42
    - hash_type: sha256
```

In the new style, the state ID (test.random_hash, in this case) is irrelevant when using module.run. It could have very well been written:

```yaml
Generate a random hash:
  module.run:
    - test.random_hash:
      - size: 42
      - hash_type: sha256
```

For a simple state like that it's not a big deal, but if the module you're using has certain parameters, things can get cluttered, fast. Using the contrived custom module (stuck in /srv/salt/_modules/foo.py, or your configured file_roots):

```python
def bar(name, names, fun, state, saltenv):
    return "Name: {name} Names: {names} Fun: {fun} State: {state} Saltenv: {saltenv}".format(**locals())
```

Your legacy state has to look like this:

```yaml
# Legacy style
Unfortunate example:
  module.run:
    - name: foo.bar
    - m_name: Some name
    - m_names:
      - Such names
      - very wow
```

(continues on next page)
- `m_state`: Arkansas
- `m_fun`: Such fun
- `m_saltenv`: Salty

With the new style it's much cleaner:

```
# New style
Better:
module.run:
  - foo.bar:
    - name: Some name
    - names:
      - Such names
      - very wow
    - state: Arkansas
    - fun: Such fun
    - saltenv: Salty
```

The new style also allows multiple modules in one state. For instance, you can do this:

```
Do many things:
module.run:
  - test.random_hash:
    - size: 10
    - hash_type: md5
      # Note the `:` at the end
  - test.true:
  - test.arg:
    - this
    - has
    - args
    - and: kwargs
    - isn't: that neat?
      # Note the `:` at the end, too
  - test.version:
  - test.fib:
    - 4
```

Where in the legacy style you would have had to split your states like this:

```
test.random_hash:
  module.run:
    - size: 10
    - hash_type: md5

test.nop:
  module.run

test.arg:
  module.run:
    - args:
      - this
      - has
      - args
    - kwargs:
      and: kwargs
```
Another difference is that in the legacy style, unconsumed arguments to the `module` state were simply passed into the module function being executed:

```
show off module.run with args:
    module.run:
      - name: test.random_hash
      - size: 42
      - hash_type: sha256
```

The new style is much more explicit, with the arguments and keyword arguments being nested under the name of the function:

```
show off module.run with args:
    module.run:
      # Note the lack of `name: `, and trailing `:`
      - test.random_hash:
        - size: 42
        - hash_type: sha256
```

If the function takes `*args`, they can be passed in as well:

```
args and kwargs:
    module.run:
      - test.arg:
        - isn't
        - this
        - fun
        - this: that
        - salt: stack
```

Modern Examples

Here are some other examples using the modern `module.run`:

```
fetch_out_of_band:
    module.run:
      - git.fetch:
        - cwd: /path/to/my/repo
        - user: myuser
        - opts: '--all'
```

A more complex example:

```
eventsviewer:
    module.run:
      - task.create_task:
        - name: events-viewer
        - user_name: System
        - action_type: Execute
```
- `cmd`: 'c:\netops\scripts\events_viewer.bat'
- `trigger_type`: 'Daily'
- `start_date`: '2017-1-20'
- `start_time`: '11:59PM'

It is sometimes desirable to trigger a function call after a state is executed, for this the `module.wait` state can be used:

```yaml
add example to hosts:
  file.append:
    - name: /etc/hosts
    - text: 203.0.113.13 example.com

# New Style
mine.send:
  module.wait:
    # Again, note the trailing `:`
    - hosts.list_hosts:
    - watch:
      - file: add example to hosts
```

Legacy (Default) Examples

If you’re using the legacy `module.run`, due to how the state system works, if a module function accepts an argument called, `name`, then `m_name` must be used to specify that argument, to avoid a collision with the `name` argument.

Here is a list of keywords hidden by the state system, which must be prefixed with `m_`:

- fun
- name
- names
- state
- saltenv

For example:

```yaml
disable_nfs:
  module.run:
    - name: service.disable
    - m_name: nfs
```

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

```yaml
mine.send:
  module.run:
    - func: network.ip_addrs
    - kwargs:
      interface: eth0
```

```yaml
cloud.create:
  module.run:
```
- **func**: `cloud.create`
- **provider**: `test-provider`
- **m_names**:
  - `test-vlad`
- **kwargs**:
  ```
  ssh_username: 'ubuntu',
  image: 'ami-8d6d9daa',
  securitygroup: 'default',
  size: 'c3.large',
  location: 'ap-northeast-1',
  delvol_on_destroy: 'True'
  ```

Other modules take the keyword arguments using this style:

```python
mac_enable_ssh:
  module.run:
    - name: system.set_remote_login
    - enable: True
```

Another example that creates a recurring task that runs a batch file on a Windows system:

```python
eventsviewer:
  module.run:
    - name: task.create_task
    - m_name: 'events-viewer'
    - user_name: System
    - kwargs:
      ```
      action_type: 'Execute',
      cmd: 'c:\netops\scripts\events_viewer.bat',
      trigger_type: 'Daily',
      start_date: '2017-1-20',
      start_time: '11:59PM'
      ```
```

```python
salt.states.module.run(**kwargs)
```
Run a single module function or a range of module functions in a batch. Supersedes `module.run` function, which requires `m_` prefix to function-specific parameters.

Parameters:
- **returner** -- Specify a common returner for the whole batch to send the return data
- **kwargs** -- Pass any arguments needed to execute the function(s)

```python
some_id_of_state:
  module.run:
    - network.ip_addrs:
    - interface: eth0
    - cloud.create:
      - names:
        - test-isbm-1
        - test-isbm-2
      - ssh_username: sles
      - image: sles12sp2
      - securitygroup: default
      - size: 'c3.large'
      - location: ap-northeast-1
      - delvol_on_destroy: True
```

...
Returns

salt.states.module.wait(name, **kwargs)

Run a single module function only if the watch statement calls it

name The module function to execute
**kwargs Pass any arguments needed to execute the function

Note: Like the cmd.run state, this state will return True but not actually execute, unless one of the following two things happens:
1. The state has a watch requisite, and the state which it is watching changes.
2. Another state has a watch_in requisite which references this state, and the state with the watch_in changes.

23.19.186 salt.states.mongodb_database

Management of MongoDB Databases

depends
    • pymongo Python module

Only deletion is supported, creation doesn’t make sense and can be done using mongodb_user.present.

salt.states.mongodb_database.absent(name, user=None, password=None, host=None, port=None, authdb=None)

Ensure that the named database is absent. Note that creation doesn’t make sense in MongoDB.

name The name of the database to remove
user The user to connect as (must be able to create the user)
password The password of the user
host The host to connect to
port The port to connect to
authdb The database in which to authenticate

23.19.187 salt.states.mongodb_user

Management of MongoDB Users

depends
    • pymongo Python module

salt.states.mongodb_user.absent(name, passwd, database='admin', user=None, password=None, host='localhost', port=27017, authdb=None)

Ensure that the user is present with the specified properties

Ensure that the user is absent

name The name of the user to remove
user MongoDB user with sufficient privilege to create the user
password Password for the admin user specified by the user parameter
host The hostname/IP address of the MongoDB server
port The port on which MongoDB is listening
database The database from which to remove the user specified by the name parameter
authdb The database in which to authenticate

salt.states.mongodb_user.present(name, passwd, database='admin', user=None, password=None, host='localhost', port=27017, authdb=None, roles=None)

Ensure that the user is present with the specified properties
**name** The name of the user to manage
**passwd** The password of the user to manage
**user** MongoDB user with sufficient privilege to create the user
**password** Password for the admin user specified with the **user** parameter
**host** The hostname/IP address of the MongoDB server
**port** The port on which MongoDB is listening
**database** The database in which to create the user

---

**Note:** If the database doesn’t exist, it will be created.

**authdb** The database in which to authenticate
**roles** The roles assigned to user specified with the **name** parameter

Example:

```bash
mongouser-myapp:
    mongodb_user.present:
        - name: myapp
        - passwd: password-of-myapp
        - database: admin
        # Connect as admin:sekrit
        - user: admin
        - password: sekrit
        - roles:
            - readWrite
            - userAdmin
            - dbOwner
```

---

### 23.19.188 salt.states.monit

**Monit state**

Manage monit states

```bash
monit_enable_service_monitoring:
    monit.monitor:
        - name: service

monit_disable_service_monitoring:
    monit.unmonitor:
        - name: service
```

---

**Note:** Use of these states require that the **monit** execution module is available.

salt.states.monit.monit(**name**)

Get the summary from module monit and try to see if service is being monitored. If not then monitor the service.

salt.states.monit.unmonitor(**name**)

Get the summary from module monit and try to see if service is being monitored. If it is then stop monitoring the service.
23.19.189 salt.states.mount

Mounting of filesystems

Mount any type of mountable filesystem with the mounted function:

```
/mnt/sdb:
  mount.mounted:
    - device: /dev/sdb1
    - fstype: ext4
    - mkmnt: True
    - opts: defaults

/srv/bigdata:
  mount.mounted:
    - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
    - fstype: xfs
    - opts: nobootwait,noatime,nodiratime,nobarrier,logbufs=8
    - dump: 0
    - pass_num: 2
    - persist: True
    - mkmnt: True

/var/lib/bigdata:
  mount.mounted:
    - device: /srv/bigdata
    - fstype: none
    - opts: bind
    - dump: 0
    - pass_num: 0
    - persist: True
    - mkmnt: True
```

salt.states.mount.fstab_absent(name, fs_file, mount_by=None, config='/etc/fstab')

Makes sure that a fstab mount point is absent.

- **name**: The name of block device. Can be any valid fs_spec value.
- **fs_file**: Mount point (target) for the filesystem.
- **mount_by**: Select the final value for fs_spec. Can be [None, device, label, uuid, partlabel, partuuid]. If None, the value for fs_spec will be the parameter name, in other case will search the correct value based on the device name. For example, for uuid, the value for fs_spec will be of type 'UUID=xxx' instead of the device name set in name.
- **config**: Place where the fstab file lives

salt.states.mount.fstab_present(name, fs_file, fs_vfstype, fs_mntops='defaults', fs_freq=0, fs_passno=0, mount_by=None, config='/etc/fstab', mount=True, match_on='auto', not_change=False, fs_mount=True)

Makes sure that a fstab mount point is present.

- **name**: The name of block device. Can be any valid fs_spec value.
- **fs_file**: Mount point (target) for the filesystem.
- **fs_vfstype**: The type of the filesystem (e.g. ext4, xfs, btrfs, ...)
- **fs_mntops**: The mount options associated with the filesystem. Default is defaults.
- **fs_freq**: Field is used by dump to determine which fs need to be dumped. Default is 0
- **fs_passno**: Field is used by fsck to determine the order in which filesystem checks are done at boot time. Default is 0
- **fs_mount**: Field is used only in AIX systems to determine if the filesystem will be mounted by mount all
- **mount_by**: Select the final value for fs_spec. Can be [None, device, label, uuid, partlabel,
partuuid]. If None, the value for fs_spec will be the parameter name, in other case will search the correct value based on the device name. For example, for uuid, the value for fs_spec will be of type 'UUID=xxx' instead of the device name set in name.

config Place where the fstab file lives. Default is /etc/fstab

mount Set if the mount should be mounted immediately. Default is True

match_on A name or list of fstab properties on which this state should be applied. Default is auto, a special value indicating to guess based on fstype. In general, auto matches on name for recognized special devices and device otherwise.

not_change By default, if the entry is found in the fstab file but is different from the expected content (like different options), the entry will be replaced with the correct content. If this parameter is set to True and the line is found, the original content will be preserved.

salt.states.mount.mod_watch(name, user=None, **kwargs)

The mounted watcher, called to invoke the watch command.

Parameters for this function should be set by the state being triggered.

---

name The name of the mount point

salt.states.mount.mounted(name, device, fstype, mkmnt=False, opts='defaults', dump=0, pass_num=0, config='/etc/fstab', persist=True, mount=True, user=None, match_on='auto', device_name_regex=None, extra_mount_invisible_options=None, extra_mount_invisible_keys=None, extra_mount_ignore_fs_keys=None, extra_mount_translate_options=None, hidden_opts=None, **kwargs)

Verify that a device is mounted

name The path to the location where the device is to be mounted
device The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314 or LABEL=DATA
fstype The filesystem type, this will be xfs, ext2/3/4 in the case of classic filesystems, fuse in the case of fuse mounts, and nfs in the case of nfs mounts
mkmnt If the mount point is not present then the state will fail, set mkmnt: True to create the mount point if it is otherwise not present

dump The dump value to be passed into the fstab, Default is 0
pass_num The pass value to be passed into the fstab, Default is 0
config Set an alternative location for the fstab, Default is /etc/fstab
persist Set if the mount should be saved in the fstab, Default is True

termediate is True
user The account used to execute the mount; this defaults to the user salt is running as on the minion

match_on A name or list of fstab properties on which this state should be applied. Default is auto, a special value indicating to guess based on fstype. In general, auto matches on name for recognized special devices and device otherwise.

device_name_regex A list of device exact names or regular expressions which should not force a remount.

For example, glusterfs may be mounted with a comma-separated list of servers in fstab, but the /proc/self/mountinfo will show only the first available server.

```python
{% set glusterfs_ip_list = ['10.0.0.1', '10.0.0.2', '10.0.0.3'] %}
mount glusterfs volume:
    mount.mounted:
    - name: /mnt/glusterfs_mount_point
```

(continues on next page)
New in version 2016.11.0.

- **device**: `{{ glusterfs_ip_list|join(',')} }}:/volume_name
- **fstype**: glusterfs
- **opts**: _netdev,rw,defaults,direct-io-mode=disable
- **mkmnt**: True
- **persist**: True
- **dump**: 0
- **pass_num**: 0
- **device_name_regex**:
  - `{{ glusterfs_ip_list|join('|')} }}:/volume_name`

**extra_mount_invisible_options** A list of extra options that are not visible through the `/proc/self/mountinfo` interface.

If a option is not visible through this interface it will always remount the device. This option extends the builtin `mount_invisible_options` list.

**extra_mount_invisible_keys** A list of extra key options that are not visible through the `/proc/self/mountinfo` interface.

If a key option is not visible through this interface it will always remount the device. This option extends the builtin `mount_invisible_keys` list.

A good example for a key option is the password option:

```python
password=badsecret
```

**extra_mount_ignore_fs_keys** A dict of filesystem options which should not force a remount. This will update the internal dictionary. The dict should look like this:

```python
{
    'ramfs': ['size']
}
```

**extra_mount_translate_options** A dict of mount options that gets translated when mounted. To prevent a remount add additional options to the default dictionary. This will update the internal dictionary. The dictionary should look like this:

```python
{
    'tcp': 'proto=tcp',
    'udp': 'proto=udp'
}
```

**hidden_opts** A list of mount options that will be ignored when considering a remount as part of the state application

New in version 2015.8.2.

salt.states.mount.swap(name, persist=True, config='/etc/fstab')
Activates a swap device

/root/swapfile:

```
mount.swap
```

**Note**: swap does not currently support LABEL

salt.states.mount.unmounted(name, device=None, config='/etc/fstab', persist=False, user=None, **kwargs)

New in version 0.17.0.
Verify that a device is not mounted

- **name**: The path to the location where the device is to be unmounted from
- **device**: The device to be unmounted. This is optional because the device could be mounted in multiple places.

New in version 2015.5.0.

- **config**: Set an alternative location for the fstab. Default is `/etc/fstab`
- **persist**: Set if the mount should be purged from the fstab. Default is `False`
- **user**: The user to own the mount; this defaults to the user `salt` is running as on the minion

### 23.19.190 salt.states.mssql_database

**Management of Microsoft SQLServer Databases**

The `mssql_database` module is used to create and manage SQL Server Databases

```py
yolo:
    mssql_database.present
```

```py
salt.states.mssql_database.absent(name, **kwargs)
    Ensure that the named database is absent
    name: The name of the database to remove
```

```py
salt.states.mssql_database.present(name, containment='NONE', options=None, **kwargs)
    Ensure that the named database is present with the specified options
    name: The name of the database to manage
    containment: Defaults to NONE
    options: Can be a list of strings, a dictionary, or a list of dictionaries
```

### 23.19.191 salt.states.mssql_login

**Management of Microsoft SQLServer Logins**

The `mssql_login` module is used to create and manage SQL Server Logins

```py
frank:
    mssql_login.present
    - domain: mydomain
```

```py
salt.states.mssql_login.absent(name, **kwargs)
    Ensure that the named login is absent
    name: The name of the login to remove
```

```py
salt.states.mssql_login.present(name, password=None, domain=None, server_roles=None, options=None, **kwargs)
    Checks existence of the named login. If not present, creates the login with the specified roles and options.
    name: The name of the login to manage
    password: Creates a SQL Server authentication login. Since hashed passwords are varbinary values, if the
               new_login_password is 'long', it will be considered to be HASHED.
    domain: Creates a Windows authentication login. Needs to be NetBIOS domain or hostname
    server_roles: Add this login to all the server roles in the list
    options: Can be a list of strings, a dictionary, or a list of dictionaries
```
23.19.192 salt.states.mssql_role

Management of Microsoft SQLServer Databases

The mssql_role module is used to create and manage SQL Server Roles

```yaml
yolo:
  mssql_role.present
```

```
salt.states.mssql_role.absent(name, **kwargs)
   Ensure that the named database is absent
   name  The name of the database to remove
```

```
salt.states.mssql_role.present(name, owner=None, grants=None, **kwargs)
   Ensure that the named database is present with the specified options
   name  The name of the database to manage
   owner Adds owner using AUTHORIZATION option
   grants Can only be a list of strings
```

23.19.193 salt.states.mssql_user

Management of Microsoft SQLServer Users

The mssql_user module is used to create and manage SQL Server Users

```yaml
frank:
  mssql_user.present:
    - database: yolo
```

```
salt.states.mssql_user.absent(name, **kwargs)
   Ensure that the named user is absent
   name  The username of the user to remove
```

```
salt.states.mssql_user.present(name, login=None, domain=None, database=None, roles=None, options=None, **kwargs)
   Checks existence of the named user. If not present, creates the user with the specified roles and options.
   name  The name of the user to manage
   login If not specified, will be created WITHOUT LOGIN
   domain Creates a Windows authentication user. Needs to be NetBIOS domain or hostname
   database The database of the user (not the login)
   roles Add this user to all the roles in the list
   options Can be a list of strings, a dictionary, or a list of dictionaries
```

23.19.194 salt.states.msteams

Send a message card to Microsoft Teams

This state is useful for sending messages to Teams during state runs.

New in version 2017.7.0.

```yaml
teams-message:
  msteams.post_card:
```

(continues on next page)
- **message**: 'This state was executed successfully.'
- **hook_url**: https://outlook.office.com/webhook/837

The hook_url can be specified in the master or minion configuration like below:

```yaml
msteams:
  hook_url: https://outlook.office.com/webhook/837
```

salt.states.msteams.post_card(name, message, hook_url=None, title=None, theme_color=None)

Send a message to a Microsoft Teams channel

```python
send-msteams-message:
msteams.post_card:
  - message: 'This state was executed successfully.'
  - hook_url: https://outlook.office.com/webhook/837
```

The following parameters are required:
- **message** The message that is to be sent to the MS Teams channel.

The following parameters are optional:
- **hook_url** The webhook URL given configured in Teams interface, if not specified in the configuration options of master or minion.
- **title** The title for the card posted to the channel
- **theme_color** A hex code for the desired highlight color

### 23.19.195 salt.states.mysql_database

Management of MySQL databases (schemas)

```yaml
depends
  - MySQLdb Python module

configuration
  See salt.modules.mysql for setup instructions.
```

The mysql_database module is used to create and manage MySQL databases. Databases can be set as either absent or present.

```yaml
frank:
  mysql_database.present
```

salt.states.mysql_database.absent(name, **connection_args)

Ensure that the named database is absent

```yaml
name The name of the database to remove
```

salt.states.mysql_database.present(name, character_set=None, collate=None, **connection_args)

Ensure that the named database is present with the specified properties

```yaml
name The name of the database to manage
```
23.19.196 salt.states.mysql_grants

Management of MySQL grants (user permissions)

depends

- MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_grants module is used to grant and revoke MySQL permissions.

The name you pass in purely symbolic and does not have anything to do with the grant itself.

The database parameter needs to specify a 'priv_level' in the same specification as defined in the MySQL documentation:

- *
- **
- db_name.*
- db_name.tbl_name
- etc...

This state is not able to set password for the permission from the specified host. See salt.states.mysql_user for further instructions.

```yaml
frank_exampledb:
  mysql_grants.present:
    - grant: select,insert,update
    - database: exampledb.*
    - user: frank
    - host: localhost

frank_otherdb:
  mysql_grants.present:
    - grant: all privileges
    - database: otherdb.*
    - user: frank

restricted_singletable:
  mysql_grants.present:
    - grant: select
    - database: somedb.sometable
    - user: joe
```

salt.states.mysql_grants.absent(name, grant=None, database=None, user=None, host='localhost',
grant_option=False, escape=True, **connection_args)

Ensure that the grant is absent

name The name (key) of the grant to add
grant The grant priv_type (i.e. select,insert,update OR all privileges)
database The database priv_level (i.e. db.tbl OR db.*)
user The user to apply the grant to
host The network/host that the grant should apply to

salt.states.mysql_grants.present(name, grant=None, database=None, user=None,
host='localhost', grant_option=False, escape=True, revoke_first=False,
ssl_option=False, **connection_args)

Ensure that the grant is present with the specified properties
name  The name (key) of the grant to add
grant  The grant priv_type (i.e. select,insert,update OR all privileges)
database  The database priv_level (i.e. db.tbl OR db.*)
user  The user to apply the grant to
host  The network/host that the grant should apply to
grant_option  Adds the WITH GRANT OPTION to the defined grant. Default is False
escape  Defines if the database value gets escaped or not. Default is True
revoke_first  By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what's already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.tbl/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the 'revoke_first options.

WARNING: This will remove permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

Default is False
ssl_option  Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dicts in the value:

- SSL: True
- X509: True
- SUBJECT: <subject>
- ISSUER: <issuer>
- CIPHER: <cipher>

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified by the MySQL documentation for these options.

Default is False (no ssl options will be used)

23.19.197 salt.states.mysql_query

Execution of MySQL queries

New in version 2014.7.0.

depends
- MySQLdb Python module

configuration  See salt.modules.mysql for setup instructions.

The mysql_query module is used to execute queries on MySQL databases. Its output may be stored in a file or in a grain.

query_id:
mysql_query.run
- database: my_database
- query: "SELECT * FROM table;"
- output: "/tmp/query_id.txt"

salt.states.mysql_query.run(name, database, query, output=None, grain=None, key=None, overwrite=True, check_db_exists=True, client_flags=None, **connection_args)

Execute an arbitrary query on the specified database
name  Used only as an ID
database  The name of the database to execute the query on
query  The query to execute
output  grain: output in a grain other: the file to store results None: output to the result comment (default)
grain:  grain to store the output (need output=grain)
key:  the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
overwrite:  The file or grain will be overwritten if it already exists (default)
check_db_exists:  The state run will check that the specified database exists (default=True) before running any queries

salt.states.mysql_query.run_file(name, database, query_file=None, output=None, grain=None, key=None, overwrite=True, saltenv=None, check_db_exists=True, client_flags=None, **connection_args)

Execute an arbitrary query on the specified database

New in version 2017.7.0.

name  Used only as an ID
database  The name of the database to execute the query_file on
query_file  The file of mysql commands to run
output  grain: output in a grain other: the file to store results None: output to the result comment (default)
grain:  grain to store the output (need output=grain)
key:  the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
overwrite:  The file or grain will be overwritten if it already exists (default)
saltenv:  The saltenv to pull the query_file from
check_db_exists:  The state run will check that the specified database exists (default=True) before running any queries

23.19.198  salt.states.mysql_user

Management of MySQL users

depends

- MySQLdb Python module

configuration  See salt.modules.mysql for setup instructions.

```
frank:
  mysql_user.present:
    - host: localhost
    - password: bobcat
```

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments:  connection_host, connection_port, connection_user, connection_pass, connection_db, connection_unix_socket, connection_default_file and connection_charset.
This state is not able to grant permissions for the user. See `salt.states.mysql_grants` for further instructions.

```python
salt.states.mysql_user.absent(name, host='localhost', **connection_args)
```

Ensure that the named user is absent

- **name**: The name of the user to remove

```python
salt.states.mysql_user.present(name, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, password_column=None, auth_plugin='mysql_native_password', **connection_args)
```

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting `password` and `password_hash`, and setting `allow_passwordless` to `True`.

- **name**: The name of the user to manage
- **host**: Host for which this user/password combo applies
- **password**: The password to use for this user. Will take precedence over the `password_hash` option if both are specified.
- **password_hash**: The password in hashed form. Be sure to quote the password because YAML doesn't like the `*`. A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+------------------------------------------+
| PASSWORD('mypass')                      |
| ----------------------------------------+
| +6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
| +----------------------------------------+
| 1 row in set (0.00 sec)                 |
```

- **allow_passwordless**: If `True`, then `password` and `password_hash` can be omitted to permit a passwordless login.

  New in version 0.16.2.

- **unix_socket**: If `True` and `allow_passwordless` is `True`, the `unix_socket` auth plugin will be used.

23.19.199 `salt.states.net_napalm_yang`

**NAPALM YANG state**

Manage the configuration of network devices according to the YANG models (OpenConfig/IETF).

New in version 2017.7.0.
Dependencies

- napalm-yang
- pyangbing > 0.5.11

To be able to load configuration on network devices, it requires NAPALM library to be installed: `pip install napalm`. Please check Installation for complete details.

```python
salt.states.net_napalm_yang.configured(name, data, **kwargs)
```
Configure the network device, given the input data structured according to the YANG models.

**Note:** The main difference between this function and managed is that the later generates and loads the configuration only when there are differences between the existing configuration on the device and the expected configuration. Depending on the platform and hardware capabilities, one could be more optimal than the other. Additionally, the output of the managed is different, in such a way that the pchange field in the output contains structured data, rather than text.

```python
data  YANG structured data.
models A list of models to be used when generating the config.
profiles: `None` Use certain profiles to generate the config. If not specified, will use the platform default profile(s).
test: `False` Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
debug: `False` Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.
replace: `False` Should replace the config with the new generate one?
```

State SLS example:

```python
{% set expected_config = pillar.get('openconfig_interfaces_cfg') %}
interfaces_config:
  napalm_yang.configured:
    - data: {{ expected_config | json }}
    - models:
      - models.openconfig_interfaces
    - debug: true
```

Pillar example:

```python
openconfig_interfaces_cfg:
  _kwargs:
    filter: true
  interfaces:
    interface:
      Et1:
        config:
          mtu: 9000
      Et2:
        config:
          description: "description example"
```

```python
salt.states.net_napalm_yang.managed(name, data, **kwargs)
```
Manage the device configuration given the input data structured according to the YANG models.

```python
data  YANG structured data.
```
models A list of models to be used when generating the config.
profiles: None Use certain profiles to generate the config. If not specified, will use the platform default profile(s).
compliance_report: False Return the compliance report in the comment.

New in version 2017.7.3.
test: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
debug: False Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.
replace: False Should replace the config with the new generate one?

State SLS example:

```yaml
{% set expected_config = pillar.get('openconfig_interfaces_cfg') %}

interfaces_config:
  napalm_yang.managed:
    - data: {{ expected_config | json }}
    - models:
      - models.openconfig_interfaces
    - debug: true
```

Pillar example:

```yaml
openconfig_interfaces_cfg:
  _kwargs:
    filter: true
  interfaces:
    interface:
      Et1:
        config:
          mtu: 9000
      Et2:
        config:
          description: "description example"
```

23.19.200 salt.states.netacl

Network ACL

Manage the firewall configuration on the network device managed through NAPALM. The firewall configuration is generated by Capirca.

New in version 2017.7.0.

codeauthor Mircea Ulinic <ping@mirceaulinic.net>
maturity new
depends capirca, napalm
platform unix
Dependencies

Capirca

To install Capirca, execute: pip install capirca.

NAPALM

To be able to load configuration on network devices, it requires NAPALM library to be installed: pip install napalm. Please check Installation for complete details.

salt.states.netacl.filter(name, filter_name, filter_options=None, terms=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)

Generate and load the configuration of a policy filter.

- **filter_name**: The name of the policy filter.
- **filter_options**: Additional filter options. These options are platform-specific. See the complete list of options.
- **terms**: Dictionary of terms for this policy filter. If not specified or empty, will try to load the configuration from the pillar, unless merge_pillar is set as False.
- **prepend**: When merge_pillar is set as True, the final list of terms generated by merging the terms from terms with those defined in the pillar (if any): new terms are prepended at the beginning, while existing ones will preserve the position. To add the new terms at the end of the list, set this argument to False.
- **pillar_key**: acl The key in the pillar containing the default attributes values. Default: acl.
- **pillarenv**: Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.
- **saltenv**: Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.
- **merge_pillar**: False Merge terms with the corresponding value from the pillar. Default: False.

**Note**: By default this state does not merge, to avoid any unexpected behaviours.

The merge logic depends on the prepend argument.

The terms specified through the terms argument have higher priority than the pillar.

- **only_lower_merge**: False Specify if it should merge only the terms fields. Otherwise it will try to merge also filters fields. Default: False. This option requires merge_pillar, otherwise it is ignored.
- **revision_id**: Add a comment in the filter config having the description for the changes applied.
- **revision_no**: The revision count.
- **revision_date**: True Boolean flag: display the date when the filter configuration was generated. Default: True.
- **revision_date_format**: %Y/%m/%d The date format to be used when generating the perforce data. Default: %Y/%m/%d (<year>/<month>/<day>).
- **test**: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
- **commit**: True Commit? Default: True.
- **debug**: False Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.

CLI Example:
salt 'edge01.flw01' state.sls router.acl test=True

Output Example:

edge01.flw01:

```
ID: my-filter
Function: netacl.filter
Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:24:40.598232
Duration: 2437.139 ms
Changes:

loaded:

 Summary for edge01.flw01

Succeeded: 1 (unchanged=1, changed=1)
Failed: 0

Total states run: 1
Total run time: 2.437 s

Pillar example:

```

 acl:
 - my-filter:
   options:
     inet6
   terms:
     - my-term:
       source_port: [1234, 1235]
       protocol:
         - tcp
         - udp
```

(continues on next page)
source_address: 1.2.3.4
description: reject
- my-other-term:
  source_port:
    - [5678, 5680]
  protocol: tcp
description: accept

State SLS Example:

```
{% set filter_name = 'my-filter' %}
{% set my_filter_cfg = salt.netacl.get_filter_pillar(filter_name, pillar_key='firewall') %}
my_first_filter_state:
  netacl.filter:
    - filter_name: {{ filter_name }}
    - options: {{ my_filter_cfg['options'] | json }}
    - terms: {{ my_filter_cfg['terms'] | json }}
    - revision_date: false
    - revision_no: 5
    - debug: true

Or:

my_first_filter_state:
  netacl.filter:
    - filter_name: my-filter
    - merge_pillar: true
    - pillar_key: firewall
    - revision_date: false
    - revision_no: 5
    - debug: true
```

In the example above, as inet6 has been specified in the filter_options, the configuration chunk referring to my-term has been ignored as it referred to IPv4 only (from source_address field).

**Note:** The first method allows the user to eventually apply complex manipulation and/or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`` | json``), instead of relying on the default Python serializer.

```
salt.states.netacl.managed(name, filters=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)
```

Manage the whole firewall configuration.

- **filters** Dictionary of filters for this policy. If not specified or empty, will try to load the configuration from the pillar, unless merge_pillar is set as False.
- **prepend: True** When merge_pillar is set as True, the final list of filters generated by merging the filters from filters with those defined in the pillar (if any): new filters are prepended at the beginning, while
existing ones will preserve the position. To add the new filters at the end of the list, set this argument to False.

**pillar_key:** acl The key in the pillar containing the default attributes values. Default: acl.

**pillarenv** Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.

**saltenv** Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.

**merge_pillar:** False Merge the filters will the corresponding values from the pillar. Default: False.

---

**Note:** By default this state does not merge, to avoid any unexpected behaviours.

The merge logic depends on the prepend argument.

The filters specified through the filters argument have higher priority than the pillar.

**only_lower_merge:** False Specify if it should merge only the filters and terms fields. Otherwise it will try to merge everything at the policy level. Default: False. This option requires merge_pillar, otherwise it is ignored.

**test:** False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.

**revision_id** Add a comment in the policy config having the description for the changes applied.

**revision_no** The revision count.

**revision_date:** True Boolean flag: display the date when the policy configuration was generated. Default: True.

**revision_date_format:** %Y/%m/%d The date format to be used when generating the perforce data. Default: %Y/%m/%d (<year>/<month>/<day>).

**commit:** True Commit? Default: True.

**debug:** False Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.

---

**CLI Example:**

```
salt 'edge01.bjm01' state.sls router.acl test=True
```

---

**Output Example:**

```
edge01.bjm01:
-------------
ID: netacl_example
Function: netacl.managed
Result: None
Comment: Testing mode: Configuration discarded.

+  }
+  }
+} 
loaded: 
firewall {
  family inet {
    replace:
    /*
    ** $Id: netacl_example $  
    ** $Date: 2017/07/03 $  
    ** $Revision: 2 $  
    */
    filter my-filter {
      interface-specific;
      term my-term {
        from {
          source-address {
            1.2.3.4/32;
          }
          protocol [ tcp udp ];
          source-port [ 1234 1235 ];
        }
      }
    }
  }
The policy configuration has been loaded from the pillar, having the following structure:

```
firewall:
  - my-filter:
    terms:
      - my-term:
          source_port: [1234, 1235]
          protocol:
            - tcp
            - udp
```

source_address: 1.2.3.4
action: reject
  - my-other-term:
    source_port:
      - [5678, 5680]
    protocol: tcp
    action: accept
  - block-icmp:
    terms:
      - first-term:
        protocol: icmp
        action: reject

Example SLS file:

```yaml
{%- set fw_filters = pillar.get('firewall', {}) -%}
netacl_example:
  netacl.managed:
    - filters: {{ fw_filters | json }}
    - revision_no: 2
    - debug: true

Or:

netacl_example:
  netacl.managed:
    - pillar_key: firewall
    - merge_pillar: true
    - revision_no: 2
    - debug: true

Note: The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

Note: When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`| json`), instead of relying on the default Python serializer.

salt.states.netacl.term(name, filter_name, term_name, filter_options=None, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False, source_service=None, destination_service=None, **term_fields)

Manage the configuration of a specific policy term.

filter_name The name of the policy filter.
term_name The name of the term.
filter_options Additional filter options. These options are platform-specific. See the complete list of options.
pillar_key: acl The key in the pillar containing the default attributes values. Default: acl.
pillarenv Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.
saltenv Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.
merge_pillar: False Merge the CLI variables with the pillar. Default: False.

The properties specified through the state arguments have higher priority than the pillar.
revision_id Add a comment in the term config having the description for the changes applied.
revision_no 'The revision count.
revision_date: True Boolean flag: display the date when the term configuration was generated. Default: True.
revision_date_format: %Y/%m/%d The date format to be used when generating the perforce data. Default: %Y/%m/%d (<year>/<month>/<day>).
test: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
debug: False Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.
source_service A special service to choose from. This is a helper so the user is able to select a source just using the name, instead of specifying a source_port and protocol. As this module is available on Unix platforms only, it reads the IANA port assignment from /etc/services. If the user requires additional shortcuts to be referenced, they can add entries under /etc/services, which can be managed using the file state.
destination_service A special service to choose from. This is a helper so the user is able to select a source just using the name, instead of specifying a destination_port and protocol. Allows the same options as source_service.
term_fields Term attributes. To see what fields are supported, please consult the list of supported keywords. Some platforms have few other optional keywords.

Note: The following fields are accepted:
  • action
  • address
  • address_exclude
  • comment
  • counter
  • expiration
  • destination_address
  • destination_address_exclude
  • destination_port
  • destination_prefix
  • forwarding_class
  • forwarding_class_except
  • logging
  • log_name
  • loss_priority
  • option
  • policer
  • port
  • precedence
  • principals
  • protocol
  • protocol_except
  • qos
  • pan_application
  • routing_instance
  • source_address
  • source_address_exclude
- source_port
- source_prefix
- verbatim
- packet_length
- fragment_offset
- hop_limit
- icmp_type
- ether_type
- traffic_class_count
- traffic_type
- translated
- dscp_set
- dscp_match
- dscp_except
- next_ip
- flexible_match_range
- source_prefix_except
- destination_prefix_except
- vpn
- source_tag
- destination_tag
- source_interface
- destination_interface
- flattened
- flattened_addr
- flattened_saddr
- flattened_daddr
- priority

**Note:** The following fields can be also a single value and a list of values:
- action
- address
- address_exclude
- comment
- destination_address
- destination_address_exclude
- destination_port
- destination_prefix
- forwarding_class
- forwarding_class_except
- logging
- option
- port
- precedence
- principals
- protocol
- protocol_except
- pan_application
- source_address
- source_address_exclude
- source_port
- source_prefix
• verbatim
• icmp_type
• ether_type
• traffic_type
• dscp_match
• dscp_except
• flexible_match_range
• source_prefix_except
• destination_prefix_except
• source_tag
• destination_tag
• source_service
• destination_service

Example: destination_address can be either defined as:

```
destination_address: 172.17.17.1/24
```

or as a list of destination IP addresses:

```
destination_address:
  - 172.17.17.1/24
  - 172.17.19.1/24
```

or a list of services to be matched:

```
source_service:
  - ntp
  - snmp
  - ldap
  - bgpd
```

Note: The port fields source_port and destination_port can be used as above to select either a single value, either a list of values, but also they can select port ranges. Example:

```
source_port:
  - [1000, 2000]
  - [3000, 4000]
```

With the configuration above, the user is able to select the 1000-2000 and 3000-4000 source port ranges.

CLI Example:

```
salt 'edge01.bjm01' state.sls router.acl
```

Output Example:

```
edge01.bjm01:
----------
ID: update_icmp_first_term
Function: netacl.term
Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:49:09.174179
Duration: 5751.882 ms
```

(continues on next page)
Changes:
--------

```diff
[edit firewall]
+ family inet {
+   /*
+   ** $Id: update_icmp_first_term $
+   ** $Date: 2017/02/30 $*
+   +
+   + filter block-icmp {
+   +   term first-term {
+   +     from {
+   +       protocol icmp;
+   +     }
+   +     then {
+   +       reject;
+   +     }
+   +   }
+   + }
+   + }
```

Summary for edge01.bjm01
------------------------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
------------------------
Total states run: 1
Total run time: 5.752 s

Pillar example:

```yaml
firewall:
- block-icmp:
  terms:
    - first-term:
      protocol: icmp
      action: reject
```

State SLS example:

```python
{% set filter_name = 'block-icmp' -%}
{% set term_name = 'first-term' -%}
{% set my_term_cfg = salt.netacl.get_term_pillar(filter_name, term_name) -%}

update_icmp_first_term:
  netacl.term:
    - filter_name: {{ filter_name }}
    - filter_options:
        - not-interface-specific
    - term_name: {{ term_name }}
    - {{ my_term_cfg | json }}
```

Or directly referencing the pillar keys:
**update_icmp_first_term:**
```yaml
netacl.term:
  - filter_name: block-icmp
  - filter_options:
    - not-interface-specific
  - term_name: first-term
  - merge_pillar: true
```

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`\ | json\`), instead of relying on the default Python serializer.

### 23.19.201 salt.states.netconfig

**Network Config**

Manage the configuration on a network device given a specific static config or template.

- **codeauthor** Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>
- **maturity** new
- **depends** napalm
- **platform** unix

**Dependencies**

- *NAPALM proxy minion*
- *Network-related basic features execution module*

New in version 2017.7.0.

**salt.states.netconfig.commit_cancelled(name)**

New in version 2019.2.0.

Cancel a commit scheduled to be executed via the commit_in and commit_at arguments from the `net. load_template` or `net.load_config` execution functions. The commit ID is displayed when the commitment is scheduled via the functions named above.

State SLS Example:

```python
'20180726083540640360':
    netconfig.commit_cancelled
```

**salt.states.netconfig.commit_confirmed(name)**

New in version 2019.2.0.
Confirm a commit scheduled to be reverted via the `revert_in` and `revert_at` arguments from the `net.load_template` or `net.load_config` execution functions. The commit ID is displayed when the commit confirmed is scheduled via the functions named above.

State SLS Example:

```yaml
'20180726083540640360':
    netconfig.commit_confirmed
```

salt.states.netconfig.managed(name, template_name=None, template_source=None, template_hash=None, template_hash_name=None, saltenv='base', template_engine='jinja', skip_verify=False, context=None, defaults=None, test=False, commit=True, replace=False, commit_in=None, commit_at=None, revert_in=None, revert_at=None, **template_vars)

Manages the configuration on network devices.

By default this state will commit the changes on the device. If there are no changes required, it does not commit and the field `already_configured` from the output dictionary will be set as `True` to notify that.

To avoid committing the configuration, set the argument `test` to `True` (or via the CLI argument `test=True`) and will discard (dry run).

To preserve the changes, set `commit` to `False` (either as CLI argument, either as state parameter). However, this is recommended to be used only in exceptional cases when there are applied few consecutive states and/or configuration changes. Otherwise the user might forget that the config DB is locked and the candidate config buffer is not cleared/merged in the running config.

To replace the config, set `replace` to `True`. This option is recommended to be used with caution!

**template_name** Identifies path to the template source. The template can be either stored on the local machine, either remotely. The recommended location is under the `file_roots` as specified in the master config file. For example, let's suppose the `file_roots` is configured as:

```yaml
file_roots:
    base:
      - /etc/salt/states
```

Placing the template under `/etc/salt/states/templates/example.jinja`, it can be used as `salt://templates/example.jinja`. Alternatively, for local files, the user can specify the absolute path. If remotely, the source can be retrieved via `http`, `https` or `ftp`.

Examples:

- `salt://my_template.jinja`
- `/absolute/path/to/my_template.jinja`
- `http://example.com/template.cheetah`
- `https://example.com/template.mako`
- `ftp://example.com/template.py`

Changed in version 2019.2.0: This argument can now support a list of templates to be rendered. The resulting configuration text is loaded at once, as a single configuration chunk.

**template_source**: `None` Inline config template to be rendered and loaded on the device.

**template_hash**: `None` Hash of the template file. Format: `{hash_type: 'md5', 'hsum': <md5sum>}`

**template_hash_name**: `None` When `template_hash` refers to a remote file, this specifies the filename to look for in that file.

**saltenv**: `base` Specifies the template environment. This will influence the relative imports inside the templates.

**template_engine**: `jinja` The following templates engines are supported:

- `cheetah`
- `genshi`
skip_verify: False If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

Changed in version 2017.7.1.
test: False Dry run? If set to True, will apply the config, discard and return the changes. Default: False (will commit the changes on the device).
debug: False Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw result after the template was rendered.

Note: This argument cannot be used directly on the command line. Instead, it can be passed through the pillar variable when executing either of the state.sls or state.apply (see below for an example).

commit_in: None Commit the changes in a specific number of minutes / hours. Example of accepted formats: 5 (commit in 5 minutes), 2m (commit in 2 minutes), 1h (commit the changes in 1 hour), 5h30m (commit the changes in 5 hours and 30 minutes).

Note: This feature works on any platforms, as it does not rely on the native features of the network operating system.

Note: After the command is executed and the diff is not satisfactory, or for any other reasons you have to discard the commit, you are able to do so using the net.cancel_commit execution function, using the commit ID returned by this function.

Warning: Using this feature, Salt will load the exact configuration you expect, however the diff may change in time (i.e., if an user applies a manual configuration change, or a different process or command changes the configuration in the meanwhile).

New in version 2019.2.0.
commit_at: None Commit the changes at a specific time. Example of accepted formats: 1am (will commit the changes at the next 1AM), 13:20 (will commit at 13:20), 1:20am, etc.

Note: This feature works on any platforms, as it does not rely on the native features of the network operating system.

Note: After the command is executed and the diff is not satisfactory, or for any other reasons you have to discard the commit, you are able to do so using the net.cancel_commit execution function, using the commit ID returned by this function.
Warning: Using this feature, Salt will load the exact configuration you expect, however the diff may change in time (i.e., if an user applies a manual configuration change, or a different process or command changes the configuration in the meanwhile).

New in version 2019.2.0.

```yaml
revert_in: None
```

Commit and revert the changes in a specific number of minutes / hours. Example of accepted formats: 5 (revert in 5 minutes), 2m (revert in 2 minutes), 1h (revert the changes in 1 hour), 5h30m (revert the changes in 5 hours and 30 minutes).

**Note:** To confirm the commit, and prevent reverting the changes, you will have to execute the `net.confirm_commit` function, using the commit ID returned by this function.

**Warning:** This works on any platform, regardless if they have or don't have native capabilities to confirming a commit. However, please be very cautious when using this feature: on Junos (as it is the only NAPALM core platform supporting this natively) it executes a commit confirmed as you would do from the command line. All the other platforms don't have this capability natively, therefore the revert is done via Salt. That means, your device needs to be reachable at the moment when Salt will attempt to revert your changes. Be cautious when pushing configuration changes that would prevent you reach the device.

Similarly, if an user or a different process apply other configuration changes in the meanwhile (between the moment you commit and till the changes are reverted), these changes would be equally reverted, as Salt cannot be aware of them.

New in version 2019.2.0.

```yaml
revert_at: None
```

Commit and revert the changes at a specific time. Example of accepted formats: `1am` (will commit and revert the changes at the next 1AM), `13:20` (will commit and revert at 13:20), `1:20am`, etc.

**Note:** To confirm the commit, and prevent reverting the changes, you will have to execute the `net.confirm_commit` function, using the commit ID returned by this function.

**Warning:** This works on any platform, regardless if they have or don't have native capabilities to confirming a commit. However, please be very cautious when using this feature: on Junos (as it is the only NAPALM core platform supporting this natively) it executes a commit confirmed as you would do from the command line. All the other platforms don't have this capability natively, therefore the revert is done via Salt. That means, your device needs to be reachable at the moment when Salt will attempt to revert your changes. Be cautious when pushing configuration changes that would prevent you reach the device.

Similarly, if an user or a different process apply other configuration changes in the meanwhile (between the moment you commit and till the changes are reverted), these changes would be equally reverted, as Salt cannot be aware of them.

New in version 2019.2.0.

```yaml
replace: False
```

Load and replace the configuration. Default: `False` (will apply load merge).

```yaml
context: None
```

Overrides default context variables passed to the template.
New in version 2019.2.0.

**defaults:** None  Default variables/context passed to the template.

**template_vars** Dictionary with the arguments/context to be used when the template is rendered. Do not explicitly specify this argument. This represents any other variable that will be sent to the template rendering system. Please see an example below! In both `ntp_peers_example_using_pillar` and `ntp_peers_example`, `peers` is sent as template variable.

**Note:** It is more recommended to use the `context` argument instead, to avoid any conflicts with other arguments.

SLS Example (e.g.: under salt://router/config.sls):

```yaml
whole_config_example:
  netconfig.managed:
    - template_name: salt://path/to/complete_config.jinja
    - debug: True
    - replace: True

bgp_config_example:
  netconfig.managed:
    - template_name: /absolute/path/to/bgp_neighbors.mako
    - template_engine: mako

prefix_lists_example:
  netconfig.managed:
    - template_name: prefix_lists.cheetah
    - debug: True
    - template_engine: cheetah

ntp_peers_example:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - skip_verify: False
    - debug: True
    - peers:
      - 192.168.0.1
      - 192.168.0.1

ntp_peers_example_using_pillar:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - peers: {{ pillar.get('ntp.peers', []) }}

Multi template example:

```yaml
hostname_and_ntp:
  netconfig.managed:
    - template_name:
    - debug: true
    - context:
      hostname: {{ opts.id }}
      servers:
        - 172.17.17.1
        - 172.17.17.2
      peers:
        - 192.168.0.1
        - 192.168.0.2
```
Usage examples:

```
$ sudo salt 'juniper.device' state.sls router.config test=True
$ sudo salt -N all-routers state.sls router.config pillar="{'debug': True}" 
```

`router.config` depends on the location of the SLS file (see above). Running this command, will be executed all five steps from above. These examples above are not meant to be used in a production environment, their sole purpose is to provide usage examples.

Output example:

```
$ sudo salt 'juniper.device' state.sls router.config test=True
juniper.device:
----------
ID: ntp_peers_example_using_pillar
Function: netconfig.managed
Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:01:40.744535
Duration: 8755.788 ms
Changes:
----------
diff:
 [edit system ntp]
  peer 192.168.0.1 { ... }
+ peer 172.17.17.1;
+ peer 172.17.17.3;

Summary for juniper.device
----------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
----------
Total states run: 1
Total run time: 8.756 s
```

Raw output example (useful when the output is reused in other states/execution modules):

```
$ sudo salt --out=pprint 'juniper.device' state.sls router.config test=True
   --debug=True
[
  'juniper.device': {
    'netconfig_|-ntp_peers_example_using_pillar_|-ntp_peers_example_using_
       pillar_|-managed': {
      '__id__': 'ntp_peers_example_using_pillar',
      '__run_num__': 0,
      'already_configured': False,
      'changes': {
        'diff': '[edit system ntp] peer 192.168.0.1 { ... }+ peer 172.
        17.17.1;+ peer 172.17.17.3;'
      },
      'comment': 'Testing mode: Configuration discarded.',
      'duration': 7400.759,
      'loaded_config': 'system { ntp { peer 172.17.17.1; peer 172.17.17.
         3; } }',
      'name': 'ntp_peers_example_using_pillar',
    }
  }
]
```
salt.states.netconfig.replace_pattern(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, search_only=False, show_changes=True, backslash_literal=False, source='running', path=None, test=False, replace=True, debug=False, commit=True)

New in version 2019.2.0.

Replace occurrences of a pattern in the configuration source. If show_changes is True, then a diff of what changed will be returned, otherwise a True will be returned when changes are made, and False when no changes are made. This is a pure Python implementation that wraps Python's sub().

pattern A regular expression, to be matched using Python's search().
repl The replacement text.
count: 0 Maximum number of pattern occurrences to be replaced. If count is a positive integer n, only n occurrences will be replaced, otherwise all occurrences will be replaced.
flags (list or int): 8 A list of flags defined in the re module documentation from the Python standard library. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Optionally, flags may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which supports 'MULTILINE').
bufsize (int or str): 1 How much of the configuration to buffer into memory at once. The default value 1 processes one line at a time. The special value file may be specified which will read the entire file into memory before processing.
append_if_not_found: False If set to True, and pattern is not found, then the content will be appended to the file.
prepend_if_not_found: False If set to True and pattern is not found, then the content will be prepended to the file.
not_found_content Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.
search_only: False If set to true, this no changes will be performed on the file, and this function will simply return True if the pattern was matched, and False if not.
show_changes: True If True, return a diff of changes made. Otherwise, return True if changes were made, and False if not.
backslash_literal: False Interpret backslashes as literal backslashes for the repl and not escape characters. This will help when using append/prepend so that the backslashes are not interpreted for the repl on the second run of the state.
path Save the temporary configuration to a specific path, then read from there.
test: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
commit: True Commit the configuration changes? Default: True.
dereg debug: False Debug mode. Will insert a new key in the output dictionary, as loaded_config containing the raw configuration loaded on the device.
replace: True Load and replace the configuration. Default: True.
If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:
State SLS Example:

```python
update_policy_name:
  netconfig.replace_pattern:
    - pattern: OLD-POLICY-NAME
    - repl: new-policy-name
    - debug: true

salt.states.netconfig.saved(name, source='running', user=None, group=None, mode=None,
  attrs=None, makedirs=False, dir_mode=None, replace=True,
  backup='', show_changes=True, create=True, tmp_dir='',
  encoding=None, encoding_errors='strict', allow_empty=False,
  follow_symlinks=True, check_cmd=None, win_owner=None,
  win_perms=None, win_deny_perms=None, win_inheritance=True,
  win_perms_reset=False, **kwargs)
```

New in version 2019.2.0.

Save the configuration to a file on the local file system.

- **name** Absolute path to file where to save the configuration. To push the files to the Master, use `cp.push` Execution function.
- **source:** `running` The configuration source. Choose from: running, candidate, startup. Default: running.
- **user** The user to own the file, this defaults to the user salt is running as on the minion
- **group** The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored
- **mode** The permissions to set on this file, e.g. 644, 0775, or 4664. The default mode for new files and directories corresponds to the umask of the salt process. The mode of existing files and directories will only be changed if mode is specified.

**Note:** This option is not supported on Windows.

- **attrs** The attributes to have on this file, e.g. a, i. The attributes can be any or a combination of the following characters: aAcCdDeijPsStTu.

**Note:** This option is not supported on Windows.

- **makedirs:** `False` If set to `True`, then the parent directories will be created to facilitate the creation of the named file. If `False`, and the parent directory of the destination file doesn't exist, the state will fail.
- **dir_mode** If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

  The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

- **replace:** `True` If set to `False` and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.
- **backup** Overrides the default backup mode for this specific file. See `backup_mode documentation` for more details.
- **show_changes:** `True` Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made.
- **create:** `True` If set to `False`, then the file will only be managed if the file already exists on the system.
- **encoding** If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See `https://docs.python.org/3/library/codecs.html#standard-encodings` for the list of available encodings.
encoding_errors: 'strict' Error encoding scheme. Default is 'strict'. See https://docs.python.org/2/library/codecs.html#codec-base-classes for the list of available schemes.
allow_empty: True If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.
follow_symlinks: True If the desired path is a symlink follow it and make changes to the file to which the symlink points.
check_cmd The specified command will be run with an appended argument of a temporary file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.
tmp_dir Directory for temp file created by check_cmd. Useful for checkers dependent on config file location (e.g. daemons restricted to their own config directories by an apparmor profile).
tmp_ext Suffix for temp file created by check_cmd. Useful for checkers dependent on config file extension (e.g. the init-checkconf upstart config checker).

win_owner: None The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.
win_perms: None A dictionary containing permissions to grant and their propagation. For example:
{ 'Administrators': { 'perms': 'full_control' } } Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to does not apply to file objects.
win_deny_perms: None A dictionary containing permissions to deny and their propagation. For example:
{ 'Administrators': { 'perms': 'full_control' } } Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to does not apply to file objects.
win_inheritance: True True to inherit permissions from the parent directory, False not to inherit permission.
win_perms_reset: False If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

State SLS Example:

```
/var/backups/{{ opts.id }}/{{ salt.status.time('%s') }}.cfg:
  netconfig.saved:
    - source: running
    - makedirs: true
```

The state SLS above would create a backup config grouping the files by the Minion ID, in chronological files. For example, if the state is executed at on the 3rd of August 2018, at 5:15PM, on the Minion core1.lon01, the configuration would saved in the file: /var/backups/core01.lon01/1533316558.cfg

23.19.202 salt.states.netntp

Network NTP

New in version 2016.11.0.
Manage the configuration of NTP peers and servers on the network devices through the NAPALM proxy.

codeauthor Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>
maturity new
depends napalm
platform unix
Dependencies

- Requires `netaddr` to be installed: `pip install netaddr` to check if IP Addresses are correctly specified
- Requires `dnspython` to be installed: `pip install dnspython` to resolve the nameserver entities (in case the user does not configure the peers/servers using their IP addresses)

- **NAPALM proxy minion**
- **NTP operational and configuration management module**

`salt.states.netntp.managed(name, peers=None, servers=None)`

Manages the configuration of NTP peers and servers on the device, as specified in the state SLS file. NTP entities not specified in these lists will be removed whilst entities not configured on the device will be set.

SLS Example:

```yaml
netntp_example:
  netntp.managed:
    - peers:
      - 192.168.0.1
      - 172.17.17.1
    - servers:
      - 24.124.0.251
      - 138.236.128.36
```

Output example:

```yaml
{  
  'edge01.nrt04': {  
    'netntp_|-netntp_example_|-netntp_example_|-managed': {  
      'comment': 'NTP servers already configured as needed.',  
      'name': 'netntp_example',  
      'start_time': '12:45:24.056659',  
      'duration': 2938.857,  
      'changes': {  
        'peers': {  
          'removed': [  
            '192.168.0.2',  
            '192.168.0.3'  
          ],  
          'added': [  
            '192.168.0.1',  
            '172.17.17.1'  
          ]  
        }  
      },  
      'result': None  
    }  
  }  
}
```
23.19.203 salt.states.netsnmp

Network SNMP

Manage the SNMP configuration on network devices.

codeauthor Mircea Ulinic <ping@mirceaulinic.net>
maturity new
depends napalm
platform unix

Dependencies

- napalm snmp management module (salt.modules.napalm_snmp)

New in version 2016.11.0.

salt.states.netsnmp.managed(name, config=None, defaults=None)

Configures the SNMP on the device as specified in the SLS file.

SLS Example:

```
snmp_example:
    netsnmp.managed:
        - config:
            location: Honolulu, HI, US
        - defaults:
            contact: noc@cloudflare.com
```

Output example (for the SLS above, e.g. called snmp.sls under /router/):

```
$ sudo salt edge01.hnl01 state.sls router.snmp test=True
edge01.hnl01:
        ID: snmp_example
        Function: netsnmp.managed
        Result: None
        Comment: Testing mode: configuration was not changed!
        Started: 13:29:06.872363
        Duration: 920.466 ms
        Changes:
        added:
        chassis_id:
            None
        contact:
            noc@cloudflare.com
        location:
            Honolulu, HI, US

Summary for edge01.hnl01

Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
```
(continues on next page)
23.19.204  *salt.states.netusers*

**Network Users**

Manage the users configuration on network devices via the NAPALM proxy.

**codeauthor** Mircea Ulinic <ping@mirceaulinic.net>

**maturity** new

**depends** napalm

**platform** unix

**Dependencies**

- NAPALM proxy minion
- Users configuration management module

New in version 2016.11.0.

**salt.states.netusers.managed** *(name, users=None, defaults=None)*

Manages the configuration of the users on the device, as specified in the state SLS file. Users not defined in that file will be removed whilst users not configured on the device, will be added.

**SLS Example:**

```
netusers_example:
  netusers.managed:
    - users:
      admin:
        level: 15
        password: $1$knmhgPPv$g8745biu4rb.Zf.IF/U1
        sshkeys: []
      restricted:
        level: 1
        password: $1$j34jsk44b$4d5SVjTiz1l.Zf.IF/K7
      martin:
        level: 15
        password: ''
        sshkeys:
          ssh-dss AAAAB3NzaC1kc3MAAACBAK9dP3KariMlM/→JmFW9rTsm5cXs4nR8+o6FTHP9o+bOLXMBTP8R4vwWHhOw
        →JPjQmJYafAqZTnlgi0srGjyifFwPtOdpqDWCgLe2M4LXnu3Qnr54w344zPHP3iFwWhRhrZKtCj08kbWCa+
        →X528+i87t6r5e4ersdfxgcghvjbknli087t6r5drcfhgjhbnbino8976tycv7t86f7yi870z1nKsKuNzm2csoUQj3
        →trmRfpjsOPNookmOz5wGWxhWDMKse6fWK+ATk1oIP+QT39fn4G77j8o+e4WAwxM570s350f/
        →V8z00ccj7j53sXn
```

23.19.205 salt.states.network

Configuration of network interfaces

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

Note: RedHat-based systems (RHEL, CentOS, Scientific, etc.) have been supported since version 2014.1.0.

Debian-based systems (Debian, Ubuntu, etc.) have been supported since version 2017.7.0. The following options are not supported: ipaddr_start, and ipaddr_end.

Other platforms are not yet supported.
Note: On Debian-based systems, networking configuration can be specified in /etc/network/interfaces or via included files such as (by default) /etc/network/interfaces.d/*. This can be problematic for configuration management. It is recommended to use either file.managed or network.managed.

If using network.managed, it can be useful to ensure interfaces.d/ is empty. This can be done using the following state

```
/etc/network/interfaces.d:
  file.directory:
    - clean: True
```

### Configuring Global Network Settings

Use the `network.system` state to set global network settings:

```
system:
  network.system:
    - enabled: True
    - hostname: server1.example.com
    - gateway: 192.168.0.1
    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True
    - apply_hostname: True
```

Note: The use of `apply_hostname` above will apply changes to the hostname immediately.

Changed in version 2015.5.0: `apply_hostname` added

### retain_settings

New in version 2016.11.0.

Use `retain_settings` to retain current network settings that are not otherwise specified in the state. Particularly useful if only setting the hostname. Default behavior is to delete unspecified network settings.

```
system:
  network.system:
    - hostname: server2.example.com
    - apply_hostname: True
    - retain_settings: True
```
Configuring Network Routes

Use the `network.routes` state to set network routes.

```yaml
routes:
  network.routes:
    - name: eth0
      routes:
        - name: secure_network
          ipaddr: 10.2.0.0
          netmask: 255.255.255.0
          gateway: 10.1.0.3
        - name: HQ_network
          ipaddr: 10.100.0.0
          netmask: 255.255.0.0
          gateway: 10.1.0.10
```

Managing Network Interfaces

The `network.managed` state is used to configure network interfaces. Here are several examples:

**Ethernet Interface**

```yaml
eth0:
  network.managed:
    - enabled: True
    - type: eth
    - proto: static
    - ipaddr: 10.1.0.7
    - netmask: 255.255.255.0
    - gateway: 10.1.0.1
    - enable_ipv6: true
    - ipv6proto: static
    - ipv6addrs:
      - 2001:db8:dead:beef::3/64
      - 2001:db8:dead:beef::7/64
    - ipv6gateway: 2001:db8:dead:beef::1
    - ipv6netmask: 64
    - dns:
      - 8.8.8.8
      - 8.8.4.4
    - channels:
      rx: 4
      tx: 4
      other: 4
      combined: 4
```
Ranged Interfaces (RHEL/CentOS Only)

New in version 2015.8.0.

Ranged interfaces can be created by including the word `range` in the interface name.

**Important:** The interface type must be `eth`.

```yaml
eth0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

bond0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

eth1.0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - vlan: True
    - mtu: 9000

bond0.1-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - vlan: True
    - mtu: 9000
```

Bond Interfaces

To configure a bond, you must do the following:

- Configure the bond slaves with a `type` of `slave`, and a `master` option set to the name of the bond interface.

- Configure the bond interface with a `type` of `bond`, and a `slaves` option defining the bond slaves for the bond interface.

```yaml
eth2:
  network.managed:
    - enabled: True
    - type: slave
```

(continues on next page)
VLANs

Set `type` to `vlan` to configure a VLANs. These VLANs are configured on the bond interface defined above.

```yaml
bond0.2:
  network.managed:
    - type: vlan
    - ipaddr: 10.1.0.2
    - use:
      - network: bond0
    - require:
```
- network: bond0

bond0.3:
    network.managed:
    - type: vlan
    - ipaddr: 10.1.0.3
    - use:
        - network: bond0
    - require:
        - network: bond0

bond0.10:
    network.managed:
    - type: vlan
    - ipaddr: 10.1.0.4
    - use:
        - network: bond0
    - require:
        - network: bond0

bond0.12:
    network.managed:
    - type: vlan
    - ipaddr: 10.1.0.5
    - use:
        - network: bond0
    - require:
        - network: bond0

Bridge Interfaces

eth4:
    network.managed:
    - enabled: True
    - type: eth
    - proto: dhcp
    - bridge: br0

br0:
    network.managed:
    - enabled: True
    - type: bridge
    - proto: dhcp
    - bridge: br0
    - delay: 0
    - ports: eth4
    - bypassfirewall: True
    - use:
        - network: eth4
    - require:
        - network: eth4

Note: When managing bridged interfaces on a Debian/Ubuntu based system, the ports argument is required.
RedHat-based systems will ignore the argument.

Network Teaming (RHEL/CentOS 7 and later)

New in version 3002.

- Configure the members of the team interface with a type of teamport, and a team_master option set to the name of the bond interface.
  - master also works, but will be ignored if both team_master and master are present.
  - If applicable, include a team_port_config option. This should be formatted as a dictionary. Keep in mind that due to a quirk of PyYAML, dictionaries nested under a list item must be double-indented (see example below for interface eth5).

- Configure the team interface with a type of team. The team configuration should be passed via the team_config option. As with team_port_config, the dictionary should be double-indented.

```yaml
eth5:
  network.managed:
    - type: teamport
    - team_master: team0
    - team_port_config:
      prio: 100

eth6:
  network.managed:
    - type: teamport
    - team_master: team0

team0:
  network.managed:
    - type: team
    - ipaddr: 172.24.90.42
    - netmask: 255.255.255.128
    - enable_ipv6: True
    - ipv6addr: 'fee1:dead:beef:af43::'
    - team_config:
      runner:
        hwaddr_policy: by_active
        name: activebackup
      link_watch:
        name: ethtool
```

Note: While teamd must be installed to manage a team interface, it is not required to configure a separate pkg.installed state for it, as it will be silently installed if needed.
Configuring the Loopback Interface

Use `network.managed` with a `type` of `eth` and a `proto` of `loopback`.

```yaml
lo:
  network.managed:
    - name: lo
    - type: eth
    - proto: loopback
    - onboot: yes
    - userctl: no
    - ipv6_autoconf: no
    - enable_ipv6: true
```

Other Useful Options

**noifupdown**

The `noifupdown` option, if set to `True`, will keep Salt from restart the interface if changes are made, requiring them to be restarted manually. Here are a couple examples:

```yaml
eth7:
  network.managed:
    - enabled: True
    - type: eth
    # Automatic IP/DNS
    - proto: dhcp
    - noifupdown: True

eth8:
  network.managed:
    - type: eth
    - noifupdown: True
    # IPv4
    - proto: static
    - ipaddr: 192.168.4.9
    - netmask: 255.255.255.0
    - gateway: 192.168.4.1
    - enable_ipv6: True
    # IPv6
    - ipv6proto: static
    - ipv6addr: 2001:db8:dead:c0::3
    - ipv6netmask: 64
    - ipv6gateway: 2001:db8:dead:c0::1
    # override shared; makes those options v4-only
    - ipv6ttl: 15
    # Shared
    - mtu: 1480
    - ttl: 18
    - dns:
      - 8.8.8.8
      - 8.8.4.4
```
salt.states.network.managed(name, enabled=True, **kwargs)
    Ensure that the named interface is configured properly.
    name The name of the interface to manage
    type [eth] Type of interface and configuration
        Changed in version 3002.
    enabled Designates the state of this interface.

salt.states.network.routes(name, **kwargs)
    Manage network interface static routes.
    name Interface name to apply the route to.
    kwargs Named routes

salt.states.network.system(name, **kwargs)
    Ensure that global network settings are configured properly.
    name Custom name to represent this configuration change.
    kwargs The global parameters for the system.

23.19.206 salt.states.neutron_network

Management of OpenStack Neutron Networks

New in version 2018.3.0.

    depends shade

    configuration see salt.modules.neutronng for setup instructions

Example States

create network:
    neutron_network.present:
        - name: network1

delete network:
    neutron_network.absent:
        - name: network1

create network with optional params:
    neutron_network.present:
        - name: network1
        - vlan: 200
        - shared: False
        - external: False
        - project: project1

salt.states.neutron_network.absent(name, auth=None, **kwargs)
    Ensure a network does not exists
    name Name of the network

salt.states.neutron_network.present(name, auth=None, **kwargs)
    Ensure a network exists and is up-to-date
    name Name of the network
    provider A dict of network provider options.
    shared Set the network as shared.
    external Whether this network is externally accessible.
    admin_state_up Set the network administrative state to up.
    vlan Vlan ID. Alias for provider
• physical_network: provider
• network_type: vlan
• segmentation_id: (vlan id)

23.19.207 salt.states.neutron_secgroup

Management of OpenStack Neutron Security Groups

New in version 2018.3.0.

depends shade

collection see salt.modules.neutronng for setup instructions

Example States

create security group;
neutron_secgroup.present:
  - name: security_group1
  - description: "Very Secure Security Group"

delete security group:
neutron_secgroup.absent:
  - name_or_id: security_group1
  - project_name: Project1

create security group with optional params:
neutron_secgroup.present:
  - name: security_group1
  - description: "Very Secure Security Group"
  - project_id: 1dcac318a83b4610b7a7f7ba01465548

create security group with optional params:
neutron_secgroup.present:
  - name: security_group1
  - description: "Very Secure Security Group"
  - project_name: Project1

salt.states.neutron_secgroup.absent(name, auth=None, **kwargs)

Ensure a security group does not exist
name Name of the security group

salt.states.neutron_secgroup.present(name, auth=None, **kwargs)

Ensure a security group exists.

You can supply either project_name or project_id.

Creating a default security group will not show up as a change; it gets created through the lookup process.
name Name of the security group
description Description of the security group
project_name Name of Project
project_id ID of Project
23.19.208 salt.states.neutron_secgroup_rule

Management of OpenStack Neutron Security Group Rules

New in version 2018.3.0.

depends shade

collection see salt.modules.neutronng for setup instructions

Example States

create security group rule:
  neutron_secgroup_rule.present:
    - name: security_group1
    - project_name: Project1
    - protocol: icmp

delete security group:
  neutron_secgroup_rule.absent:
    - name_or_id: security_group1

create security group with optional params:
  neutron_secgroup_rule.present:
    - name: security_group1
    - description: "Very Secure Security Group"
    - project_id: 1dcac318a83b4610b7a7f7ba01465548

salt.states.neutron_secgroup_rule.absent(name, auth=None, **kwargs)
  Ensure a security group rule does not exist
  name  name or id of the security group rule to delete
  rule_id uuid of the rule to delete
  project_id id of project to delete rule from

salt.states.neutron_secgroup_rule.present(name, auth=None, **kwargs)
  Ensure a security group rule exists
  defaults: port_range_min=None, port_range_max=None, protocol=None, remote_ip_prefix=None, remote_group_id=None, direction='ingress', ethertype='IPv4', project_id=None
  name  Name of the security group to associate with this rule
  project_name  Name of the project associated with the security group
  protocol  The protocol that is matched by the security group rule. Valid values are None, tcp, udp, and icmp.

23.19.209 salt.states.neutron_subnet

Management of OpenStack Neutron Subnets

New in version 2018.3.0.

depends shade

collection see salt.modules.neutronng for setup instructions

Example States

create subnet:
  neutron_subnet.present:
    - name: subnet1

(continues on next page)
- `network_name_or_id`: network1
- `cidr`: 192.168.199.0/24

**delete subnet:**
- `neutron_subnet.absent`:
  - `name`: subnet2

**create subnet with optional params:**
- `neutron_subnet.present`:
  - `name`: subnet1
  - `network_name_or_id`: network1
  - `enable_dhcp`: True
  - `cidr`: 192.168.199.0/24
  - `allocation_pools`:
    - `start`: 192.168.199.5
    - `end`: 192.168.199.250
  - `host_routes`:
    - `destination`: 192.168..0.0/24
    - `nexthop`: 192.168.0.1
  - `gateway_ip`: 192.168.199.1
  - `dns_nameservers`:
    - 8.8.8.8
    - 8.8.8.7

**create ipv6 subnet:**
- `neutron_subnet.present`:
  - `name`: v6subnet1
  - `network_name_or_id`: network1
  - `ip_version`: 6

```
salt.states.neutron_subnet.absent(name, auth=None)
Ensure a subnet does not exists
  name Name of the subnet

call.states.neutron_subnet.present(name, auth=None, **kwargs)
Ensure a subnet exists and is up-to-date
  name Name of the subnet
  network_name_or_id The unique name or ID of the attached network. If a non-unique name is supplied, an
  exception is raised.
  allocation_pools A list of dictionaries of the start and end addresses for the allocation pools
  gateway_ip The gateway IP address.
  dns_nameservers A list of DNS name servers for the subnet.
  host_routes A list of host route dictionaries for the subnet.
  ipv6_ra_mode IPv6 Router Advertisement mode. Valid values are: ‘dhcpv6-stateful’, ‘dhcpv6-stateless’, or
  ‘slaac’.
  ipv6_address_mode IPv6 address mode. Valid values are: ‘dhcpv6-stateful’, ‘dhcpv6-stateless’, or ‘slaac’.
```

23.19. state modules
23.19.210 salt.states.nexus

This state downloads artifacts from Nexus 3.x.

New in version 2018.3.0.

salt.states.nexus.downloaded(name, artifact, target_dir='/tmp', target_file=None)

Ensures that the artifact from nexus exists at given location. If it doesn't exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in nexus. If it is different then the step will fail.

artifact Details of the artifact to be downloaded from nexus. Various options are:
  • nexus_url: URL of the nexus instance
  • repository: Repository in nexus
  • artifact_id: Artifact ID
  • group_id: Group ID
  • packaging: Packaging
  • classifier: Classifier
  • version: Version One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
  • username: nexus username
  • password: nexus password
target_dir Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.
target_file Target file to download artifact to. By default file name is resolved by nexus.

An example to download an artifact to a specific file:

```python
jboss_module_downloaded:
  nexus.downloaded:
    - artifact:
        nexus_url: http://nexus.intranet.example.com/repository
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
        - target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```python
maven_artifact_downloaded:
  nexus.downloaded:
    - artifact:
        nexus_url: http://nexus.intranet.example.com/repository
        repository: 'maven-releases'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'zip'
        classifier: 'dist'
        version: '1.0'
        - target_dir: /opt/maven/modules/com/company/release
```
23.19.211 salt.states.nfs_export

Management of NFS exports

New in version 2018.3.0.

To ensure an NFS export exists:

```
add_simple_export:
  nfs_export.present:
    - name: '/srv/nfs'
    - hosts: '10.0.2.0/24'
    - options: '-rw'
```

This creates the following in /etc/exports:

```
/srv/nfs 10.0.2.0/24(rw)
```

For more complex exports with multiple groups of hosts, use `clients`:

```
add_complex_export:
  nfs_export.present:
    - name: '/srv/nfs'
    - clients:
        # First export, same as simple one above
        - hosts: '10.0.2.0/24'
        options:
          - 'rw'
        # Second export
        - hosts: '*.example.com'
        options:
          - 'ro'
          - 'subtree_check'
```

This creates the following in /etc/exports:

```
/srv/nfs 10.0.2.0/24(rw) 192.168.0.0/24,172.19.0.0/16(ro,subtree_check)
```

Any export of the given path will be modified to match the one specified.

To ensure an NFS export is absent:

```
delete_export:
  nfs_export.absent:
    - name: '/srv/nfs'
```

salt.states.nfs_export.absent(name, exports='/etc/exports')

Ensure that the named path is not exported

name The export path to remove

salt.states.nfs_export.present(name, clients=None, hosts=None, options=None, exports='/etc/exports')

Ensure that the named export is present with the given options

name The export path to configure

clients A list of hosts and the options applied to them. This option may not be used in combination with the `hosts` or `options` shortcuts.
- **clients:**
  # First export
  - **hosts:** '10.0.2.0/24'
    - **options:**
      - 'rw'
  # Second export
  - **hosts:** '*.example.com'
    - **options:**
      - 'ro'
      - 'subtree_check'

**hosts** A string matching a number of hosts, for example:

- **hosts:** '10.0.2.123'
- **hosts:** '10.0.2.0/24'
- **hosts:** 'minion1.example.com'
- **hosts:** '*.example.com'
- **hosts:** '*'

**options** A list of NFS options, for example:

- **options:**
  - 'rw'
  - 'subtree_check'

## 23.19.212 salt.states.nftables

**Management of nftables**

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```python
httpd:
    nftables.append:
    - table: filter
    - chain: input
    - jump: accept
    - match: state
    - connstate: new
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
```

```python
httpd:
    nftables.append:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
```

(continues on next page)
- **connstate**: NEW
- **dport**: 80
- **proto**: tcp
- **sport**: 1025:65535
- **save**: True

**httpd**:

```yaml
nftables.insert:
  - **position**: 1
  - **table**: filter
  - **chain**: INPUT
  - **jump**: ACCEPT
  - **match**: state
  - **connstate**: NEW
  - **dport**: 80
  - **proto**: tcp
  - **sport**: 1025:65535
  - **save**: True
```

**httpd**:

```yaml
nftables.insert:
  - **position**: 1
  - **table**: filter
  - **family**: ipv6
  - **chain**: INPUT
  - **jump**: ACCEPT
  - **match**: state
  - **connstate**: NEW
  - **dport**: 80
  - **proto**: tcp
  - **sport**: 1025:65535
  - **save**: True
```

**httpd**:

```yaml
nftables.delete:
  - **table**: filter
  - **chain**: INPUT
  - **jump**: ACCEPT
  - **match**: state
  - **connstate**: NEW
  - **dport**: 80
  - **proto**: tcp
  - **sport**: 1025:65535
  - **save**: True
```

**httpd**:

```yaml
nftables.delete:
  - **position**: 1
  - **table**: filter
  - **chain**: INPUT
  - **jump**: ACCEPT
  - **match**: state
  - **connstate**: NEW
  - **dport**: 80
  - **proto**: tcp
  - **sport**: 1025:65535
```

(continues on next page)
- **save**: True

**httpd**

```yaml
- nftables.delete:
  - **table**: filter
  - **family**: ipv6
  - **chain**: INPUT
  - **jump**: ACCEPT
  - **match**: state
  - **connstate**: NEW
  - **dport**: 88
  - **proto**: tcp
  - **sport**: 1025:65535
  - **save**: True

**output**

- nftables.chain_present:
  - **family**: ip
  - **table**: filter

**output**

- nftables.chain_absent:
  - **family**: ip
  - **table**: filter
```

```python
salt.states.nftables.append(name, family='ipv4', **kwargs)
```

New in version 0.17.0.

Append a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

```python
salt.states.nftables.chain_absent(name, table='filter', family='ipv4')
```

New in version 2014.7.0.

Verify the chain is absent.

**family** Networking family, either ipv4 or ipv6

```python
salt.states.nftables.chain_present(name, table='filter', table_type=None, hook=None, priority=None, family='ipv4')
```

New in version 2014.7.0.

Changed in version 3002.

Verify a chain exists in a table.

**name** A user-defined chain name.

**table** The table to own the chain.

**family** Networking family, either ipv4 or ipv6

```python
salt.states.nftables.delete(name, family='ipv4', **kwargs)
```

New in version 2014.7.0.

Delete a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Networking family, either ipv4 or ipv6
All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

```
salt.states.nftables.flush(name, family='ipv4', ignore_absence=False, **kwargs)
```

New in version 2014.7.0.

Changed in version 3002.

Flush current nftables state

- **family**: Networking family, either ipv4 or ipv6
- **ignore_absence**: If set to True, attempts to flush a non-existent table will not result in a failed state.

```
salt.states.nftables.insert(name, family='ipv4', **kwargs)
```

New in version 2014.7.0.

Insert a rule into a chain

- **name**: A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
- **family**: Networking family, either ipv4 or ipv6
- **all other arguments**: are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

```
salt.states.nftables.set_policy(name, table='filter', family='ipv4', **kwargs)
```

New in version 3002.

Sets the default policy for nftables chains

- **table**: The table that owns the chain that should be modified
- **family**: Networking family, either ipv4 or ipv6
- **policy**: The requested table policy (accept or drop)
- **save**: Boolean to save the in-memory nftables settings to a file.
- **save_filename**: The filename to save the nftables settings (default: /etc/nftables or /etc/nftables/salt-all-in-one.nft if the former is a directory)

```
salt.states.nftables.table_absent(name, family='ipv4', **kwargs)
```

New in version 3002.

Ensure an nftables table is absent

- **name**: Name of the table to ensure is absent
- **family**: Networking family, either ipv4 or ipv6

```
salt.states.nftables.table_present(name, family='ipv4', **kwargs)
```

New in version 3002.

Ensure an nftables table is present

- **name**: A user-defined table name.
- **family**: Networking family, either ipv4 or ipv6

### 23.19.213 salt.states.npm

**Installation of NPM Packages**

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state for the package which provides npm (simply `npm` in most cases). Example:
**npm:**

```python
pkg.installed
```

**yml:**

```yaml
yaml:
  npm.installed:
    - require:
      - pkg: npm
```

```python
salt.states.npm.bootstrap(name, user=None, silent=True)
```

Bootsraps a node.js application.

Will execute 'npm install --json' on the specified directory.

**user** The user to run NPM with

New in version 0.17.0.

```python
salt.states.npm.cache_cleaned(name=None, user=None, force=False)
```

Ensure that the given package is not cached.

If no package is specified, this ensures the entire cache is cleared.

**name** The name of the package to remove from the cache, or None for all packages

**user** The user to run NPM with

**force** Force cleaning of cache. Required for npm@5 and greater

New in version 2016.11.6.

```python
salt.states.npm.installed(name, pkgs=None, dir=None, user=None, force_reinstall=False, registry=None, env=None)
```

Verify that the given package is installed and is at the correct version (if specified).

```yaml
coffee-script:  # A package installed
  npm.installed:
    - user: someuser

coffee-script@1.0.1:  # A specific version of the package installed
  npm.installed: []
```

**name** The package to install

Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.

**pkgs** A list of packages to install with a single npm invocation; specifying this argument will ignore the name argument

New in version 2014.7.0.

**dir** The target directory in which to install the package, or None for global installation

**user** The user to run NPM with

New in version 0.17.0.

**registry** The NPM registry from which to install the package

New in version 2014.7.0.

**env** A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

New in version 2014.7.0.

**force_reinstall** Install the package even if it is already installed

```python
salt.states.npm.removed(name, dir=None, user=None)
```

Verify that the given package is not installed.

**dir** The target directory in which to install the package, or None for global installation
The user to run NPM with

New in version 0.17.0.

23.19.214 salt.states.ntp

Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```python
win_ntp:
  ntp.managed:
    - servers:
      - pool.ntp.org
      - us.pool.ntp.org
```

salt.states.ntp.managed(name, servers=None)

Manage NTP servers

servers A list of NTP servers

23.19.215 salt.states.nxos

State module for Cisco NX-OS Switch Proxy and Native minions

New in version 2016.11.0.

For documentation on setting up the nxos proxy minion look in the documentation for salt.proxy.nxos.

salt.states.nxos.config_absent(name)

Ensure a specific configuration line does not exist in the running config

name config line to remove

Examples:

```python
add snmp group:
  nxos.config_absent:
    - names:
      - snmp-server community randoSNMPstringHERE group network-operator
      - snmp-server community AnotherRandomSNMPString group network-admin
```

Note: For certain cases extra lines could be removed based on dependencies. In this example, included after the example for config_present, the ACLs would be removed because they depend on the existence of the group.

salt.states.nxos.config_present(name)

Ensure a specific configuration line exists in the running config

name config line to set

Examples:

```python
add snmp group:
  nxos.config_present:
    - names:
      - snmp-server community randoSNMPstringHERE group network-operator
```

(continues on next page)
- `snmp-server community AnotherRandomSNMPString group network-admin`

```shell
add snmp acl:
```
```shell
  nxos.config_present:
  - names:
    - `snmp-server community randoSNMPstringHERE use-acl snmp-acl-ro`
    - `snmp-server community AnotherRandomSNMPString use-acl snmp-acl-rw`
```

```python
salt.states.nxos.replace(name, repl, full_match=False)
```
Replace all instances of a string or full line in the running config

- `name`: String to replace
- `repl`: The replacement text
- `full_match`: Whether `name` will match the full line or only a subset of the line. Defaults to `False`. When `False`, `*` is added around `name` for matching in the `show run` config.

Examples:

```python
replace snmp string:
  nxos.replace:
    - name: randoSNMPstringHERE
    - repl: NEWrandoSNMPstringHERE
```

```python
replace full snmp string:
  nxos.replace:
    - name: ^snmp-server community randoSNMPstringHERE group network-operator$
    - repl: snmp-server community NEWrandoSNMPstringHERE group network-operator
    - full_match: True
```

**Note:** The first example will replace the SNMP string on both the group and the ACL, so you will not lose the ACL setting. Because the second is an exact match of the line, when the group is removed, the ACL is removed, but not readded, because it was not matched.

```python
salt.states.nxos.user_absent(name)
```
Ensure a user is not present

- `name`: username to remove if it exists

Examples:

```python
delete:
  nxos.user_absent:
    - name: daniel
```

```python
salt.states.nxos.user_present(name, password=None, roles=None, encrypted=False, crypt_salt=None, algorithm='sha256')
```
Ensure a user is present with the specified groups

- `name`: Name of user
- `password`: Encrypted or Plain Text password for user
- `roles`: List of roles the user should be assigned. Any roles not in this list will be removed
- `encrypted`: Whether the password is encrypted already or not. Defaults to `False`
- `crypt_salt`: Salt to use when encrypting the password. Default is `None` (salt is randomly generated for unhashed passwords)
- `algorithm`: Algorithm to use for hashing password. Defaults to `sha256`. Accepts md5, blowfish, sha256, sha512

Examples:
create:
  nxos.user_present:
    - name: daniel
    - roles:
      - vdc-admin

set_password:
  nxos.user_present:
    - name: daniel
    - password: admin
    - roles:
      - network-admin

update:
  nxos.user_present:
    - name: daniel
    - password: AiN9jaoP
    - roles:
      - network-admin
      - vdc-admin

23.19.216 salt.states.nxos_upgrade

Manage NX-OS System Image Upgrades.
New in version 3001.

maturity new
platform nxos
codeauthor Michael G Wiebe

For documentation on setting up the nxos proxy minion look in the documentation for \texttt{salt.proxy.nxos}.

\texttt{salt.states.nxos_upgrade.image\_running(name, system\_image, kickstart\_image=None, issu=True, **kwargs)}

Ensure the NX-OS system image is running on the device.

name Name of the salt state task
system_image Name of the system image file on bootflash:
kickstart_image Name of the kickstart image file on bootflash: This is not needed if the system_image is a combined system and kickstart image Default: None
issu Ensure the correct system is running on the device using an in service software upgrade, or force a disruptive upgrade by setting the option to False. Default: False
timeout Timeout in seconds for long running 'install all' upgrade command. Default: 900

Examples:

\texttt{upgrade\_software\_image\_n9k:}
\texttt{nxos.image\_running:}
  - name: Ensure nxos.7.0.3.I7.5a.bin is running
  - system_image: nxos.7.0.3.I7.5a.bin
  - issu: True

\texttt{upgrade\_software\_image\_n7k:}
\texttt{nxos.image\_running:}
  - name: Ensure n7000-s2-kickstart.8.0.1.bin is running
  - kickstart_image: n7000-s2-kickstart.8.0.1.bin

(continues on next page)
23.19.217  salt.states.openstack_config

Manage OpenStack configuration file settings.

maintainer Jeffrey C. Ollie <jeff@ocjtech.us>
maturity new
depends
platform linux

salt.states.openstack_config.absent(name, filename, section, parameter=None)
Ensure a value is not set in an OpenStack configuration file.
filename The full path to the configuration file
section The section in which the parameter will be set
parameter (optional) The parameter to change. If the parameter is not supplied, the name will be used as the parameter.

salt.states.openstack_config.present(name, filename, section, value, parameter=None)
Ensure a value is set in an OpenStack configuration file.
filename The full path to the configuration file
section The section in which the parameter will be set
parameter (optional) The parameter to change. If the parameter is not supplied, the name will be used as the parameter.
value The value to set

23.19.218  salt.states.openvswitch_bridge

Management of Open vSwitch bridges.

saltstates.openvswitch_bridge.absent(name)
Ensures that the named bridge does not exist, eventually deletes it.
Parameters name -- The name of the bridge.

saltstates.openvswitch_bridge.present(name)
Ensures that the named bridge exists, eventually creates it.
Parameters name -- The name of the bridge.

23.19.219  salt.states.openvswitch_port

Management of Open vSwitch ports.

saltstates.openvswitch_port.absent(name, bridge=None)
Ensures that the named port exists on bridge, eventually deletes it. If bridge is not set, port is removed from whatever bridge contains it.
Parameters
  • name -- The name of the port.
  • bridge -- The name of the bridge.
salt.states.openvswitch_port.present(name, bridge, tunnel_type=None, id=None, remote=None, dst_port=None, internal=False)

Ensures that the named port exists on bridge, eventually creates it.

Parameters
- **name** -- The name of the port.
- **bridge** -- The name of the bridge.
- **tunnel_type** -- Optional type of interface to create, currently supports: vlan, vxlan and gre.
- **id** -- Optional tunnel's key.
- **remote** -- Remote endpoint’s IP address.
- **dst_port** -- Port to use when creating tunnelport in the switch.
- **internal** -- Create an internal port if one does not exist

23.19.220 salt.states.ops genie

Create/Close an alert in OpsGenie

New in version 2018.3.0.

This state is useful for creating or closing alerts in OpsGenie during state runs.

```
used_space:
    disk.status:
        - name: /
        - maximum: 79%
        - minimum: 20%

ops genie_create_action_sender:
ops genie.create_alert:
    - api_key: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
    - reason: 'Disk capacity is out of designated range,'
    - name: disk.status
    - onfail:
        - disk: used_space

ops genie_close_action_sender:
ops genie.close_alert:
    - api_key: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
    - name: disk.status
    - require:
        - disk: used_space
```

salt.states.ops genie.close_alert(name=None, api_key=None, reason='Conditions are met.', action_type='Close')

Close an alert in OpsGenie. It’s a wrapper function for create_alert. Example usage with Salt’s requisites and other global state arguments could be found above.

Required Parameters:
- **name** It will be used as alert’s alias. If you want to use the close functionality you must provide name field for both states like in above case.

Optional Parameters:
- **api_key** It’s the API Key you’ve copied while adding integration in OpsGenie.
- **reason** It will be used as alert’s default message in OpsGenie.
- **action_type** OpsGenie supports the default values Create/Close for action_type. You can customize this field with OpsGenie’s custom actions for other purposes like adding notes or acknowledging alerts.
salt.states.opsgenie.create_alert(name=None, api_key=None, reason=None, action_type='Create')

Create an alert in OpsGenie. Example usage with Salt's requisites and other global state arguments could be found above.

Required Parameters:
- api_key: It's the API Key you've copied while adding integration in OpsGenie.
- reason: It will be used as alert's default message in OpsGenie.

Optional Parameters:
- name: It will be used as alert's alias. If you want to use the close functionality you must provide name field for both states like in above case.
- action_type: OpsGenie supports the default values Create/Close for action_type. You can customize this field with OpsGenie's custom actions for other purposes like adding notes or acknowledging alerts.

23.19.221 salt.states.pagerduty

Create an Event in PagerDuty

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.

```
server-warning-message:
    pagerduty.create_event:
        - name: 'This is a server warning message'
        - details: 'This is a much more detailed message'
        - service_key: 9abcd123456789efabcde362783cdaaf
        - profile: my-pagerduty-account
```

salt.states.pagerduty.create_event(name, details, service_key, profile)

Create an event on the PagerDuty service

```
server-warning-message:
    pagerduty.create_event:
        - name: 'This is a server warning message'
        - details: 'This is a much more detailed message'
        - service_key: 9abcd123456789efabcde362783cdaaf
        - profile: my-pagerduty-account
```

The following parameters are required:
- name: This is a short description of the event.
- details: This can be a more detailed description of the event.
- service_key: This key can be found by using pagerduty.list_services.
- profile: This refers to the configuration profile to use to connect to the PagerDuty service.
**23.19.222 salt.states.pagerduty_escalation_policy**

Manage PagerDuty escalation policies.

Schedules and users can be referenced by pagerduty ID, or by name, or by email address.

For example:

```yaml
ensure test escalation policy:
  pagerduty_escalation_policy.present:
    - name: bruce test escalation policy
      escalation_rules:
        - type: schedule
          id: 'bruce test schedule level1'
        - type: user
          id: 'Bruce Sherrod'
        escalation_delay_in_minutes: 15
        targets:
          - type: schedule
            id: 'bruce test schedule level2'
          - type: user
            id: 'Bruce TestUser1'
          - type: user
            id: 'Bruce TestUser2'
          - type: user
            id: 'Bruce TestUser3'
          - type: user
            id: 'bruce+test4@lyft.com'
          escalation_delay_in_minutes: 15
```

salt.states.pagerduty_escalation_policy.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a PagerDuty escalation policy does not exist. Accepts all the arguments that pagerduty_escalation_policy.present accepts; but ignores all arguments except the name.

Name can be the escalation policy id or the escalation policy name.

salt.states.pagerduty_escalation_policy.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty escalation policy exists. Will create or update as needed.

This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/escalation_policies/create. In addition, user and schedule id's will be translated from name (or email address) into PagerDuty unique ids. For example:

```yaml
pagerduty_escalation_policy.present:
  - name: bruce test escalation policy
  escalation_rules:
    - targets:
      - type: schedule
        id: 'bruce test schedule level1'
      - type: user
        id: 'Bruce Sherrod'
```

In this example, 'Bruce Sherrod' will be looked up and replaced with the PagerDuty id (usually a 7 digit all-caps string, e.g. PX6GQL7)
23.19.223 salt.states.pagerduty_schedule

Manage PagerDuty schedules.

Example:

```python
def ensure_test_schedule:
    pagerduty_schedule.present:
        - name: 'bruce test schedule level1'
        - schedule:
            name: 'bruce test schedule level1'
            time_zone: 'Pacific Time (US & Canada)'
            schedule_layers:
                - name: 'Schedule Layer 1'
                  start: '2015-01-01T00:00:00'
                  users:
                    - user:
                        'id': 'Bruce TestUser1'
                        member_order: 1
                    - user:
                        'id': 'Bruce TestUser2'
                        member_order: 2
                    - user:
                        'id': 'bruce@test3@lyft.com'
                        member_order: 3
                    - user:
                        'id': 'bruce@test4@lyft.com'
                        member_order: 4
                  rotation_virtual_start: '2015-01-01T00:00:00'
                  priority: 1
                  rotation_turn_length_seconds: 604800
```

salt.states.pagerduty_schedule.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule does not exist. Name can be pagerduty schedule id or pagerduty schedule name.

salt.states.pagerduty_schedule.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule exists. This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/schedules/create. This means that most arguments are in a dict called "schedule."

User id’s can be pagerduty id, or name, or email address.

23.19.224 salt.states.pagerduty_service

Manage PagerDuty services

Escalation policies can be referenced by pagerduty ID or by namea.

For example:

```python
def ensure_test_service:
    pagerduty_service.present:
        - name: 'my service'
        - escalation_policy_id: 'my escalation policy'
        - type: nagios
```
salt.states.pagerduty_service.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure a pagerduty service does not exist. Name can be the service name or pagerduty service id.

salt.states.pagerduty_service.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty service exists. This method accepts as arguments everything defined in https://developer.pagerduty.com/documentation/rest/services/create

Note that many arguments are mutually exclusive, depending on the "type" argument.

Examples:

```python
# create a PagerDuty email service at test-email@DOMAIN.pagerduty.com
evaluate generic email service exists:
   pagerduty_service.present:
      - name: my email service
      - service:
         description: "email service controlled by salt"
         escalation_policy_id: "my escalation policy"
         type: "generic_email"
         service_key: "test-email"
```

```python
# create a pagerduty service using cloudwatch integration
evaluate my cloudwatch service exists:
   pagerduty_service.present:
      - name: my cloudwatch service
      - service:
         escalation_policy_id: "my escalation policy"
         type: aws_cloudwatch
         description: "my cloudwatch service controlled by salt"
```

23.19.225 salt.states.pagerduty_user

Manage PagerDuty users.

Example

```python
ensure bruce test user 1:
   pagerduty.user_present:
      • name: 'Bruce TestUser1'
      • email: bruce+test1@lyft.com
      • requester_id: P1GV5NT
```

salt.states.pagerduty_user.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty user does not exist. Name can be pagerduty id, email address, or user name.

salt.states.pagerduty_user.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

23.19.226 salt.states.panos

A state module to manage Palo Alto network devices.

- codeauthor Spencer Ervin <spencer_ervin@hotmail.com>
- maturity new
- depends none
- platform unix

About

This state module was designed to handle connections to a Palo Alto based firewall. This module relies on the Palo Alto proxy module to interface with the devices.

This state module is designed to give extreme flexibility in the control over XPATH values on the PANOS device. It exposes the core XML API commands and allows state modules to chain complex XPATH commands.

Below is an example of how to construct a security rule and move to the top of the policy. This will take a config lock to prevent execution during the operation, then remove the lock. After the XPATH has been deployed, it will commit to the device.

```python
panos/take_lock:
    panos.add_config_lock

panos/service_tcp_22:
    panos.set_config:
        - xpath: /config/devices/entry[@name='localhost.localdomain']/vsys/
          entry[@name='vsys1']/service
        - value: <entry name='tcp-22'/><protocol><tcp><port>22</port></tcp></protocol>
    - commit: False

panos/create_rule1:
    panos.set_config:
        - xpath: /config/devices/entry[@name='localhost.localdomain']/vsys/
          entry[@name='vsys1']/rulebase/security/rules
        - value: '
            <entry name="rule1">
                <from><member>trust</member></from>
                <to><member>untrust</member></to>
                <source><member>10.0.0.1</member></source>
                <destination><member>10.0.1.1</member></destination>
                <service><member>tcp-22</member></service>
                <application><member>any</member></application>
                <action>allow</action>
                <disabled>no</disabled>
            </entry>
        - commit: False

panos/move_rule_top:
    panos.move_config:
        - xpath: /config/devices/entry[@name='localhost.localdomain']/vsys/
          entry[@name='vsys1']/rulebase/security/rules/entry[@name='rule1']
        - where: top
        - commit: False

panos/remove_lock:
    panos.remove_config_lock

panos/commit:
    panos.commit_config
```

3898 Chapter 23. Salt Module Reference
Version Specific Configurations

Palo Alto devices running different versions will have different supported features and different command structures. In order to account for this, the proxy module can be leveraged to check if the panos device is at a specific revision level.

The proxy['panos.is_required_version'] method will check if a panos device is currently running a version equal or greater than the passed version. For example, proxy['panos.is_required_version']('7.0.0') would match both 7.1.0 and 8.0.0.

```python
{% if proxy['panos.is_required_version']('8.0.0') %}
panos/deviceconfig/system/motd-and-banner:
    panos.set_config:
        - xpath: /config/devices/entry[@name='localhost.localdomain']/deviceconfig/system/motd-and-banner
        - value: |
            <banner-header>BANNER TEXT</banner-header>
            <banner-header-color>color2</banner-header-color>
            <banner-header-text-color>color18</banner-header-text-color>
            <banner-header-footer-match>yes</banner-header-footer-match>
        - commit: False
{% endif %}
```

See also:

Palo Alto Proxy Module

salt.states.panos.add_config_lock(name)
Prevent other users from changing configuration until the lock is released.

name: The name of the module function to execute.

SLS Example:

```python
panos/take_lock:
    panos.add_config_lock
```

salt.states.panos.address_exists(name, addressname=None, vsys=1, ipnetmask=None, iprange=None, fqdn=None, description=None, commit=False)
Ensures that an address object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will only process a single address type (ip-netmask, ip-range, or fqdn). It will process the specified value if the following order: ip-netmask, ip-range, fqdn. For proper execution, only specify a single address type.

name: The name of the module function to execute.

addressname(str): The name of the address object. The name is case-sensitive and can have up to 31 characters, which an be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

ipnetmask(str): The IPv4 or IPv6 address or IP address range using the format ip_address/mask or ip_address where the mask is the number of significant binary digits used for the network portion of the address. Ideally, for IPv6, you specify only the network portion, not the host portion.

iprange(str): A range of addresses using the format ip_address–ip_address where both addresses can be IPv4 or both can be IPv6.
fqdn(str): A fully qualified domain name format. The FQDN initially resolves at commit time. Entries are subsequently refreshed when the firewall performs a check every 30 minutes; all changes in the IP address for the entries are picked up at the refresh cycle.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/address/h-10.10.10.10:
    panos.address_exists:
        - addressname: h-10.10.10.10
        - vsys: 1
        - ipnetmask: 10.10.10.10
        - commit: False

panos/address/10.0.0.1-10.0.0.50:
    panos.address_exists:
        - addressname: r-10.0.0.1-10.0.0.50
        - vsys: 1
        - iprange: 10.0.0.1-10.0.0.50
        - commit: False

panos/address/foo.bar.com:
    panos.address_exists:
        - addressname: foo.bar.com
        - vsys: 1
        - fqdn: foo.bar.com
        - description: My fqdn object
        - commit: False
```

salt.states.panos.address_group_exists(name, groupname=None, vsys=1, members=None, description=None, commit=False)

Ensures that an address group object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will enforce group membership. If a group exists and contains members this state does not include, those members will be removed and replaced with the specified members in the state.

name: The name of the module function to execute.

groupname(str): The name of the address group object. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

members(str, list): The members of the address group. These must be valid address objects or address groups on the system that already exist prior to the execution of this state.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/address-group/my-group:
    panos.address_group_exists:
        - groupname: my-group
        - vsys: 1
```

(continues on next page)
salt.states.panos.clone_config(name, xpath=None, newname=None, commit=False)
Clone a specific XPATH and set it to a new name.
	name: The name of the module function to execute.
	xpath(str): The XPATH of the configuration API tree to clone.

newname(str): The new name of the XPATH clone.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

    panos/clonerule:
        panos.clone_config:
            - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules&from=/config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules/entry[@name='rule1']
            - value: rule2
            - commit: True

salt.states.panos.commit_config(name)
Commits the candidate configuration to the running configuration.

name: The name of the module function to execute.

SLS Example:

    panos/commit:
        panos.commit_config

salt.states.panos.delete_config(name, xpath=None, commit=False)
Deletes a Palo Alto XPATH to a specific value.

Use the xpath parameter to specify the location of the object to be deleted.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

    panos/deletegroup:
        panos.delete_config:
            - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/address-group/entry[@name='test']
            - commit: True

salt.states.panos.download_software(name, version=None, synch=False, check=False)
Ensures that a software version is downloaded.

name: The name of the module function to execute.
version(str): The software version to check. If this version is not already downloaded, it will attempt to download the file from Palo Alto.

synch(bool): If true, after downloading the file it will be synched to its peer.

check(bool): If true, the PANOS device will first attempt to pull the most recent software inventory list from Palo Alto.

SLS Example:

```yaml
panos/version8.0.0:
    panos.download_software:
        - version: 8.0.0
        - synch: False
        - check: True
```

**salt.states.panos.edit_config(name, xpath=None, value=None, commit=False)**

Edits a Palo Alto XPATH to a specific value. This will always overwrite the existing value, even if it is not changed.

You can replace an existing object hierarchy at a specified location in the configuration with a new value. Use the xpath parameter to specify the location of the object, including the node to be replaced.

This is the recommended state to enforce configurations on a xpath.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

value(str): The XML value to edit. This must be a child to the XPATH.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/addressgroup:
    panos.edit_config:
        - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/address-group/
          → entry[@name='test']
        - value: <static><entry name='test'><member>abc</member><member>xyz</member></entry></static>
        - commit: True
```

**salt.states.panos.move_config(name, xpath=None, where=None, dst=None, commit=False)**

Moves a XPATH value to a new location.

Use the xpath parameter to specify the location of the object to be moved, the where parameter to specify type of move, and dst parameter to specify the destination path.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to move.

where(str): The type of move to execute. Valid options are after, before, top, bottom. The after and before options will require the dst option to specify the destination of the action. The top action will move the XPATH to the top of its structure. The bottom action will move the XPATH to the bottom of its structure.

dst(str): Optional. Specifies the destination to utilize for a move action. This is ignored for the top or bottom action.

commit(bool): If true the firewall will commit the changes, if false do not commit changes. If the operation is not successful, it will not commit.

SLS Example:
Salt Documentation, Release 3003.1

```yaml
panos/moveruletop:
    panos.move_config:
        - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/
                    rules/entry[@name='rule1']
        - where: top
        - commit: True

panos/moveruleafter:
    panos.move_config:
        - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/
                    rules/entry[@name='rule1']
        - where: after
        - dst: rule2
        - commit: True
```

salt.states.panos.remove_config_lock(name)

Release config lock previously held.

name: The name of the module function to execute.

SLS Example:

```yaml
panos/takelock:
    panos.remove_config_lock
```

salt.states.panos.rename_config(name, xpath=None, newname=None, commit=False)

Rename a Palo Alto XPATH to a specific value. This will always rename the value even if a change is not needed.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

newname(str): The new name of the XPATH value.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/renamegroup:
    panos.rename_config:
        - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/address/
                    entry[@name='old_address']
        - value: new_address
        - commit: True
```

salt.states.panos.security_rule_exists(name, rulename=None, vsys='1', action=None, disabled=None, sourcezone=None, destinationzone=None, source=None, destination=None, application=None, service=None, description=None, logsetting=None, logstart=None, logend=None, negatesource=None, negatedestination=None, profilegroup=None, datafilter=None, fileblock=None, spyware=None, urlfilter=None, virus=None, vulnerability=None, wildfire=None, move=None, movetarget=None, commit=False)

Ensures that a security rule exists on the device. Also, ensure that all configurations are set appropriately.

This method will create the rule if it does not exist. If the rule does exist, it will ensure that the configurations are set appropriately.

23.19. state modules 3903
If the rule does not exist and is created, any value that is not provided will be provided as the default. The action, to, from, source, destination, application, and service fields are mandatory and must be provided.

This will enforce the exact match of the rule. For example, if the rule is currently configured with the log-end option, but this option is not specified in the state method, it will be removed and reset to the system default.

It is strongly recommended to specify all options to ensure proper operation.

When defining the profile group settings, the device can only support either a profile group or individual settings. If both are specified, the profile group will be preferred and the individual settings are ignored. If neither are specified, the value will be set to system default of none.

name: The name of the module function to execute.

rulename(str): The name of the security rule. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

action(str): The action that the security rule will enforce. Valid options are: allow, deny, drop, reset-client, reset-server, reset-both.

disabled(bool): Controls if the rule is disabled. Set 'True' to disable and 'False' to enable.

sourcezone(str, list): The source zone(s). The value 'any' will match all zones.

destinationzone(str, list): The destination zone(s). The value 'any' will match all zones.

source(str, list): The source address(es). The value ‘any’ will match all addresses.

destination(str, list): The destination address(es). The value ‘any’ will match all addresses.

application(str, list): The application(s) matched. The value ‘any’ will match all applications.

service(str, list): The service(s) matched. The value ‘any’ will match all services. The value ‘application-default’ will match based upon the application defined ports.

description(str): A description for the policy (up to 255 characters).

logsetting(str): The name of a valid log forwarding profile.

logstart(bool): Generates a traffic log entry for the start of a session (disabled by default).

logend(bool): Generates a traffic log entry for the end of a session (enabled by default).

negatesource(bool): Match all but the specified source addresses.

negatedestination(bool): Match all but the specified destination addresses.

profilegroup(str): A valid profile group name.

datafilter(str): A valid data filter profile name. Ignored with the profilegroup option set.

fileblock(str): A valid file blocking profile name. Ignored with the profilegroup option set.

spyware(str): A valid spyware profile name. Ignored with the profilegroup option set.

urlfilter(str): A valid URL filtering profile name. Ignored with the profilegroup option set.

virus(str): A valid virus profile name. Ignored with the profilegroup option set.

tvulnerability(str): A valid vulnerability profile name. Ignored with the profilegroup option set.

wildfire(str): A valid vulnerability profile name. Ignored with the profilegroup option set.
move(str): An optional argument that ensures the rule is moved to a specific location. Valid options are 'top', 'bottom', 'before', or 'after'. The 'before' and 'after' options require the use of the 'movetarget' argument to define the location of the move request.

movetarget(str): An optional argument that defines the target of the move operation if the move argument is set to 'before' or 'after'.

commit(bool): If true, the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/rulebase/security/rule01:
  panos.security_rule_exists:
    - rulename: rule01
    - vsys: 1
    - action: allow
    - disabled: False
    - sourcezone: untrust
    - destinationzone: trust
    - source:
      - 10.10.10.0/24
      - 1.1.1.1
    - destination:
      - 2.2.2.2-2.2.2.4
    - application:
      - any
    - service:
      - tcp-25
    - description: My test security rule
    - logsetting: logprofile
    - logstart: False
    - logend: True
    - negatesource: False
    - negatedestination: False
    - profilegroup: myprofilegroup
    - move: top
    - commit: False
```

(continues on next page)
- datafilter: foobar
- fileblock: foobar
- spyware: foobar
- urlfilter: foobar
- virus: foobar
- vulnerability: foobar
- wildfire: foobar
- move: after
- movetarget: rule02
- commit: False

```
salt.states.panos.service_exists(name, servicename=\_\_None, vsys=1, protocol=\_\_None, port=\_\_None, description=\_\_None, commit=False)
```

Ensures that a service object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

name: The name of the module function to execute.

servicename(str): The name of the security object. The name is case-sensitive and can have up to 31 characters, which an be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

protocol(str): The protocol that is used by the service object. The only valid options are tcp and udp.

port(str): The port number that is used by the service object. This can be specified as a single integer or a valid range of ports.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/service/tcp-80:
    panos.service_exists:
        - servicename: tcp-80
        - vsys: 1
        - protocol: tcp
        - port: 80
        - description: Hypertext Transfer Protocol
        - commit: False

panos/service/udp-500-550:
    panos.service_exists:
        - servicename: udp-500-550
        - vsys: 3
        - protocol: udp
        - port: 500-550
        - commit: False
```

```
salt.states.panos.service_group_exists(name, groupname=\_\_None, vsys=1, members=\_\_None, description=\_\_None, commit=False)
```

Ensures that a service group object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will enforce group membership. If a group exists and contains members this state does not include, those members will be removed and replaced with the specified members in the state.
name: The name of the module function to execute.

groupname(str): The name of the service group object. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

members(str, list): The members of the service group. These must be valid service objects or service groups on the system that already exist prior to the execution of this state.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/service-group/my-group:
  panos.service_group_exists:
    - groupname: my-group
    - vsys: 1
    - members:
      - tcp-80
      - custom-port-group
    - description: A group that needs to exist
    - commit: False
```

salt.states.panos.set_config(name, xpath=None, value=None, commit=False)

Sets a Palo Alto XPATH to a specific value. This will always overwrite the existing value, even if it is not changed.

You can add or create a new object at a specified location in the configuration hierarchy. Use the xpath parameter to specify the location of the object in the configuration hierarchy.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

value(str): The XML value to set. This must be a child to the XPATH.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/hostname:
  panos.set_config:
    - xpath: /config/devices/entry[@name='localhost.localdomain']/deviceconfig/system
    - value: <hostname>foobar</hostname>
    - commit: True
```
23.19.227 salt.states.pbm

Manages VMware storage policies (called pbm because the vCenter endpoint is /pbm)

Examples

Storage policy

```json
{
    "name": "salt_storage_policy",
    "description": "Managed by Salt. Random capability values.",
    "resource_type": "STORAGE",
    "subprofiles": [
        {
            "capabilities": [
                {
                    "setting": {
                        "type": "scalar",
                        "value": 2
                    },
                    "namespace": "VSAN",
                    "id": "hostFailuresToTolerate"
                },
                {
                    "setting": {
                        "type": "scalar",

 },
]
}
}

Dependencies

- pyVmomi Python Module

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 <https://github.com/saltstack/salt/issues/29537> for more information.

salt.states.pbm.default_storage_policy_assigned(name, policy, datastore)

Assigns a default storage policy to a datastore

- policy Name of storage policy
- datastore Name of datastore

salt.states.pbm.default_vsan_policy_configured(name, policy)

Configures the default VSAN policy on a vCenter. The state assumes there is only one default VSAN policy on a vCenter.

- policy Dict representation of a policy

salt.states.pbm.storage_policies_configured(name, policies)

Configures storage policies on a vCenter.

- policies List of dict representation of the required storage policies

23.19.228 salt.states.pcs

Management of Pacemaker/Corosync clusters with PCS

A state module to manage Pacemaker/Corosync clusters with the Pacemaker/Corosync configuration system (PCS)

New in version 2016.110.

- depends pcs

Requirements: PCS is installed, pcs service is started and the password for the hacluster user is set and known.
Remark on the cibname variable used in the examples: The use of the cibname variable is optional. Use it only if you want to deploy your changes into a cibfile first and then push it. This makes only sense if you want to deploy multiple changes (which require each other) at once to the cluster.

At first the cibfile must be created:

```yaml
mysql_pcs__cib_present_cib_for_galera:
  pcs.cib_present:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

Then the cibfile can be modified by creating resources (creating only 1 resource for demonstration, see also 7):

```yaml
mysql_pcs__resource_present_galera:
  pcs.resource_present:
    - resource_id: galera
    - resource_type: "ocf:heartbeat:galera"
    - resource_options:
      - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,
        → node3.example.org'
      - '--master'
    - cibname: cib_for_galera
```

After modifying the cibfile, it can be pushed to the live CIB in the cluster:

```yaml
mysql_pcs__cib_pushed_cib_for_galera:
  pcs.cib_pushed:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

Create a cluster from scratch:

1. Authorize nodes to each other:

```yaml
pcs_auth__auth:
  pcs.auth:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsuser: hacluster
    - pcspasswd: hoonetorg
    - extra_args: []
```

2. Do the initial cluster setup:

```yaml
pcs_setup__setup:
  pcs.cluster_setup:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsclustername: pcscluster
    - extra_args:
      - '--start'
      - '--enable'
```

3. Optional: Set cluster properties:
4. Optional: Set resource defaults:

```
pcs_properties__prop_has_value_no-quorum-policy:
  pcs.prop_has_value:
    - prop: no-quorum-policy
    - value: ignore
    - cibname: cib_for_cluster_settings
```

5. Optional: Set resource op defaults:

```
pcs_properties__resource_op_defaults_to_monitor-interval:
  pcs.resource_op_defaults_to:
    - op_default: monitor-interval
    - value: 60s
    - cibname: cib_for_cluster_settings
```

6. Configure Fencing (is often not optional on production ready cluster!):

```
pcs_stonith__created_eps_fence:
  pcs.stonith_present:
    - stonith_id: eps_fence
    - stonith_device_type: fence_eps
    - stonith_device_options:
      - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
      - 'ipaddr=myepsdevice.example.org'
      - 'power_wait=5'
      - 'verbose=1'
      - 'debug=/var/log/pcsd/eps_fence.log'
      - 'login=hidden'
      - 'passwd=hoonetorg'
    - cibname: cib_for_stonith
```

7. Add resources to your cluster:

```
mysql_pcs__resource_present_galera:
  pcs.resource_present:
    - resource_id: galera
    - resource_type: "ocf:heartbeat:galera"
    - resource_options:
      - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,→
        node3.example.org'
    - cibname: cib_for_galera
```

8. Optional: Add constraints (locations, colocations, orders):

```
haproxy_pcs__constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
  pcs.constraint_present:
    - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
    - constraint_type: colocation
    - constraint_options:
```

(continues on next page)
- 'add'
- 'vip_galera'
- 'with'
- 'haproxy-clone'
  - cibname: cib_for_haproxy

New in version 2016.3.0.

salt.states.pcs.auth(name, nodes, pcsuser='hacluster', pcspasswd='hacluster', extra_args=None)

Ensure all nodes are authorized to the cluster

- name: Irrelevant, not used (recommended: pcs_auth__auth)
- nodes: a list of nodes which should be authorized to the cluster
- pcsuser: user for communication with pcs (default: hacluster)
- pcspasswd: password for pcsuser (default: hacluster)
- extra_args: list of extra args for the 'pcs cluster auth' command

Example:

```
pcs_auth__auth:
  pcs.auth:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsuser: hacluster
    - pcspasswd: hoonetorg
    - extra_args: []
```

salt.states.pcs.cib_present(name, cibname, scope=None, extra_args=None)

Ensure that a CIB-file with the content of the current live CIB is created

- name: Irrelevant, not used (recommended: {{formulaname}}__cib_present_{{cibname}})
- cibname: name/path of the file containing the CIB
- scope: specific section of the CIB (default: None)
- extra_args: additional options for creating the CIB-file

Example:

```
mysql_pcs__cib_present_cib_for_galera:
  pcs.cib_present:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

salt.states.pcs.cib_pushed(name, cibname, scope=None, extra_args=None)

Ensure that a CIB-file is pushed if it is changed since the creation of it with pcs.cib_present

- name: Irrelevant, not used (recommended: {{formulaname}}__cib_pushed_{{cibname}})
- cibname: name/path of the file containing the CIB
- scope: specific section of the CIB
- extra_args: additional options for creating the CIB-file

Example:

```
mysql_pcs__cib_pushed_cib_for_galera:
  pcs.cib_pushed:
    - cibname: cib_for_galera
```

(continues on next page)
Salt Documentation, Release 3003.1

salt.states.pcs.cluster_node_present(name, node, extra_args=None)
Add a node to the Pacemaker cluster via PCS Should be run on one cluster node only (there may be races) Can only be run on a already setup/added node
name Irrelevant, not used (recommended: pcs_setup__node_add_{{node}})
node node that should be added
extra_args list of extra args for the 'pcs cluster node add' command
Example:

```
pcs_setup__node_add_node1.example.com:
    pcs.cluster_node_present:
        - node: node1.example.com
        - extra_args:
            - '--start'
            - '--enable'
```

salt.states.pcs.cluster_setup(name, nodes, pcsclustername='pcscluster', extra_args=None)
Setup Pacemaker cluster on nodes. Should be run on one cluster node only (there may be races)
name Irrelevant, not used (recommended: pcs_setup__setup)
nodes a list of nodes which should be set up
pcsclustername Name of the Pacemaker cluster
extra_args list of extra args for the 'pcs cluster setup' command
Example:

```
pcs_setup__setup:
    pcs.cluster_setup:
        - nodes:
            - node1.example.com
            - node2.example.com
        - pcsclustername: pcscluster
        - extra_args:
            - '--start'
            - '--enable'
```

salt.states.pcs.constraint_present(name, constraint_id, constraint_type, constraint_options=None, cibname=None)
Ensure that a constraint is created
Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync
name Irrelevant, not used (recommended: {{formulaname}}__constraint_present_{{constraint_id}})
constraint_id name for the constraint (try first to create manually to find out the autocreated name)
constraint_type constraint type (location, colocation, order)
constraint_options options for creating the constraint
cibname use a cached CIB-file named like cibname instead of the live CIB
Example:

```
haproxy_pcs__constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
    pcs.constraint_present:
        - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
        - constraint_type: colocation
        - constraint_options:
            - 'add'
```
salt.states.pcs.prop_has_value(name, prop, value, extra_args=None, cibname=None)

Ensure that a property in the cluster is set to a given value

Should be run on one cluster node only (there may be races)
name Irrelevant, not used (recommended: pcs_properties__prop_has_value_{{prop}})
prop name of the property
value value of the property
extra_args additional options for the pcs property command
cibname use a cached CIB-file named like cibname instead of the live CIB

Example:

```bash
pcs_properties__prop_has_value_no-quorum-policy:
  pcs.prop_has_value:
    - prop: no-quorum-policy
    - value: ignore
    - cibname: cib_for_cluster_settings
```

salt.states.pcs.resource_defaults_to(name, default, value, extra_args=None, cibname=None)

Ensure a resource default in the cluster is set to a given value

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync
name Irrelevant, not used (recommended: pcs_properties__resource_defaults_to_{{default}})
default name of the default resource property
value value of the default resource property
extra_args additional options for the pcs command
cibname use a cached CIB-file named like cibname instead of the live CIB

Example:

```bash
pcs_properties__resource_defaults_to_resource-stickiness:
  pcs.resource_defaults_to:
    - default: resource-stickiness
    - value: 100
    - cibname: cib_for_cluster_settings
```

salt.states.pcs.resource_op_defaults_to(name, op_default, value, extra_args=None, cibname=None)

Ensure a resource operation default in the cluster is set to a given value

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync
name Irrelevant, not used (recommended: pcs_properties__resource_op_defaults_to_{{op_default}})
op_default name of the operation default resource property
value value of the operation default resource property
extra_args additional options for the pcs command
cibname use a cached CIB-file named like cibname instead of the live CIB

Example:

```bash
pcs_properties__resource_op_defaults_to_monitor-interval:
  pcs.resource_op.defaults_to:
    - op_default: monitor-interval
```
salt.states.pcs.resource_present(name, resource_id, resource_type, resource_options=None, cibname=None)

Ensure that a resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

name Irrelevant, not used (recommended: {{formulaname}}_resource_present_{{resource_id}})
resource_id name for the resource
resource_type resource type (f.e. ocf:heartbeat:IPaddr2 or VirtualIP)
resource_options additional options for creating the resource
cibname use a cached CIB-file named like cibname instead of the live CIB

Example:

```
mysql_pcs__resource_present_galera:
  pcs.resource_present:
    - resource_id: galera
    - resource_type: "ocf:heartbeat:galera"
    - resource_options:
      - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
      - '--master'
    - cibname: cib_for_galera
```

salt.states.pcs.stonith_present(name, stonith_id, stonith_device_type, stonith_device_options=None, cibname=None)

Ensure that a fencing resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

name Irrelevant, not used (recommended: pcs_stonith__created_{{stonith_id}})
stonith_id name for the stonith resource
stonith_device_type name of the stonith agent fence_eps, fence_xvm f.e.
stonith_device_options additional options for creating the stonith resource
cibname use a cached CIB-file named like cibname instead of the live CIB

Example:

```
pcs_stonith__created_eps_fence:
  pcs.stonith_present:
    - stonith_id: eps_fence
    - stonith_device_type: fence_eps
    - stonith_device_options:
      - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
      - 'ipaddr=myepsdevice.example.org'
      - 'power_wait=5'
      - 'verbose=1'
      - 'debug=/var/log/pcsd/eps_fence.log'
      - 'login=hidden'
      - 'passwd=hoonetorg'
    - cibname: cib_for_stonith
```
23.19.229 salt.states.pdbedit

Manage accounts in Samba’s passdb using pdbedit

maintainer Jorge Schrauwen <sjorge@blackdot.be>
maturity new
depends pdbedit
platform posix

New in version 2017.7.0.

| wash: | pdbedit.absent |
| kaylee: | pdbedit.managed: |
| | - password: A70C708517B5DD0EDB67714FE25336EB |
| | - password_hashed: True |
| | - drive: 'X:' |
| | - homedir: '\\serenity\mechanic\profile' |

salt.states.pdbedit.absent(name)
Ensure user account is absent
name [string] username

salt.states.pdbedit.managed(name, **kwargs)
Manage user account
login [string] login name
password [string] password
password_hashed [boolean] set if password is a nt hash instead of plain text
domain [string] users domain
profile [string] profile path
script [string] logon script
drive [string] home drive
homedir [string] home directory
fullname [string] full name
account_desc [string] account description
machine_sid [string] specify the machines new primary group SID or rid
user_sid [string] specify the users new primary group SID or rid
account_control [string] specify user account control properties

| Note: | Only the following can be set: - N: No password required - D: Account disabled - H: Home directory required - L: Automatic Locking - X: Password does not expire |

reset_login_hours [boolean] reset the users allowed logon hours
reset_bad_password_count [boolean] reset the stored bad login counter

salt.states.pdbedit.present(name, **kwargs)
Alias for pdbedit.managed
23.19.230 salt.states.pecl

Installation of PHP Extensions Using pecl

These states manage the installed pecl extensions. Note that php-pear must be installed for these states to be available, so pecl states should include a requisite to a pkg.installed state for the package which provides pecl (php-pear in most cases). Example:

```yaml
salt.states.pecl.installed(name, version=None, defaults=False, force=False, preferred_state='stable')
```

New in version 0.17.0.

Make sure that a pecl extension is installed.

- `name` The pecl extension name to install
- `version` The pecl extension version to install. This option may be ignored to install the latest stable version.
- `defaults` Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.
- `force` Whether to force the installed version or not
- `preferred_state` The pecl extension state to install

salt.states.pecl.removed(name)

Make sure that a pecl extension is not installed.

- `name` The pecl extension name to uninstall

23.19.231 salt.states.pip_state

Installation of Python Packages Using pip

These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a pkg.installed state for the package which provides pip (python-pip in most cases). Example:

```yaml
salt.states.pip_state
```

Make sure that a pip package is installed.

- `name` The pip package name to install
- `version` The pip package version to install. This option may be ignored to install the latest version.
- `defaults` Use default answers for extensions such as pip which ask questions before installation.
- `force` Whether to force the installed version or not
- `preferred_state` The pip package state to install

salt.states.pip_state.removed(name)

Make sure that a pip package is not installed.

- `name` The pip package name to uninstall
salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, repo=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, install_options=None, global_options=None, user=None, cwd=None, pre_releases=False, cert=None, allow_all_external=False, allow_external=None, allow_unverified=False, process_dependency_links=False, env_vars=None, use_vt=False, trusted_host=None, no_cache_dir=False, cache_dir=None, no_binary=None, extra_args=None, **kwargs)

Make sure the package is installed

**name** The name of the python package to install. You can also specify version numbers here using the standard operators ==, >=, <=. If **requirements** is given, this parameter will be ignored.

Example:

```yaml
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
    - pkg: python-pip
```

This will install the latest Django version greater than 1.6 but less than 1.7.

**requirements** Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

**user** The user under which to run pip

**use_wheel** [False] Prefer wheel archives (requires pip>=1.4)

**no_use_wheel** [False] Force to not use wheel archives (requires pip>=1.4)

**no_binary** Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages, :none: to empty the set, or a list of one or more packages

Example:

```yaml
django:
  pip.installed:
    - no_binary: ':all:'
flask:
  pip.installed:
    - no_binary:
      - itsdangerous
      - click
```

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**editable** install something editable (i.e. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)

**find_links** URL to look for packages at

**index_url** Base URL of Python Package Index

**extra_index_url** Extra URLs of package indexes to use in addition to **index_url**
no_index  Ignore package index
mirrors  Specific mirror URL(s) to query (automatically adds --use-mirrors)
build  Unpack packages into build dir
target  Install packages into target dir
download  Download packages into download instead of installing them
download_cache  Cache downloaded packages in download_cache dir
source  Check out editable packages into source dir
upgrade  Upgrade all packages to the newest available version
force_reinstall  When upgrading, reinstall all packages even if they are already up-to-date.
ignore_installed  Ignore the installed packages (reinstalling instead)
exists_action  Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
no_deps  Ignore package dependencies
no_install  Download and unpack all packages, but don't actually install them
no_cache_dir: Disable the cache.
cwd  Current working directory to run pip from
pre_releases  Include pre-releases in the available versions
cert  Provide a path to an alternate CA bundle
allow_all_external  Allow the installation of all externally hosted files
allow_external  Allow the installation of externally hosted files (comma separated list)
allow_unverified  Allow the installation of insecure and unverifiable files (comma separated list)
process_dependency_links  Enable the processing of dependency links
bin_env  [None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at /foo/.virtualenvs/bar.
env_vars  Add or modify environment variables. Useful for tweaking build steps, such as specifying INCLUDE or LIBRARY paths in Makefiles, build scripts or compiler calls. This must be in the form of a dictionary or a mapping.

Example:

```yaml
django:
  pip.installed:
    - name: django_app
    - env_vars:
        CUSTOM_PATH: /opt/django_app
        VERBOSE: True
```

use_vt  Use VT terminal emulation (see output while installing)
trusted_host  Mark this host as trusted, even though it does not have valid or any HTTPS.

Example:

```yaml
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar/bin/pip
    - require:
        - pkg: python-pip
```

Or

Example:

```yaml
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar/bin/pip
    - require:
        - pkg: python-pip
```
Attention
The following arguments are deprecated, do not use.

**pip_bin** [None] Deprecated, use `bin_env`

Changed in version 0.17.0: `use_wheel` option added.

**install_options**
Extra arguments to be supplied to the setup.py install command. If you are using an option with a directory path, be sure to use absolute path.

Example:

```
django:
  pip.installed:
    - name: django
    - install_options:
        - --prefix=/blah
    - require:
        - pkg: python-pip
```

**global_options** Extra global options to be supplied to the setup.py call before the install command.

New in version 2014.1.3.

Attention
As of Salt 0.17.0 the pip state needs an importable pip module. This usually means having the system's pip package installed or running Salt from an active virtualenv.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements. It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip library. It's functionality duplication and it's more error prone.

Attention
Please set `reload_modules: True` to have the salt minion import this module after installation.

Example:

```
pyopenssl:
  pip.installed:
    - name: pyOpenSSL
    - reload_modules: True
    - exists_action: i
```

**extra_args** pip keyword and positional arguments not yet implemented in salt

```
pandas:
  pip.installed:
    - name: pandas
    - extra_args:
        - --latest-pip-kwarg: param
        - --latest-pip-arg
```
Warning: If unsupported options are passed here that are not supported in a minion's version of pip, a No such option error will be thrown.

salt.states.pip_state.pip_has_exceptions_mod(ver)
   True when the pip version has the pip.exceptions module

salt.states.pip_state.pip_has_internal_exceptions_mod(ver)
   True when the pip version has the pip._internal.exceptions module

salt.states.pip_state.purge_pip()
   Purge pip and its sub-modules

salt.states.pip_state.removed(name, requirements=None, bin_env=None, log=None, proxy=None, timeout=None, user=None, cwd=None, use_vt=False)
   Make sure that a package is not installed.
   **name**  The name of the package to uninstall
   **user**  The user under which to run pip
   **bin_env**  [None] the pip executable or virtualenv to use
   **use_vt**  Use VT terminal emulation (see output while installing)

salt.states.pip_state.uptodate(name, bin_env=None, user=None, cwd=None, use_vt=False)
   New in version 2015.5.0.
   Verify that the system is completely up to date.
   **name**  The name has no functional value and is only used as a tracking reference
   **user**  The user under which to run pip
   **bin_env**  the pip executable or virtualenv to use
   **use_vt**  Use VT terminal emulation (see output while installing)

23.19.232 salt.states.pkg

Installation of packages using OS package managers such as yum or apt-get

**Note:** On minions running systemd>=205, as of version 2015.8.12, 2016.3.3, and 2016.11.0, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing the package manager commands spawned by Salt, when Salt updates itself (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.use_scope, with a value of False (no quotes).

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

**vim:**
   pkg.installed

A more involved example involves pulling from a custom repository.

**base:**
   pkgrepo.managed:
      - name: ppa:wolfnet/logstash
      - dist: precise
      - file: /etc/apt/sources.list.d/logstash.list
      - keyid: 28B04E4A

(continues on next page)
Multiple packages can also be installed with the use of the pkgs state module

```yaml
dotdeb.repo:
  pkgrepo.managed:
    - name: deb http://packages.dotdeb.org wheezy-php55 all
    - dist: wheezy-php55
    - file: /etc/apt/sources.list.d/dotdeb.list
    - keyid: 89DF5277
    - keyserver: keys.gnupg.net
    - refresh_db: true

php.packages:
  pkg.installed:
    - fromrepo: wheezy-php55
    - pkgs:
      - php5-fpm
      - php5-cli
      - php5-curl
```

**Warning:** Package names are currently case-sensitive. If the minion is using a package manager which is not case-sensitive (such as `pkgng`), then this state will fail if the proper case is not used. This will be addressed in a future release of Salt.

```python
salt.states.pkg.downloaded(name, version=None, pkgs=None, fromrepo=None, **kwargs)
```

New in version 2017.7.0.

Ensure that the package is downloaded, and that it is the correct version (if specified).

**Note:** Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like saltenv, or reload_modules, will be passed through to the call to `pkg.install` to download the package(s). For example, you can include a `disablerepo` argument on platforms that use yum/dnf to disable that repo:

```python
mypkg:
  pkg.downloaded:
    - disablerepo: base,updates
```

To see what is supported, check this page to find the documentation for your platform's pkg module, then look at the documentation for the `install` function.

Any argument that is passed through to the `install` function, which is not defined for that function, will be silently ignored.

Currently supported for the following pkg providers: `yumpkg`, `zypper` and `zypper`
download packages from a software repository.

- **version** *(str)* -- Download a specific version of a package.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.downloaded:
  - version: 2:7.4.160-1.el7
```

An **ignore_epoch** argument has been added to which causes the epoch to be disregarded when the state checks to see if the desired version was installed.

You can install a specific version when using the **pkgs** argument by including the version after the package:

```
common_packages:
pkg.downloaded:
  - pkgs:
    - unzip
    - dos2unix
    - salt-minion: 2015.8.5-1.el6
```

- **resolve_capabilities** *(bool)* -- Turn on resolving capabilities. This allow one to name "provides" or alias names for packages.

CLI Example:

```
zsh:
pkg.downloaded:
  - version: 5.0.5-4.63
  - fromrepo: "myrepository"
```

`salt.states.pkg.group_installed*(name, skip=None, include=None, **kwargs)*

New in version 2015.8.0.

Changed in version 2016.11.0: Added support in pacman

Ensure that an entire package group is installed. This state is currently only supported for the *yum* and *pacman* package managers.

**skip** Packages that would normally be installed by the package group ("default" packages), which should not be installed.

```
Load Balancer:
pkg.group_installed:
  - skip:
    - piranha
```

**include** Packages which are included in a group, which would not normally be installed by a *yum groupinstall* ("optional" packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed.

```
Load Balancer:
pkg.group_installed:
```

(continues on next page)
- **include:**
  - haproxy

Changed in version 2016.3.0: This option can no longer be passed as a comma-separated list, it must now be passed as a list (as shown in the above example).

**Note:** Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed on to the call to `pkg.install`.

### salt.states.pkg.installed

```
salt.states.pkg.installed(name, version=None, refresh=None, fromrepo=None, skip_verify=False, skip_suggestions=False, pkgs=None, sources=None, allow_updates=False, pkg_verify=False, normalize=True, ignore_epoch=None, reinstall=False, update_holds=False, **kwargs)
```

Ensure that the package is installed, and that it is the correct version (if specified).

**Note:** Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like `saltenv`, or `reload_modules`, will be passed through to the call to `pkg.install` to install the package(s). For example, you can include a `disablerepo` argument on platforms that use yum/dnf to disable that repo:

```
mypkg:
  pkg.installed:
    - disablerepo: base,updates
```

To see what is supported, check this page to find the documentation for your platform’s `pkg` module, then look at the documentation for the `install` function.

Any argument that is passed through to the `install` function, which is not defined for that function, will be silently ignored.

#### Parameters

- **name** *(str)* -- The name of the package to be installed. This parameter is ignored if either "pkgs" or "sources" is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the "sources" option detailed below.

- **version** *(str)* -- Install a specific version of a package. This option is ignored if "sources" is used. Currently, this option is supported for the following pkg providers: `apt`, `ebuild`, `pacman`, `pkgin`, `win_pkg`, `yumpkg`, and `zypper`. The version number includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the `pkg.latest_version` function for an uninstalled package will tell you the version available.

```
# salt myminion pkg.latest_version vim-enhanced
mypackage:
  2:7.4.160-1.el7
```

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the `pkg.latest_version` output above) must have the epoch included when specifying the version number. For example:
In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed`, `pkg.removed`, and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed.

Also, while this function is not yet implemented for all pkg frontends, `pkg.list_repo_pkgs` will show all versions available in the various repositories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs bash
myminion: 
---------
bash:
    - 4.2.46-21.el7_3
    - 4.2.46-20.el7_2
```

This function was first added for `pkg.list_repo_pkgs` in 2014.1.0, and was expanded to Debian/Ubuntu and Arch Linux-based distros in the 2017.7.0 release.

The version strings returned by either of these functions can be used as version specifiers in pkg states.

You can install a specific version when using the `pkgs` argument by including the version after the package:

```
common_packages:
    pkg.installed:
        - pkgs:
            - unzip
            - dos2unix
            - salt-minion: 2015.8.5-1.el6
```

If the version given is the string `latest`, the latest available package version will be installed à la `pkg.latest`.

**WILDCARD VERSIONS**

As of the 2017.7.0 release, this state now supports wildcards in package versions for SUSE SLES/Leap/Tumbleweed, Debian/Ubuntu, RHEL/CentOS, Arch Linux, and their derivatives. Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like `1.2.34-5.el7`. An example of the usage for this would be:

```
mpkg:
    pkg.installed:
        - version: '1.2.34*'
```

Keep in mind that using wildcard versions will result in a slower state run since Salt must gather the available versions of the specified packages and figure out which of them match the specified wildcard expression.

- `refresh` (*bool*) -- This parameter controls whether or not the package repo database is updated prior to installing the requested package(s).

If True, the package database will be refreshed (`apt-get update` or equivalent, depending on platform) before installing.
If `False`, the package database will *not* be refreshed before installing.

If unset, then Salt treats package database refreshes differently depending on whether or not a `pkg` state has been executed already during the current Salt run. Once a refresh has been performed in a `pkg` state, for the remainder of that Salt run no other refreshes will be performed for `pkg` states which do not explicitly set `refresh` to `True`. This prevents needless additional refreshes from slowing down the Salt run.

- **`cache_valid_time (str)`** -- New in version 2016.11.0.

  This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the `refresh` parameter's default behavior.

  Example:

  ```yaml
  httpd:
    pkg.installed:
      - fromrepo: mycustomrepo
      - skip_verify: True
      - skip_suggestions: True
      - version: 2.0.6~ubuntu3
      - refresh: True
      - cache_valid_time: 300
      - allow_updates: True
      - hold: False
  ```

  In this case, a refresh will not take place for 5 minutes since the last `apt-get update` was executed on the system.

  **Note:** This parameter is available only on Debian based distributions and has no effect on the rest.

- **`fromrepo (str)`** -- Specify a repository from which to install

  **Note:** Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

  ```bash
  deb http://ppa.launchpad.net/saltstack/salt/ubuntu precise main
  ```

  The packages provided by this source would be made available via the `precise` release, therefore `fromrepo` would need to be set to `precise` for Salt to install the package from this source.

  Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the `version` parameter.

  If the `pkgs` parameter is being used to install multiple packages in the same state, then instead of using `version`, use the method of version specification described in the Multiple Package Installation Options section below.

  Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:
root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policy ffmpeg'
ubuntu01:
    ffmpeg:
        Installed: (none)
        Candidate: 7:0.10.11-1-precise1
        Version table:
            7:0.10.11-1-precise1 0
            500 http://ppa.launchpad.net/jon-severinsson/ffmpeg/ubuntu/ precise/main amd64 Packages
            4:0.8.10-0ubuntu0.12.04.1 0
            500 http://us.archive.ubuntu.com/ubuntu/ precise-updates/main amd64 Packages
            500 http://security.ubuntu.com/ubuntu/ precise-security/main amd64 Packages
            4:0.8.1-0ubuntu1 0
            500 http://us.archive.ubuntu.com/ubuntu/ precise/main amd64 Packages
The release is located directly after the source’s URL. The actual release name is the part before the slash, so to install version 4:0.8.10-0ubuntu0.12.04.1 either precise-updates or precise-security could be used for the fromrepo value.

- **skip_verify** *(bool)* -- Skip the GPG verification check for the package to be installed
- **skip_suggestions** *(bool)* -- Force strict package naming. Disables lookup of package alternatives.

New in version 2014.1.1.

- **resolve_capabilities** *(bool)* -- Turn on resolving capabilities. This allow one to name “provides” or alias names for packages.

New in version 2018.3.0.

- **allow_updates** *(bool)* -- Allow the package to be updated outside Salt’s control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a reinstall of the package.

New in version 2014.7.0.

Example:

```
httpd:
    pkg.installed:
        - fromrepo: mycustomrepo
          - skip_verify: True
          - skip_suggestions: True
          - version: 2.0.6-ubuntu3
          - refresh: True
          - allow_updates: True
          - hold: False
```

- **pkg_verify** *(bool)* -- New in version 2014.7.0.

For requested packages that are already installed and would not be targeted for upgrade or downgrade, use pkg.verify to determine if any of the files installed by the package have been altered. If files have been altered, the reinstall option of pkg.install is used to force a reinstall. Types to ignore can be passed to pkg.verify. Additionally,
verify_options can be used to modify further the behavior of pkg.verify. See examples below. Currently, this option is supported for the following pkg providers: yumpkg.

Examples:

```yaml
httpd:
  pkg.installed:
    - version: 2.2.15-30.el6.centos
    - pkg_verify: True

mypkgs:
  pkg.installed:
    - pkgs:
        - foo
        - bar: 1.2.3-4
        - baz
    - pkg_verify:
        - ignore_types:
            - config
            - doc

mypkgs:
  pkg.installed:
    - pkgs:
        - foo
        - bar: 1.2.3-4
        - baz
    - pkg_verify:
        - ignore_types:
            - config
            - doc
        - verify_options:
            - nodeps
            - nofiledigest
```

- **ignore_types** *(list)* -- List of types to ignore when verifying the package
  
  New in version 2014.7.0.

- **verify_options** *(list)* -- List of additional options to pass when verifying the package. These options will be added to the `rpm -V` command, prepended with `--` (for example, when `nodeps` is passed in this option, `rpm -V` will be run with `--nodeps`).
  
  New in version 2016.11.0.

- **normalize** *(bool)* -- Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.
  
  New in version 2014.7.0.

Example:

```yaml
gdfs.gplbin-2.6.32-279.31.1.el6.x86_64:
  pkg.installed:
    - normalize: False
```
• **ignore_epoch** (*bool*) -- If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to `True` to explicitly ignore the epoch, and `False` to strictly enforce it.

New in version 2015.8.9.

Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to `True`.

MULTIPLE PACKAGE INSTALLATION OPTIONS: (not supported in pkgng)

Parameters

- **pkgs** (*list*) -- A list of packages to install from a software repository. All packages listed under `pkgs` will be installed via a single command.

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar
      - baz
      - hold: True
```

**NOTE:** For `apt`, `ebuild`, `pacman`, `winrepo`, `yumpkg`, and `zypper`, version numbers can be specified in the `pkgs` argument. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
```

Additionally, `ebuild`, `pacman`, `zypper`, `yum/dnf`, and `apt` support the `<`, `<=`, `>=`, and `>` operators for more control over what versions will be installed. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: '>=1.2.3-4'
      - baz
```

**NOTE:** When using comparison operators, the expression must be enclosed in quotes to avoid a YAML render error.

With `ebuild` is also possible to specify a use flag list and/or if the given packages should be in `package.accept_keywords` file and/or the overlay from which you want the package to be installed. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
```
- foo: '~= '
- bar: '~=>=1.2:slot::overlay[use,-otheruse]'
- baz

- sources (list) -- A list of packages to install, along with the source URI or local path from which to install each package. In the example below, foo, bar, baz, etc. refer to the name of the package, as it would appear in the output of the pkg, version or pkg.list_pkgs salt CLI commands.

```yaml
mpkgs:
    pkg.installed:
      - sources:
          - foo: salt://rpms/foo.rpm
          - bar: http://somesite.org/bar.rpm
          - baz: ftp://someothersite.org/baz.rpm
          - qux: /minion/path/to/qux.rpm
```

**PLATFORM-SPECIFIC ARGUMENTS**

These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.

**Parameters**

- **hold (bool)** -- Force the package to be held at the current installed version.

  Supported on YUM/DNF & APT based systems.

  New in version 2014.7.0.

  Supported on Zypper-based systems.

  New in version 3003.

- **update_holds (bool)** -- If True, and this function would update the package version, any packages which are being held will be temporarily unheld so that they can be updated. Otherwise, if this function attempts to update a held package, the held package(s) will be skipped and the state will fail. By default, this parameter is set to False.

  Supported on YUM/DNF & APT based systems.

  New in version 2016.11.0.

  Supported on Zypper-based systems.

  New in version 3003.

- **names (list)** -- A list of packages to install from a software repository. Each package will be installed individually by the package manager.

  **Warning:** Unlike pkgs, the names parameter cannot specify a version. In addition, it makes a separate call to the package management frontend to install each package, whereas pkgs makes just a single call. It is therefore recommended to use pkgs instead of names to install multiple packages, both for the additional features and the performance improvement that it brings.

- **install_recommends (bool)** -- Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.

  New in version 2015.5.0.
httpd:
  pkg.installed:
    - install_recommends: False

• **only_upgrade (bool)** -- Only upgrade the packages, if they are already installed. Default is `False`. Currently only works with APT-based systems.

  New in version 2015.5.0.

httpd:
  pkg.installed:
    - only_upgrade: True

Note: If this parameter is set to `True` and the package is not already installed, the state will fail.

• **report_reboot_exit_codes (bool)** -- If the installer exits with a recognized exit code indicating that a reboot is required, the module function

  `win_system.set_reboot_required_witnessed`

will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, `3010` is the only recognized exit code, but this is subject to future refinement. The value of this param defaults to `True`. This parameter has no effect on non-Windows systems.

  New in version 2016.11.0.

**ms vcpp installed:**
  pkg.installed:
    - name: ms-vcpp
    - version: 10.0.40219
    - report_reboot_exit_codes: False

Returns A dictionary containing the state of the software installation

Rtype dict

Note: The `pkg.installed` state supports the usage of `reload_modules`. This functionality allows you to force Salt to reload all modules. In many cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require the package which was installed. However, there are some edge cases where this may not be the case, which is what `reload_modules` is meant to resolve.

You should only use `reload_modules` if your `pkg.installed` does some sort of installation where if you do not reload the modules future items in your state which rely on the software being installed will fail. Please see the `Reloading Modules` documentation for more information.

See also:

unless and onlyif

If running pkg commands together with `aggregate` isn't an option, you can use the `creates, unless, or onlyif` syntax to skip a full package run. This can be helpful in large environments with multiple states that include requisites for packages to be installed.

# Using creates for a simple single-factor check

```shell
install_nginx:
  pkg.installed:
```

(continues on next page)
- name: nginx
  - creates:
    - /etc/nginx/nginx.conf

# Using file.file_exists for a single-factor check
install_nginx:
  pkg.installed:
    - name: nginx
    - unless:
      - fun: file.file_exists
        args:
        - /etc/nginx/nginx.conf

# Using unless with a shell test
install_nginx:
  pkg.installed:
    - name: nginx
    - unless: test -f /etc/nginx/nginx.conf

# Using file.search for a two-factor check
install_nginx:
  pkg.installed:
    - name: nginx
    - unless:
      - fun: file.search
        args:
        - /etc/nginx/nginx.conf
        - 'user www-data;'

The above examples use different methods to reasonably ensure that a package has already been installed. First, with checking for a file that would be created with the package. Second, by checking for specific text within a file that would be created or managed by salt. With these requisists satisfied, creates/unless will return True and the pkg.installed state will be skipped.

# Example of state run without unless used
salt 'saltdev' state.apply nginx
saltdev:
  -----------
  ID: install_nginx
  Function: pkg.installed
  Name: nginx
  Result: True
  Comment: All specified packages are already installed
  Started: 20:11:56.388331
  Duration: 4290.0 ms
  Changes:

# Example of state run using unless requisite
salt 'saltdev' state.apply nginx
saltdev:
  -----------
  ID: install_nginx
  Function: pkg.installed
  Name: nginx
  Result: True

(continues on next page)
The result is a reduction of almost 3 seconds. In larger environments, small reductions in waiting time can add up.

**Unless Requisite**

```
salt.states.pkg.latest(name, refresh=None, fromrepo=None, skip_verify=False, pkgs=None, watch_flags=True, **kwargs)
```

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the `installed` function to be used, as `latest` will update the package whenever a new package is available.

**Note:** Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like `saltenv`, or `reload_modules`, will be passed through to the call to `pkg.install` to install the package(s). For example, you can include a `disablerepo` argument on platforms that use yum/dnf to disable that repo:

```
mypkg:
  pkg.latest:
    - disablerepo: base,updates
```

To see what is supported, check [this page](#) to find the documentation for your platform’s `pkg` module, then look at the documentation for the `install` function.

Any argument that is passed through to the `install` function, which is not defined for that function, will be silently ignored.

**name** The name of the package to maintain at the latest available version. This parameter is ignored if "pkgs" is used.

**fromrepo** Specify a repository from which to install

**skip_verify** Skip the GPG verification check for the package to be installed

**refresh** This parameter controls whether or not the package repo database is updated prior to checking for the latest available version of the requested packages.

- **True** - the package database will be refreshed (`apt-get update` or equivalent, depending on platform) before checking for the latest available version of the requested packages.

- **False** - the package database will not be refreshed before checking.

If unset, then Salt treats package database refreshes differently depending on whether or not a `pkg` state has been executed already during the current Salt run. Once a refresh has been performed in a `pkg` state, for the remainder of that Salt run no other refreshes will be performed for `pkg` states which do not explicitly set `refresh` to `True`. This prevents needless additional refreshes from slowing down the Salt run.

**param str cache_valid_time** New in version 2016.11.0.

This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the `refresh` parameter's default behavior.

Example:
In this case, a refresh will not take place for 5 minutes since the last `apt-get update` was executed on the system.

**Note:** This parameter is available only on Debian based distributions and has no effect on the rest.

### param bool resolve_capabilities

Turn on resolving capabilities. This allows one to name “provides” or alias names for packages.

New in version 2018.3.0.

Multiple Package Installation Options:

*(Not yet supported for: FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)*

**pkgs** A list of packages to maintain at the latest available version.

```yaml
mypkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz
```

**install_recommends** Whether to install the packages marked as recommended. Default is `True`. Currently only works with APT-based systems.

New in version 2015.5.0.

```yaml
httpd:
  pkg.latest:
    - install_recommends: False
```

**only_upgrade** Only upgrade the packages, if they are already installed. Default is `False`. Currently only works with APT-based systems.

New in version 2015.5.0.

```yaml
httpd:
  pkg.latest:
    - only_upgrade: True
```

**Note:** If this parameter is set to `True` and the package is not already installed, the state will fail.

**report_reboot_exit_codes** If the installer exits with a recognized exit code indicating that a reboot is required, the module function `win_system.set_reboot_required_witnessed` will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, `3010` is the only recognized exit code, but this is subject to future refinement. The value of this param defaults to `True`. This parameter has no effect on non-Windows systems.

New in version 2016.11.0.
salt.states.pkg.mod_aggregate(*low, chunks, running*)
The mod_aggregate function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

salt.states.pkg.mod_beacon(name, **kwargs)
Create a beacon to monitor a package or packages based on a beacon state argument.

Note: This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

salt.states.pkg.mod_watch(name, **kwargs)
Install/reinstall a package based on a watch requisite

Note: This state exists to support special handling of the watch requisite. It should not not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.pkg.patch_downloaded(name, advisory_ids=None, **kwargs)
New in version 2017.7.0.
Ensure that packages related to certain advisory ids are downloaded.
Currently supported for the following pkg providers: yumpkg and zypper

CLI Example:

```
preparing-to-fix-issues:  
pkg.patch_downloaded:    
  - advisory_ids:         
    - SUSE-SLE-SERVER-12-SP2-2017-185  
    - SUSE-SLE-SERVER-12-SP2-2017-150  
    - SUSE-SLE-SERVER-12-SP2-2017-120
```

salt.states.pkg.patch_installed(name, advisory_ids=None, downloadonly=None, **kwargs)
New in version 2017.7.0.
Ensure that packages related to certain advisory ids are installed.

Note: Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like saltenv, or reload_modules, will be passed through to the call to pkg.install to install the patch(es).

To see what is supported, check this page to find the documentation for your platform's pkg module, then look at the documentation for the install function.

Any argument that is passed through to the install function, which is not defined for that function, will be silently ignored.

Currently supported for the following pkg providers: yumpkg and zypper

CLI Example:
**issue-foo-fixed:**

**pkg.patch_installed:**

- **advisory_ids:**
  - SUSE-SLE-SERVER-12-SP2-2017-185
  - SUSE-SLE-SERVER-12-SP2-2017-150
  - SUSE-SLE-SERVER-12-SP2-2017-120

`salt.states.pkg.purged(name, version=None, pkgs=None, normalize=True, ignore_epoch=None, **kwargs)`

Verify that a package is not installed, calling `pkg.purge` if necessary to purge the package. All configuration files are also removed.

- **name** The name of the package to be purged.
- **version** The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```text
vim-enhanced:
pkg.purged:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed`, `pkg.removed`, and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If `ignore_epoch` was not set to `True`, and instead of `2:7.4.160-1.el7` a version of `7.4.160-1.el7` were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

- **normalize** `[True]` Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

  New in version 2015.8.0.

- **ignore_epoch** `[None]` If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to `True` to explicitly ignore the epoch, and `False` to strictly enforce it.

  New in version 2015.8.9.

  Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to `True`.

**Multiple Package Options:**

- **pkgs** A list of packages to purge. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

  New in version 0.16.0.

`salt.states.pkg.removed(name, version=None, pkgs=None, normalize=True, ignore_epoch=None, **kwargs)`

Verify that a package is not installed, calling `pkg.remove` if necessary to remove the package.

- **name** The name of the package to be removed.
- **version** The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.
Important: As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
  pkg.removed:
    - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed`, `pkg.removed`, and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If `ignore_epoch` was not set to `True`, and instead of `2:7.4.160-1.el7` a version of `7.4.160-1.el7` were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

ignore_epoch [None] If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to `True` to explicitly ignore the epoch, and `False` to strictly enforce it.

New in version 2015.8.9.

Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to `True`.

Multiple Package Options:

 pkgs A list of packages to remove. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

```
salt.states.pkg.uptodate(name, refresh=False, pkgs=None, **kwargs)
```

New in version 2014.7.0.

Changed in version 2018.3.0: Added support for the `pkgin` provider.

Verify that the system is completely up to date.

name The name has no functional value and is only used as a tracking reference

refresh refresh the package database before checking for new upgrades

pkgs list of packages to upgrade

Parameters

- `cache_valid_time(str)` -- This parameter sets the value in seconds after which cache marked as invalid, and cache update is necessary. This overwrite `refresh` parameter default behavior.

  In this case cache_valid_time is set, refresh will not take place for amount in seconds since last `apt-get update` executed on the system.

  **Note:** This parameter available only on Debian based distributions, and have no effect on the rest.

- `resolve_capabilities(bool)` -- Turn on resolving capabilities. This allow one to name “provides” or alias names for packages.
New in version 2018.3.0.

**kwargs**  Any keyword arguments to pass through to `pkg.upgrade`.

New in version 2015.5.0.

### 23.19.233 salt.states.pkgbuild

The `pkgbuild` state is the front of Salt package building backend. It automatically builds DEB and RPM packages from specified sources

New in version 2015.8.0.

```python
salt_2015.5.2:
    pkgbuild.built:
        - runas: thatch
        - results:
            - salt-2015.5.2-2.el7.centos.noarch.rpm
            - salt-api-2015.5.2-2.el7.centos.noarch.rpm
            - salt-cloud-2015.5.2-2.el7.centos.noarch.rpm
            - salt-master-2015.5.2-2.el7.centos.noarch.rpm
            - salt-minion-2015.5.2-2.el7.centos.noarch.rpm
            - salt-ssh-2015.5.2-2.el7.centos.noarch.rpm
            - salt-syndic-2015.5.2-2.el7.centos.noarch.rpm
        - dest_dir: /tmp/pkg
        - spec: salt://pkg/salt/spec/salt.spec
        - template: jinja
        - deps:
            - salt://pkg/salt/sources/required_dependency.rpm
        - tgt: epel-7-x86_64
        - sources:
            - salt://pkg/salt/sources/logrotate.salt
            - salt://pkg/salt/sources/README.fedora
            - salt://pkg/salt/sources/salt-2015.5.2.tar.gz
            - salt://pkg/salt/sources/salt-2015.5.2-tests.patch
            - salt://pkg/salt/sources/salt-api
            - salt://pkg/salt/sources/salt-api.service
            - salt://pkg/salt/sources/salt-master
            - salt://pkg/salt/sources/salt-master.service
            - salt://pkg/salt/sources/salt-minion
            - salt://pkg/salt/sources/salt-minion.service
            - salt://pkg/salt/sources/saltpkg.sls
            - salt://pkg/salt/sources/salt-syndic
            - salt://pkg/salt/sources/salt-syndic.service
            - salt://pkg/salt/sources/SaltTesting-2015.5.8.tar.gz
/tmp/pkg:
    pkgbuild.repo
```

salt.states.pkgbuild.built(name, runas, dest_dir, spec, sources, tgt, template=None, deps=None, env=None, results=None, force=False, saltenv='base', log_dir='/var/log/salt/pkgbUILD')

Ensure that the named package is built and exists in the named directory

**name**  The name to track the build, the name value is otherwise unused

**runas**  The user to run the build process as

**dest_dir**  The directory on the minion to place the built package(s)

**spec**  The location of the spec file (used for rpms)

**sources**  The list of package sources

**tgt**  The target platform to run the build on
template  Run the spec file through a templating engine

Changed in version 2015.8.2: This argument is now optional, allowing for no templating engine to be used if none is desired.

deps Packages required to ensure that the named package is built can be hosted on either the salt master server or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials

env A dictionary of environment variables to be set prior to execution. Example:

```
- env:
    DEB_BUILD_OPTIONS: 'nocheck'
```

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

results The names of the expected rpms that will be built

force [False] If True, packages will be built even if they already exist in the dest_dir. This is useful when building a package for continuous or nightly package builds.

New in version 2015.8.2.

saltenv The saltenv to use for files downloaded from the salt filesever

log_dir [/var/log/salt/rpmbuild] Root directory for log files created from the build. Logs will be organized by package name, version, OS release, and CPU architecture under this directory.

New in version 2015.8.2.

salt.states.pkgbuild.repo(name, keyid=None, env=None, use_passphrase=False, gnupghome='/etc/salt/gpgkeys', runas='builder', timeout=15.0)

Make a package repository and optionally sign it and packages present

The name is directory to turn into a repo. This state is best used with onchanges linked to your package building states.

name The directory to find packages that will be in the repository

keyid Changed in version 2016.3.0.

Optional Key ID to use in signing packages and repository. Utilizes Public and Private keys associated with keyid which have been loaded into the minion's Pillar data.

For example, contents from a Pillar data file with named Public and Private keys as follows:

```
gpg_pkg_priv_key: |
-----BEGIN PGP PRIVATE KEY BLOCK-----
Version: GnuPG v1

lQO+BFciIfQBCADAPCtzx7I5Rl32escCMZsPzaEKWe7bIX1em4KCKkBoX47IG54bw82PCE8Y1jF/9Uk2m3RKWmp3Ycllc7Ap3gj6VQ/yvVz28UbnhPsIK0lf2cq8qc .
Ebe+8JCQTqwSXPRTrzxy/b5WXDeM79CkLwvuGpXFor76D+ECMRPv/rawukEcNptnR50mHqvydEn0Qw8JzQ09YX/Us0SMHBvzLC8ei5ZIopzalvX=JvW8
-----END PGP PRIVATE KEY BLOCK-----

gpg_pkg_priv_keyname: gpg_pkg_key.pem

gpg_pkg_pub_key: |
```
(continues on next page)
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1
mQENBFciIfQBCADAPCtzx7I5Rl32escCMZsPzaEKWe7bIX1em4KCKkBoX47IG54b
w92PCE8Y1jF/9Uk2m3RKWwp3Ycllc7Ap3gj6VO4ysvVz28UbnhPxsIkOl6f2cq8qc
bYP7t5iw3mQqFMyNiYRt7wkJBPCpJc9FPNebL9vlZcN4zv0KQta+4alcWivvoP
4QIxE+/-trC6QRw2m2dHk6aAeq/J0Sc7ilZufwnNA71hf9SzRIwcFXMsLx4iLki
inNqW9c=
=s1CX
-----END PGP PUBLIC KEY BLOCK-----
gpg_pkg_pub_keyname: gpg_pkg_key.pub

env  Changed in version 2016.3.0.

A dictionary of environment variables to be utilized in creating the repository. Example:

```
- env:
  OPTIONS: 'ask-passphrase'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Use of OPTIONS on some platforms, for example: ask-passphrase, will require gpg-agent or similar to cache passphrases.

**Note:** This parameter is not used for making yum repositories.

use_passphrase  [False] New in version 2016.3.0.

Use a passphrase with the signing key presented in keyid. Passphrase is received from Pillar data which could be passed on the command line with pillar parameter. For example:

```
pillar='{ "gpg_passphrase" : "my_passphrase" }'
```

gnupghome  [/etc/salt/gpgkeys] New in version 2016.3.0.

Location where GPG related files are stored, used with 'keyid'

runas  [builder] New in version 2016.3.0.

User to create the repository as, and optionally sign packages.

**Note:** Ensure the user has correct permissions to any files and directories which are to be utilized.

timeout  [15.0] New in version 2016.3.4.

Timeout in seconds to wait for the prompt for inputting the passphrase.
23.19.234 salt.states.pkgng

Manage package remote repo using FreeBSD pkgng

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```python
pkgng_clients:
    pkgng.update_packaging_site:
        name: "http://192.168.0.2"
```

salt.states.pkgng.update_packaging_site(name)

23.19.235 salt.states.pkgrepo

Management of APT/DNF/YUM/Zypper package repos

States for managing software package repositories on Linux distros. Supported package managers are APT, DNF, YUM and Zypper. Here is some example SLS:

```python
base:
    pkgrepo.managed:
        - humanname: CentOS-$releasever - Base
        - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os
        - comments:
            - 'http://mirror.centos.org/centos/$releasever/os/$basearch/'
        - gpgcheck: 1
        - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

base:
    pkgrepo.managed:
        - humanname: Logstash PPA
        - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
        - dist: precise
        - file: /etc/apt/sources.list.d/logstash.list
        - keyid: 28B04E4A
        - keyserver: keyserver.ubuntu.com
        - require_in:
            - pkg: logstash

pkg.latest:
    - name: logstash
    - refresh: True

base:
    pkgrepo.managed:
        - humanname: deb-multimedia
        - name: deb http://www.deb-multimedia.org stable main
        - file: /etc/apt/sources.list.d/deb-multimedia.list
        - key_url: salt://deb-multimedia/files/marillat.pub

base:
    pkgrepo.managed:
```

(continues on next page)
- `humanname`: Google Chrome
- `name`: deb http://dl.google.com/linux/chrome/deb/ stable main
- `dist`: stable
- `file`: /etc/apt/sources.list.d/chrome-browser.list
- `require_in`
  - `pkg`: google-chrome-stable
- `gpgcheck`: 1
- `key_url`: https://dl-ssl.google.com/linux/linux_signing_key.pub

```yaml
base:
  pkgrepo.managed:
    - `ppa`: wolfnet/logstash
  pkgrepo.latest:
    - `name`: logstash
    - `refresh`: True
```

**Note:** On Ubuntu systems, the `python-software-properties` package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`.

On Ubuntu & Debian systems, the `python-apt` package is required to be installed. To check if this package is installed, run `dpkg -l python-apt`. `python-apt` will need to be manually installed if it is not present.

```yaml
hello-copr:
  pkgrepo.managed:
    - `copr`: mymindstorm/hello
  pkgrepo.installed:
    - `name`: hello
```

salt.states.pkgrepo.absent(name, **kwargs)

This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`

**name** The name of the package repo, as it would be referred to when running the regular package manager commands.

**FEDORA/REDHAT-SPECIFIC OPTIONS**

`copr` Use community packages outside of the main package repository.

New in version 3002.

```yaml
hello-copr:
  pkgrepo.absent:
    - `copr`: mymindstorm/hello
```

**UBUNTU-SPECIFIC OPTIONS**

`ppa` On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

```yaml
logstash-ppa:
  pkgrepo.absent:
    - `ppa`: wolfnet/logstash
```

`ppa_auth` For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be specified. This is required for matching if the name format uses the `ppa` specifier and is private (requires username/password to access, which is encoded in the URI).

```yaml
logstash-ppa_auth:
  pkgrepo.absent:
    - `ppa`: wolfnet/logstash
```
**logstash-ppa:**

```
pkgrepo.absent:
  - ppa: wolfnet/logstash
  - ppa_auth: username:password
```

**keyid** If passed, then the GPG key corresponding to the passed KeyID will also be removed.

**keyid_ppa** [False] If set to True, the GPG key's ID will be looked up from ppa.launchpad.net and removed, and the keyid argument will be ignored.

**Note:** This option will be disregarded unless the ppa argument is present.

salt.states.pkgrepo.managed(
    name, ppa=None, copr=None, **kwargs)

This state manages software package repositories. Currently, yum, apt, and zypper repositories are supported.

**YUM/DNF/ZYPPER-BASED SYSTEMS**

**Note:** One of baseurl or mirrorlist below is required. Additionally, note that this state is not presently capable of managing more than one repo in a single repo file, so each instance of this state will manage a single repo file containing the configuration for a single repo.

**name** This value will be used in two ways: Firstly, it will be the repo ID, as seen in the entry in square brackets (e.g. [foo]) for a given repo. Secondly, it will be the name of the file as stored in /etc/yum.repos.d (e.g. /etc/yum.repos.d/foo.conf).

**enabled** [True] Whether the repo is enabled or not. Can be specified as True/False or 1/0.

**disabled** [False] Included to reduce confusion due to APT's use of the disabled argument. If this is passed for a YUM/DNF/Zypper-based distro, then the reverse will be passed as enabled. For example passing disabled=True will assume enabled=False.

**copr** Fedora and RedHat based distributions only. Use community packages outside of the main package repository.

New in version 3002.

**humanname** This is used as the name value in the repo file in /etc/yum.repos.d (or /etc/zypp/repos.d for SUSE distros).

**baseurl** The URL to a yum repository

**mirrorlist** A URL which points to a file containing a collection of baseurls

**comments** Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (#) in front.

**gpgautoimport** Only valid for Zypper package manager. If set to True, automatically trust and import the new repository signing key. The key should be specified with gpgkey parameter. See details below.

Additional configuration values seen in YUM/DNF/Zypper repo files, such as gpgkey or gpgcheck, will be used directly as key-value pairs. For example:

```
foo:
  pkgrepo.managed:
    - humanname: Personal repo for foo
    - baseurl: https://mydomain.tld/repo/foo/$releasever/$basearch
    - gpgkey: file:///etc/pki/rpm-gpg/foo-signing-key
    - gpgcheck: 1
```

**APT-BASED SYSTEMS**

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set auto-
matically. You can override any of the below settings by simply setting them as you would normally.

For example:

```
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
```

### ppa_auth
For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.

```
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
  - ppa_auth: username:password
```

### name
On apt-based systems this must be the complete entry as it would be seen in the `sources.list` file. This can have a limited subset of components (e.g. `main`) which can be added/modifed with the `comps` option.

```
precise-repo:
pkgrepo.managed:
  - name: deb http://us.archive.ubuntu.com/ubuntu precise main
```

**Note:** The above example is intended as a more readable way of configuring the SLS, it is equivalent to the following:

```
deb http://us.archive.ubuntu.com/ubuntu precise main
```

### disabled
[False] Toggles whether or not the repo is used for resolving dependencies and/or installing packages.

### enabled
[True] Included to reduce confusion due to YUM/DNF/Zypper's use of the `enabled` argument. If this is passed for an APT-based distro, then the reverse will be passed as `disabled`. For example, passing `enabled=False` will assume `disabled=False`.

### architectures
On apt-based systems, `architectures` can restrict the available architectures that the repository provides (e.g. only `amd64`). `architectures` should be a comma-separated list.

### comps
On apt-based systems, `comps` dictate the types of packages to be installed from the repository (e.g. `main`, `nonfree`, ...). For purposes of this, `comps` should be a comma-separated list.

### file
The filename for the `*.list` that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages.

### dist
This dictates the release of the distro the packages should be built for (e.g. `unstable`). This option is rarely needed.

### keyid
The KeyID or a list of KeyIDs of the GPG key to install. This option also requires the `keyserver` option to be set.

### keyserver
This is the name of the keyserv er to retrieve GPG keys from. The `keyid` option must also be set for this option to work.

### key_url

**Note:** Use either `keyid/keyserver` or `key_url`, but not both.

### key_text
The string representation of the GPG key to install.

New in version 2018.3.0.

**Note:** Use either `keyid/keyserver`, `key_url`, or `key_text` but not more than one method.
consolidate  [False] If set to True, this will consolidate all sources definitions to the sources.list file, cleanup the now unused files, consolidate components (e.g. main) for the same URI, type, and architecture to a single line, and finally remove comments from the sources.list file. The consolidation will run every time the state is processed. The option only needs to be set on one repo managed by Salt to take effect.
clean_file  [False] If set to True, empty the file before configuring the defined repository

Note: Use with care. This can be dangerous if multiple sources are configured in the same file.

New in version 2015.8.0.
refresh  [True] If set to False this will skip refreshing the apt package database on Debian based systems.
refresh_db  [True] Deprecated since version 2018.3.0: Use refresh instead.
require_in  Set this to a list of pkg.installed or pkg.latest to trigger the running of apt-get update prior to attempting to install these packages. Setting a require in the pkg state will not work for this.

23.19.236  salt.states.portage_config

Management of Portage package configuration on Gentoo

A state module to manage Portage configuration on Gentoo

salt:
  - portage_config.flags:
    - use:
      - openssl

salt.states.portage_config.flags(name, use=None, accept_keywords=None, env=None, license=None, properties=None, unmask=False, mask=False)

Enforce the given flags on the given package or DEPEND atom.

Warning: In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

name  The name of the package or its DEPEND atom
use  A list of USE flags
accept_keywords  A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords
env  A list of environment files
license  A list of accepted licenses
properties  A list of additional properties
unmask  A boolean to unmask the package
mask  A boolean to mask the package
23.19.237 salt.states.ports

Manage software from FreeBSD ports

New in version 2014.1.0.

Note: It may be helpful to use a higher timeout when running a `ports.installed` state, since compiling the port may exceed Salt’s timeout.

```
salt -t 1200 '*' state.highstate
```

salt.states.ports.installed(name, options=None)

Verify that the desired port is installed, and that it was compiled with the desired options.

- **options** Make sure that the desired non-default options are set

**Warning:** Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous `make config`.

Example usage:

```
security/nmap:
  ports.installed:
    - options:
    - IPV6: off
```

23.19.238 salt.states.postgres_cluster

Management of PostgreSQL clusters

The `postgres_cluster` state module is used to manage PostgreSQL clusters. Clusters can be set as either absent or present

```
create cluster 9.3 main:
  postgres_cluster.present:
    - name: 'main'
    - version: '9.3'
```

salt.states.postgres_cluster.absent(version, name)

Ensure that the named cluster is absent

- **version** Version of the postgresql server of the cluster to remove
- **name** The name of the cluster to remove

New in version 2016.3.0.

salt.states.postgres_cluster.present(version, name, port=None, encoding=None, locale=None, datadir=None, allow_group_access=None, data_checksums=None, wal_segsze=None)

Ensure that the named cluster is present with the specified properties. For more information about all of these options see `man pg_createcluster(1)`

- **version** Version of the postgresql cluster
- **name** The name of the cluster
- **port** Cluster port
- **encoding** The character encoding scheme to be used in this database
locale  Locale with which to create cluster
datadir  Where the cluster is stored
allow_group_access  Allows users in the same group as the cluster owner to read all cluster files created by initdb
data_checksums  Use checksums on data pages
wal_segsiz  Set the WAL segment size, in megabytes

New in version 2016.3.0.

23.19.239  salt.states.postgres_database

Management of PostgreSQL databases

The postgres_database module is used to create and manage Postgres databases. Databases can be set as either absent or present

```
salt.states.postgres_database.absent(name, user=None, maintenance_db=None, 
db_password=None, db_host=None, db_port=None, 
db_user=None)
```

Ensure that the named database is absent
name  The name of the database to remove
db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default
user  System user all operations should be performed on behalf of

New in version 0.17.0.

```
salt.states.postgres_database.present(name, tablespace=None, encoding=None, 
lc_collate=None, lc_ctype=None, owner=None, 
owner_recuse=False, template=None, user=None, 
maintenance_db=None, db_password=None, 
db_host=None, db_port=None, db_user=None)
```

Ensure that the named database is present with the specified properties. For more information about all of these options see man createdb(1)
name  The name of the database to manage
tablespace  Default tablespace for the database
encoding  The character encoding scheme to be used in this database
lc_collate  The LC_COLLATE setting to be used in this database
lc_ctype  The LC_CTYPE setting to be used in this database
owner  The username of the database owner
owner_recuse  Recurse owner change to all relations in the database
template  The template database from which to build this database
user  System user all operations should be performed on behalf of
db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default

New in version 0.17.0.
23.19.240 salt.states.postgres_extension

Management of PostgreSQL extensions

A module used to install and manage PostgreSQL extensions.

```
adminpack:
  postgres_extension.present
```

New in version 2014.7.0.

```
salt.states.postgres_extension.absent(name, if_exists=None, restrict=None, cascade=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)
```

Ensure that the named extension is absent.

- **name** Extension name of the extension to remove
- **if_exists** Add if exist slug
- **restrict** Add restrict slug
- **cascade** Drop on cascade
- **user** System user all operations should be performed on behalf of
- **maintenance_db** Database to act on
- **db_user** Database username if different from config or default
- **db_password** User password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default

```
salt.states.postgres_extension.present(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)
```

Ensure that the named extension is present.

---

**Note:** Before you can use the state to load an extension into a database, the extension’s supporting files must be already installed.

For more information about all of these options see CREATE EXTENSION SQL command reference in the PostgreSQL documentation.

- **name** The name of the extension to be installed
- **if_not_exists** Add an IF NOT EXISTS parameter to the DDL statement
- **schema** Schema to install the extension into
- **ext_version** Version to install
- **from_version** Old extension version if already installed
- **user** System user all operations should be performed on behalf of
- **maintenance_db** Database to act on
- **db_user** Database username if different from config or default
- **db_password** User password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default
23.19.241  salt.states.postgres_group

Management of PostgreSQL groups (roles)

The postgres_group module is used to create and manage Postgres groups.

```python
frank:
    postgres_group.present
```

salt.states.postgres_group.absent(name, user=None, maintenance_db=None, 
    db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is absent

- **name**: The groupname of the group to remove
- **user**: System user all operations should be performed on behalf of

New in version 0.17.0.

- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

salt.states.postgres_group.present(name, createdb=None, createroles=None, encrypted=None, 
    superuser=None, inherit=None, replication=None, password=None, refresh_password=None, 
    groups=None, user=None, maintenance_db=None, 
    db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is present with the specified privileges

- **name**: The name of the group to manage
- **createdb**: Is the group allowed to create databases?
- **createroles**: Is the group allowed to create other roles/users
- **encrypted**: How the password should be stored.

If encrypted is None, True, or md5, it will use PostgreSQL's MD5 algorithm.

If encrypted is False, it will be stored in plaintext.

If encrypted is scram-sha-256, it will use the algorithm described in RFC 7677.

Changed in version 3003: Prior versions only supported True and False

- **login**: Should the group have login perm
- **inherit**: Should the group inherit permissions
- **superuser**: Should the new group be a "superuser"
- **replication**: Should the new group be allowed to initiate streaming replication
- **password**: The group's password. It can be either a plain string or a pre-hashed password:

```
'md5{MD5OF{{password}{role}}}'
'sCRAM-SHA-256${iterations}:${salt}${stored_key}:${server_key}'
```

If encrypted is not False, then the password will be converted to the appropriate format above, if not already. As a consequence, passwords that start with "md5" or "SCRAM-SHA-256" cannot be used.

- **refresh_password**: Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.
If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.

- **groups**: A string of comma separated groups the group should be in
- **user**: System user all operations should be performed on behalf of

New in version 0.17.0.
- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

### 23.19.242 salt.states.postgres_initdb

**Initialization of PostgreSQL data directory**

The postgres_initdb module is used to initialize the postgresql data directory.

New in version 2016.3.0.

```yaml
pgsql-data-dir:
pgresql_initdb.present:
  - name: /var/lib/pgsql/data
  - auth: password
  - user: postgres
  - password: strong_password
  - encoding: UTF8
  - locale: C
  - runas: postgres
  - checksums: True
  - waldir: /var/postgresql/wal
```

**salt.states.postgres_initdb.present**(*name*, *user=None*, *password=None*, *auth='password'*, *encoding='UTF8'*, *locale=None*, *runas=None*, *waldir=None*, *checksums=False*)

Initialize the PostgreSQL data directory
- **name**: The name of the directory to initialize
- **user**: The database superuser name
- **password**: The password to set for the postgres user
- **auth**: The default authentication method for local connections
- **encoding**: The default encoding for new databases
- **locale**: The default locale for new databases
- **waldir**: The transaction log (WAL) directory (default is to keep WAL inside the data directory)

New in version 2019.2.0.
- **checksums**: If True, the cluster will be created with data page checksums.

**Note**: Data page checksums are supported since PostgreSQL 9.3.

New in version 2019.2.0.
- **runas**: The system user the operation should be performed on behalf of
23.19.243 salt.states.postgres_language

Management of PostgreSQL languages

The postgres_language module is used to create and manage Postgres languages. Languages can be set as either absent or present.

New in version 2016.3.0.

```yaml
plpgsql:
  postgres_language.present:
    - maintenance_db: testdb

plpgsql:
  postgres_language.absent:
    - maintenance_db: testdb
```

salt.states.postgres_language.absent(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is absent in the specified database.

- name: The name of the language to remove
- maintenance_db: The name of the database in which the language is to be installed
- user: System user all operations should be performed on behalf of
- db_user: Database username if different from config or default
- db_password: User password if any password for a specified user
- db_host: Database host if different from config or default
- db_port: Database port if different from config or default

salt.states.postgres_language.present(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is present in the specified database.

- name: The name of the language to install
- maintenance_db: The name of the database in which the language is to be installed
- user: System user all operations should be performed on behalf of
- db_user: Database username if different from config or default
- db_password: User password if any password for a specified user
- db_host: Database host if different from config or default
- db_port: Database port if different from config or default

23.19.244 salt.states.postgres_privileges

Management of PostgreSQL Privileges

The postgres_privileges module is used to manage Postgres privileges. Privileges can be set as either absent or present.

Privileges can be set on the following database object types:

- database
- schema
- tablespace
- table
• sequence
• language
• group

Setting the grant option is supported as well.

New in version 2016.3.0.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>baruwa:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| **postgres_privileges.present:** | object_name: awl
- object_type: table
- privileges:
  - SELECT
  - INSERT
  - DELETE
  - grant_option: False
  - prepend: public
  - maintenance_db: testdb |
| **andrew:** | |
| **postgres_privileges.present:** | object_name: admins
- object_type: group
- grant_option: False
- maintenance_db: testdb |
| **baruwa:** | |
| **postgres_privileges.absent:** | object_name: awl
- object_type: table
- privileges:
  - SELECT
  - INSERT
  - DELETE
  - prepend: public
  - maintenance_db: testdb |
| **andrew:** | |
| **postgres_privileges.absent:** | object_name: admins
- object_type: group
- maintenance_db: testdb |

**salt.states.postgres_privileges.absent**(name, object_name, object_type, privileges=None, prepend='public', maintenance_db=None, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Revoke the requested privilege(s) on the specified object(s)

**name** Name of the role whose privileges should be revoked

**object_name** Name of the object on which the revoke is to be performed

**object_type** The object type, which can be one of the following:
- table
- sequence
- schema
- tablespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>baruwa:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| **postgres_privileges.absent:** | object_name: awl
- object_type: table
- privileges:
  - SELECT
  - INSERT
  - DELETE
  - prepend: public
  - maintenance_db: testdb |
| **andrew:** | |
| **postgres_privileges.absent:** | object_name: admins
- object_type: group
- maintenance_db: testdb |
View permissions should specify `object_type: table`.

**privileges** Comma separated list of privileges to revoke, from the list below:

- INSERT
- CREATE
- TRUNCATE
- CONNECT
- TRIGGER
- SELECT
- USAGE
- TEMPORARY
- UPDATE
- EXECUTE
- REFERENCES
- DELETE
- ALL

Note: privileges should not be set when revoking group membership

**prepend** Table and Sequence object types live under a schema so this should be provided if the object is not under the default `public` schema

**maintenance_db** The name of the database in which the language is to be installed

**user** System user all operations should be performed on behalf of

**db_user** database username if different from config or default

**db_password** user password if any password for a specified user

**db_host** Database host if different from config or default

**db_port** Database port if different from config or default

```python
salt.states.postgres_privileges.present(name, object_name, object_type, privileges=None, grant_option=None, prepend='public', maintenance_db=None, user=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Grant the requested privilege(s) on the specified object to a role

**name** Name of the role to which privileges should be granted

**object_name** Name of the object on which the grant is to be performed. 'ALL' may be used for objects of type 'table' or 'sequence'.

**object_type** The object type, which can be one of the following:

- table
- sequence
- schema
- tablespace
- language
- database
- group
- function

View permissions should specify `object_type: table`.

**privileges** List of privileges to grant, from the list below:

- INSERT
- CREATE
- TRUNCATE
- CONNECT
- TRIGGER
- SELECT
- USAGE
- TEMPORARY
- UPDATE
- EXECUTE
- REFERENCES
- DELETE
- ALL
Salt Documentation, Release 3003.1

- USAGE
- TEMPORARY
- UPDATE
- EXECUTE
- REFERENCES
- DELETE
- ALL

note privileges should not be set when granting group membership
grant_option If grant_option is set to True, the recipient of the privilege can in turn grant it to others
prepend Table and Sequence object types live under a schema so this should be provided if the object is not
under the default public schema
maintenance_db The name of the database in which the language is to be installed
user System user all operations should be performed on behalf of
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

23.19.245 salt.states.postgres_schema

Management of PostgreSQL schemas

The postgres_schemas module is used to create and manage Postgres schemas.

```python
public:
    postgres_schema.present 'dbname' 'name'
```

salt.states.postgres_schema.absent(dbname, name, user=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is absent.
dbname The database's name will work on
name The name of the schema to remove
user system user all operations should be performed on behalf of
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_schema.present(dbname, name, owner=None, user=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is present in the database.
dbname The database's name will work on
name The name of the schema to manage
user system user all operations should be performed on behalf of
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
23.19.246 salt.states.postgres_tablespace

Management of PostgreSQL tablespace

A module used to create and manage PostgreSQL tablespaces.

```
ssd-tablespace:
  postgres_tablespace.present:
    - name: indexes
    - directory: /mnt/ssd-data
```

New in version 2015.8.0.

```
salt.states.postgres_tablespace.absent(name, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)
```

Ensure that the named tablespace is absent.

- **name** The name of the tablespace to remove
- **user** System user all operations should be performed on behalf of
- **maintenance_db** Database to act on
- **db_user** Database username if different from config or default
- **db_password** User password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default

```
salt.states.postgres_tablespace.present(name, directory, options=None, owner=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Ensure that the named tablespace is present with the specified properties. For more information about all of these options run `man 7 create_tablespace`.

- **name** The name of the tablespace to create/manage.
- **directory** The directory where the tablespace will be located, must already exist
- **options** A dictionary of options to specify for the tablespace. Currently, the only tablespace options supported are `seq_page_cost` and `random_page_cost`. Default values are shown in the example below:

```
my_space:
  postgres_tablespace.present:
    - directory: /srv/my_tablespace
    - options:
      seq_page_cost: 1.0
      random_page_cost: 4.0
```

- **owner** The database user that will be the owner of the tablespace. Defaults to the user executing the command (i.e. the `user` option)
- **user** System user all operations should be performed on behalf of
- **maintenance_db** Database to act on
- **db_user** Database username if different from config or default
- **db_password** User password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default
salt.states.postgres_user

Management of PostgreSQL users (roles)

The postgres_users module is used to create and manage Postgres users.

```python
frank:
  postgres_user.present
```

salt.states.postgres_user.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is absent

- **name**: The username of the user to remove
- **user**: System user all operations should be performed on behalf of

  New in version 0.17.0.

- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

salt.states.postgres_user.present(name, createdb=None, createroles=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, default_password=None, refresh_password=None, valid_until=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

- **name**: The name of the system user to manage.
- **createdb**: Is the user allowed to create databases?
- **createroles**: Is the user allowed to create other users?
- **encrypted**: How the password should be stored.

  - If encrypted is `None`, `True`, or `md5`, it will use PostgreSQL's MD5 algorithm.
  - If encrypted is `False`, it will be stored in plaintext.
  - If encrypted is `scram-sha-256`, it will use the algorithm described in RFC 7677.

  Changed in version 3003: Prior versions only supported `True` and `False`

- **login**: Should the group have login perm
- **inherit**: Should the group inherit permissions
- **superuser**: Should the new user be a "superuser"
- **replication**: Should the new user be allowed to initiate streaming replication
- **password**: The user's password. It can be either a plain string or a pre-hashed password:

  
  ```
  'md5{MD5OF{{password}{role}}}'
  'SCRAM-SHA-256${iterations}:${salt}${stored_key}:${server_key}'
  ```

  If encrypted is not `False`, then the password will be converted to the appropriate format above, if not already. As a consequence, passwords that start with "md5" or "SCRAM-SHA-256" cannot be used.

- **default_password**: The password used only when creating the user, unless password is set.

  New in version 2016.3.0.

- **refresh_password**: Password refresh flag

  Boolean attribute to specify whether to password comparison check should be performed.
If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.

valid_until A date and time after which the role's password is no longer valid.
groups A string of comma separated groups the user should be in
user System user all operations should be performed on behalf of

New in version 0.17.0.

db_user Postgres database username, if different from config or default.
db_password Postgres user's password, if any password, for a specified db_user.
db_host Postgres database host, if different from config or default.
db_port Postgres database port, if different from config or default.

23.19.248 salt.states.powerpath

Powerpath configuration support

Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.

key:
  powerpath.license_present: []

salt.states.powerpath.license_absent(name)
Ensures that the specified PowerPath license key is absent on the host.
  name The license key to ensure is absent

codeauthor Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>
maturity new
depends napalm
platform unix

23.19.249 salt.states.probes

Network Probes

Configure RPM (JunOS)/SLA (Cisco) probes on the device via NAPALM proxy.
Dependencies

• napalm probes management module

New in version 2016.11.0.

salt.states.probes.managed(name, probes, defaults=None)

Ensure the networks device is configured as specified in the state SLS file. Probes not specified will be removed, while probes not configured as expected will trigger config updates.

Parameters

• probes -- Defines the probes as expected to be configured on the device. In order to ease the configuration and avoid repeating the same parameters for each probe, the next parameter (defaults) can be used, providing common characteristics.

• defaults -- Specifies common parameters for the probes.

SLS Example:

```yaml
rpmprobes:
  probes.managed:
    - probes:
      probe_name1:
        probe1_test1:
          source: 192.168.0.2
          target: 192.168.0.1
        probe1_test2:
          target: 172.17.17.1
        probe1_test3:
          target: 8.8.8.8
          probe_type: http-ping
      probe_name2:
        probe2_test1:
          test_interval: 100
      - defaults:
        target: 10.10.10.10
        probe_count: 15
        test_interval: 3
        probe_type: icmp-ping
```

In the probes configuration, the only mandatory attribute is target (specified either in probes configuration, either in the defaults dictionary). All the other parameters will use the operating system defaults, if not provided:

• source - Specifies the source IP Address to be used during the tests. If not specified will use the IP Address of the logical interface loopback0.

• target - Destination IP Address.

• probe_count - Total number of probes per test (1..15). System defaults: 1 on both JunOS & Cisco.

• probe_interval - Delay between tests (0..86400 seconds). System defaults: 3 on JunOS, 5 on Cisco.

• probe_type - Probe request type. Available options:
  - icmp-ping
  - tcp-ping
  - udp-ping

Using the example configuration above, after running the state, on the device will be configured 4 probes, with the following properties:

```yaml
probe_name1:
  probe1_test1:
    source: 192.168.0.2
    target: 192.168.0.1
```

(continues on next page)
23.19.250  salt.states.process

Process Management

Ensure a process matching a given pattern is absent.

```
httpd-absent:
  process.absent:
    - name: apache2
```

salt.states.process.absent(name, user=None, signal=None)
Ensures that the named command is not running.
name The pattern to match.
user The user to which the process belongs
signal Signal to send to the process(es).

23.19.251  salt.states.proxy

Allows you to manage proxy settings on minions

Setup proxy settings on minions

```
192.168.1.4:
  proxy.managed:
    - port: 3128
    - bypass_domains:
      - localhost
      - 127.0.0.1
```

salt.states.proxy.managed(name, port, services=None, user=None, password=None, bypass_domains=None, network_service='Ethernet')
Manages proxy settings for this minion
name The proxy server to use
port  The port used by the proxy server
services  A list of the services that should use the given proxy settings, valid services include http, https and ftp. If no service is given all of the valid services will be used.
user  The username to use for the proxy server if required
password  The password to use for the proxy server if required
bypass_domains  An array of the domains that should bypass the proxy
network_service  The network service to apply the changes to, this only necessary on macOS

23.19.252  salt.states.pushover

Send a message to PushOver

This state is useful for sending messages to PushOver during state runs.

New in version 2015.5.0.

```yaml
pushover-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
    - message: 'This state was executed successfully.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```yaml
pushover: token: peWcBm059HrZG15peWcBm059HrZG15
```

```python
salt.states.pushover.post_message(name, user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)
```

Send a message to a PushOver channel.

```yaml
pushover-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
    - message: This state was executed successfully.
```

The following parameters are required:
name  The unique name for this event.
user  The user or group of users to send the message to. Must be ID of user, not name or email address.
message  The message that is to be sent to the PushOver channel.
The following parameters are optional:
title  The title to use for the message.
device  The device for the user to send the message to.
priority  The priority for the message.
expire  The message should expire after specified amount of seconds.
retry  The message should be resent this many times.
token The token for PushOver to use for authentication, if not specified in the configuration options of master or minion.

23.19.253 salt.states.pyenv

Managing python installations with pyenv

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to /usr/local/pyenv, otherwise it will be installed to the users ~/.pyenv directory. To make pyenv available in the shell you may need to add the pyenv/shims and pyenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access pyenv then you will need to add pyenv_ROOT to their environment.

This is how a state configuration could look like:

```yaml
pyenv-deps:
  pkg.installed:
    - pkgs:
        - make
        - build-essential
        - libssl-dev
        - zlib1g-dev
        - libbz2-dev
        - libreadline-dev
        - libsqlite3-dev
        - wget
        - curl
        - llvm

python-2.6:
  pyenv.absent:
    - require:
      - pkg: pyenv-deps

python-2.7.6:
  pyenv.installed:
    - default: True
    - require:
      - pkg: pyenv-deps
```

Note: Git needs to be installed and available via PATH if pyenv is to be installed automatically by the module.

salt.states.pyenv.absent(name, user=None)

Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.

name The version of python to uninstall
user: None The user to run pyenv as.

New in version 0.17.0.
New in version 0.16.0.

salt.states.pyenv.install_pyenv(name, user=None)

Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.
Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.

user: None The user to run pyenv as.

salt.states.pyenv.installed(name, default=False, user=None)

Verify that the specified python is installed with pyenv. pyenv is installed if necessary.

name The version of python to install

default [False] Whether to make this python the default.

user: None The user to run pyenv as.

New in version 0.17.0.
New in version 0.16.0.

23.19.254 salt.states.pyrax_queues

Manage Rackspace Queues

New in version 2015.5.0.

Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.

This module uses pyrax, which can be installed via package, or pip. This module is greatly inspired by boto_* modules from SaltStack code source.

```yaml
myqueue:
  pyrax_queues.present:
    - provider: my-pyrax

myqueue:
  pyrax_queues.absent:
    - provider: my-pyrax
```

salt.states.pyrax_queues.absent(name, provider)

Ensure the named Rackspace queue is deleted.

name Name of the Rackspace queue.

provider Salt Cloud provider

salt.states.pyrax_queues.present(name, provider)

Ensure the RackSpace queue exists.

name Name of the Rackspace queue.

provider Salt Cloud Provider

23.19.255 salt.states.quota

Management of POSIX Quotas

The quota can be managed for the system:

```yaml
/:  
  quota.mode:
    mode: off  
    quotatype: user
```

salt.states.quota.mode(name, mode, quotatype)

Set the quota for the system
name  The filesystem to set the quota mode on
mode  Whether the quota system is on or off
quotatype  Must be user or group

23.19.256  salt.states.rabbitmq_cluster

Manage RabbitMQ Clusters

Example:

rabbit@rabbit.example.com:
rabbitmq_cluster.join:
   - user: rabbit
   - host: rabbit.example.com

salt.states.rabbitmq_cluster.join(name, host, user='rabbit', ram_node=None, runas='root')
This function is an alias of joined.
   Ensure the current node joined to a cluster with node user@host
   name  Irrelevant, not used (recommended: user@host)
   user  The user of node to join to (default: rabbit)
   host  The host of node to join to
   ram_node  Join node as a RAM node
   runas  The user to run the rabbitmq command as

salt.states.rabbitmq_cluster.joined(name, host, user='rabbit', ram_node=None, runas='root')
   Ensure the current node joined to a cluster with node user@host
   name  Irrelevant, not used (recommended: user@host)
   user  The user of node to join to (default: rabbit)
   host  The host of node to join to
   ram_node  Join node as a RAM node
   runas  The user to run the rabbitmq command as

23.19.257  salt.states.rabbitmq_plugin

Manage RabbitMQ Plugins

New in version 2014.1.0.

Example:

some_plugin:
rabbitmq_plugin.enabled: []

salt.states.rabbitmq_plugin.disabled(name, runas=None)
   Ensure the RabbitMQ plugin is disabled.
   name  The name of the plugin
   runas  The user to run the rabbitmq-plugin command as

salt.states.rabbitmq_plugin.enabled(name, runas=None)
   Ensure the RabbitMQ plugin is enabled.
   name  The name of the plugin
   runas  The user to run the rabbitmq-plugin command as
23.19.258 salt.states.rabbitmq_policy

Manage RabbitMQ Policies

maintainer Benn Eichhorn <benn@getlocalmeasure.com>
maturity new
platform all

Example:

```yaml
rabbit_policy:
  rabbitmq_policy.present:
    - name: HA
    - pattern: '.*'
    - definition: '{"ha-mode": "all"}'
```

salt.states.rabbitmq_policy.absent(name, vhost='/', runas=None)
Ensure the named policy is absent

Reference: http://www.rabbitmq.com/ha.html
name The name of the policy to remove
runas Name of the user to run the command as

salt.states.rabbitmq_policy.present(name, pattern, definition, priority=0, vhost='/', runas=None, apply_to=None)
Ensure the RabbitMQ policy exists.

Reference: http://www.rabbitmq.com/ha.html
name Policy name
pattern A regex of queues to apply the policy to
definition A json dict describing the policy
priority Priority (defaults to 0)
vhost Virtual host to apply to (defaults to '/')
runas Name of the user to run the command as
apply_to Apply policy to 'queues', 'exchanges' or 'all' (default to 'all')

23.19.259 salt.states.rabbitmq_upstream

Manage RabbitMQ Upstreams

Example:

```yaml
rabbit_upstream:
  rabbitmq_upstream.present:
    - name: upstream_1
    - uri: amqp://my_user:my_password@rabbitmq_host
    - trust_user_id: True
    - ack_mode: on-confirm
    - max_hops: 1
```

New in version 3000.

salt.states.rabbitmq_upstream.absent(name, runas=None)
Ensure the named upstream is absent.

Parameters

- **name (str)** -- The name of the upstream to remove
**runas** *(str)* -- User to run the command

New in version 3000.

```python
salt.states.rabbitmq_upstream.present(name, uri, prefetch_count=None, reconnect_delay=None, ack_mode=None, trust_user_id=None, exchange=None, max_hops=None, expires=None, message_ttl=None, ha_policy=None, queue=None, runas=None)
```

Ensure the RabbitMQ upstream exists.

**Parameters**

- **name** *(str)* -- The name of the upstream connection
- **uri** *(str)* -- The URI to connect to. If upstream is a cluster and can have several URIs, you can enter them here separated by spaces. Examples: `- amqp://user:password@server_name - amqp://user:password@server_name/vhost` When connecting with SSL, several URI-parameters need also be specified: `- cacert-file=/path/to/cacert.pem - certfile=/path/to/cert.pem - keyfile=/path/to/key.pem - verify=verify_peer - fail_if_no_peer_cert=true | false - auth_mechanism=external` Example: `- amqp://user:password@server_name?cacertfile=/path/to/cacert.pem&certfile=/path/to/cert.pem&keyfile=/path/to/key.pem&verify=verify_peer - amqp://server-name?cacertfile=/path/to/cacert.pem&certfile=/path/to/cert.pem&keyfile=/path/to/key.pem&verify=verify_peer&fail_if_no_peer_cert=true&auth_mechanism=external`
- **prefetch_count** *(int)* -- Maximum number of unacknowledged messages that may be in flight over a federation link at one time. Default: 1000
- **reconnect_delay** *(int)* -- Time in seconds to wait after a network link goes down before attempting reconnection. Default: 5
- **ack_mode** *(str)* -- The following values are allowed: on-confirm: Messages are acknowledged to the upstream broker after they have been confirmed downstream. Handles network errors and broker failures without losing messages. The slowest option, and the default. on-publish: Messages are acknowledged to the upstream broker after they have been published downstream. Handles network errors without losing messages, but may lose messages in the event of broker failures. no-ack: Message acknowledgements are not used. The fastest option, but you may lose messages in the event of network or broker failures.
- **trust_user_id** *(bool)* -- Set True to preserve the "user-id" field across a federation link, even if the user-id does not match that used to republish the message. Set to False to clear the "user-id" field when messages are federated. Only set this to True if you trust the upstream broker not to forge user-ids.
- **exchange** *(str)* -- The name of the upstream exchange. Default is to use the same name as the federated exchange.
- **max_hops** *(int)* -- Maximum number of federation links that messages can traverse before being dropped. Defaults to 1 if not set.
- **expires** *(int)* -- Time in milliseconds that the upstream should remember about this node for. After this time all upstream state will be removed. Set to None (Default) to mean "forever".
- **message_ttl** *(int)* -- Time in milliseconds that undelivered messages should be held upstream when there is a network outage or backlog. Set to None (default) to mean "forever".
- **ha_policy** *(str)* -- Determines the "x-ha-policy"-argument for the upstream queue for a federated exchange. Default is "none" meaning the queue is not HA.
- **queue** *(str)* -- The name of the upstream queue. Default is to use the same name as the federated queue.

New in version 3000.
23.19.260 salt.states.rabbitmq_user

Manage RabbitMQ Users

Example:

```
rabbit_user:
    rabbitmq_user.present:
      - password: password
      - force: True
      - tags:
        - monitoring
        - user
      - perms:
        - '/':
          - '.*'
          - '.*'
          - '.*'
      - runas: rabbitmq
```

```
salt.states.rabbitmq_user.absent(name, runas=None)
    Ensure the named user is absent
    name  The name of the user to remove
    runas User to run the command
```

```
salt.states.rabbitmq_user.present(name, password=None, force=False, tags=None, perms=(), runas=None)
    Ensure the RabbitMQ user exists.
    name  User name
    password User's password, if one needs to be set
    force  If user exists, forcibly change the password
    tags  Optional list of tags for the user
    perms  A list of dicts with vhost keys and 3-tuple values
    runas Name of the user to run the command
```

23.19.261 salt.states.rabbitmq_vhost

Manage RabbitMQ Virtual Hosts

Example:

```
virtual_host:
    rabbitmq_vhost.present:
      - user: rabbit_user
      - conf: .*
      - write: .*
      - read: .*
```

```
salt.states.rabbitmq_vhost.absent(name)
    Ensure the RabbitMQ Virtual Host is absent
    name  Name of the Virtual Host to remove
    runas User to run the command
    
    Deprecated since version 2015.8.0.
```
salt.states.rabbitmq_vhost.present(name)
Ensure the RabbitMQ VHost exists.
name VHost name
user Initial user permission to set on the VHost, if present
  Deprecated since version 2015.8.0.
owner Initial owner permission to set on the VHost, if present
  Deprecated since version 2015.8.0.
conf Initial conf string to apply to the VHost and user. Defaults to .*
  Deprecated since version 2015.8.0.
write Initial write permissions to apply to the VHost and user. Defaults to .*
  Deprecated since version 2015.8.0.
read Initial read permissions to apply to the VHost and user. Defaults to .*
  Deprecated since version 2015.8.0.
runas Name of the user to run the command
  Deprecated since version 2015.8.0.

23.19.262 salt.states.rbac_solaris

Management of Solaris RBAC
maintainer Jorge Schrauwen <sjorge@blackdot.be>
maturity new
depends rbac_solaris,solaris_user
platform solaris,illumos
New in version 2016.11.0.

```
sjorge:
  rbac.managed:
    - roles:
        - netcfg
    - profiles:
        - System Power
    - authorizations:
        - solaris.audit.*
```

salt.states.rbac_solaris.managed(name, roles=None, profiles=None, authorizations=None)
Manage RBAC properties for user
name [string] username
roles [list] list of roles for user
profiles [list] list of profiles for user
authorizations [list] list of authorizations for user

Warning: All existing roles, profiles and authorizations will be replaced! An empty list will remove everything.
Set the property to None to not manage it.
23.19.263 salt.states.rbenv

Managing Ruby installations with rbenv

This module is used to install and manage ruby installations with rbenv and the ruby-build plugin. Different versions of ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which rbenv will need to compile the versions of ruby. If your version of ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: https://github.com/rbenv/ruby-build/wiki

If rbenv is run as the root user then it will be installed to /usr/local/rbenv, otherwise it will be installed to the users ~/.rbenv directory. To make rbenv available in the shell you may need to add the rbenv/shims and rbenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access rbenv then you will need to add RBENV_ROOT to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

```
ruby-1.9.3-p429:
  rbenv.absent:
    require:
      - pkg: rbenv-deps

ruby-2.0.0-p598:
  rbenv.installed:
    default: True
    require:
      - pkg: rbenv-deps
```

salt.states.rbenv.absent(name, user=None)

Verify that the specified ruby is not installed with rbenv. Rbenv is installed if necessary.

name  The version of ruby to uninstall
user: None  The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

salt.states.rbenv.install_rbenv(name, user=None)

Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any rubies.
Use the rbenv.root configuration option to set the path for rbenv if you want a system wide install that is not in a user home dir.

user: None The user to run rbenv as.

salt.states.rbenv-installed(name, default=False, user=None)
Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.

name The version of ruby to install

default [False] Whether to make this ruby the default.

user: None The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

23.19.264 salt.states.rdp

Manage RDP Service on Windows servers

salt.states.rdp-disabled(name)
Disable the RDP service

salt.states.rdp-enabled(name)
Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration

23.19.265 salt.states.redismod

Management of Redis server

New in version 2014.7.0.

depends

- redis Python module

configuration See salt.modules.redis for setup instructions.

<table>
<thead>
<tr>
<th>key_in_redis</th>
</tr>
</thead>
<tbody>
<tr>
<td>redis.string</td>
</tr>
<tr>
<td>- value: string data</td>
</tr>
</tbody>
</table>

The redis server information specified in the minion config file can be overridden in states using the following arguments: host, post, db, password.

<table>
<thead>
<tr>
<th>key_in_redis</th>
</tr>
</thead>
<tbody>
<tr>
<td>redis.string</td>
</tr>
<tr>
<td>- value: string data</td>
</tr>
<tr>
<td>- host: localhost</td>
</tr>
<tr>
<td>- port: 6379</td>
</tr>
<tr>
<td>- db: 0</td>
</tr>
<tr>
<td>- password: somuchkittycat</td>
</tr>
</tbody>
</table>

salt.states.redismod.absent(name, keys=None, **connection_args)

Ensure key absent from redis

name Key to ensure absent from redis

keys list of keys to ensure absent, name will be ignored if this is used
salt.states.redismod.slaveof(name, sentinel_host=None, sentinel_port=None, sentinel_password=None, **connection_args)

Set this redis instance as a slave.

New in version 2016.3.0.

name Master to make this a slave of
sentinel_host Ip of the sentinel to check for the master
sentinel_port Port of the sentinel to check for the master

salt.states.redismod.string(name, value, expire=None, expireat=None, **connection_args)

Ensure that the key exists in redis with the value specified

name Redis key to manage
value Data to persist in key
expire Sets time to live for key in seconds
expireat Sets expiration time for key via UNIX timestamp, overrides expire

23.19.266 salt.states.reg

Manage the Windows registry

Many python developers think of registry keys as if they were python keys in a dictionary which is not the case. The windows registry is broken down into the following components:

Hives

This is the top level of the registry. They all begin with HKEY.

- HKEY_CLASSES_ROOT (HKCR)
- HKEY_CURRENT_USER(HKCU)
- HKEY_LOCAL_MACHINE (HKLM)
- HKEY_USER (HKU)
- HKEY_CURRENT_CONFIG

Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

When passing the hivekey values they must be quoted correctly depending on the backslashes being used (\ vs \\). The way backslashes are handled in the state file is different from the way they are handled when working on the CLI. The following are valid methods of passing the hivekey:

Using single backslashes: HKLMSOFTWAREPython 'HKLMSOFTWAREPython'

Using double backslashes: "HKLM\SOFTWARE\Python"
Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. The name is (Default) with a displayed value of (value not set). The actual value is Null.

Example

The following example is taken from the windows startup portion of the registry:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run]
"RTHDVCPL"="C:\\Program Files\\Realtek\\Audio\\HDA\\RtkNGUI64.exe" -s
"NvBackend"="C:\\Program Files (x86)\\NVIDIA Corporation\\Update Core\\NvBackend. exe"
"BTMTrayAgent"="rundll32.exe "C:\\Program Files (x86)\\Intel\\Bluetooth\\btmshell. dll",TrayApp"
```

In this example these are the values for each:

Hive: HKEY_LOCAL_MACHINE
Key and subkeys: SOFTWARE\Microsoft\Windows\CurrentVersion\Run
Value:
• There are 3 value names: RTHDVCPL, NvBackend, and BTMTrayAgent
• Each value name has a corresponding value

```
salt.states.reg.absent(name, vname=None, use_32bit_registry=False)
```

Ensure a registry value is removed. To remove a key use key_absent.

Parameters
• **name** (str) -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:

  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include:
  – HKEY_CURRENT_USER or HKCU
  – HKEY_LOCAL_MACHINE or HKLM
  – HKEY_USERS or HKU
• **vname** (str) -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value
• **use_32bit_registry** (bool) -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

Returns A dictionary showing the results of the registry operation.

Return type dict

CLI Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':
    reg.absent
    - vname: version
```

In the above example the value named version will be removed from the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive. If vname was not passed, the (Default) value would be deleted.

```
salt.states.reg.key_absent(name, use_32bit_registry=False)
```

New in version 2015.5.4.
Ensure a registry key is removed. This will remove the key, subkeys, and all value entries.

**Parameters**

- **name (str)** -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following:
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USERS or HKU

- **use_32bit_registry (bool)** -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

**Returns** A dictionary showing the results of the registry operation.

**Return type** dict

**CLI Example:**

The following example will delete the SOFTWARE\DeleteMe key in the HKEY_LOCAL_MACHINE hive including all its subkeys and value pairs.

```python
remove_key_demo:
    reg.key_absent:
        - name: HKEY_CURRENT_USER\SOFTWARE\DeleteMe
```

In the above example the path is interpreted as follows:

- HKEY_CURRENT_USER is the hive
- SOFTWARE\DeleteMe is the key

**salt.states.reg.present** (name, vname=None, vdata=None, vtype='REG_SZ', use_32bit_registry=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False)

Ensure a registry key or value is present.

**Parameters**

- **name (str)** -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:
  
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include:
  - HKEY_CURRENT_USER or HKCU
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_USERS or HKU

- **vname (str)** -- The name of the value you’d like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

- **vdata (str, int, list, bytes)** -- The value you'd like to set. If a value name (vname) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

The type of data this parameter expects is determined by the value type specified in vtype. The correspondence is as follows:

- REG_BINARY: Binary data (str in Py2, bytes in Py3)
- REG_DWORD: int
- REG_EXPAND_SZ: str
- REG_MULTI_SZ: list of str
- REG_QWORD: int
- REG_SZ: str

**Note:** When setting REG_BINARY, string data will be converted to binary automatically. To pass binary data, use the built-in yaml tag `!!binary` to denote the actual binary characters. For example, the following lines will both set the same data in the registry:
- vdata: Salty Test
- vdata: !!binary U2FsdHkgVGVzdA==

For more information about the `!!binary` tag see [here](#).

---

**Note:** The type for the (Default) value is always `REG_SZ` and cannot be changed. This parameter is optional. If not passed, the Key will be created with no associated item/value pairs.

- **vtype (str)** -- The value type for the data you wish to store in the registry. Valid values are:
  - `REG_BINARY`
  - `REG_DWORD`
  - `REG_EXPAND_SZ`
  - `REG_MULTI_SZ`
  - `REG_QWORD`
  - `REG_SZ` (Default)

- **use_32bit_registry (bool)** -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

- **win_owner (str)** -- The owner of the registry key. If this is not passed, the account under which Salt is running will be used.

---

**Note:** Owner is set for the key that contains the value/data pair. You cannot set ownership on value/data pairs themselves.

New in version 2019.2.0.

- **win_perms (dict)** -- A dictionary containing permissions to grant and their propagation. If not passed the 'Grant' permissions will not be modified.

---

**Note:** Permissions are set for the key that contains the value/data pair. You cannot set permissions on value/data pairs themselves.

For each user specify the account name, with a sub dict for the permissions to grant and the `Applies to` setting. For example: ```
{'Administrators': {'perms': 'full_control', 'applies_to': 'this_key_subkeys'}}
```

Registry permissions are specified using the `perms` key. You can specify a single basic permission or a list of advanced perms. The following are valid perms:

**Basic (passed as a string):**
- full_control
- read
- write

**Advanced (passed as a list):**
- delete
- query_value
- set_value
- create_subkey
- enum_subkeys
- notify
- create_link
- read_control
The 'Applies to' setting is optional. It is specified using the applies_to key. If not specified this_key_subkeys is used. Valid options are:

- this_key_only
- this_key_subkeys
- subkeys_only

New in version 2019.2.0.

- win_deny_perms (dict) -- A dictionary containing permissions to deny and their propagation. If not passed the Deny permissions will not be modified.

Note: Permissions are set for the key that contains the value/data pair. You cannot set permissions on value/data pairs themselves.

Valid options are the same as those specified in win_perms

Note: 'Deny' permissions always take precedence over 'grant' permissions.

New in version 2019.2.0.

- win_inheritance (bool) -- True to inherit permissions from the parent key. False to disable inheritance. Default is True.

Note: Inheritance is set for the key that contains the value/data pair. You cannot set inheritance on value/data pairs themselves.

New in version 2019.2.0.

- win_perms_reset (bool) -- If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False

Note: Perms are reset for the key that contains the value/data pair. You cannot set permissions on value/data pairs themselves.

New in version 2019.2.0.

Returns A dictionary showing the results of the registry operation.

Return type dict

Example:

The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1:

<table>
<thead>
<tr>
<th>HKEY_CURRENT_USER\SOFTWARE\Salt:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- reg.present:</td>
</tr>
<tr>
<td>- vdata: 2016.3.1</td>
</tr>
</tbody>
</table>

Example:

The following example will set the value for the version entry under the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1. The value will be reflected in Wow6432Node:
**HKEY_CURRENT_USER\SOFTWARE\Salt:**

```
reg.present:
  - vname: version
  - vdata: 2016.3.1
```

In the above example the path is interpreted as follows:
- **HKEY_CURRENT_USER** is the hive
- **SOFTWARE\Salt** is the key
- **vname** is the value name ('version') that will be created under the key
- **vdata** is the data that will be assigned to 'version'

Example:

Binary data can be set in two ways. The following two examples will set a binary value of **Salty Test**

```
no_conversion:
  reg.present:
    - name: HKLM\SOFTWARE\SaltTesting
    - vname: test_reg_binary_state
    - vdata: Salty Test
    - vtype: REG_BINARY

conversion:
  reg.present:
    - name: HKLM\SOFTWARE\SaltTesting
    - vname: test_reg_binary_state_with_tag
    - vdata: !!binary U2FsdHkgVGVzdA==
    - vtype: REG_BINARY
```

Example:

To set a **REG_MULTI_SZ** value:

```
reg_multi_sz:
  reg.present:
    - name: HKLM\SOFTWARE\Salt
    - vname: reg_multi_sz
    - vdata:
      - list item 1
      - list item 2
```

Example:

To ensure a key is present and has permissions:

```
set_key_permissions:
  reg.present:
    - name: HKLM\SOFTWARE\Salt
    - vname: version
    - vdata: 2016.3.1
    - win_owner: Administrators
    - win_perms:
      jsnuffy:
        perms: full_control
      sjones:
        perms:
          - read_control
          - enum_subkeys
          - query_value
```

(continues on next page)
23.19.267  salt.states.rsync

State to synchronize files and directories with rsync.

New in version 2016.3.0.

/salt states.rsync.synchronized:

salt.states.rsync.synchronized(name, source, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None, prepare=False, dryrun=False, additional_opts=None)

Guarantees that the source directory is always copied to the target.

name  Name of the target directory.
source  Source directory.
prepare  Create destination directory if it does not exists.
delete  Delete extraneous files from the destination dirs (True or False)
force  Force deletion of dirs even if not empty
update  Skip files that are newer on the receiver (True or False)
passwordfile  Read daemon-access password from the file (path)
exclude  Exclude files, that matches pattern.
excludefrom  Read exclude patterns from the file (path)
dryrun  Perform a trial run with no changes made. Is the same as doing test=True

New in version 2016.3.1.

additional_opts  Pass additional options to rsync, should be included as a list.

New in version 2018.3.0.

23.19.268  salt.states.rvm

Managing Ruby installations and gemsets with Ruby Version Manager (RVM)

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it's not present. This module will not automatically install packages that RVM depends on or ones that are needed to build ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself. This is how a state configuration could look like:

rvm:
  group.present: []
  user.present:
- gid: rvm
- home: /home/rvm
- require:
  - group: rvm

rvm-deps:
  pkg.installed:
  - pkgs:
    - bash
    - coreutils
    - gzip
    - bzip2
    - gawk
    - sed
    - curl
    - git-core
    - subversion

mri-deps:
  pkg.installed:
  - pkgs:
    - build-essential
    - openssl
    - libreadline6
    - libreadline6-dev
    - curl
    - git-core
    - zlib1g
    - zlib1g-dev
    - libyaml-dev
    - libsqlite3-0
    - libsqlite3-dev
    - sqlite3
    - libxml2-dev
    - libxslt1-dev
    - autoconf
    - libc6-dev
    - libncurses5-dev
    - automake
    - libtool
    - bison
    - subversion
    - ruby

jruby-deps:
  pkg.installed:
  - pkgs:
    - curl
    - g++
    - openjdk-6-jre-headless

ruby-1.9.2:
  rvm.installed:
  - default: True
  - user: rvm
- **require:**
  - **pkg:** rvm-deps
  - **pkg:** mri-deps
  - **user:** rvm

**jruby:**

```plaintext
rvm.installed:
- **user:** rvm
- **require:**
  - **pkg:** rvm-deps
  - **pkg:** jruby-deps
  - **user:** rvm
```

**jgemset:**

```plaintext
rvm.gemset_present:
- **ruby:** jruby
- **user:** rvm
- **require:**
  - **rvm:** jruby
```

**mygemset:**

```plaintext
rvm.gemset_present:
- **ruby:** ruby-1.9.2
- **user:** rvm
- **require:**
  - **rvm:** ruby-1.9.2
```

**salt.states.rvm.gemset_present** *(name, ruby='default', user=None)*

Verify that the gemset is present.

*name* The name of the gemset.

*ruby: default* The ruby version this gemset belongs to.

*user: None* The user to run rvm as.

New in version 0.17.0.

**salt.states.rvm.installed** *(name, default=False, user=None, opts=None, env=None)*

Verify that the specified ruby is installed with RVM. RVM is installed when necessary.

*name* The version of ruby to install

*default* [False] Whether to make this ruby the default.

*user: None* The user to run rvm as.

*env: None* A list of environment variables to set (ie, RUBY_CONFIGURE_OPTS)

*opts: None* A list of option flags to pass to RVM (ie -C, --patch)

New in version 0.17.0.

### 23.19.269 salt.states.salt_proxy

Salt proxy state

New in version 2015.8.2.

State to deploy and run salt-proxy processes on a minion.

Set up pillar data for your proxies per the documentation.

Run the state as below
This state will configure the salt proxy settings within /etc/salt/proxy (if /etc/salt/proxy doesn't exists) and start the salt-proxy process (default true), if it isn't already running.

```python
salt.states.salt_proxy.configure_proxy(name, proxynname='p8000', start=True)
```

Create the salt proxy file and start the proxy process if required

Parameters
- **name** -- The name of this state
- **proxynname** -- Name to be used for this proxy (should match entries in pillar)
- **start** -- Boolean indicating if the process should be started

Example:

```python
salt-proxy-configure:
    salt_proxy.configure_proxy:
      - proxynname: p8000
      - start: True
```

---

**23.19.270 salt.states.saltmod**

Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt's Python API.

New in version 2016.11.0.

Support for masterless minions was added to the `salt.state` function, so they can run orchestration sls files. This is particularly useful when the rendering of a state is dependent on the execution of another state. Orchestration will render and execute each orchestration block independently, while honoring requisites to ensure the states are applied in the correct order.

See also:

More Orchestrate documentation
- Full Orchestrate Tutorial
- The Orchestrate runner

```python
salt.states.saltmod.function(name, tgt, ssh=False, tgt_type='glob', ret='', ret_config=None, ret_kwars=None, expect_minions=False, fail_minions=None, fail_function=None, arg=None, kwarg=None, timeout=None, batch=None, subset=None, failhard=None, **kwargs)
```

Execute a single module function on a remote minion via salt or salt-ssh

- **name** The name of the function to run, aka cmd.run or pkg.install
- **tgt** The target specification, aka '*' for all minions
- **tgt_type** The target type, defaults to `glob`
- **arg** The list of arguments to pass into the function
- **kwarg** The dict (not a list) of keyword arguments to pass into the function
- **ret** Optionally set a single or a list of returners to use
- **ret_config** Use an alternative returner configuration
- **ret_kwargs** Override individual returner configuration items
- **expect_minions** An optional boolean for failing if some minions do not respond
fail_minions  An optional list of targeted minions where failure is an option
fail_function  An optional string that points to a salt module that returns True or False based on the returned
data dict for individual minions
ssh  Set to True to use the ssh client instead of the standard salt client
batch  Execute the command in batches, E.g.: 10%.
subset  Number of minions from the targeted set to randomly use

New in version 2017.7.0.
failhard  pass failhard down to the executing state
New in version 2019.2.2.

salt.states.saltmod.parallel_runners(name, runners, **kwargs)
Executes multiple runner modules on the master in parallel.
New in version 2018.3.0.

A separate thread is spawned for each runner. This state is intended to be used with the orchestrate runner in place of the saltmod.runner state when different tasks should be run in parallel. In general, Salt states are not safe when used concurrently, so ensure that they are used in a safe way (e.g. by only targeting separate minions in parallel tasks).

name: name identifying this state. The name is provided as part of the output, but not used for anything else.
runners: list of runners that should be run in parallel. Each element of the list has to be a dictionary. This dictionary’s name entry stores the name of the runner function that shall be invoked. The optional kwarg entry stores a dictionary of named arguments that are passed to the runner function.

```
parallel-state:
salt.parallel_runners:
  - runners:
    my_runner_1:
      - name: state.orchestrate
      - kwarg:
        mods: orchestrate_state_1
    my_runner_2:
      - name: state.orchestrate
      - kwarg:
        mods: orchestrate_state_2
```

salt.states.saltmod.runner(name, **kwargs)
Execute a runner module on the master
New in version 2014.7.0.
name  The name of the function to run
kwargs  Any keyword arguments to pass to the runner function

```
run-manage-up:
salt.runner:
  - name: manage.up
```

salt.states.saltmod.state(name, tgt, ssh=False, tgt_type='glob', ret='', ret_config=None, ret_kwarg=None, highstate=None, sls=None, top=None, saltenv=None, test=None, pillar=None, pillarenv=None, expect_minions=True, fail_minions=None, allow_fail=0, concurrent=False, timeout=None, batch=None, queue=False, subset=None, orchestration_jid=None, failhard=None, **kwargs)
Invoke a state run on a given target
name  An arbitrary name used to track the state execution
tgt  The target specification for the state run.
New in version 2016.11.0.

Masterless support: When running on a masterless minion, the \texttt{tgt} is ignored and will always be the local minion.

\begin{description}
\item[tgt\_type] The target type to resolve, defaults to \texttt{glob}
\item[ret] Optionally set a single or a list of returners to use
\item[ret\_config] Use an alternative returner configuration
\item[ret\_kwargs] Override individual returner configuration items
\item[highstate] Defaults to None, if set to True the target systems will ignore any \texttt{sls} references specified in the \texttt{sls} option and call \texttt{state.highstate} on the targeted minions
\item[\texttt{top}] Should be the name of a top file. If set \texttt{state.top} is called with this top file instead of \texttt{state.sls}.
\item[\texttt{sls}] A group of \texttt{sls} files to execute. This can be defined as a single string containing a single \texttt{sls} file, or a list of \texttt{sls} files
\item[\texttt{test}] Pass \texttt{test=true} or \texttt{test=false} through to the state function. This can be used to override a test mode set in the minion's config file. If left as the default of None and the \texttt{test} mode is supplied on the command line, that value is passed instead.
\item[\texttt{pillar}] Pass the \texttt{pillar} kwarg through to the state function
\item[\texttt{pillarenv}] The pillar environment to grab pillars from
\end{description}

New in version 2017.7.0.

\begin{description}
\item[saltenv] The default salt environment to pull \texttt{sls} files from
\item[ssh] Set to \texttt{True} to use the ssh client instead of the standard salt client
\item[roster] In the event of using salt-ssh, a roster system can be set
\item[expect\_minions] An optional boolean for failing if some minions do not respond
\item[fail\_minions] An optional list of targeted minions where failure is an option
\item[allow\_fail] Pass in the number of minions to allow for failure before setting the result of the execution to False
\item[concurrent] Allow multiple state runs to occur at once.
\end{description}

WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same Do not use this flag for performance optimization.

\begin{description}
\item[queue] Pass \texttt{queue=true} through to the state function
\item[batch] Execute the command \texttt{in batches}. E.g.: 10%.
\end{description}

New in version 2016.3.0.

\begin{description}
\item[subset] Number of minions from the targeted set to randomly use
\end{description}

New in version 2017.7.0.

\begin{description}
\item[failhard] pass failhard down to the executing state
\end{description}

New in version 2019.2.2.

Examples:

Run a list of \texttt{sls} files via \texttt{state.sls} on target minions:

\begin{verbatim}
\textbf{webservers}:
\textbf{salt.state}:
  - \texttt{tgt}: 'web*'
  - \texttt{sls}:
    - apache
    - django
    - core
  - \texttt{saltenv}: prod
\end{verbatim}

Run a full \texttt{state.highstate} on target minions.

\begin{verbatim}
\textbf{databases}:
\textbf{salt.state}:
  - \texttt{tgt}: role:database
\end{verbatim}
salt.states.saltmod.wait_for_event(name, id_list, event_id='id', timeout=300, node='master')

Watch Salt’s event bus and block until a condition is met

New in version 2014.7.0.

name An event tag to watch for; supports Reactor-style globbing.
id_list A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched the event data is inspected for event_id, if found it is removed from id_list. When id_list is empty this function returns success.
event_id [id] The name of a key in the event data. Default is id for the minion ID, another common value is name for use with orchestrating salt-cloud events.
timeout [300] The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

```python
reboot_all_minions:
  salt.function:
    - name: system.reboot
    - tgt: '*'

wait_for_reboots:
  salt.wait_for_event:
    - name: salt/minion/*/start
    - id_list:
      - jerry
      - stuart
      - dave
      - phil
      - kevin
      - mike
    - require:
      - salt: reboot_all_minions
```

salt.states.saltmod.wheel(name, **kwargs)

Execute a wheel module on the master

New in version 2014.7.0.

name The name of the function to run
kwargs Any keyword arguments to pass to the wheel function

```python
accept_minion_key:
  salt.wheel:
    - name: key.accept
    - match: frank
```
23.19.271 salt.states.saltutil

Saltutil State

This state wraps the saltutil execution modules to make them easier to run from a states. Rather than needing to use module.run this state allows for improved change detection.

New in version 3000.

salt.states.saltutil.sync_all(name, **kwargs)
Performs the same task as saltutil.sync_all module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_all:
    - refresh: True
```

salt.states.saltutil.sync_beacons(name, **kwargs)
Performs the same task as saltutil.sync_beacons module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_beacons:
    - refresh: True
```

salt.states.saltutil.sync_clouds(name, **kwargs)
Performs the same task as saltutil.sync_clouds module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_clouds:
    - refresh: True
```

salt.states.saltutil.sync_engines(name, **kwargs)
Performs the same task as saltutil.sync_engines module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_engines:
    - refresh: True
```

salt.states.saltutil.sync_executors(name, **kwargs)
Performs the same task as saltutil.sync_executors module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_executors:
    - refresh: True
```

salt.states.saltutil.sync_grains(name, **kwargs)
Performs the same task as saltutil.sync_grains module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_grains:
    - refresh: True
```
salt.states.saltutil.sync_log_handlers(name, **kwargs)
    Performs the same task as saltutil.sync_log_handlers module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_log_handlers:
        - refresh: True

salt.states.saltutil.sync_matchers(name, **kwargs)
    Performs the same task as saltutil.sync_matchers module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_matchers:
        - refresh: True

salt.states.saltutil.sync_modules(name, **kwargs)
    Performs the same task as saltutil.sync_modules module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_modules:
        - refresh: True

salt.states.saltutil.sync_output(name, **kwargs)
    Performs the same task as saltutil.sync_output module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_output:
        - refresh: True

salt.states.saltutil.sync_outputters(name, **kwargs)
    Performs the same task as saltutil.sync_outputters module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_outputters:
        - refresh: True

salt.states.saltutil.sync_pillar(name, **kwargs)
    Performs the same task as saltutil.sync_pillar module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_pillar:
        - refresh: True

salt.states.saltutil.sync_proxymodules(name, **kwargs)
    Performs the same task as saltutil.sync_proxymodules module See saltutil module for full list of options

    sync_everything:
    saltutil.sync_proxymodules:
        - refresh: True
salt.states.saltutil.sync_renderers(name, **kwargs)
Performs the same task as saltutil.sync_renderers module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_renderers:
    - refresh: True
```

salt.states.saltutil.sync_returners(name, **kwargs)
Performs the same task as saltutil.sync_returners module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_returners:
    - refresh: True
```

salt.states.saltutil.sync_sdb(name, **kwargs)
Performs the same task as saltutil.sync_sdb module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_sdb:
    - refresh: True
```

salt.states.saltutil.sync_serializers(name, **kwargs)
Performs the same task as saltutil.sync_serializers module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_serializers:
    - refresh: True
```

salt.states.saltutil.sync_states(name, **kwargs)
Performs the same task as saltutil.sync_states module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_states:
    - refresh: True
```

salt.states.saltutil.sync_thorium(name, **kwargs)
Performs the same task as saltutil.sync_thorium module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_thorium:
    - refresh: True
```

salt.states.saltutil.sync_utils(name, **kwargs)
Performs the same task as saltutil.sync_utils module See saltutil module for full list of options

```
sync_everything:
  saltutil.sync_utils:
    - refresh: True
```
23.19.272  salt.states.schedule

Management of the Salt scheduler

```yaml
job3:
  schedule.present:
    - function: test.ping
    - seconds: 3600
    - splay: 10

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 0 and 10 seconds
```

```
job2:
  schedule.present:
    - function: test.ping
    - seconds: 15
    - splay:
      start: 10
      end: 20

This will schedule the command: test.ping every 15 seconds splaying the time between 10 and 20 seconds
```

```
job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that python-dateutil is installed on the minion.
```

```
job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - cron: '*/5 * * * *

Scheduled jobs can also be specified using the format used by cron. This will schedule the command: state.sls httpd test=True to run every 5 minutes. Requires that python-croniter is installed on the minion.
```

(continues on next page)
- **function**: state.sls
- **job_args**: httpd
- **job_kwargs**:  
  - **test**: True

- **when**:  
  - Monday 5:00pm  
  - Tuesday 3:00pm  
  - Wednesday 5:00pm  
  - Thursday 3:00pm  
  - Friday 5:00pm
- **returner**: xmpp  
- **return_config**: xmpp_state_run  
- **return_kwargs**:  
  - **recipient**: user@domain.com

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the xmpp returner to return the results of the scheduled job, with the alternative configuration options found in the xmpp_state_run section.

---

**job1:**

```
  schedule.present:
  - **function**: state.sls
  - **job_args**: httpd
  - **job_kwargs**:  
    - **test**: True
    - **hours**: 1
    - **skip_during_range**:  
      - **start**: 2pm
      - **end**: 3pm
    - **run_after_skip_range**: True
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that python-dateutil is installed on the minion.

---

**salt.states.schedule.absent**(name,**kwargs**)

Ensure a job is absent from the schedule  
**name** The unique name that is given to the scheduled job.  
**persist** Whether the job should persist between minion restarts, defaults to True.

**salt.states.schedule.disabled**(name,**kwargs**)

Ensure a job is disabled in the schedule  
**name** The unique name that is given to the scheduled job.  
**persist** Whether the job should persist between minion restarts, defaults to True.

**salt.states.schedule.enabled**(name,**kwargs**)

Ensure a job is enabled in the schedule  
**name** The unique name that is given to the scheduled job.  
**persist** Whether the job should persist between minion restarts, defaults to True.

**salt.states.schedule.present**(name,**kwargs**)

Ensure a job is present in the schedule  
**name** The unique name that is given to the scheduled job.  
**seconds** The scheduled job will be executed after the specified number of seconds have passed.
minutes  The scheduled job will be executed after the specified number of minutes have passed.
hours  The scheduled job will be executed after the specified number of hours have passed.
days   The scheduled job will be executed after the specified number of days have passed.

when   This will schedule the job at the specified time(s). The when parameter must be a single value or a
dictionary with the date string(s) using the dateutil format. Requires python-dateutil.
cron   This will schedule the job at the specified time(s) using the crontab format. Requires python-croniter.
run_on_start  Whether the job will run when Salt minion starts, or the job will be skipped once and run at
              the next scheduled run. Value should be a boolean.

function  The function that should be executed by the scheduled job.
job_args The arguments that will be used by the scheduled job.
job_kwargs The keyword arguments that will be used by the scheduled job.
maxrunning Ensure that there are no more than N copies of a particular job running.
jid_include Include the job into the job cache.
splay  The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds
        or as a dictionary range with 'start' and 'end' values.
range   This will schedule the command within the range specified. The range parameter must be a dictionary
        with the date strings using the dateutil format. Requires python-dateutil.

once   This will schedule a job to run once on the specified date.
once_fmt The default date format is ISO 8601 but can be overridden by also specifying the once_fmt option.
enabled Whether the job should be enabled or disabled. Value should be a boolean.
return_job Whether to return information to the Salt master upon job completion.
metadata Using the metadata parameter special values can be associated with a scheduled job. These values
        are not used in the execution of the job, but can be used to search for specific jobs later if combined with
        the return_job parameter. The metadata parameter must be specified as a dictionary, otherwise it will be
        ignored.
returner The returner to use to return the results of the scheduled job.
return_config The alternative configuration to use for returner configuration options.
return_kwargs Any individual returner configuration items to override. Should be passed as a dictionary.
persist  Whether the job should persist between minion restarts, defaults to True.
skip_during_range This will ensure that the scheduled command does not run within the range specified.
        The range parameter must be a dictionary with the date strings using the dateutil format. Requires
        python-dateutil.
run_after_skip_range Whether the job should run immediately after the skip_during_range time period ends.

23.19.273 salt.states.selinux

Management of SELinux rules

If SELinux is available for the running system, the mode can be managed and booleans can be set.

```yaml
enforcing:
    - selinux.mode

samba_create_home_dirs:
    - selinux.boolean:
      - value: True
      - persist: True

nginx:
    - selinux.module:
      - enabled: False
```
Note: Use of these states require that the selinux execution module is available.

salt.states.selinux.boolean(name, value, persist=False)
Set up an SELinux boolean
name The name of the boolean to set
value The value to set on the boolean
persist Defaults to False, set persist to true to make the boolean apply on a reboot

salt.states.selinux.fcontext_policy_absent(name, filetype='a', sel_type=None, sel_user=None, sel_level=None)
New in version 2017.7.0.
Makes sure an SELinux file context policy for a given filespec (name), filetype and SELinux context type is absent.
name filespec of the file or directory. Regex syntax is allowed.
filetype The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
Defaults to 'a' (all files).
sel_type The SELinux context type. There are many.
sel_user The SELinux user.
sel_level The SELinux MLS range.

salt.states.selinux.fcontext_policy_applied(name, recursive=False)
New in version 2017.7.0.
Checks and makes sure the SELinux policies for a given filespec are applied.

salt.states.selinux.fcontext_policy_present(name, sel_type, filetype='a', sel_user=None, sel_level=None)
New in version 2017.7.0.
Makes sure a SELinux policy for a given filespec (name), filetype and SELinux context type is present.
name filespec of the file or directory. Regex syntax is allowed.
filetype The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
Defaults to 'a' (all files).
sel_type SELinux context type. There are many.
sel_user The SELinux user.
sel_level The SELinux MLS range.

salt.states.selinux.mode(name)
Verifies the mode SELinux is running in, can be set to enforcing, permissive, or disabled

Note: A change to or from disabled mode requires a system reboot. You will need to perform this yourself.

name The mode to run SELinux in, permissive, enforcing, or disabled.

salt.states.selinux.module(name, module_state='Enabled', version='any', **opts)
Enable/Disable and optionally force a specific version for an SELinux module
name The name of the module to control
module_state Should the module be enabled or disabled?
version Defaults to no preference, set to a specified value if required. Currently can only alert if the version
is incorrect.
install Setting to True installs module
source Points to module source file, used only when install is True
remove Setting to True removes module
New in version 2016.3.0.
salt.states.selinux.module_install(name)
Installs custom SELinux module from given file
name Path to file with module to install
New in version 2016.11.6.

salt.states.selinux.module_remove(name)
Removes SELinux module
name The name of the module to remove
New in version 2016.11.6.

salt.states.selinux.port_policy_absent(name, sel_type=None, protocol=None, port=None)
New in version 2019.2.0.
Makes sure an SELinux port policy for a given port, protocol and SELinux context type is absent.
name The protocol and port spec. Can be formatted as (tcp|udp)/(port|port-range).
sel_type The SELinux Type. Optional; can be used in determining if policy is present, ignored by semanage
port --delete.
protocol The protocol for the port, tcp or udp. Required if name is not formatted.
port The port or port range. Required if name is not formatted.

salt.states.selinux.port_policy_present(name, sel_type, protocol=None, port=None, sel_range=None)
New in version 2019.2.0.
Makes sure an SELinux port policy for a given port, protocol and SELinux context type is present.
name The protocol and port spec. Can be formatted as (tcp|udp)/(port|port-range).
sel_type The SELinux Type.
protocol The protocol for the port, tcp or udp. Required if name is not formatted.
port The port or port range. Required if name is not formatted.
sel_range The SELinux MLS/MCS Security Range.

23.19.274  salt.states.serverdensity_device

Monitor Server with Server Density
New in version 2014.7.0.
Server Density Is a hosted monitoring service.

Warning:  This state module is beta. It might be changed later to include more or less automation.

Note:  This state module requires a pillar for authentication with Server Density To install a v1 agent:

```yaml
serverdensity:
    api_token: "b97da80a41c4f61bff05975ee51eb1aa"
    account_url: "https://your-account.serverdensity.io"
```

To install a v2 agent:

```yaml
serverdensity:
    api_token: "b97da80a41c4f61bff05975ee51eb1aa"
    account_name: "your-account"
```
Note: Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```python
'server_name':
    serverdensity_device.monitored
```

```python
salt.states.serverdensity_device.monitored(name, group=None, salt_name=True, salt_params=True, agent_version=1, **params)
```

Device is monitored with Server Density.

- **name**: Device name in Server Density.
- **salt_name**: If True (default), takes the name from the `id` grain. If False, the provided name is used.
- **group**: Group name under with device will appear in Server Density dashboard. Default - None.
- **agent_version**: The agent version you want to use. Valid values are 1 or 2. Default - 1.
- **salt_params**: If True (default), needed config parameters will be sourced from grains and from `status.all_status`.
- **params**: Add parameters that you want to appear in the Server Density dashboard. Will overwrite the `salt_params` parameters. For more info, see the API docs.

Usage example:

```python
'server_name':
    serverdensity_device.monitored

'server_name':
    serverdensity_device.monitored:
    - group: web-servers

'my_special_server':
    serverdensity_device.monitored:
    - salt_name: False
    - group: web-servers
    - cpuCores: 2
    - os: '{"code": "linux", "name": "Linux"}'
```

23.19.275 salt.states.service

Starting or restarting of services and daemons

Services are defined as system daemons and are typically launched using system init or rc scripts. This service state uses whichever service module is loaded on the minion with the virtualname of `service`. Services can be defined as either running or dead.

If you need to know if your init system is supported, see the list of supported service modules for your desired init system (systemd, sysvinit, launchctl, etc.).

Note that Salt's service execution module, and therefore this service state, uses OS grains to ascertain which service module should be loaded and used to execute service functions. As existing distributions change init systems or new distributions are created, OS detection can sometimes be incomplete. If your service states are running into trouble with init system detection, please see the Overriding Virtual Module Providers section of Salt's module documentation to work around possible errors.

23.19. state modules
Note: The current status of a service is determined by the return code of the init/rc script status command. A status return code of 0 it is considered running. Any other return code is considered dead.

```
httpd:
    service.running: []
```

The service can also be set to start at runtime via the enable option:

```
openvpn:
    service.running:
        - enable: True
```

By default if a service is triggered to refresh due to a watch statement the service is restarted. If the desired behavior is to reload the service, then set the reload value to True:

```
redis:
    service.running:
        - enable: True
        - reload: True
        - watch:
            - pkg: redis
```

Note: More details regarding watch can be found in the Requisites documentation.

The time in seconds to wait for the service to stop before returning. Default is the default for win_service.stop.

```
salt.states.service.dead(name, enable=None, sig=None, init_delay=None, **kwargs)
    Ensure that the named service is dead by stopping the service if it is running
    name  The name of the init or rc script used to manage the service
    enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named
    sig    service to be disabled. The default is None, which does not enable or disable anything.
    init_delay  Add a sleep command (in seconds) before the check to make sure service is killed.
    no_block  [False] For systemd minions only. Stops the service using --no-block.
    New in version 2017.7.0.
    timeout  For Windows minions only.
    The time in seconds to wait for the service to stop before returning. Default is the default for
    win_service.stop.
    New in version 2017.7.0, 2018.3.4.
```

```
salt.states.service.disabled(name, **kwargs)
    Ensure that the service is disabled on boot, only use this state if you don’t want to manage the running process, remember that if you want to disable a service to use the enable: False option for the running or dead function.
    name  The name of the init or rc script used to manage the service
```

```
salt.states.service.enabled(name, **kwargs)
    Ensure that the service is enabled on boot, only use this state if you don’t want to manage the running process, remember that if you want to enable a running service to use the enable: True option for the running or dead function.
    name  The name of the init or rc script used to manage the service
```

```
salt.states.service.masked(name, runtime=False)
    New in version 2017.7.0.
```
Note: This state is only available on minions which use systemd.

Ensures that the named service is masked (i.e. prevented from being started).

**name** Name of the service to mask

**runtime** [False] By default, this state will manage an indefinite mask for the named service. Set this argument to True to runtime mask the service.

Note: It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will manage a runtime or indefinite mask independently of each other. This means that if the service is already indefinitely masked, running this state with runtime set to True will _not_ remove the indefinite mask before setting a runtime mask. In these cases, if it is desirable to ensure that the service is runtime masked and not indefinitely masked, pair this state with a service.unmasked state, like so:

```yaml
mask_runtime_foo:
  service.masked:
    - name: foo
    - runtime: True

unmask_indefinite_foo:
  service.unmasked:
    - name: foo
    - runtime: False
```

salt.states.service.mod_beacon(*name, **kwargs*)

Create a beacon to monitor a service based on a beacon state argument.

Note: This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

salt.states.service.mod_watch(*name, sfun=None, sig=None, reload=False, full_restart=False, init_delay=None, force=False, **kwargs*)

The service watcher, called to invoke the watch command. When called, it will restart or reload the named service.

Note: This state exists to support invoke the watch command. It should not be called directly.

Parameters for this function should be set by the watching service. (i.e. service.running)

**name** The name of the init or rc script used to manage the service

**sfun** The original function which triggered the mod_watch call (service.running, for example).

**sig** The string to search for when looking for the service process with ps

**reload** When set, reload the service instead of restarting it. (i.e. service nginx reload)

**full_restart** Perform a full stop/start of a service by passing --full-restart. This option is ignored if reload is set and is supported by only a few service modules.

**force** Use service.force_reload instead of reload (needs reload to be set to True)

**init_delay** Add a sleep command (in seconds) before the service is restarted/reloaded

salt.states.service.running(*name, enable=None, sig=None, init_delay=None, **kwargs*)

Ensure that the service is running

**name** The name of the init or rc script used to manage the service

**enable** Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
sig  The string to search for when looking for the service process with ps
init_delay  Some services may not be truly available for a short period after their startup script indicates to
the system that they are. Provide an 'init_delay' to specify that this state should wait an additional given
number of seconds after a service has started before returning. Useful for requisite states wherein a
dependent state might assume a service has started but is not yet fully initialized.

no_block  [False] For systemd minions only. Starts the service using --no-block.

    New in version 2017.7.0.

timeout  For Windows minions only.

    The time in seconds to wait for the service to start before returning. Default is the default for
    win_service.start.

    New in version 2017.7.0, 2018.3.4.

unmask  [False] For systemd minions only. Set to True to remove an indefinite mask before attempting to
start the service.

    New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any
changes. This behavior is no longer the default.

unmask_runtime  [False] For systemd minions only. Set to True to remove a runtime mask before attempting to
start the service.

    New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any
changes. This behavior is no longer the default.

wait  [3] For systemd minions only. Passed through when using service.status to determine whether
the service is running or not.

    New in version 2019.2.3.

Note:

watch can be used with service.running to restart a service when another state changes (example: a
file.managed state that creates the service’s config file). More details regarding watch can be found in
the Requisites documentation.

salt.states.service.unmasked(name, runtime=False)
New in version 2017.7.0.

Note: This state is only available on minions which use systemd.

Ensures that the named service is unmasked
name  Name of the service to unmask
runtime  [False] By default, this state will manage an indefinite mask for the named service. Set this argument
to True to ensure that the service is runtime masked.

Note: It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will
manage a runtime or indefinite mask independently of each other. This means that if the service is indefinitely
masked, running this state with runtime set to True will not remove the indefinite mask.
23.19.276  salt.states.slack

Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

```python
slack-message:

  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The api key can be specified in the master or minion configuration like below:

```python
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The following parameters are required:

**api_key parameters:**
- **name** The unique name for this event.
- **channel** The channel to send the message to. Can either be the ID or the name.
- **from_name** The name of that is to be shown in the "from" field.
- **message** The message that is to be sent to the Slack channel.

The following parameters are optional:
- **api_key** The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.
- **icon** URL to an image to use as the icon for this message

**webhook parameters:**
- **name** The unique name for this event.
- **message** The message that is to be sent to the Slack channel.
- **color** The color of border of left side
- **short** An optional flag indicating whether the value is short enough to be displayed side-by-side with other values.
- **webhook** The identifier of WebHook (URL or token).
- **channel** The channel to use instead of the WebHook default.
- **username** Username to use instead of WebHook default.
- **icon_emoji** Icon to use instead of WebHook default.
23.19.277 salt.states.smartos

Management of SmartOS Standalone Compute Nodes

maintainer  Jorge Schrauwen <sjorge@blackdot.be>
maturity   new
depends    vmadm, imgadm
platform   smartos

New in version 2016.3.0.

```
vmtest.example.org:
  smartos.vm_present:
    - config:  
      reprovision: true
    - vmconfig:
      image_uuid: c02a2044-c1bd-11e4-bd8c-dfc1db8b0182
      brand: joyent
      alias: vmtest
      quota: 5
      max_physical_memory: 512
      tags:
        label: 'test vm'
        owner: 'sjorge'
      nics:
        "82:1b:8e:49:e9:12":

        mtu: 1500
        ips:
          - 172.16.1.123/16
          - 192.168.2.123/24
        vlan_id: 10
        "82:1b:8e:49:e9:13":  
        nic_tag: trunk
        mtu: 1500
        ips:
          - dhcp
        vlan_id: 30
  filesystems:
    "/bigdata": 
    source: "/bulk/data"
    type: lofs
    options:
      - ro
      - nodevices

kvmtest.example.org:
  smartos.vm_present:
    - vmconfig:
      brand: kvm
      alias: kvmtest
      cpu_type: host
      ram: 512
      vnc_port: 9
      tags:
        label: 'test kvm'
        owner: 'sjorge'
```

(continues on next page)
disks:
  disk0:
    size: 2048
    model: virtio
    compression: lz4
    boot: true
nics:
  "82:1b:8e:49:e9:15":
    nic_tag: trunk
    mtu: 1500
    ips:
      - dhcp
    vlan_id: 30
  "82:1b:8e:49:e9:18":
    nic_tag: trunk
    mtu: 1500
    ips:
      - 172.16.1.118/24
    vlan_id: 10

filesystems:
  "/config:
    source: "/vmdata/emby_config"
    type: lofs
    options:
      - nodevices

Note: Keep in mind that when removing properties from vmconfig they will not get removed from the vm's current configuration, except for nics, disk, tags, ... they get removed via add_*, set_*, update_*, and remove_*_. Properties must be manually reset to their default value. The same behavior as when using 'vmadm update'.

Warning: For HVM (bhyve and KVM) brands the image_uuid field should go on the boot disks, this disk should NOT have a size specified. (See man vmadm)
salt.states.smartos.config_absent(name)
   Ensure configuration property is absent in /usbkey/config
   name  [string] name of property

salt.states.smartos.config_present(name, value)
   Ensure configuration property is set to value in /usbkey/config
   name  [string] name of property
   value [string] value of property

salt.states.smartos.image_absent(name)
   Ensure image is absent on the computenode
   name  [string] uuid of image

   Note: computenode.image_absent will only remove the image if it is not used by a vm.

salt.states.smartos.image_present(name)
   Ensure image is present on the computenode
   name  [string] uuid of image

salt.states.smartos.image_vacuum(name)
   Delete images not in use or installed via image_present

   Warning: Only image_present states that are included via the top file will be detected.

salt.states.smartos.source_absent(name)
   Ensure an image source is absent on the computenode
   name  [string] source url

salt.states.smartos.source_present(name, source_type='imgapi')
   Ensure an image source is present on the computenode
   name  [string] source url
   source_type [string] source type (imgapi or docker)

salt.states.smartos.vm_absent(name, archive=False)
   Ensure vm is absent on the computenode
   name  [string] hostname of vm
   archive [boolean] toggle archiving of vm on removal

   Note: State ID is used as hostname. Hostnames must be unique.

salt.states.smartos.vm_present(name, vmconfig, config=None)
   Ensure vm is present on the computenode
   name  [string] hostname of vm
   vmconfig [dict] options to set for the vm
   config  [dict] fine grain control over vm_present

   Note:
   The following configuration properties can be toggled in the config parameter.
   •   kvm_reboot (true) - reboots of kvm zones if needed for a config update
   •   auto_import (false) - automatic importing of missing images
   •   auto_lx_vars (true) - copy kernel_version and docker:* variables from image
   •   reprovision (false) - reprovision on image_uuid changes
   •   enforce_tags (true) - false = add tags only, true = add, update, and remove tags
   •   enforce_routes (true) - false = add tags only, true = add, update, and remove routes
- enforce_internal_metadata (true) - false = add metadata only, true = add, update, and remove metadata
- enforce_customer_metadata (true) - false = add metadata only, true = add, update, and remove metadata

Note: State ID is used as hostname. Hostnames must be unique.

Note: If hostname is provided in vmconfig this will take president over the State ID. This allows multiple states to be applied to the same vm.

Note: The following instances should have a unique ID.
- nic : mac
- filesystem: target
- disk : path or diskN for zvols
  e.g. disk0 will be the first disk added, disk1 the 2nd,...

Changed in version 2019.2.0: Added support for docker image uuids, added auto_lx_vars configuration, documented some missing configuration options.

salt.states.smartos.vm_running(name)
Ensure vm is in the running state on the computenode
name [string] hostname of vm

Note: State ID is used as hostname. Hostnames must be unique.

salt.states.smartos.vm_stopped(name)
Ensure vm is in the stopped state on the computenode
name [string] hostname of vm

Note: State ID is used as hostname. Hostnames must be unique.

23.19.278 salt.states.smtp

Sending Messages via SMTP

New in version 2014.7.0.
This state is useful for firing messages during state runs, using the SMTP protocol

```
server-warning-message:
  smtp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - recipient: admins@example.com
```

23.19. state modules
`salt.states.smtp.send_msg(name, recipient, subject, sender=None, profile=None, use_ssl='True', attachments=None)`

Send a message via SMTP

```
server-warning-message:
smtplib.send_msg:
  - name: 'This is a server warning message'
  - profile: my-smtp-account
  - subject: 'Message from Salt'
  - recipient: admin@example.com
  - sender: admin@example.com
  - use_ssl: True
  - attachments:
    - /var/log/syslog
    - /var/log/messages
```

`name` The message to send via SMTP

### 23.19.279 `salt.states.snapper`

Managing implicit state and baselines using snapshots

New in version 2016.11.0.

Salt can manage state against explicitly defined state, for example if your minion state is defined by:

```
/etc/config_file:
  file.managed:
    - source: salt://configs/myconfig
```

If someone modifies this file, the next application of the highstate will allow the admin to correct this deviation and the file will be corrected.

Now, what happens if somebody creates a file `/etc/new_config_file` and deletes `/etc/important_config_file`? Unless you have an explicit rule, this change will go unnoticed.

The snapper state module allows you to manage state implicitly, in addition to explicit rules, in order to define a baseline and iterate with explicit rules as they show that they work in production.

The workflow is: once you have a working and audited system, you would create your baseline snapshot (eg. with `salt tgt snapper.create_snapshot`) and define in your state this baseline using the identifier of the snapshot (in this case: 20):

```
my_baseline:
  snapper.baseline_snapshot:
    - number: 20
    - include_diff: False
    - ignore:
      - /var/log
      - /var/cache
```

Baseline snapshots can be also referenced by tag. Most recent baseline snapshot is used in case of multiple snapshots with the same tag:

```
my_baseline_external_storage:
  snapper.baseline_snapshot:
    • tag: my_custom_baseline_tag
```
If you have this state, and you haven't done changes to the system since the snapshot, and you add a user, the state will show you the changes (including full diffs) to /etc/passwd, /etc/shadow, etc if you call it with test=True and will undo all changes if you call it without.

This allows you to add more explicit state knowing that you are starting from a very well defined state, and that you can audit any change that is not part of your explicit configuration.

So after you made this your state, you decided to introduce a change in your configuration:

```yaml
my_baseline:
  snapper.baseline_snapshot:
    - number: 20
    - ignore:
      - /var/log
      - /var/cache

hosts_entry:
  file.blockreplace:
    - name: /etc/hosts
    - content: 'First line of content'
    - append_if_not_found: True
```

The change in /etc/hosts will be done after any other change that deviates from the specified snapshot are reverted. This could be for example, modifications to the /etc/passwd file or changes in the /etc/hosts that could render your the hosts_entry rule void or dangerous.

Once you take a new snapshot and you update the baseline snapshot number to include the change in /etc/hosts the hosts_entry rule will basically do nothing. You are free to leave it there for documentation, to ensure that the change is made in case the snapshot is wrong, but if you remove anything that comes after the snapper baseline_snapshot as it will have no effect; by the moment the state is evaluated, the baseline state was already applied and include this change.

**Warning:** Make sure you specify the baseline state before other rules, otherwise the baseline state will revert all changes if they are not present in the snapshot.

**Warning:** Do not specify more than one baseline rule as only the last one will affect the result.

```python
codeauthor Duncan Mac-Vicar P. <dmacvicar@suse.de>
codeauthor Pablo Suárez Hernández <psuarezhernandez@suse.de>
maturity new
platform Linux

salt.states.snapper.baseline_snapshot(name, number=None, tag=None, include_diff=True, config='root', ignore=None)

Enforces that no file is modified comparing against a previously defined snapshot identified by number.
number Number of selected baseline snapshot.
tag Tag of the selected baseline snapshot. Most recent baseline baseline snapshot is used in case of multiple snapshots with the same tag. (tag and number cannot be used at the same time)
include_diff Include a diff in the response (Default: True)
config Snapper config name (Default: root)
```
ignore List of files to ignore. (Default: None)

23.19.280 salt.states.solrcloud

States for solrcloud alias and collection configuration
New in version 2017.7.0.
salt.states.solrcloud.alias(name, collections, **kwargs)
Create alias and enforce collection list.
Use the solrcloud module to get alias members and set them.
You can pass additional arguments that will be forwarded to http.query
name The collection name
collections list of collections to include in the alias

salt.states.solrcloud.collection(name, options=None, **kwargs)
Create collection and enforce options.
Use the solrcloud module to get collection parameters.
You can pass additional arguments that will be forwarded to http.query
name The collection name
options [{},] options to ensure

23.19.281 salt.states.splunk

Splunk User State Module
New in version 2016.3.0.
This state is used to ensure presence of users in splunk.

Ensure example test user 1:
splunk.present:
    - name: 'Example TestUser1'
    - email: example@domain.com

Ensure a splunk user is absent

Ensure example test user 1:
splunk.absent:
    - email: 'example@domain.com'
    - name: 'exampleuser'

The following parameters are required:
email This is the email of the user in splunk
name This is the splunk username used to identify the user.

Ensure a user is present

Ensure example test user 1:
splunk.user_present:
    - realname: 'Example TestUser1'
    - name: 'exampleuser'

(continues on next page)
The following parameters are required:
  - **email**  This is the email of the user in splunk

23.19.282  salt.states.splunk_search

Splunk Search State Module
New in version 2015.5.0.
This state is used to ensure presence of splunk searches.

```yaml
server-warning-message:
splunk_search.present:
  - name: This is the splunk search name
  - search: index=main sourcetype=

salt.states.splunk_search.absent(name, profile='splunk')
Ensure a search is absent

API Error Search:
splunk_search.absent

The following parameters are required:
  - **name**  This is the name of the search in splunk

salt.states.splunk_search.present(name, profile='splunk', **kwargs)
Ensure a search is present

API Error Search:
splunk_search.present:
  search: index=main sourcetype=blah
  template: alert_5min

The following parameters are required:
  - **name**  This is the name of the search in splunk

23.19.283  salt.states.sqlite3

Management of SQLite3 databases
New in version 2016.3.0.

  - **depends**
    - SQLite3 Python Module

configuration  See `salt.modules.sqlite3` for setup instructions

The sqlite3 module is used to create and manage sqlite3 databases and execute queries
Here is an example of creating a table using sql statements:
Here is an example of creating a table using yaml/jinja instead of sql:

```
users:
  sqlite3.table_present:
    - db: /var/www/app.sqlite
    - schema: CREATE TABLE `users` (`username` TEXT COLLATE NOCASE UNIQUE NOT NULL, `password` BLOB NOT NULL, `salt` BLOB NOT NULL, `last_login` INT)
```

Here is an example of making sure a table is absent:

```
badservers:
  sqlite3.table_absent:
    - db: /var/www/data/users.sqlite
```

Sometimes you would have specific data in tables to be used by other services Here is an example of making sure rows with specific data exist:

```
user_john_doe_xyz:
  sqlite3.row_present:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email='john.doe@companyxyz.com'
    - data:
      email: john.doe@companyxyz.com
      lastname: doe
      firstname: john
      company: companyxyz.com
      password: abcdef012934125
      salt: abcdef012934125
    - require:
      - sqlite3: users
```

Here is an example of removing a row from a table:

```
user_john_doe_abc:
  sqlite3.row_absent:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email="john.doe@companyabc.com"
    - require:
      - sqlite3: users
```

Note that there is no explicit state to perform random queries, however, this can be approximated with sqlite3's module functions and module.run:
Salt Documentation, Release 3003.1

```
zone-delete:
  module.run:
    - name: sqlite3.modify
      - db: {{ db }}
      - sql: "DELETE FROM records WHERE id > {{ count[0] }} AND domain_id = {{ domain_id }}"
      - watch:
        - sqlite3: zone-insert-12
```

salt.states.sqlite3.row_absent(name, db, table, where_sql, where_args=None)

Makes sure the specified row is absent in db. If multiple rows match where_sql, then the state will fail.

name Only used as the unique ID
db The database file name	
table The table name to check
where_sql The sql to select the row to check
where_args The list parameters to substitute in where_sql

salt.states.sqlite3.row_present(name, db, table, data, where_sql, where_args=None, update=False)

Checks to make sure the given row exists. If row exists and update is True then row will be updated with data. Otherwise it will leave existing row unmodified and check it against data. If the existing data doesn't match data_check the state will fail. If the row doesn't exist then it will insert data into the table. If more than one row matches, then the state will fail.

name Only used as the unique ID
db The database file name	
table The table name to check the data
data The dictionary of key/value pairs to check against if row exists, insert into the table if it doesn't
where_sql The sql to select the row to check
where_args The list parameters to substitute in where_sql
update True will replace the existing row with data When False and the row exists and data does not equal the row data then the state will fail

salt.states.sqlite3.table_absent(name, db)

Make sure the specified table does not exist

name The name of the table
db The name of the database file

salt.states.sqlite3.table_present(name, db, schema, force=False)

Make sure the specified table exists with the specified schema

name The name of the table
db The name of the database file
schema The dictionary containing the schema information
force If the name of the table exists and force is set to False, the state will fail. If force is set to True, the existing table will be replaced with the new table

23.19.284 salt.states.ssh_auth

Control of entries in SSH authorized_key files

The information stored in a user's SSH authorized key file can be easily controlled via the ssh_auth state. Defaults can be set by the enc, options, and comment keys. These defaults can be overridden by including them in the name.

Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML 'explicit key', as demonstrated in the second example below.
AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==
    ssh_auth.present:
        - user: root
        - enc: ssh-dss

? AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==...
    ssh_auth.present:
        - user: root
        - enc: ssh-dss

thatch:
    ssh_auth.present:
        - user: root
        - source: salt://ssh_keys/thatch.id_rsa.pub
        - config: '%h/.ssh/authorized_keys'

sshkeys:
    ssh_auth.present:
        - user: root
        - enc: ssh-rsa
        - options:
            - option1="value1"
            - option2="value2 flag2"
            - comment: myuser
        - names:
            - AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==
            - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
            - option3="value3" ssh-dss AAAAB3NzaC1kcQ9J5bYTEyY== other@testdomain
            - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

sshkeys:
    ssh_auth.manage:
        - user: root
        - enc: ssh-rsa
        - options:
            - option1="value1"
            - option2="value2 flag2"
            - comment: myuser
        - ssh_keys:
            - AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==
            - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
            - option3="value3" ssh-dss AAAAB3NzaC1kcQ9J5bYTEyY== other@testdomain
            - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

salt.states.ssh_auth.absent(name, user, enc='ssh-rsa', comment='', source='', options=None, config='ssh/authorized_keys', fingerprint_hash_type=None)

Verifies that the specified SSH key is absent
name  The SSH key to manage
user  The user who owns the SSH authorized keys file to modify
enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment  The comment to be placed with the SSH public key
options  The options passed to the key, pass a list object
source  The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment, enc and options will be ignored.
    New in version 2015.8.0.
config  The location of the authorized keys file relative to the user's home directory, defaults to
fingerprint_hash_type  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

New in version 2016.11.7.

salt.states.ssh_auth.manage(name, ssh_keys, user, enc='ssh-rsa', comment='', source='', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None, **kwargs)

New in version 3000.

Ensures that only the specified ssh_keys are present for the specified user

- ssh_keys  The SSH key to manage
- user  The user who owns the SSH authorized keys file to modify
- enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
- comment  The comment to be placed with the SSH public key
- source  The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment and enc will be ignored.

**Note:** The source file must contain keys in the format <enc> <key> <comment>. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key:

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

- options  The options passed to the keys, pass a list object
- config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

salt.states.ssh_auth.present(name, user, enc='ssh-rsa', comment='', source='', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None, **kwargs)

Verifies that the specified SSH key is present for the specified user

- name  The SSH key to manage
- user  The user who owns the SSH authorized keys file to modify
- enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
- comment  The comment to be placed with the SSH public key
- source  The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment and enc will be ignored.

**Note:** The source file must contain keys in the format <enc> <key> <comment>. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key:

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

- options  The options passed to the key, pass a list object
- config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

fingerprint_hash_type  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.
hashed with. This defaults to `sha256` if not specified.

## 23.19.285 `salt.states.ssh_known_hosts`

Control of SSH known_hosts entries

Manage the information stored in the known_hosts files.

```yaml
github.com:
  ssh_known_hosts:
    - present
    - user: root
    - fingerprint_hash_type: md5

example.com:
  ssh_known_hosts:
    - absent
    - user: root
```

### `salt.states.ssh_known_hosts.absent(name, user=None, config=None)`

Verifies that the specified host is not known by the given user

- **name** The host name. Note that only single host names are supported. If `foo.example.com` and `bar.example.com` are the same machine and you need to exclude both, you will need one Salt state for each.
- **user** The user who owns the ssh authorized keys file to modify
- **config** The location of the authorized keys file relative to the user's home directory, defaults to `".ssh/known_hosts"`. If no user is specified, defaults to `"/etc/ssh/ssh_known_hosts"`. If present, must be an absolute path when a user is not specified.

### `salt.states.ssh_known_hosts.present(name, user=None, fingerprint=None, key=None, port=None, enc=None, config=None, hash_known_hosts=True, timeout=5, fingerprint_hash_type=None)`

Verifies that the specified host is known by the specified user

On many systems, specifically those running with openssh 4 or older, the `enc` option must be set, only openssh 5 and above can detect the key type.

- **name** The name of the remote host (e.g. "github.com") Note that only a single hostname is supported, if `foo.example.com` and `bar.example.com` have the same host you will need two separate Salt States to represent them.
- **user** The user who owns the ssh authorized keys file to modify
- **fingerprint** The fingerprint of the key which must be present in the known_hosts file (optional if key specified)
- **key** The public key which must be present in the known_hosts file (optional if fingerprint specified)
- **port** Optional parameter, port which will be used to when requesting the public key from the remote host, defaults to port 22.
- **enc** Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss
- **config** The location of the authorized keys file relative to the user's home directory, defaults to "ssh/known_hosts". If no user is specified, defaults to "/etc/ssh/ssh_known_hosts". If present, must be an absolute path when a user is not specified.
- **hash_known_hosts** [True] Hash all hostnames and addresses in the known hosts file.
- **timeout** [int] Set the timeout for connection attempts. If `timeout` seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, then the connection is closed and the host in question considered unavailable. Default is 5 seconds.

New in version 2016.3.0.
fingerprint_hash_type: The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

New in version 2016.11.4.

Changed in version 2017.7.0: default changed from md5 to sha256

23.19.286 salt.states.stateconf

Stateconf System

The stateconf system is intended for use only with the stateconf renderer. This State module presents the set function. This function does not execute any functionality, but is used to interact with the stateconf renderer.

salt.states.stateconf.context(name, **kwargs)
    No-op state to support state config via the stateconf renderer.

salt.states.stateconf.set(name, **kwargs)
    No-op state to support state config via the stateconf renderer.

23.19.287 salt.states.status

Minion status monitoring

Maps to the status execution module.

salt.states.status.loadavg(name, maximum=None, minimum=None)
    Return the current load average for the specified minion. Available values for name are 1-min, 5-min and 15-min. minimum and maximum values should be passed in as strings.

salt.states.status.process(name)
    Return whether the specified signature is found in the process tree. This differs slightly from the services states, in that it may refer to a process that is not managed via the init system.

23.19.288 salt.states.statuspage

StatusPage

Manage the StatusPage configuration.

In the minion configuration file, the following block is required:

```
statuspage:
    api_key: <API_KEY>
    page_id: <PAGE_ID>
```

New in version 2017.7.0.

salt.states.statuspage.create(name, endpoint='incidents', api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)
    Insert a new entry under a specific endpoint.
    endpoint: incidents Insert under this specific endpoint.
    page_id: Page ID. Can also be specified in the config file.
    api_key: API key. Can also be specified in the config file.
    api_version: 1 API version. Can also be specified in the config file.
    api_url: Custom API URL in case the user has a StatusPage service running in a custom environment.
kwarg Other params.
SLS Example:

```
create-my-component:
    statuspage.create:
        - endpoint: components
        - name: my component
        - group_id: 993vgplshj12
```

```
salt.states.statuspage.delete(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None)
```
Remove an entry from an endpoint.

```
delete-my-component:
    statuspage.delete:
        - endpoint: components
        - id: ftgks5isfs2d
```

```
salt.states.statuspage.managed(name, config, api_url=None, page_id=None, api_key=None, api_version=None, pace=1, allow_empty=False)
```
Manage the StatusPage configuration.

```
my-statuspage-config:
    statuspage.managed:
        - config:
            components:
                - name: component1
                  group_id: uy4g37rf
                - name: component2
                  group_id: 3n4uyu4gf
            incidents:
                - name: incident1
                  status: resolved
                  impact: major
                  backfilled: false
                - name: incident2
                  status: investigating
                  impact: minor
```

```
salt.states.statuspage.update(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)
```

Update attribute(s) of a specific endpoint.

id The unique ID of the endpoint entry.

endpoint: incidents Endpoint name.

page_id Page ID. Can also be specified in the config file.

api_key API key. Can also be specified in the config file.

api_version: 1 API version. Can also be specified in the config file.

api_url Custom API URL in case the user has a StatusPage service running in a custom environment.

SLS Example:

```
update-my-incident:
  statuspage.update:
    - id: dz959yz2nd4l
    - status: resolved
```

23.19.289 salt.states.supervisord

Interaction with the Supervisor daemon

```
wsgi_server:
  supervisord.running:
    - require:
    - pkg: supervisor
    - watch:
      - file: /etc/nginx/sites-enabled/wsgi_server.conf
```

salt.states.supervisord.dead

Ensure the named service is dead (not running).

name Service name as defined in the supervisor configuration file

user Name of the user to run the supervisorctl command

New in version 0.17.0.

conf_file path to supervisorctl config file

bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

salt.states.supervisord.mod_watch

The supervisord watcher, called to invoke the watch command. Always restart on watch

Note: This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.supervisord.running

Ensure the named service is running.

name Service name as defined in the supervisor configuration file

restart Whether to force a restart

update Whether to update the supervisor configuration.

user Name of the user to run the supervisorctl command

New in version 0.17.0.

conf_file path to supervisorctl config file

bin_env path to supervisorctl bin or path to virtualenv with supervisor installed
Manage SVN repositories

Manage repository checkouts via the svn vcs system. Note that subversion must be installed for these states to be available, so svn states should include a requisite to a pkg.installed state for the package which provides subversion (subversion in most cases). Example:

```bash
subversion:
  pkg.installed

http://unladen-swallow.googlecode.com/svn/trunk/:

svn.latest:
  - target: /tmp/swallow

salt.states.svn.dirty(name, target=None, username=None, password=None, ignore_unversioned=False)

  Determine if the working directory has been changed.

salt.states.svn.export(name, target=None, rev=None, user=None, username=None, password=None, force=False, overwrite=False, externals=True, trust=False, trust_failures=None)

  Export a file or directory from an SVN repository
  name Address and path to the file or directory to be exported.
  target Name of the target directory where the checkout will put the working directory
  rev [None] The name revision number to checkout. Enable "force" if the directory already exists.
  user [None] Name of the user performing repository management operations
  username [None] The user to access the name repository with. The svn default is the current user
  password Connect to the Subversion server with this password

  New in version 0.17.0.
  force [False] Continue if conflicts are encountered
  overwrite [False] Overwrite existing target
  externals [True] Change to False to not checkout or update externals
  trust [False] Automatically trust the remote server. SVN's --trust-server-cert
  trust_failures [None] Comma-separated list of certificate trust failures, that shall be ignored. This can be used
  if trust=True is not sufficient. The specified string is passed to SVN's --trust-server-cert-failures option
  as-is.

  New in version 2019.2.0.

salt.states.svn.latest(name, target=None, rev=None, user=None, username=None, password=None, force=False, externals=True, trust=False, trust_failures=None)

  Checkout or update the working directory to the latest revision from the remote repository.
  name Address of the name repository as passed to "svn checkout"
  target Name of the target directory where the checkout will put the working directory
  rev [None] The name revision number to checkout. Enable "force" if the directory already exists.
  user [None] Name of the user performing repository management operations
  username [None] The user to access the name repository with. The svn default is the current user
  password Connect to the Subversion server with this password

  New in version 0.17.0.
  force [False] Continue if conflicts are encountered
  externals [True] Change to False to not checkout or update externals
  trust [False] Automatically trust the remote server. SVN's --trust-server-cert
  trust_failures [None] Comma-separated list of certificate trust failures, that shall be ignored. This can be used
  if trust=True is not sufficient. The specified string is passed to SVN's --trust-server-cert-failures option
```
23.19.291 salt.states.sysctl

Configuration of the kernel using sysctl

Control the kernel sysctl system.

```
vmswappiness:
  sysctl.present:
    - value: 20
```

salt.states.sysctl.present(name, value, config=None)

Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default
sysctl configuration file is /etc/sysctl.conf

- name: The name of the sysctl value to edit
- value: The sysctl value to apply
- config: The location of the sysctl configuration file. If not specified, the proper location will be detected based on platform.

23.19.292 salt.states.syslog_ng

State module for syslog_ng

- maintainer: Tibor Benke <btibi@sch.bme.hu>
- maturity: new
- depends: cmd, ps, syslog_ng
- platform: all

Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

Details

The service module is not available on all system, so this module includes syslog_ng.reloaded, syslog_ng.stopped, and syslog_ng.started functions. If the service module is available on the computers, users should use that.

Users can generate syslog-ng configuration with syslog_ng.config function. For more information see syslog-ng state usage.
Syslog-ng configuration file format

The syntax of a configuration snippet in syslog-ng.conf:

```
object_type object_id {<options>};
```

These constructions are also called statements. There are options inside of them:

```
option(parameter1, parameter2); option2(parameter1, parameter2);
```

salt.states.syslog_ng.config(name, config, write=True)
Builds syslog-ng configuration.
name : the id of the Salt document
config : the parsed YAML code
write : if True, it writes the config into the configuration file, otherwise just returns it

salt.states.syslog_ng.reloaded(name)
Reloads syslog-ng.

tsalt.states.syslog_ng.started(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None, *args, **kwargs)
Ensures, that syslog-ng is started via the given parameters.
Users shouldn't use this function, if the service module is available on their system.

tsalt.states.syslog_ng.stopped(name=None)
Kills syslog-ng.

23.19.293 salt.states.sysrc

State to work with sysrc

tsalt.states.sysrc.absent(name, **kwargs)
Ensure a sysrc variable is absent.
name The variable name to set
file (optional) The rc file to add the variable to.
jail (option) the name or JID of the jail to set the value in.

salt.states.sysrc.managed(name, value, **kwargs)
Ensure a sysrc variable is set to a specific value.
name The variable name to set
value Value to set the variable to
file (optional) The rc file to add the variable to.
jail (option) the name or JID of the jail to set the value in.

Example:

```
syslogd:
sysrc.managed:
  - name: syslogd_flags
  - value: -ss
```
23.19.294 salt.states.telemetry_alert

Manage Telemetry alert configurations

New in version 2016.3.0.

Create, Update and destroy Mongo Telemetry alert configurations.

This module uses requests, which can be installed via package, or pip.

This module accepts explicit credential (telemetry api key) or can also read api key credentials from a pillar. Example:

```yaml
ensure telemetry alert X is defined on deployment Y:
  telemetry_alert.present:
    - deployment_id: "rs-XXXXXX"
    - metric_name: "testMetric"
    - alert_config:
        max: 1
        filter: SERVER_ROLE_MONGOD_PRIMARY
        escalate_to: "example@pagerduty.com"
        name: "**MANAGED BY ORCA DO NOT EDIT BY HAND** manages alarm on testMetric"
```

**salt.states.telemetry_alert.absent**

Ensure the telemetry alert config is deleted

- **name** An optional description of the alarms (not currently supported by telemetry API)
- **deployment_id** Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached
- **metric_name** Specifies the unique ID of the metric to whose values these thresholds will be applied
- **api_key** Telemetry api key for the user
- **profile** A dict with telemetry config data. If present, will be used instead of api_key.

**salt.states.telemetry_alert.present**

Ensure the telemetry alert exists.

- **name** An optional description of the alarm (not currently supported by telemetry API)
- **deployment_id** Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached
- **metric_name** Specifies the unique ID of the metric to whose values these thresholds will be applied
- **alert_config** Is a list of dictionaries where each dict contains the following fields:
  - **filter** By default the alert will apply to the deployment and all its constituent resources. If the alert only applies to a subset of those resources, a filter may be specified to narrow this scope.
  - **min** the smallest "ok" value the metric may take on; if missing or null, no minimum is enforced.
  - **max** the largest "ok" value the metric may take on; if missing or null, no maximum is enforced.
  - **notify_all** Used to indicate if you want to alert both onCallEngineer and apiNotifications
- **api_key** Telemetry api key for the user
- **profile** A dict of telemetry config information. If present, will be used instead of api_key.
23.19.295  salt.states.test

Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

```yaml
always-passes-with-any-kwarg:
  - name: foo
  - something: else
  - foo: bar

always-passes:
  test.succeed_without_changes:
    - name: foo

always-fails:
  test.fail_without_changes:
    - name: foo

always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo

always-changes-and-fails:
  test.fail_with_changes:
    - name: foo

my-custom-combo:
  test.configurable_test_state:
    - name: foo
    - changes: True
    - result: False
    - comment: bar.baz
    - warnings: A warning

is-pillar-foo-present-and-bar-is-int:
  test.check_pillar:
    - present:
      - foo
    - integer:
      - bar
```

You may also use these states for controlled failure in state definitions, for example if certain conditions in pillar or grains do not apply. The following state definition will fail with a message "OS not supported!" when `grains['os']` is neither Ubuntu nor CentOS:

```yaml
{% if grains['os'] in ['Ubuntu', 'CentOS'] %}
# Your state definitions go here

{% else %}
failure:
  test.fail_without_changes:
    - name: "OS not supported!"
    - failhard: True

(continues on next page)  ```
salt.states.test.check_pillar(name, present=None, boolean=None, integer=None, string=None, listing=None, dictionary=None, verbose=False)

Checks the presence and, optionally, the type of given keys in Pillar

Supported kwargs for types are: - boolean (bool) - integer (int) - string (str) - listing (list) - dictionary (dict)

Checking for None type pillars is not implemented yet.

is-pillar-foo-present-and-bar-is-int:
  test.check_pillar:
    - present:
    - foo
    - integer:
    - bar

salt.states.test.configurable_test_state(name, changes=True, result=True, comment='', warnings=None)

New in version 2014.7.0.

A configurable test state which allows for more control over the return data

name A unique string to serve as the state’s ID

changes [True] Controls whether or not the state reports that there were changes. There are three supported values for this argument:
  • If True, the state will report changes
  • If False, the state will report no changes
  • If "Random", the state will randomly report either changes or no changes.

result [True] Controls the result for for the state. Like changes, there are three supported values for this argument:
  • If True, the state will report a True result
  • If False, the state will report a False result
  • If "Random", the state will randomly report either True

Note: The result will be reported as None if all of the following are true:

1. The state is being run in test mode (i.e. test=True on the CLI)
2. result is True (either explicitly, or via being set to "Random")
3. changes is True (either explicitly, or via being set to "Random")

comment ["] Comment field field for the state. By default, this is an empty string.

warnings A string (or a list of strings) to fill the warnings field with. Default is None

New in version 3000.

salt.states.test.fail_with_changes(name, **kwargs)

New in version 2014.7.0.

Returns False with an non-empty changes dictionary. Useful for testing requisites.

name A unique string to serve as the state’s ID

salt.states.test.fail_without_changes(name, **kwargs)

New in version 2014.7.0.

Returns failure

name A unique string to serve as the state’s ID

salt.states.test.mod_watch(name, sfun=None, **kwargs)

Call this function via a watch statement
New in version 2014.7.0.

Any parameters in the state return dictionary can be customized by adding the keywords `result`, `comment`, and `changes`.

```python
this_state_will_return_changes:
    test.succeed_with_changes

test.succeed_without_changes

this_state_will_NOT_return_changes:
    test.succeed_without_changes

this_state_is_watching_another_state:
    test.succeed_without_changes:
        - comment: 'This is a custom comment'
        - watch:
            - test: this_state_will_return_changes
            - test: this_state_will_NOT_return_changes

test.succeed_without_changes:
    - watch:
        - test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
    test.succeed_without_changes:
        - watch:
            - test: this_state_will_NOT_return_changes
```

salt.states.test.nop(name, **kwargs)

A no-op state that does nothing. Useful in conjunction with the `use` requisite, or in templates which could otherwise be empty due to jinja rendering.

name A unique string to serve as the state's ID

salt.states.test.show_notification(name, text=None, **kwargs)

New in version 2015.8.0.

Simple notification using text argument.

name A unique string to serve as the state's ID
text Text to return in the comment field

salt.states.test.succeed_with_changes(name, **kwargs)

New in version 2014.7.0.

Returns `True` with an non-empty `changes` dictionary. Useful for testing requisites.

name A unique string to serve as the state's ID

salt.states.test.succeed_without_changes(name, **kwargs)

New in version 2014.7.0.

Returns successful

name A unique string to serve as the state's ID
23.19.296  salt.states.testinframod

23.19.297  salt.states.timezone

Management of timezones

The timezone can be managed for the system:

```
America/Denver:
  timezone.system
```

The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to localtime, meaning it is set to the same time as the system clock. If `utc` is set to True, then the hardware clock will be set to UTC, and the system clock will be an offset of that.

```
America/Denver:
  timezone.system:
    - utc: True
```

The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot with Windows. This is explained in greater detail here.

```
salt.states.timezone.system(name, utc=True)
```

Set the timezone for the system.

- `name`: The name of the timezone to use (e.g.: America/Denver)
- `utc`: Whether or not to set the hardware clock to UTC (default is True)

23.19.298  salt.states.tls

Enforce state for SSL/TLS

```
salt.states.tls.valid_certificate(name, weeks=0, days=0, hours=0, minutes=0, seconds=0)
```

Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks, days, minutes, and seconds.

23.19.299  salt.states.tomcat

Manage Apache Tomcat web applications

**Note:** This state requires the Tomcat Manager webapp to be installed and running.

The following grains/pillars must be set for communication with Tomcat Manager to work:

```
tomcat-manager:
  user: 'tomcat-manager'
  passwd: 'Passw0rd'
```
Configuring Tomcat Manager

To manage webapps via the Tomcat Manager, you'll need to configure a valid user in the file `conf/tomcat-users.xml`.

Listing 1: conf/tomcat-users.xml

```xml
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
  <role rolename="manager-script"/>
  <user username="tomcat-manager" password="Passw0rd" roles="manager-script"/>
</tomcat-users>
```

Notes

- Using multiple versions (aka. parallel deployments) on the same context path is not supported.
- If you use only this module for deployments you might want to restrict access to the manager so it’s only accessible via localhost. For more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)
- Last tested on:
  - Tomcat Version: Apache Tomcat/7.0.54
  - JVM Vendor: Oracle Corporation
  - JVM Version: 1.8.0_101-b13
  - OS Architecture: amd64
  - OS Name: Linux
  - OS Version: 3.10.0-327.22.2.el7.x86_64

salt.states.tomcat.mod_watch(name, url='http://localhost:8080/manager', timeout=180)

The tomcat watcher, called to invoke the watch command. When called, it will reload the webapp in question

Note: This state exists to support special handling of the `watch` requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.tomcat.undeployed(name, url='http://localhost:8080/manager', timeout=180)

Enforce that the WAR will be undeployed from the server

ame name The context path to undeploy.
timeout [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```
salt.states.tomcat.wait(name, url='http://localhost:8080/manager', timeout=180)
Wait for the Tomcat Manager to load.

Notice that if tomcat is not running we won't wait for it start and the state will fail. This state can be required in the tomcat.war_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment.
timeout [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```python
tomcat-service:
  service.running:
    - name: tomcat
    - enable: True

wait-for-tomcatmanager:
  tomcat.wait:
    - timeout: 300
    - require:
      - service: tomcat-service

deploy-jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager
```

salt.states.tomcat.war_deployed(name, war, force=False, url='http://localhost:8080/manager', timeout=180, temp_war_location=None, version=True)
Enforce that the WAR will be deployed and started in the context path, while making use of WAR versions in the filename.

Note: For more info about Tomcats file paths and context naming, please see [http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming](http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming)

name The context path to deploy (incl. forward slash) the WAR to.
war Absolute path to WAR file (should be accessible by the user running Tomcat) or a path supported by the
salt.modules.cp.get_url function.
force [False] Force deployment even if the version strings are the same. Disabled by default.
timeout [180] Timeout for HTTP requests to the Tomcat Manager.
temp_war_location [None] Use another location to temporarily copy the WAR file to. By default the system's
temp directory is used.
version [''] Specify the WAR version. If this argument is provided, it overrides the version encoded in the
WAR file name, if one is present.

Use False or blank value to prevent guessing the version and keeping it blank.

New in version 2016.11.0.

Example:

```python
jenkins:
  tomcat.war_deployed:
```
(continues on next page)
- **name**: /salt-powered-jenkins
- **war**: salt://jenkins-1.2.4.war
- **require**:
  - **service**: application-service

**Note:** Be aware that in the above example the WAR jenkins-1.2.4.war will be deployed to the context path salt-powered-jenkins##1.2.4. To avoid this either specify a version yourself, or set version to False.

### 23.19.300 salt.states.trafficserver

**Control Apache Traffic Server**

New in version 2015.8.0.

salt.states.trafficserver.bounce_cluster(name)

```
bounce_ats_cluster:
  trafficserver.bounce_cluster
```

salt.states.trafficserver.bounce_local(name, drain=False)

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

```
bounce_ats_local:
  trafficserver.bounce_local

bounce_ats_local:
  trafficserver.bounce_local
  - drain: True
```

salt.states.trafficserver.clear_cluster(name)
Clears accumulated statistics on all nodes in the cluster.

```
clear_ats_cluster:
  trafficserver.clear_cluster
```

salt.states.trafficserver.clear_node(name)
Clears accumulated statistics on the local node.

```
clear_ats_node:
  trafficserver.clear_node
```

salt.states.trafficserver.config(name, value)
Set Traffic Server configuration variable values.
proxy.config.proxy_name:
  trafficserver.config:
    - value: cdn.site.domain.tld

OR

traffic_server_setting:
  trafficserver.config:
    - name: proxy.config.proxy_name
    - value: cdn.site.domain.tld

salt.states.trafficserver.offline(name, path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

offline_ats_path:
  trafficserver.offline:
    - path: /path/to/cache

salt.states.trafficserver.refresh(name)
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

refresh_ats:
  trafficserver.refresh

salt.states.trafficserver.restart_cluster(name)
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

restart_ats_cluster:
  trafficserver.restart_cluster

salt.states.trafficserver.restart_local(name, drain=False)
Restart the traffic_manager and traffic_server processes on the local node.

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

restart_ats_local:
  trafficserver.restart_local

restart_ats_local_drain:
  trafficserver.restart_local
  - drain: True

salt.states.trafficserver.shutdown(name)
Shut down Traffic Server on the local node.

shutdown_ats:
  trafficserver.shutdown
salt.states.trafficserver.startup(name)
Start Traffic Server on the local node.

```yaml
startup_ats:
  trafficserver.startup
```

salt.states.trafficserver.zero_cluster(name)
Reset performance statistics to zero across the cluster.

```yaml
zero_ats_cluster:
  trafficserver.zero_cluster
```

salt.states.trafficserver.zero_node(name)
Reset performance statistics to zero on the local node.

```yaml
zero_ats_node:
  trafficserver.zero_node
```

23.19.301 salt.states.tuned

Interface to Red Hat tuned-adm module

- maintainer Syed Ali <alicsyed@gmail.com>
- maturity new
- depends cmd.run
- platform Linux

salt.states.tuned.off(name=None)
Turns 'tuned' off. Example tuned.sls file for turning tuned off:

```yaml
tuned:
tuned.off: []
```

To see a valid list of states call execution module: tuned.list

salt.states.tuned.profile(name)
This state module allows you to modify system tuned parameters

Example tuned.sls file to set profile to virtual-guest

```yaml
tuned:
  profile
  name: virtual-guest
```

To see a valid list of states call execution module: tuned.list

23.19.302 salt.states.uptime

Monitor Web Server with Uptime

Uptime is an open source remote monitoring application using Node.js, MongoDB, and Twitter Bootstrap.

**Warning:** This state module is beta. It might be changed later to include more or less automation.
Note: This state module requires a pillar to specify the location of your uptime install

```yaml
uptime:
  application_url: "http://uptime-url.example.org"
```

Example:

```python
url:
  uptime.monitored
url/sitemap.xml:
  uptime.monitored:
    - polling: 600 # every hour
```

```python
salt.states.uptime.monitored(name, **params)
    Makes sure an URL is monitored by uptime. Checks if URL is already monitored, and if not, adds it.
```

### 23.19.303 salt.states.user

#### Management of user accounts

The user module is used to create and manage user settings, users can be set as either absent or present

```python
fred:
  user.present:
    - fullname: Fred Jones
    - shell: /bin/zsh
    - home: /home/fred
    - uid: 4000
    - gid: 4000
    - groups:
      - wheel
      - storage
      - games

testuser:
  user.absent
```

```python
salt.states.user.absent(name, purge=False, force=False)
    Ensure that the named user is absent
    name The name of the user to remove
    purge Set purge to True to delete all of the user’s files as well as the user, Default is False.
    force If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if they are logged in. Not supported in FreeBSD and Solaris, Default is False.
```

```python
salt.states.user.present(name, uid=None, gid=None, usergroup=None, groups=None, op-
tional_groups=None, remove_groups=True, home=None, createhome=True, password=None, hash_password=False, enforce_password=True, empty_password=False, shell=None, unique=True, system=False, full-
name=None, roomnumber=None, workphone=None, homephone=None, other=None, loginclass=None, date=None, mindays=None, maxdays=None, inactdays=None, warndays=None, expire=None, win_homedrive=None, win_profile=None, win_logonscript=None, win_description=None, nologinit=False, allow_uid_change=False, allow_gid_change=False, **kwargs)
```

23.19. state modules 4025
Ensure that the named user is present with the specified properties

**name**  The name of the user to manage

**uid**  The user id to assign. If not specified, and the user does not exist, then the next available uid will be assigned.

**gid**  The id of the default group to assign to the user. Either a group name or gid can be used. If not specified, and the user does not exist, then the next available gid will be assigned.

**allow_uid_change**  [False] Set to True to allow the state to update the uid.

New in version 2018.3.1.

**allow_gid_change**  [False] Set to True to allow the state to update the gid.

New in version 2018.3.1.

**usergroup**  If True, a group with the same name as the user will be created. If False, a group with the same name as the user will not be created. The default is distribution-specific. See the USERGROUPS_ENAB section of the login.defs(5) man page.

**groups**  A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will fail. If set to the empty list, the user will be removed from all groups except the default group. If unset, salt will assume current groups are still wanted, and will make no changes to them.

**optional_groups**  A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will silently ignore it.

**remove_groups**  Remove groups that the user is a member of that weren’t specified in the state, Default is True.

**home**  The custom login directory of user. Uses default value of underlying system if not set. Notice that this directory does not have to exist. This also the location of the home directory to create if createhome is set to True.

**createhome**  [True] If set to False, the home directory will not be created if it doesn’t already exist.

**nologinit**  [False] If set to True, it will not add the user to lastlog and faillog databases.

**password**  A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD, OpenBSD, and Solaris. If the empty_password argument is set to True then password is ignored. For Windows this is the plain text password. For Linux, the hash can be generated with `mkpasswd -m sha-256`.

Changed in version 0.16.0: BSD support added.

**hash_password**  Set to True to hash the clear text password. Default is False.

**enforce_password**  Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the "password" field. This option will be ignored if "password" is not specified, Default is True.

**empty_password**  Set to True to enable password-less login for user, Default is False.
shell  The login shell, defaults to the system default shell
unique  Require a unique UID, Default is True.
system  Choose UID in the range of FIRST_SYSTEM_UID and LAST_SYSTEM_UID, Default is False.
loginclass  The login class, defaults to empty (BSD only)
User comment field (GECOS) support (currently Linux, BSD, and MacOS only):

The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

fullname  The user’s full name
roomnumber  The user’s room number (not supported in MacOS)
workphone  The user’s work phone number (not supported in MacOS)
homephone  The user’s home phone number (not supported in MacOS)
other  The user’s other attribute (not supported in MacOS) If GECOS field contains more than 4 commas, this field will have the rest of ’em

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):

The below values should be specified as integers.
date  Date of last change of password, represented in days since epoch (January 1, 1970).
mindays  The minimum number of days between password changes.
maxdays  The maximum number of days between password changes.
inactdays  The number of days after a password expires before an account is locked.
warndays  Number of days prior to maxdays to warn users.
expire  Date that account expires, represented in days since epoch (January 1, 1970).

The below parameters apply to windows only:

win_homedrive (Windows Only)  The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie:
- win_homedrive: 'U:

Changed in version 2015.8.0.

win_profile (Windows Only)  The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.8.0.

win_logonscript (Windows Only)  The full path to the logon script to run when the user logs in.

Changed in version 2015.8.0.

win_description (Windows Only)  A brief description of the purpose of the users account.

Changed in version 2015.8.0.

---

23.19.304  salt.states.vagrant

Manage Vagrant VMs

Manage execution of Vagrant virtual machines on Salt minions.

Vagrant is a tool for building and managing virtual machine environments. It can use various providers, such as VirtualBox, Docker, or VMware, to run its VMs. Vagrant provides some of the functionality of a light-weight hypervisor. The combination of Salt modules, Vagrant running on the host, and a virtual machine provider, gives hypervisor-like functionality for developers who use Vagrant to quickly define their virtual environments.

New in version 2018.3.0.

The configuration of each virtual machine is defined in a file named Vagrantfile which must exist on the VM host machine. The essential parameters which must be defined to start a Vagrant VM are the directory where the
Vagrantfile is located (argument cwd:), and the username which will own the Vagrant box created for the VM (argument vagrant_runas).

A single Vagrantfile may define one or more virtual machines. Use the machine argument to chose among them. The default (blank) value will select the primary (or only) machine in the Vagrantfile.

[NOTE:] Each virtual machine host must have the following:

- a working salt-minion
- a Salt sdb database configured for vagrant_sdb_data.
- Vagrant installed and the vagrant command working
- a suitable VM provider

```
# EXAMPLE:
# file /etc/salt/minion.d/vagrant_sdb.conf on the host computer
# -- this sdb database is required by the Vagrant module --

vagrant_sdb_data: # The sdb database must have this name.
  driver: sqlite3  # Let's use SQLite to store the data ...
  database: /var/cache/salt/vagrant.sqlite # ... in this file ...
  table: sdb    # ... using this table name.
  create_table: True # if not present
```

salt.states.vagrant.destroyed(name)

Stops a VM (or VMs) and removes all references to it (them). (Runs vagrant destroy.)

Subsequent re-use of the same machine will require another operation of vagrant.running or a call to the vagrant.init execution module.

Parameters name -- May be a Salt_id node or a POSIX-style wildcard string.

```
node_name:
  vagrant.destroyed
```

salt.states.vagrant.initialized(name, **kwargs)

Defines a new VM with specified arguments, but does not start it.

Parameters name -- the Salt_id node name you wish your VM to have.

Each machine must be initialized individually using this function or the "vagrant.running" function, or the vagrant.init execution module call.

This command will not change the state of a running or paused machine.

Possible keyword arguments:

- cwd: The directory (path) containing the Vagrantfile
- machine: (") the name of the machine (in the Vagrantfile) if not default
- vagrant_runas: (root) the username who owns the vagrantbox file
- vagrant_provider: the provider to run the VM (usually 'virtualbox')
- vm: ([]) a dictionary containing these or other keyword arguments

```
node_name1:
  vagrant.initialized
    - cwd: /projects/my_project
    - vagrant_runas: my_username
    - machine: machine1

node_name2:
  vagrant.initialized
    - cwd: /projects/my_project
    - vagrant_runas: my_username
```

(continues on next page)
- machine: machine2

start_nodes:
vagrant.start:
  - name: node_name

salt.states.vagrant.paused(name)
Stores the state of a VM (or VMs) for fast restart. (Runs vagrant suspend.)

Parameters name -- May be a Salt_id node or a POSIX-style wildcard string.

node_name: vagrant.paused

salt.states.vagrant.powered_off(name)
Stops a VM (or VMs) by power off. (Runs vagrant halt.)

This method is provided for compatibility with other VM-control state modules. For Vagrant, the action is identical with stopped.

Parameters name -- May be a Salt_id node or a POSIX-style wildcard string.

node_name: vagrant.unpowered

salt.states.vagrant.rebooted(name)
Reboots a running, paused, or stopped VM (or VMs). (Runs vagrant reload.)

The will re-run the provisioning

Parameters name -- May be a Salt_id node or a POSIX-style wildcard string.

node_name: vagrant.reloaded

salt.states.vagrant.running(name, **kwargs)
Defines and starts a new VM with specified arguments, or restart a VM (or group of VMs). (Runs vagrant up.)

Parameters name -- the Salt_id node name you wish your VM to have.
If name contains a "?" or "*" then it will re-start a group of VMs which have been paused or stopped.

Each machine must be initially started individually using this function or the vagrant.init execution module call.

[NOTE:] Keyword arguments are silently ignored when re-starting an existing VM.

Possible keyword arguments:
• cwd: The directory (path) containing the Vagrantfile
• machine: (") the name of the machine (in the Vagrantfile) if not default
• vagrant_runas: ("root") the username who owns the vagrantbox file
• vagrant_provider: the provider to run the VM (usually 'virtualbox')
• vm: ({} a dictionary containing these or other keyword arguments

node_name: vagrant.running

node_name:
vagrant.running:
  - cwd: /projects/my_project

(continues on next page)
```
- vagrant_runas: my_username
- machine: machine1
```

```
salt.states.vagrant.stopped(name)

Stops a VM (or VMs) by shutting it (them) down nicely. (Runs vagrant halt)

Parameters

name -- May be a Salt_id node, or a POSIX-style wildcard string.
```

```
node_name:
vagrant.stopped
```

### 23.19.305 salt.states.vault

States for managing Hashicorp Vault. Currently handles policies. Configuration instructions are documented in the execution module docs.

- maintainer: SaltStack
- maturity: new
- platform: all

New in version 2017.7.0.

```
salt.states.vault.policy_present(name, rules)

Ensure a Vault policy with the given name and rules is present.

name The name of the policy
rules Rules formatted as in-line HCL
```

```
demo-policy:
  vault.policy_present:
  - name: foo/bar
  - rules: |
    path "secret/top-secret/*" {
      policy = "deny"
    }
    path "secret/not-very-secret/*" {
      policy = "write"
    }
```

### 23.19.306 salt.states.vbox_guest

VirtualBox Guest Additions installer state

```
salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)

Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

name The name has no functional value and is only used as a tracking reference.
reboot [False] Restart OS to complete installation.
upgrade_os [False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).
```

```
salt.states.vbox_guest.additions_removed(name, force=False)

Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.

name The name has no functional value and is only used as a tracking reference.
```
force  Force VirtualBox Guest Additions removing.

salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)
Grant access to auto-mounted shared folders to the users.

name  Name of the user to grant access to auto-mounted shared folders to.
users  List of names of users to grant access to auto-mounted shared folders to. If specified, name will not be taken into account.

23.19.307  salt.states.victorops

Create an Event in VictorOps

New in version 2015.8.0.

This state is useful for creating events on the VictorOps service during state runs.

```python
webserver-warning-message:
  victorops.create_event:
    - message_type: 'CRITICAL'
    - entity_id: 'webserver/diskspace'
    - state_message: 'Webserver diskspace is low.'

salt.states.victorops.create_event(name, message_type, routing_key='everyone', **kwargs)
Create an event on the VictorOps service

webserver-warning-message:
  victorops.create_event:
    - message_type: 'CRITICAL'
    - entity_id: 'webserver/diskspace'
    - state_message: 'Webserver diskspace is low.'

database-server-warning-message:
  victorops.create_event:
    - message_type: 'WARNING'
    - entity_id: 'db_server/load'
    - state_message: 'Database Server load is high.'
    - entity_is_host: True
    - entity_display_name: 'dbdserver.example.com'

The following parameters are required:
name  This is a short description of the event.
message_type  One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:
routing_key  The key for where messages should be routed. By default, sent to 'everyone' route.
entity_id  The name of alerting entity. If not provided, a random name will be assigned.
timestamp  Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.
timestamp_fmt  The date format for the timestamp parameter. Defaults to '%Y-%m-%dT%H:%M:%S'.
state_start_time  The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
state_start_time_fmt  The date format for the timestamp parameter. Defaults to '%Y-%m-%dT%H:%M:%S'.
```
**state_message** Any additional status information from the alert item.

**entity_is_host** Used within VictorOps to select the appropriate display format for the incident.

**entity_display_name** Used within VictorOps to display a human-readable name for the entity.

**ack_message** A user entered comment for the acknowledgment.

**ack_author** The user that acknowledged the incident.

### 23.19.308 salt.states.virt

**Manage virt**

For the key certificate this state uses the external pillar in the master to call for the generation and signing of certificates for systems running libvirt:

```python
libvirt_keys:
    virt.keys

salt.states.virt.defined(name, cpu=None, mem=None, vm_type=None, disk_profile=None, disks=None, nic_profile=None, interfaces=None, graphics=None, seed=True, install=True, pub_key=None, priv_key=None, connection=None, username=None, password=None, os_type=None, arch=None, boot=None, numa_tune=None, boot_dev=None, hypervisor_features=None, clock=None, serials=None, consoles=None, stop_on_reboot=False, live=True, host_devices=None)
```

Starts an existing guest, or defines and starts a new VM with specified arguments.

New in version 3001.

**Parameters**

- **name** -- name of the virtual machine to run
- **cpu** -- Number of virtual CPUs to assign to the virtual machine or a dictionary with detailed information to configure cpu model and topology, numa node tuning, cpu tuning and iothreads allocation. The structure of the dictionary is documented in `cpu parameters definition`.

```python
cpu:
    placement: static
cpuset: 0-11
    current: 5
    maximum: 12
    vcpus:
        0:
            enabled: 'yes'
            hotpluggable: 'no'
            order: 1
        1:
            enabled: 'no'
            hotpluggable: 'yes'
    match: minimum
    mode: custom
    check: full
    vendor: Intel
    model:
        name: core2duo
        fallback: allow
        vendor_id: GenuineIntel
    topology:
```

New in version 3003.

- **mem** -- Amount of memory to allocate to the virtual machine in MiB. Since 3002, a dictionary can be used to contain detailed configuration which support memory allocation or tuning. Supported parameters are `boot`, `current`, `max`, `slots`, `hard_limit`, `soft_limit`, `swap_hard_limit`, `min_guarantee`, `hugepages`, `nosharepages`, `locked`, `source`, `access`, `allocation` and `discard`. The structure of the dictionary is documented in *Memory parameter definition*. Both decimal and binary base are supported. Detail unit specification is documented in *Units specification*. Please note that the value for `slots` must be an integer.

```bash
boot: 1g
current: 1g
max: 1g
slots: 10
hard_limit: 1024
soft_limit: 512m
swap_hard_limit: 1g
min_guarantee: 512mib
hugepages:
  - size: 2m
  - nodeset: 0-2
    size: 1g
  - nodeset: 3
    size: 2g
nosharepages: True
locked: True
source: file
```

(continues on next page)
**access:** shared
**allocation:** immediate
**discard:** True

Changed in version 3002.

- **vm_type** -- force virtual machine type for the new VM. The default value is taken from the host capabilities. This could be useful for example to use 'qemu' type instead of the 'kvm' one.
- **disk_profile** -- Name of the disk profile to use for the new virtual machine
- **disks** -- List of disk to create for the new virtual machine. See Disks Definitions for more details on the items on this list.
- **nic_profile** -- Name of the network interfaces profile to use for the new virtual machine
- **interfaces** -- List of network interfaces to create for the new virtual machine. See Network Interfaces Definitions for more details on the items on this list.
- **graphics** -- Graphics device to create for the new virtual machine. See Graphics Definition for more details on this dictionary
- **saltenv** -- Fileserver environment (Default: 'base'). See cp module for more details
- **seed** -- True to seed the disk image. Only used when the image parameter is provided. (Default: True)
- **install** -- install salt minion if absent (Default: True)
- **pub_key** -- public key to seed with (Default: None)
- **priv_key** -- public key to seed with (Default: None)
- **seed_cmd** -- Salt command to execute to seed the image. (Default: 'seed.apply')
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults
- **os_type** -- type of virtualization as found in the //os/type element of the libvirt definition. The default value is taken from the host capabilities, with a preference for hvm. Only used when creating a new virtual machine.
- **arch** -- architecture of the virtual machine. The default value is taken from the host capabilities, but x86_64 is preferred over i686. Only used when creating a new virtual machine.
- **boot** -- Specifies kernel, initial ramdisk and kernel command line parameters for the virtual machine. This is an optional parameter, all of the keys are optional within the dictionary.

Refer to Boot parameters definition for the complete boot parameters description.

To update any boot parameters, specify the new path for each. To remove any boot parameters, pass a None object, for instance: 'kernel': None.

New in version 3000.

- **boot_dev** -- Space separated list of devices to boot from sorted by decreasing priority. Values can be hd, fd, cdroom or network.

By default, the value will "hd".

New in version 3002.

- **numatune** -- The optional numatune element provides details of how to tune the performance of a NUMA host via controlling NUMA policy for domain process. The optional memory element specifies how to allocate memory for the domain process on a NUMA host. memnode elements can specify memory allocation policies per
each guest NUMA node. The definition used in the dictionary can be found at \textit{cpu parameters definition}.

New in version 3003.

\begin{verbatim}
{
   'memory': {'mode': 'strict', 'nodeset': '0-11'},
   'memnodes': {0: {'mode': 'strict', 'nodeset': 1}, 1: {'mode': 'preferred', 'nodeset': 2}}
}
\end{verbatim}

\textit{hypervisor\_features} -- Enable or disable hypervisor-specific features on the virtual machine.

New in version 3003.

\textbf{hypervisor\_features}:
\begin{itemize}
\item \texttt{kvm\_hint\_dedicated} : True
\end{itemize}

\textit{clock} -- Configure the guest clock. The value is a dictionary with the following keys:
\begin{itemize}
\item \texttt{adjustment} time adjustment in seconds or \texttt{reset}
\item \texttt{utc} set to \texttt{False} to use the host local time as the guest clock. Defaults to \texttt{True}.
\item \texttt{timezone} synchronize the guest to the corresponding timezone
\end{itemize}
\begin{itemize}
\item \texttt{timers} a dictionary associating the timer name with its configuration. This configuration is a dictionary with the properties \texttt{track}, \texttt{tickpolicy}, \texttt{catchup}, \texttt{frequency}, \texttt{mode}, \texttt{present}, \texttt{slew}, \texttt{threshold} and \texttt{limit}. See \textit{libvirt time keeping documentation} for the possible values.
\end{itemize}

New in version 3003.

Set the clock to local time using an offset in seconds .. code-block:: yaml

\begin{verbatim}
clock:
   adjustment: 3600
   utc: False
\end{verbatim}

Set the clock to a specific time zone:

\begin{verbatim}
clock:
   timezone: CEST
\end{verbatim}

\textit{serials} -- Dictionary providing details on the serials connection to create. (Default: \texttt{None}) See \textit{Serials and Consoles Definitions} for more details on the possible values.

New in version 3003.

\textit{consoles} -- Dictionary providing details on the consoles device to create. (Default: \texttt{None}) See \textit{Serials and Consoles Definitions} for more details on the possible values.

New in version 3003.

\textit{stop\_on\_reboot} -- If set to \texttt{True} the guest will stop instead of rebooting. This is specially useful when creating a virtual machine with an installation cdrom or an autoinstallation needing a special first boot configuration. Defaults to \texttt{False}

New in version 3003.

\textit{live} -- If set to \texttt{False} the changes will not be applied live to the running instance, but will only apply at the next start. Note that reboot will not take those changes.

New in version 3003.

\textit{host\_devices} -- List of host devices to passthrough to the guest. The value is a list of device names as provided by the \texttt{node\_devices()} function. (Default: \texttt{None})

New in version 3003.
Example States

Make sure a virtual machine called `domain_name` is defined:

```yaml
domain_name:
  virt.defined:
    - cpu: 2
    - mem: 2048
    - boot_dev: network hd
    - disk_profile: prod
    - disks:
        - name: system
          size: 8192
          overlay_image: True
          pool: default
          image: /path/to/image.qcow2
        - name: data
          size: 16834
    - nic_profile: prod
    - interfaces:
        - name: eth0
          mac: 01:23:45:67:89:AB
        - name: eth1
          type: network
          source: admin
    - graphics:
        - type: spice
          listen:
            - type: address
              address: 192.168.0.125

salt.states.virt.keys(name, basepath='/etc/pki', **kwargs)
Manage libvirt keys.

name  The name variable used to track the execution
basepath  Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor

The following parameters are optional:

- country  The country that the certificate should use. Defaults to US.
  New in version 2018.3.0.
- state  The state that the certificate should use. Defaults to Utah.
  New in version 2018.3.0.
- locality  The locality that the certificate should use. Defaults to Salt Lake City.
  New in version 2018.3.0.
- organization  The organization that the certificate should use. Defaults to Salted.
  New in version 2018.3.0.
- expiration_days  The number of days that the certificate should be valid for. Defaults to 365 days (1 year)
  New in version 2018.3.0.

salt.states.virt.network_defined(name, bridge, forward, vport=None, tag=None, ipv4_config=None, ipv6_config=None, autostart=True, connection=None, username=None, password=None, mtu=None, domain=None, nat=None, interfaces=None, addresses=None, physical_function=None, dns=None)
Defines a new network with specified arguments.

Parameters

- name -- Network name
• **bridge** -- Bridge name

• **forward** -- Forward mode(bridge, router, nat)

  Changed in version 3003: a `None` value creates an isolated network with no forwarding at all

• **vport** -- Virtualport type (Default: 'None') The value can also be a dictionary with `type` and `parameters` keys. The `parameters` value is a dictionary of virtual port parameters.

  ```
  - vport:
    type: openvswitch
    parameters:
      interfaceid: 09b11c53-8b5c-4eeb-8f00-d84eaa0aaa4f
  ```

  Changed in version 3003: possible dictionary value

• **tag** -- Vlan tag (Default: 'None') The value can also be a dictionary with the `tags` and optional `trunk` keys. `trunk` is a boolean value indicating whether to use VLAN trunking. `tags` is a list of dictionaries with keys `id` and `nativeMode`. The `nativeMode` value can be one of tagged or untagged.

  ```
  - tag:
    trunk: True
    tags:
      - id: 42
        nativeMode: untagged
      - id: 47
  ```

  Changed in version 3003: possible dictionary value

• **ipv4_config** -- IPv4 network configuration. See the `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).

• **ipv6_config** -- IPv6 network configuration. See the `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).

• **autostart** -- Network autostart (default 'True')

• **connection** -- libvirt connection URI, overriding defaults

• **username** -- username to connect with, overriding defaults

• **password** -- password to connect with, overriding defaults

• **mtu** -- size of the Maximum Transmission Unit (MTU) of the network. (default None)

  New in version 3003.

• **domain** -- DNS domain name of the DHCP server. The value is a dictionary with a mandatory `name` property and an optional `localOnly` boolean one. (default None)

  ```
  - domain:
    name: lab.acme.org
    localOnly: True
  ```

  New in version 3003.

• **nat** -- addresses and ports to route in NAT forward mode. The value is a dictionary with optional keys `address` and `port`. Both values are a dictionary with `start` and `end` values. (default None)

  ```
  - forward: nat
    - nat:
      address:
  ```
New in version 3003.

- **interfaces** -- whitespace separated list of network interfaces devices that can be used for this network. (default None)

```yaml
  - forward: passthrough
  - interfaces: "eth10 eth11 eth12"
```

New in version 3003.

- **addresses** -- whitespace separated list of addresses of PCI devices that can be used for this network in *hostdev* forward mode. (default None)

```yaml
  - forward: hostdev
  - interfaces: "0000:04:00.1 0000:e3:01.2"
```

New in version 3003.

- **physical_function** -- device name of the physical interface to use in *hostdev* forward mode. (default None)

```yaml
  - forward: hostdev
  - physical_function: "eth0"
```

New in version 3003.

- **dns** -- virtual network DNS configuration The value is a dictionary described in *DNS configuration definition*. (default None)

```yaml
  - dns:
    forwarders:
      - domain: example.com
        addr: 192.168.1.1
      - addr: 8.8.8.8
      - domain: www.example.com
    txt:
      example.com: "v=spf1 a -all"
      _http.tcp.example.com: "name=value,paper=A4"
    hosts:
      192.168.1.2:
      - mirror.acme.lab
      - test.acme.lab
    srvs:
      - name: ldap
        protocol: tcp
        domain: ldapserver.example.com
        target: .
        port: 389
        priority: 1
        weight: 10
```

New in version 3003.

New in version 3001.
network_name:
  virt.network_defined

network_name:
  virt.network_defined:
    - bridge: main
    - forward: bridge
    - vport: openvswitch
    - tag: 180
    - autostart: True

network_name:
  virt.network_defined:
    - bridge: natted
    - forward: nat
    - ipv4_config:
      - cidr: 192.168.42.0/24
      - dhcp_ranges:
        - start: 192.168.42.10
        - end: 192.168.42.25
        - start: 192.168.42.100
        - end: 192.168.42.150
      - autostart: True

salt.states.virt.network_running(name, bridge, forward, vport=None, tag=None, ipv4_config=None, ipv6_config=None, autostart=True, connection=None, username=None, password=None, mtu=None, domain=None, nat=None, interfaces=None, addresses=None, physical_function=None, dns=None)

Defines and starts a new network with specified arguments.

Parameters

- **name** -- Network name
- **bridge** -- Bridge name
- **forward** -- Forward mode(bridge, router, nat)

Changed in version 3003: a None value creates an isolated network with no forwarding at all

- **vport** -- Virtualport type (Default: 'None') The value can also be a dictionary with type and parameters keys. The parameters value is a dictionary of virtual port parameters.

  - **vport**:
    - **type**: openvswitch
    - **parameters**:
      - **interfaceid**: 09b11c53-8b5c-4eeb-8f00-d84eaa0aaa4f

Changed in version 3003: possible dictionary value

- **tag** -- Vlan tag (Default: 'None') The value can also be a dictionary with the tags and optional trunk keys. trunk is a boolean value indicating whether to use VLAN trunking. tags is a list of dictionaries with keys id and nativeMode. The nativeMode value can be one of tagged or untagged.

  - **tag**:
    - **trunk**: True
    - **tags**:

(continues on next page)
- **id**: 42
  
  **nativeMode**: untagged

- **id**: 47

Changed in version 3003: possible dictionary value

- **ipv4_config** -- IPv4 network configuration. See the `py:func` `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).

  New in version 3000.

- **ipv6_config** -- IPv6 network configuration. See the `py:func` `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).

  New in version 3000.

- **autostart** -- Network autostart (default 'True')

- **connection** -- libvirt connection URI, overriding defaults

  New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults

  New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults

  New in version 2019.2.0.

- **mtu** -- size of the Maximum Transmission Unit (MTU) of the network. (default None)

  New in version 3003.

- **domain** -- DNS domain name of the DHCP server. The value is a dictionary with a mandatory name property and an optional localOnly boolean one. (default None)

  New in version 3003.

- **nat** -- addresses and ports to route in NAT forward mode. The value is a dictionary with optional keys address and port. Both values are a dictionary with start and end values. (default None)

  New in version 3003.

- **interfaces** -- whitespace separated list of network interfaces devices that can be used for this network. (default None)

  New in version 3003.
- **addresses** -- whitespace separated list of addresses of PCI devices that can be used for this network in `hostdev` forward mode. (default `None`)

  ```yaml
  - forward: hostdev
    interfaces: "0000:04:00.1 0000:e3:01.2"
  ```

  New in version 3003.

- **physical_function** -- device name of the physical interface to use in `hostdev` forward mode. (default `None`)

  ```yaml
  - forward: hostdev
    physical_function: "eth0"
  ```

  New in version 3003.

- **dns** -- virtual network DNS configuration. The value is a dictionary described in `DNS configuration definition`. (default `None`)

  ```yaml
  - dns:
      forwarders:
        - domain: example.com
          addr: 192.168.1.1
        - addr: 8.8.8.8
        - domain: www.example.com
      txt:
        host.widgets.com.: "printer=lpr5"
        example.com.: "This domain name is reserved for use in documentation"
      hosts:
        192.168.1.2:
          - mirror.acme.lab
          - test.acme.lab
      srvs:
        - name: ldap
          protocol: tcp
          domain: ldapserver.example.com
          target: .
          port: 389
          priority: 1
          weight: 10
  ```

  New in version 3003.

```yaml
network_name:
  virt.network_running
```

```yaml
network_name:
  virt.network_running:
    - bridge: main
    - forward: bridge
    - vport: openvswitch
    - tag: 180
    - autostart: True
```

```yaml
network_name:
  virt.network_running:
    - bridge: natted
    - forward: nat
```

(continues on next page)
- **ipv4_config**:
  - **cidr**: 192.168.42.0/24
  - **dhcp_ranges**:
    - **start**: 192.168.42.10
    - **end**: 192.168.42.25
    - **start**: 192.168.42.100
    - **end**: 192.168.42.150
  - **autostart**: True

**salt.states.virt.pool_defined**(name, ptype=None, target=None, permissions=None, source=None, transient=False, autostart=True, connection=None, username=None, password=None)

Defines a new pool with specified arguments.

New in version 3001.

**Parameters**

- **ptype** -- libvirt pool type
- **target** -- full path to the target device or folder. (Default: None)
- **permissions** -- target permissions. See Permissions definition for more details on this structure.
- **source** -- dictionary containing keys matching the source_* parameters in function `salt.modules.virt.pool_define()`.
- **transient** -- when set to True, the pool will be automatically undefined after being stopped. (Default: False)
- **autostart** -- Whether to start the pool when booting the host. (Default: True)
- **start** -- When True, define and start the pool, otherwise the pool will be left stopped.
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults

**pool_name**:

**virt.pool_defined**:

- **ptype**: netfs
- **target**: /mnt/cifs
- **permissions**:
  - **mode**: 0770
  - **owner**: 1000
  - **group**: 100
- **source**:
  - **dir**: samba_share
  - **hosts**:
    - one.example.com
    - two.example.com
  - **format**: cifs
- **autostart**: True

**salt.states.virt.pool_deleted**(name, purge=False, connection=None, username=None, password=None)

Deletes a virtual storage pool.

**Parameters**

- **name** -- the name of the pool to delete.
- **purge** -- if True, the volumes contained in the pool will be deleted as well as the pool itself. Note that these will be lost for ever. If False the pool will simply be undefined. (Default: False)
- **connection** -- libvirt connection URI, overriding defaults
In order to be purged a storage pool needs to be running to get the list of volumes to delete. Some libvirt storage drivers may not implement deleting, those actions are implemented on a best effort idea. In any case check the result's comment property to see if any of the action was unsupported.

```yaml
pool_name: uyuni_virt.pool_deleted:
  - purge: True
```

New in version 3000.

**salt.states.virt.pool_running**

```python
salt.states.virt.pool_running(name, ptype=None, target=None, permissions=None, source=None, transient=False, autostart=True, connection=None, username=None, password=None)
```

Defines and starts a new pool with specified arguments.

New in version 2019.2.0.

Parameters

- **ptype** -- libvirt pool type
- **target** -- full path to the target device or folder. (Default: None)
- **permissions** -- target permissions. See Permissions definition for more details on this structure.
- **transient** -- when set to True, the pool will be automatically undefined after being stopped. (Default: False)
- **autostart** -- Whether to start the pool when booting the host. (Default: True)
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults

```yaml
pool_name: virt.pool_running
```

```yaml
pool_name:
  virt.pool_running:
    - ptype: netfs
    - target: /mnt/cifs
    - permissions:
        - mode: 0770
        - owner: 1000
        - group: 100
    - source:
        dir: samba_share
    hosts:
        - one.example.com
        - two.example.com
    format: cifs
    - autostart: True
```

**salt.states.virt.powered_off**

```python
salt.states.virt.powered_off(name, connection=None, username=None, password=None)
```

 Stops a VM by power off.

New in version 2016.3.0.

Parameters

- **connection** -- libvirt connection URI, overriding defaults
New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults

New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults

New in version 2019.2.0.

```python
domain_name: virt.stopped
```

**salt.states.virt.rebooted**(name, connection=None, username=None, password=None)

Reboots VMs

New in version 2016.3.0.

Parameters

- **name** --
- **connection** -- libvirt connection URI, overriding defaults

New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults

New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults

New in version 2019.2.0.

**salt.states.virt.reverted**(name, snapshot=None, cleanup=False)

Deprecates since version 2016.3.0.

Reverts to the particular snapshot.

New in version 2016.3.0.

```python
domain_name: virt.reverted:
  - cleanup: True

domain_name_1: virt.reverted:
  - snapshot: snapshot_name
  - cleanup: False
```

**salt.states.virt.running**(name, cpu=None, mem=None, vm_type=None, disk_profile=None, disks=None, nic_profile=None, interfaces=None, graphics=None, seed=True, install=True, pub_key=None, priv_key=None, connection=None, username=None, password=None, os_type=None, arch=None, boot=None, boot_dev=None, numatune=None, hypervisor_features=None, clock=None, serials=None, consoles=None, stop_on_reboot=False, host_devices=None)

Starts an existing guest, or defines and starts a new VM with specified arguments.

New in version 2016.3.0.

Parameters

- **name** -- name of the virtual machine to run
- **cpu** -- Number of virtual CPUs to assign to the virtual machine or a dictionary with detailed information to configure cpu model and topology, numa node tuning, cpu tuning and iothreads allocation. The structure of the dictionary is documented in `cpu parameters definition`.

To update any cpu parameters specify the new values to the corresponding tag. To remove any element or attribute, specify `None` object. Please note that `None` object
is mapped to null in yaml, use null in sls file instead.

- **mem** -- Amount of memory to allocate to the virtual machine in MiB. Since 3002, a dictionary can be used to contain detailed configuration which support memory allocation or tuning. Supported parameters are boot, current, max, slots, hard_limit, soft_limit, swap_hard_limit, min_guarantee, hugepages, nosharepages, locked, source, access, allocation and discard. The structure of the dictionary is documented in `Memory parameter definition`. Both decimal and binary base are supported. Detail unit specification is documented in `Units specification`. Please note that the value for `slots` must be an integer.

To remove any parameters, pass a None object, for instance: `softmax`: None. Please note that None is mapped to null in sls file, pass null in sls file instead.

```yaml
- mem:
  hard_limit: null
  soft_limit: null
```

Changed in version 3002.

- **vm_type** -- force virtual machine type for the new VM. The default value is taken from the host capabilities. This could be useful for example to use 'qemu' type instead of the 'kvm' one.

  New in version 2019.2.0.

- **disk_profile** -- Name of the disk profile to use for the new virtual machine

  New in version 2019.2.0.

- **disks** -- List of disk to create for the new virtual machine. See `Disks Definitions` for more details on the items on this list.

  New in version 2019.2.0.

- **nic_profile** -- Name of the network interfaces profile to use for the new virtual machine

  New in version 2019.2.0.

- **interfaces** -- List of network interfaces to create for the new virtual machine. See `Network Interfaces Definitions` for more details on the items on this list.

  New in version 2019.2.0.

- **graphics** -- Graphics device to create for the new virtual machine. See `Graphics Definition` for more details on this dictionary

  New in version 2019.2.0.

- **saltenv** -- Fileserver environment (Default: 'base'). See `cp module for more details`

  New in version 2019.2.0.

- **seed** --

  True to seed the disk image. Only used when the `image` parameter is provided.

  (Default: True)

  New in version 2019.2.0.

- **install** -- install salt minion if absent (Default: True)

  New in version 2019.2.0.

- **pub_key** -- public key to seed with (Default: None)

  New in version 2019.2.0.

- **priv_key** -- public key to seed with (Default: None)

  New in version 2019.2.0.
- **seed_cmd** -- Salt command to execute to seed the image.  (Default: 'seed.apply')

  New in version 2019.2.0.

- **connection** -- libvirt connection URI, overriding defaults

  New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults

  New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults

  New in version 2019.2.0.

- **os_type** -- type of virtualization as found in the //os/type element of the libvirt definition. The default value is taken from the host capabilities, with a preference for hvm. Only used when creating a new virtual machine.

  New in version 3000.

- **arch** -- architecture of the virtual machine. The default value is taken from the host capabilities, but x86_64 is prefed over i686. Only used when creating a new virtual machine.

  New in version 3000.

- **boot** -- Specifies kernel, initial ramdisk and kernel command line parameters for the virtual machine. This is an optional parameter, all of the keys are optional within the dictionary.

  Refer to [Boot parameters definition](#) for the complete boot parameters description.

  To update any boot parameters, specify the new path for each. To remove any boot parameters, pass a None object, for instance: 'kernel': None.

  New in version 3000.

- **serials** -- Dictionary providing details on the serials connection to create. (Default: None) See [Serials and Consoles Definitions](#) for more details on the possible values.

  New in version 3003.

- **consoles** -- Dictionary providing details on the consoles device to create. (Default: None) See [Serials and Consoles Definitions](#) for more details on the possible values.

  New in version 3003.

- **boot_dev** -- Space separated list of devices to boot from sorted by decreasing priority. Values can be hd, fd, crom or network.

  By default, the value will "hd".

  New in version 3002.

- **numatune** -- The optional numatune element provides details of how to tune the performance of a NUMA host via controlling NUMA policy for domain process. The optional memory element specifies how to allocate memory for the domain process on a NUMA host. memnode elements can specify memory allocation policies per each guest NUMA node. The definition used in the dictionary can be found at [cpu parameters definition](#).

  To update any numatune parameters, specify the new value. To remove any numatune parameters, pass a None object, for instance: 'numatune': None. Please note that None is mapped to null in sls file, pass null in sls file instead.

  New in version 3003.
- **stop_on_reboot** -- If set to `True` the guest will stop instead of rebooting. This is specially useful when creating a virtual machine with an installation cdrom or an autoinstallation needing a special first boot configuration. Defaults to `False`.

  New in version 3003.

- **hypervisor_features** -- Enable or disable hypervisor-specific features on the virtual machine.

  New in version 3003.

  ```yaml
  hypervisor_features:
  - kvm-hint-dedicated: True
  ```

- **clock** -- Configure the guest clock. The value is a dictionary with the following keys:

  - **adjustment** time adjustment in seconds or **reset**
  - **utc** set to `False` to use the host local time as the guest clock. Defaults to `True`.
  - **timezone** synchronize the guest to the corresponding timezone
  - **timers** a dictionary associating the timer name with its configuration. This configuration is a dictionary with the properties **track**, **tickpolicy**, **catchup**, **frequency**, **mode**, **present**, **slew**, **threshold** and **limit**. See [libvirt time keeping documentation](https://libvirt.org/time.html) for the possible values.

  New in version 3003.

  Set the clock to local time using an offset in seconds .. code-block:: yaml

  ```yaml
clock:
  - adjustment: 3600
  - utc: False
  ```

  Set the clock to a specific time zone:

  ```yaml
clock:
  - timezone: CEST
  ```

- **host_devices** -- List of host devices to passthrough to the guest. The value is a list of device names as provided by the `node_devices()` function. (Default: `None`)

  New in version 3003.

**Example States**

Make sure an already-defined virtual machine called `domain_name` is running:

```yaml
domain_name:
  - virt.running
```

Do the same, but define the virtual machine if needed:

```yaml
domain_name:
  - virt.running:
    - cpu: 2
    - mem: 2048
    - disk_profile: prod
    - boot_dev: network hd
    - disks:
      - name: system
        size: 8192
        overlay_image: True
        pool: default
        image: /path/to/image.qcow2
      - name: data
```

(continues on next page)
salt.states.virt.saved(name, suffix=None)

Deprecated since version 2016.3.0: Use snapshot() instead.

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

Parameters

- connection -- libvirt connection URI, overriding defaults
  New in version 2019.2.0.
- username -- username to connect with, overriding defaults
  New in version 2019.2.0.
- password -- password to connect with, overriding defaults
  New in version 2019.2.0.

domain_name:
  virt.saved:
    - suffix: periodic

domain*:
  virt.saved:
    - suffix: periodic
	salt.states.virt.snapshot(name, suffix=None, connection=None, username=None, password=None)

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

Parameters

- connection -- libvirt connection URI, overriding defaults
  New in version 2019.2.0.
- username -- username to connect with, overriding defaults
  New in version 2019.2.0.
- password -- password to connect with, overriding defaults
  New in version 2019.2.0.

domain_name:
  virt.snapshot:
    - suffix: periodic

domain*:
  virt.snapshot:
    - suffix: periodic
	salt.states.virt.stopped(name, connection=None, username=None, password=None)

Stops a VM by shutting it down nicely.

New in version 2016.3.0.

Parameters

- connection -- libvirt connection URI, overriding defaults
New in version 2019.2.0.
• `username` -- username to connect with, overriding defaults
  New in version 2019.2.0.
• `password` -- password to connect with, overriding defaults
  New in version 2019.2.0.

```python
domain_name: virt.stopped
```

```python
class salt.states.virt.unpowered(name):
    """Deprecated since version 2016.3.0: Use powered_off() instead."""
    Stops a VM by power off.
    New in version 2016.3.0.
    ```
    ```

domain_name: virt.stopped
```

```python
class salt.states.virt.volume_defined(pool, name, size, allocation=0, format=None, type=None, permissions=None, backing_store=None, nocow=False, connection=None, username=None, password=None):
    Ensure a disk volume is existing.
    Parameters
    - `pool` -- name of the pool containing the volume
    - `name` -- name of the volume
    - `size` -- capacity of the volume to define in MiB
    - `allocation` -- allocated size of the volume in MiB. Defaults to 0.
    - `format` -- volume format. The allowed values are depending on the pool type. Check the virt.pool_capabilities output for the possible values and the default.
    - `type` -- type of the volume. One of file, block, dir, network, netdiri, ploop or None. By default, the type is guessed by libvirt from the pool type.
    - `permissions` -- Permissions to set on the target folder. This is mostly used for filesystem-based pool types. See Permissions definition for more details on this structure.
    - `backing_store` -- dictionary describing a backing file for the volume. It must contain a path property pointing to the base volume and a format property defining the format of the base volume.
      The base volume format will not be guessed for security reasons and is thus mandatory.
    - `nocow` -- disable COW for the volume.
    - `connection` -- libvirt connection URI, overriding defaults
    - `username` -- username to connect with, overriding defaults
    - `password` -- password to connect with, overriding defaults
```
**CLI Example:**

Volume on ESX:

```yaml
esx_volume:
  virt.volume_defined:
    - pool: "[local-storage]"
    - name: myvm/myvm.vmdk
    - size: 8192
```

QCow2 volume with backing file:

```yaml
myvolume:
  virt.volume_defined:
    - pool: default
    - name: myvm.qcow2
    - format: qcow2
    - size: 8192
    - permissions:
      mode: '0775'
      owner: '123'
      group: '345'
    - backing_store:
      path: /path/to/base.img
      format: raw
    - nocow: True
```

New in version 3001.

### 23.19.309 salt.states.virtualenv

Setup of Python virtualenv sandboxes.

New in version 0.17.0.

```python
salt.states.virtualenv_mod.managed(name, venv_bin=None, requirements=None, system_site_packages=False, distribute=False, use_wheel=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, user=None, cwd=None, index_url=None, extra_index_url=None, pre_releases=False, no_deps=False, pip_download=None, pip_download_cache=None, pip_exists_action=None, pip_ignore_installed=False, proxy=None, use_vt=False, env_vars=None, no_use_wheel=False, pip_upgrade=False, pip_pkgs=None, pip_no_cache_dir=False, pip_cache_dir=None, process_dependency_links=False, no_binary=None, **kwargs)
```

Create a virtualenv and optionally manage it with pip

- **name** Path to the virtualenv.
- **venv_bin** virtualenv The name (and optionally path) of the virtualenv command. This can also be set globally in the minion config file as `virtualenv.venv_bin`.
- **requirements** None Path to a pip requirements file. If the path begins with `salt://` the file will be transferred from the master file server.
- **use_wheel** False Prefer wheel archives (requires pip &gt;= 1.4).
- **python** None Python executable used to build the virtualenv
- **user** None The user under which to run virtualenv and pip.
cwd: None  Path to the working directory where `pip install` is executed.
no_deps: False  Pass `--no-deps` to `pip install`.
pip_exists_action: None  Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup.
proxy: None  Proxy address which is passed to `pip install`.
env_vars: None  Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs `INCLUDE_PATH` set to pick up a header file while compiling.
no_use_wheel: False  Force to not use wheel archives (requires pip>=1.4)
no_binary  Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages, :none: to empty the set, or a list of one or more packages
pip_upgrade: False  Pass `--upgrade` to `pip install`.
pip_pkgs: None  As an alternative to `requirements`, pass a list of pip packages that should be installed.
process_dependency_links: False  Run pip install with the `--process_dependency_links` flag.

New in version 2017.7.0.
Also accepts any kwargs that the virtualenv module will. However, some kwargs, such as the `pip` option, require `- distribute: True.

```
/var/www/myvirtualenv.com:
virtualenv.managed:
  - system_site_packages: False
  - requirements: salt://REQUIREMENTS.txt
  - env_vars:
    PATH_VAR: '/usr/local/bin/
```

**23.19.310 salt.states.webutil**

Support for htpasswd module. Requires the apache2-utils package for Debian-based distros.

New in version 2014.7.0.

```
username:
  webutil.user_exists:
    - password: secr3t
    - htpasswd_file: /etc/nginx/htpasswd
    - options: d
    - force: true
```

salt.states.webutil.user_absent(name, htpasswd_file=None, runas=None)
Make sure the user is not in the specified htpasswd file
  name  User name
  htpasswd_file  Path to the htpasswd file
  runas  The system user to run htpasswd command with

salt.states.webutil.user_exists(name, password=None, htpasswd_file=None, options='', force=False, runas=None, update=False)
Make sure the user is inside the specified htpasswd file
  name  User name
  password  User password
  htpasswd_file  Path to the htpasswd file
  options  See salt.modules.htpasswd.useradd
  force  Touch the file even if user already created
  runas  The system user to run htpasswd command with
  update  Update an existing user's password if it's different from what's in the htpasswd file (unlike force, which updates regardless)
23.19.311  salt.states.win_certutil

Installing of certificates to the Windows Certificate Manager

Install certificates to the Windows Certificate Manager

```python
certutil.add_store:
- store: TrustedPublisher
```

```
salt.states.win_certutil.add_store(name, store, saltenv='base')

Store a certificate to the given store
name The certificate to store, this can use local paths or salt:// paths
store The store to add the certificate to
saltenv The salt environment to use, this is ignored if a local path is specified
```

```
salt.states.win_certutil.del_store(name, store, saltenv='base')

Remove a certificate in the given store
name The certificate to remove, this can use local paths or salt:// paths
store The store to remove the certificate from
saltenv The salt environment to use, this is ignored if a local path is specified
```

23.19.312  salt.states.win_dacl

Windows Object Access Control Lists

Ensure an ACL is present

parameters: name - the path of the object objectType - Registry/File/Directory user - user account or SID for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

```
addAcl:
win_dacl.present:
- name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
- objectType: Registry
- user: FakeUser
- permission: FullControl
- acetype: ALLOW
- propagation: KEY&SUBKEYS
```

Ensure an ACL does not exist

parameters: name - the path of the object objectType - Registry/File/Directory user - user account or SID for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

```
removeAcl:
win_dacl.absent:
- name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
- objectType: Registry
- user: FakeUser
- permission: FullControl
- acetype: ALLOW
- propagation: KEY&SUBKEYS
```
Ensure an object is inheriting permissions

parameters: name - the path of the object objectType - Registry/File/Directory clear_existing_acl - True/False - when inheritance is enabled, should the existing ACL be kept or cleared out

```
eInherit:
  win_dacl.enableinheritance:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - clear_existing_acl: True
```

Ensure an object is not inheriting permissions

parameters: name - the path of the object objectType - Registry/File/Directory copy_inherited_acl - True/False - if inheritance is enabled, should the inherited permissions be copied to the ACL when inheritance is disabled

```
dInherit:
  win_dacl.disableinheritance:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - copy_inherited_acl: False
```

```
salt.states.win_dacl.absent(name, objectType, user, permission, acetype, propagation)
  Ensure an ACL does not exist
```

```
salt.states.win_dacl.disinherit(name, objectType, copy_inherited_acl=True)
  Ensure an object is not inheriting ACLs from its parent
```

```
salt.states.win_dacl.inherit(name, objectType, clear(existing_acl=False)
  Ensure an object is inheriting ACLs from its parent
```

```
salt.states.win_dacl.present(name, objectType, user, permission, acetype, propagation)
  Ensure an ACE is present
```

23.19.313 salt.states.win_dism

Installing of Windows features using DISM

Install windows features/capabilities with DISM

```
Language.Basic~~~en-US~0.0.1.0:
  dism.capability_installed

NetFx3:
  dism.feature_installed
```

```
salt.states.win_dism.capability_installed(name, source=None, limit_access=False, image=None, restart=False)
  Install a DISM capability
```

Parameters

- **name (str)** -- The capability to install
- **source (str)** -- The optional source of the capability
- **limit_access (bool)** -- Prevent DISM from contacting Windows Update for online images
- **image (Optional[str])** -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- **restart (Optional[bool])** -- Reboot the machine if required by the install
Example

Run `dism.available_capabilities` to get a list of available capabilities. This will help you get the proper name to use.

```python
install_dotnet35:
    dism.capability_installed:
        - name: NetFX3~~~~
```

`salt.states.win_dism.capability_removed(name, image=None, restart=False)`

Uninstall a DISM capability

Parameters

- `name (str)`: The capability to uninstall
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- `restart (Optional[bool])`: Reboot the machine if required by the install

Example

Run `dism.installed_capabilities` to get a list of installed capabilities. This will help you get the proper name to use.

```python
remove_dotnet35:
    dism.capability_removed:
        - name: NetFX3~~~~
```

`salt.states.win_dism.feature_installed(name, package=None, source=None, limit_access=False, enable_parent=False, image=None, restart=False)`

Install a DISM feature

Parameters

- `name (str)`: The feature in which to install
- `package (Optional[str])`: The parent package for the feature. You do not have to specify the package if it is the Windows Foundation Package. Otherwise, use package to specify the parent package of the feature
- `source (str)`: The optional source of the feature
- `limit_access (bool)`: Prevent DISM from contacting Windows Update for online images
- `enable_parent (Optional[bool])`: True will enable all parent features of the specified feature
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- `restart (Optional[bool])`: Reboot the machine if required by the install
Example

Run `dism.available_features` to get a list of available features. This will help you get the proper name to use.

```
install_telnet_client:
    dism.feature_installed:
        - name: TelnetClient
```

salt.states.win_dism.feature_removed(name, remove_payload=False, image=None, restart=False)

Disables a feature.

Parameters
- **name** *(str)* -- The feature to disable
- **remove_payload** *(Optional[bool]*) -- Remove the feature’s payload. Must supply source when enabling in the future.
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the install

Example

Run `dism.installed_features` to get a list of installed features. This will help you get the proper name to use.

```
remove_telnet_client:
    dism.feature_removed:
        - name: TelnetClient
        - remove_payload: True
```

salt.states.win_dism.package_installed(name, ignore_check=False, prevent_pending=False, image=None, restart=False)

Install a package.

Parameters
- **name** *(str)* -- The package to install. Can be a .cab file, a .msu file, or a folder
- **ignore_check** *(Optional[bool]*) -- Skip installation of the package if the applicability checks fail
- **prevent_pending** *(Optional[bool]*) -- Skip the installation of the package if there are pending online actions
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the install

Example

```
install_KB123123123:
    dism.package_installed:
        - name: C:\Packages\KB123123123.cab
```

salt.states.win_dism.package_removed(name, image=None, restart=False)

Uninstall a package

Parameters
• **name** (*str*) -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. This can also be the name of a package as listed in `dism.installed_packages`

• **image** (*Optional*[str]) -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

• **restart** (*Optional*[bool]) -- Reboot the machine if required by the install

**Example**

```python
# Example using source
remove_KB1231231:
    dism.package_installed:
        - name: C:\Packages\KB1231231.cab

# Example using name from `dism.installed_packages`
remove_KB1231231:
    dism.package_installed:
        - name: Package_for_KB1231231~31bf3856ad364e35~amd64--10.0.1.3
```

23.19.314 `salt.states.win_dns_client`

Module for configuring DNS Client on Windows systems

`salt.states.win_dns_client.dns_dhcp(name, interface='Local Area Connection')`

Configure the DNS server list from DHCP Server

`salt.states.win_dns_client.dns_exists(name, servers=None, interface='Local Area Connection', replace=False)`

Configure the DNS server list in the specified interface

**Example**

```python
config_dns_servers:
    win_dns_client.dns_exists:
        - replace: True #remove any servers not in the "servers" list, default is False
        - servers:
            - 8.8.8.8
            - 8.8.8.9
```

`salt.states.win_dns_client.primary_suffix(name, suffix=None, updates=False)`

New in version 2014.7.0.

Configure the global primary DNS suffix of a DHCP client.

**suffix** [None] The suffix which is advertised for this client when acquiring a DHCP lease When none is set, the explicitly configured DNS suffix will be removed.

**updates** [False] Allow syncing the DNS suffix with the AD domain when the client’s AD domain membership changes

```python
primary_dns_suffix:
    win_dns_client.primary_suffix:
        - suffix: sub.domain.tld
        - updates: True
```
23.19.315 salt.states.win_firewall

State for configuring Windows Firewall

salt.states.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in', remoteip='any')

Add a new inbound or outbound rule to the firewall policy

Parameters

- **name** *(str)* -- The name of the rule. Must be unique and cannot be "all". Required.
- **localport** *(int)* -- The port the rule applies to. Must be a number between 0 and 65535. Can be a range. Can specify multiple ports separated by commas. Required.
- **protocol** *(Optional[str]*) -- The protocol. Can be any of the following:
  - A number between 0 and 255
  - icmpv4
  - icmpv6
  - tcp
  - udp
  - any
- **action** *(Optional[str]*) -- The action the rule performs. Can be any of the following:
  - allow
  - block
  - bypass
- **dir** *(Optional[str]*) -- The direction. Can be in or out.
- **remoteip** *(Optional[str]*) -- The remote IP. Can be any of the following:
  - any
  - localsubnet
  - dns
  - dhcp
  - wins
  - defaultgateway
  - Any valid IPv4 address (192.168.0.12)
  - Any valid subnet (192.168.1.0/24)
  - Any valid range of IP addresses (192.168.0.1-192.168.0.12)
  - A list of valid IP addresses

Can be combinations of the above separated by commas.

Example:

```python
open_smb_port:
    win_firewall.add_rule:
        - name: SMB (445)
        - localport: 445
        - protocol: tcp
        - action: allow
```

salt.states.win_firewall.disabled(name='allprofiles')

Disable all the firewall profiles (Windows only)

Parameters **profile** *(Optional[str]*) -- The name of the profile to disable. Default is allprofiles. Valid options are:

- allprofiles
- domainprofile
- privateprofile
- publicprofile
Example:

```yaml
# To disable the domain profile
disable_domain:
  win_firewall.disabled:
    - name: domainprofile

# To disable all profiles
disable_all:
  win_firewall.disabled:
    - name: allprofiles
```

```python
salt.states.win_firewall.enabled(name='allprofiles')
```

Enable all the firewall profiles (Windows only)

Parameters profile (Optional[str]) -- The name of the profile to enable. Default is allprofiles. Valid options are:

- allprofiles
- domainprofile
- privateprofile
- publicprofile

Example:

```yaml
# To enable the domain profile
enable_domain:
  win_firewall.enabled:
    - name: domainprofile

# To enable all profiles
enable_all:
  win_firewall.enabled:
    - name: allprofiles
```

23.19.316 `salt.states.win_iis`

Microsoft IIS site management

This module provides the ability to add/remove websites and application pools from Microsoft IIS.

New in version 2016.3.0.

```python
salt.states.win_iis.container_setting(name, container, settings=None)
```

Set the value of the setting for an IIS container.

Parameters

- name (str) -- The name of the IIS container.
- container (str) -- The type of IIS container. The container types are: AppPools, Sites, SslBindings
- settings (str) -- A dictionary of the setting names and their values. Example of usage for the AppPools container:

```yaml
site0-apppool-setting:
  win_iis.container_setting:
    - name: site0
    - container: AppPools
    - settings:
      managedPipelineMode: Integrated
      processModel.maxProcesses: 1
```

(continues on next page)
processModel.userName: TestUser
processModel.password: TestPassword
processModel.identityType: SpecificUser

Example of usage for the Sites container:

<table>
<thead>
<tr>
<th>Site Setting</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>site0</td>
</tr>
<tr>
<td>container</td>
<td>Sites</td>
</tr>
<tr>
<td>logFile.logFormat</td>
<td>W3C</td>
</tr>
<tr>
<td>logFile.period</td>
<td>Daily</td>
</tr>
<tr>
<td>limits.maxUrlSegments</td>
<td>32</td>
</tr>
</tbody>
</table>

salt.states.win_iis.create_app(name, site, sourcepath, apppool=None)

Create an IIS application.

Parameters
- name (str) -- The IIS application.
- site (str) -- The IIS site name.
- sourcepath (str) -- The physical path.
- apppool (str) -- The name of the IIS application pool.

Example of usage with only the required arguments:

<table>
<thead>
<tr>
<th>Site</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>site0-v1</td>
<td>win_iis.create_app:</td>
</tr>
<tr>
<td></td>
<td>- name: v1</td>
</tr>
<tr>
<td></td>
<td>- site: site0</td>
</tr>
<tr>
<td></td>
<td>- sourcepath: C:\inetpub\site0\v1</td>
</tr>
</tbody>
</table>

Example of usage specifying all available arguments:

<table>
<thead>
<tr>
<th>Site</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>site0-v1</td>
<td>win_iis.create_app:</td>
</tr>
<tr>
<td></td>
<td>- name: v1</td>
</tr>
<tr>
<td></td>
<td>- site: site0</td>
</tr>
<tr>
<td></td>
<td>- sourcepath: C:\inetpub\site0\v1</td>
</tr>
<tr>
<td></td>
<td>- apppool: site0</td>
</tr>
</tbody>
</table>

salt.states.win_iis.create_apppool(name)

Create an IIS application pool.

Parameters name (str) -- The name of the IIS application pool.

Usage:

<table>
<thead>
<tr>
<th>Site</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>site0-apppool</td>
<td>win_iis.create_apppool:</td>
</tr>
<tr>
<td></td>
<td>- name: site0</td>
</tr>
</tbody>
</table>

salt.states.win_iis.create_binding(name, site, hostheader=",", ipaddress="", port=80, protocol='http', sslflags=0)

Create an IIS binding.

Parameters
- site (str) -- The IIS site name.
- hostheader (str) -- The host header of the binding.
- ipaddress (str) -- The IP address of the binding.
- port (str) -- The TCP port of the binding.
Salt Documentation, Release 3003.1

- **protocol** *(str)* -- The application protocol of the binding.
- **sslflags** *(str)* -- The flags representing certificate type and storage of the binding.

Example of usage with only the required arguments:

```python
site0-https-binding:
  win_iis.create_binding:
    - site: site0
```

Example of usage specifying all available arguments:

```python
site0-https-binding:
  win_iis.create_binding:
    - site: site0
    - hostheader: site0.local
    - ipaddress: '*'
    - port: 443
    - protocol: https
    - sslflags: 0
```

`salt.states.win_iis.create_cert_binding(name, site, hostheader='', ipaddress='*', port=443, sslflags=0)`

Assign a certificate to an IIS binding.

Parameters
- **name** *(str)* -- The thumbprint of the certificate.
- **site** *(str)* -- The IIS site name.
- **hostheader** *(str)* -- The host header of the binding.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(str)* -- The TCP port of the binding.
- **sslflags** *(str)* -- Flags representing certificate type and certificate storage of the binding.

Example of usage with only the required arguments:

```python
site0-cert-binding:
  win_iis.create_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
    - site: site0
```

Example of usage specifying all available arguments:

```python
site0-cert-binding:
  win_iis.create_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
    - site: site0
    - hostheader: site0.local
    - ipaddress: 192.168.1.199
    - port: 443
    - sslflags: 1
```

New in version 2016.11.0.

`salt.states.win_iis.create_vdir(name, site, sourcepath, app='/')`

Create an IIS virtual directory.

Parameters
- **name** *(str)* -- The virtual directory name.
- **site** *(str)* -- The IIS site name.
- **sourcepath** *(str)* -- The physical path.
- **app** *(str)* -- The IIS application.
Example of usage with only the required arguments:

```
site0-foo-vdir:
    win_iis.create_vdir:
    - name: foo
    - site: site0
    - sourcepath: C:\inetpub\vdirs\foo
```

Example of usage specifying all available arguments:

```
site0-foo-vdir:
    win_iis.create_vdir:
    - name: foo
    - site: site0
    - sourcepath: C:\inetpub\vdirs\foo
    - app: v1
```

salt.states.win_iis.deployed(name, sourcepath, apppool='', hostheader='', ipaddress='', port=80, protocol='http')

Ensure the website has been deployed.

Parameters

- **name**(str) -- The IIS site name.
- **sourcepath**(str) -- The physical path of the IIS site.
- **apppool**(str) -- The name of the IIS application pool.
- **hostheader**(str) -- The host header of the binding.
- **ipaddress**(str) -- The IP address of the binding.
- **port**(str) -- The TCP port of the binding.
- **protocol**(str) -- The application protocol of the binding.

Example of usage with only the required arguments. This will default to using the default application pool assigned by IIS:

```
site0-deployed:
    win_iis.deployed:
    - name: site0
    - sourcepath: C:\inetpub\site0
```

Example of usage specifying all available arguments:

```
site0-deployed:
    win_iis.deployed:
    - name: site0
    - sourcepath: C:\inetpub\site0
    - apppool: site0
    - hostheader: site0.local
    - ipaddress: '*'
    - port: 443
    - protocol: https
```

salt.states.win_iis.remove_app(name, site)

Remove an IIS application.

Parameters

- **name**(str) -- The application name.
- **site**(str) -- The IIS site name.

Usage:

```
site0-v1-app-remove:
    win_iis.remove_app:
```

(continues on next page)
- name: v1
- site: site0

salt.states.win_iis.remove_apppool(name)
Remove an IIS application pool.
Parameters name (str) -- The name of the IIS application pool.
Usage:
defaultapppool_remove:
  win_iis.remove_apppool:
    - name: DefaultAppPool

salt.states.win_iis.remove_binding(name, site, hostheader='', ipaddress='*', port=80)
Remove an IIS binding.
Parameters
  • site (str) -- The IIS site name.
  • hostheader (str) -- The host header of the binding.
  • ipaddress (str) -- The IP address of the binding.
  • port (str) -- The TCP port of the binding.
Example of usage with only the required arguments:
site0-https-binding-remove:
  win_iis.remove_binding:
    - site: site0
Example of usage specifying all available arguments:
site0-https-binding-remove:
  win_iis.remove_binding:
    - site: site0
    - hostheader: site0.local
    - ipaddress: '*'
    - port: 443

salt.states.win_iis.remove_cert_binding(name, site, hostheader='', ipaddress='', port=443)
Remove a certificate from an IIS binding.
Parameters
  • name (str) -- The thumbprint of the certificate.
  • site (str) -- The IIS site name.
  • hostheader (str) -- The host header of the binding.
  • ipaddress (str) -- The IP address of the binding.
  • port (str) -- The TCP port of the binding.
Example of usage with only the required arguments:
site0-cert-binding-remove:
  win_iis.remove_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
    - site: site0
Example of usage specifying all available arguments:
site0-cert-binding-remove:
  win_iis.remove_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
    - site: site0
New in version 2016.11.0.

salt.states.win_iis.remove_site(name)
Delete a website from IIS.
Parameters
  name (str) -- The IIS site name.
Usage:

```
defaultwebsite-remove:
  win_iis.remove_site:
    - name: Default Web Site
```

salt.states.win_iis.remove_vdir(name, site, app='/')
Remove an IIS virtual directory.
Parameters
  name (str) -- The virtual directory name.
  site (str) -- The IIS site name.
  app (str) -- The IIS application.
Example of usage with only the required arguments:

```
site0-foo-vdir-remove:
  win_iis.remove_vdir:
    - name: foo
    - site: site0
```

Example of usage specifying all available arguments:

```
site0-foo-vdir-remove:
  win_iis.remove_vdir:
    - name: foo
    - site: site0
    - app: v1
```

salt.states.win_iis.set_app(name, site, settings=None)
New in version 2017.7.0.
Set the value of the setting for an IIS web application.

Note: This function only configures existing app. Params are case sensitive.

Parameters
  name (str) -- The IIS application.
  site (str) -- The IIS site name.
  settings (str) -- A dictionary of the setting names and their values.

Available settings:
  physicalPath - The physical path of the webapp
  applicationPool - The application pool for the webapp
  userName "connectAs" user
  password "connectAs" password for user

Return type bool
Example of usage:

```python
site0-webapp-setting:
    win_iis.set_app:
        - name: app0
        - site: Default Web Site
        - settings:
            userName: domain\user
            password: pass
            physicalPath: c:\inetpub\wwwroot
            applicationPool: appPool0
```

```
salt.states.win_iis.webconfiguration_settings(name, settings=None)
```

Set the value of webconfiguration settings.

**Parameters**
- `name (str) --` The name of the IIS PSPath containing the settings. Possible PSPaths are: MACHINE, MACHINE/WEBROOT, IIS:, IIS:Sitessitename, ...
- `settings (dict) --` Dictionaries of dictionaries. You can match a specific item in a collection with this syntax inside a key: 'Collection[name: site0].logFile.directory'

Example of usage for the `MACHINE/WEBROOT` PSPath:

```
MACHINE-WEBOOORT-level-security:
    win_iis.webconfiguration_settings:
        - name: 'MACHINE/WEBROOT'
        - settings:
            system.web/authentication/forms:
                requireSSL: True
                protection: "All"
            credentials.passwordFormat: "SHA1"
            system.web/httpCookies:
                httpOnlyCookies: True
```

Example of usage for the `IIS:\Sites\site0` PSPath:

```
site0-IIS-Sites-level-security:
    win_iis.webconfiguration_settings:
        - name: 'IIS:\Sites\site0'
        - settings:
            system.webServer/httpErrors:
                errorMode: "DetailedLocalOnly"
            system.webServer/security/requestFiltering:
                allowDoubleEscaping: False
                verbs.Collection:
                    - verb: TRACE
                        allowed: False
                fileExtensions.allowUnlisted: False
```

Example of usage for the `IIS:\` PSPath with a collection matching:

```
site0-IIS-level-security:
    win_iis.webconfiguration_settings:
        - name: 'IIS:'
        - settings:
            system.applicationHost/sites:
                'Collection[name: site0].logFile.directory': 'C:\logs\iis\site0'
```

23.19. state modules 4065
23.19.317 salt.states.win_lgpo

Manage Windows Local Group Policy

New in version 2016.11.0.

This state module allows you to configure local Group Policy on Windows. You can ensure the setting of a single policy or multiple policies in one pass.

Single policies must specify the policy name, the setting, and the policy class (Machine/User/Both). Here are some examples for setting a single policy setting.

Example single policy configuration:

```
Ensure Account Lockout Duration:
  lgpo.set:
    - name: Account lockout duration
    - setting: 90
    - policy_class: Machine
```

Example using abbreviated form:

```
Account lockout duration:
  lgpo.set:
    - setting: 120
    - policy_class: Machine
```

It is also possible to set multiple policies in a single state. This is done by setting the settings under either `computer_policy` or `user_policy`. Here are some examples for setting multiple policy settings in a single state.

Multiple policy configuration

```
Company Local Group Policy:
  lgpo.set:
    - computer_policy:
      Deny log on locally:
        - Guest
      Account lockout duration: 120
      Account lockout threshold: 10
      Reset account lockout counter after: 120
      Enforce password history: 24
      Maximum password age: 60
      Minimum password age: 1
      Minimum password length: 14
      Password must meet complexity requirements: Enabled
      Store passwords using reversible encryption: Disabled
      Configure Automatic Updates:
        Configure automatic updating: 4 - Auto download and schedule the install
        Scheduled install day: 7 - Every Saturday
        Scheduled install time: 17:00
        Specify intranet Microsoft update service location:
          Set the intranet update service for detecting updates: http://mywsus
          Set the intranet statistics server: http://mywsus
      - user_policy:
        Do not process the legacy run list: Enabled
```
server_policy:
  lgpo.set:
    - computer_policy:
      Maximum password age: 60
      Minimum password age: 1
      Minimum password length: 14
      Account lockout duration: 120
      Account lockout threshold: 10
      Reset account lockout counter after: 120
      Manage auditing and security log:
        - "BUILTIN\Administrators"
      Replace a process level token:
        - "NT AUTHORITY\NETWORK SERVICE"
        - "NT AUTHORITY\LOCAL SERVICE"
      "Accounts: Guest account status": Disabled
      "Accounts: Rename guest account": Not_4_U
      "Audit: Audit the use of Backup and Restore privilege": Enabled
      "Interactive logon: Do not display last user name": Enabled
      "Network\DNS Client\Dynamic update": Disabled
      "System\Logon\Do not display the Getting Started welcome screen at logon": Enabled
      "Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections\Select RDP transport protocols": "Select Transport Type": "Use both UDP and TCP"
      "Windows Components\Windows Update\Allow Automatic Updates immediate": Enabled
      "Windows Components\Windows Update\Allow non-administrators to receive update notifications": Disabled
      "Windows Components\Windows Update\Always automatically restart at the scheduled time": "The restart timer will give users this much time to save their work (minutes)": 15
      "Windows Components\Windows Update\Automatic Updates detection frequency": "Check for updates at the following interval (hours)": 1
      "Windows Components\Windows Update\Configure Automatic Updates": "Schedule automatic updating": 4 - Auto download and schedule the install
      "Install during automatic maintenance": False
      "Scheduled install day": 7 - Every Saturday
      "Scheduled install time": "17:00"
      "Windows Components\Windows Update\Delay Restart for scheduled installations": "Wait the following period before proceeding with a scheduled restart (minutes)": 1
      "Windows Components\Windows Update\No auto-restart with logged on users for scheduled automatic updates installations": Disabled
      "Windows Components\Windows Update\Re-prompt for restart with scheduled installations": "Wait the following period before prompting again with a scheduled restart (minutes)": 30
      "Windows Components\Windows Update\Reschedule Automatic Updates scheduled installations": Disabled
      "Windows Components\Windows Update\Specify intranet Microsoft update service location": "Set the intranet update service for detecting updates": http://mywsus
      "Set the intranet statistics server": http://mywsus
      cumulative_rights_assignments: True
Some policy settings can't be set on their own an require that other policy
settings are set at the same time. It can be difficult to figure out what
additional settings need to be applied. The easiest way to do this is to
modify the setting manually using the Group Policy Editor (`gpedit.msc`) on
the machine. Then `get` the policy settings configured on that machine. Use
the following command:

```bash
salt-call --local lgpo.get machine
```

For example, if I want to set the Windows Update settings for a Windows
Server 2016 machine I would go into the Group Policy Editor (`gpedit.msc`) and configure the group policy. That policy can be found at: Computer
Configuration -> Administrative Templates -> Windows Components -> Windows
Update -> Configure Automatic Updates. You have the option to "Enable" the
policy and set some configuration options. In this example, just click
"Enable" and accept the default configuration options. Click "OK" to apply
the setting.

Now run the `get` command as shown above. You will find the following in
the minion return:

```bash
Windows Components\Windows Update\Configure Automatic Updates:

Define automatic updating:
  3 - Auto download and notify for install

Install during automatic maintenance:
  False

Install updates for other Microsoft products:
  False

Scheduled install day:
  0 - Every day

Scheduled install time:
  03:00
```

This shows you that to enable the "Configure Automatic Updates" policy you
also have to configure the following settings:

- Configure automatic updating
- Install during automatic maintenance
- Install updates for other Microsoft products
- Scheduled install day
- Scheduled install time

So, if you were writing a state for the above policy, it would look like
this:

```bash
configure_windows_update_settings:
  lgpo.set:
    - computer_policy:
      Configure Automatic Updates:
```
Configure automatic updating: 3 - Auto download and notify for install
Install during automatic maintenance: False
Install updates for other Microsoft products: False
Scheduled install day: 0 - Every day
Scheduled install time: 03:00

.. note::

It is important that you put names of policies and settings exactly as they are displayed in the return. That includes capitalization and punctuation such as periods, dashes, etc. This rule applies to both the setting name and the setting value.

.. warning::

From time to time Microsoft updates the Administrative templates on the machine. This can cause the policy name to change or the list of settings that must be applied at the same time. These settings often change between versions of Windows as well. For example, Windows Server 2019 allows you to also specify a specific week of the month to apply the update.

Another thing note is the long policy name returned by the `get` function:

.. code-block:: bash

    Windows Components\Windows Update\Configure Automatic Updates:

When we wrote the state for this policy we only used the final portion of the policy name, 'Configure Automatic Updates'. This usually works fine, but if you are having problems, you may try the long policy name.

When writing the long name in a state file either wrap the name in single quotes to make yaml see it as raw data, or escape the back slashes.

.. code-block:: bash

    'Windows Components\Windows Update\Configure Automatic Updates:'
    or

    Windows Components\Windows Update\Configure Automatic Updates:

salt.states.win_lgpo.set_(name, setting=None, policy_class=None, computer_policy=None, user_policy=None, cumulative_rights_assignments=True, admil_language='en-US')

Ensure the specified policy is set.

Warning: The setting argument cannot be used in conjunction with the computer_policy or user_policy arguments

Parameters

- **name**(str) -- The name of a single policy to configure
- **setting**(str, dict, list) -- The configuration setting for the single named policy. If this argument is used the computer_policy / user_policy argu-
ments will be ignored

- **policy_class** *(str)* -- The policy class of the single named policy to configure. This can be machine, user, or both

- **computer_policy** *(dict)* -- A dictionary of containing the policy name and key/value pairs of a set of computer policies to configure. If this argument is used, the name / policy_class arguments will be ignored

- **user_policy** *(dict)* -- A dictionary of containing the policy name and key/value pairs of a set of user policies to configure. If this argument is used, the name / policy_class arguments will be ignored

- **cumulative_rights_assignments** *(bool)* -- If user rights assignments are being configured, determines if any user right assignment policies specified will be cumulative or explicit

- **adml_language** *(str)* -- The adml language to use for AMDX policy data/display conversions. Default is en-US

23.19.318 salt.states.win_license

Installation and activation of windows licenses

Install and activate windows licenses

```
XXXXX-XXXXX-XXXXX-XXXXX-XXXXX:
lzence.activate
```

salt.states.win_license.activate(*name*)

Install and activate the given product key

name  The 5x5 product key given to you by Microsoft

23.19.319 salt.states.win_network

Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the network state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed.

Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: dhcp
        - ip_proto: dhcp
```

Note: Both the dns_proto and ip_proto arguments are required.

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: static
        - dns_servers:
```

(continues on next page)
- 8.8.8.8
- 8.8.4.4
- **ip_proto**: static
- **ip_addrs**: 10.2.3.4/24

Note: IP addresses are specified using the format `<ip-address>/subnet-length`. Salt provides a convenience function called `ip.get_subnet_length` to calculate the subnet length from a netmask.

Optionally, if you are setting a static IP address, you can also specify the default gateway using the `gateway` parameter:

```
Local Area Connection #2:
    network.managed:
        - **dns_proto**: static
        - **dns_servers**: 8.8.8.8
            - 8.8.4.4
        - **ip_proto**: static
        - **ip_addrs**: 10.2.3.4/24
        - **gateway**: 10.2.3.1
```

salt.states.win_network.managed(name, dns_proto=None, dns_servers=None, ip_proto=None, ip_addrs=None, gateway=None, enabled=True, **kwargs)

Ensure that the named interface is configured properly.

Parameters

- **name** *(str)* -- The name of the interface to manage
- **dns_proto** *(str)* -- None Set to `static` and use the `dns_servers` parameter to provide a list of DNS nameservers. set to `dhcp` to use DHCP to get the DNS servers.
- **dns_servers** *(list)* -- None A list of static DNS servers. To clear the list of DNS servers pass an empty list (`[]`). None will make no changes.
- **ip_proto** *(str)* -- None Set to `static` and use the `ip_addrs` and (optionally) gateway parameters to provide a list of static IP addresses and the default gateway. Set to dhcp to use DHCP.
- **ip_addrs** *(list)* -- None A list of static IP addresses with netmask flag, ie: 192.168.0.100/24
- **gateway** *(str)* -- None The gateway to set for the interface
- **enabled** *(bool)* -- True Set to `False` to ensure that this interface is disabled.

Returns A dictionary of old and new settings

Example:

```
Ethernet1:
    network.managed:
        - **dns_proto**: static
        - **dns_servers**: 8.8.8.8
            - 8.8.4.4
        - **ip_proto**: static
        - **ip_addrs**: 192.168.0.100/24
```

Clear DNS entries example:
23.19.320 salt.states.win_path

Manage the Windows System PATH

salt.states.win_path.absent(name)
Remove the directory from the SYSTEM path

Example:

'C:\sysinternals':
    win_path.absent

salt.states.win_path.exists(name, index=None)
Add the directory to the system PATH at index location
index  Position where the directory should be placed in the PATH. This is 0-indexed, so 0 means to prepend at
the very start of the PATH.

Note: If the index is not specified, and the directory needs to be added to the PATH, then the directory
will be appended to the PATH, and this state will not enforce its location within the PATH.

Examples:

'C:\python27':
    win_path.exists

'C:\sysinternals':
    win_path.exists:
        - index: 0

'C:\mystuff':
    win_path.exists:
        - index: -1

23.19.321 salt.states.win_pki

Microsoft certificate management via the Pki PowerShell module.

platform  Windows
New in version 2016.11.0.

salt.states.win_pki.import_cert(name, cert_format='cer', context='LocalMachine', store='My', exportable=True, password='', saltenv='base')
Import the certificate file into the given certificate store.

Parameters
- name (str) -- The path of the certificate file to import.
- cert_format (str) -- The certificate format. Specify 'cer' for X.509, or 'pfx' for
  PKCS #12.
- context (str) -- The name of the certificate store location context.
• **store** (*str*) -- The name of the certificate store.
• **exportable** (*bool*) -- Mark the certificate as exportable. Only applicable to pfx format.
• **password** (*str*) -- The password of the certificate. Only applicable to pfx format.
• **saltenv** (*str*) -- The environment the file resides in.

Example of usage with only the required arguments:

```python
site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.cer
```

Example of usage specifying all available arguments:

```python
site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.pfx
        - cert_format: pfx
        - context: LocalMachine
        - store: My
        - exportable: True
        - password: TestPassword
        - saltenv: base
```

salt.states.win_pki.remove_cert(*name*, *thumbprint*, *context='LocalMachine', store='My')

Remove the certificate from the given certificate store.

Parameters

• **thumbprint** (*str*) -- The thumbprint value of the target certificate.
• **context** (*str*) -- The name of the certificate store location context.
• **store** (*str*) -- The name of the certificate store.

Example of usage with only the required arguments:

```python
site0-cert-removed:
    win_pki.remove_cert:
        - thumbprint: 9988776655443322111000AAABBBCCDDDEEEFFF
```

Example of usage specifying all available arguments:

```python
site0-cert-removed:
    win_pki.remove_cert:
        - thumbprint: 9988776655443322111000AAABBBCCDDDEEEFFF
        - context: LocalMachine
        - store: My
```

**23.19.322  salt.states.win_powercfg**

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```yaml
# Set timeout to 30 minutes on battery power
monitor:
    powercfg.set_timeout:
        - value: 30
        - power: dc
```
salt.states.win_powercfg.set_timeout(name, value, power='ac', scheme=None)

Set the sleep timeouts of specific items such as disk, monitor, etc.

Parameters
- **name** (*str*) -- The setting to change, can be one of the following:
  - monitor
  - disk
  - standby
  - hibernate
- **value** (*int*) -- The amount of time in minutes before the item will timeout
- **power** (*str*) -- Set the value for AC or DC power. Default is ac. Valid options are:
  - ac (AC Power)
  - dc (Battery)
- **scheme** (*str*) -- The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

CLI Example:

```bash
# Set monitor timeout to 30 minutes on Battery
monitor:
  powercfg.set_timeout:
    - value: 30
    - power: dc

# Set disk timeout to 10 minutes on AC Power
disk:
  powercfg.set_timeout:
    - value: 10
    - power: ac
```

23.19.323 salt.states.win_servermanager

Manage Windows features via the ServerManager powershell module. Can install and remove roles/features.

Maintainer Shane Lee <slee@saltstack.com>

Platform Windows Server 2008R2 or greater

Depends win_servermanager.install

Depends win_servermanager.remove

salt.states.win_servermanager.installed(name, features=None, recurse=False, restart=False, source=None, exclude=None, **kwargs)

Install the windows feature. To install a single feature, use the name parameter. To install multiple features, use the features parameter.

*Note:* Some features require reboot after un/installation. If so, until the server is restarted other features can not be installed!

Parameters
- **name** (*str*) -- Short name of the feature (the right column in win_servermanager.list_available). This can be a single feature or a string of features in a comma delimited list (no spaces)
Note: A list is not allowed in the name parameter of any state. Use the features parameter if you want to pass the features as a list.

- **features** (*Optional*[list]) -- A list of features to install. If this is passed it will be used instead of the name parameter.

  New in version 2018.3.0.

- **recurse** (*Optional*[bool]) -- Install all sub-features as well. If the feature is installed but one of its sub-features are not installed set this will install additional sub-features. This argument was previously renamed from force. To ensure backwards compatibility force will continue to work but please update your states to use the preferred recurse arg.

- **source** (*Optional*[str]) -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None

- **restart** (*Optional*[bool]) -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is False

- **exclude** (*Optional*[str]) -- The name of the feature to exclude when installing the named feature. This can be a single feature, a string of features in a comma-delimited list (no spaces), or a list of features.

  **Warning:** As there is no exclude option for the Add-WindowsFeature or Install-WindowsFeature PowerShell commands the features named in exclude will be installed with other sub-features and will then be removed. If the feature named in `"exclude"` is not a sub-feature of one of the installed items it will still be removed.

**Example**

Do not use the role or feature names mentioned in the PKGMGR documentation. To get a list of available roles and features run the following command:

```
salt <minion_name> win_servermanager.list_available
```

Use the name in the right column of the results.

```
# Installs the IIS Web Server Role (Web-Server)
IIS-WebServerRole:
    win_servermanager.installed:
        - recurse: True
        - name: Web-Server

# Install multiple features, exclude the Web-Service
install_multiple_features:
    win_servermanager.installed:
        - recurse: True
        - features:
            - RemoteAccess
            - XPS-Viewer
            - SNMP-Service
        - exclude:
            - Web-Server
```
salt.states.win_servermanager.removed(name, features=None, remove_payload=False, restart=False)

Remove the windows feature. To remove a single feature, use the name parameter. To remove multiple features, use the features parameter.

**Parameters**

- **name** *(str)* -- Short name of the feature (the right column in `win_servermanager.list_available`). This can be a single feature or a string of features in a comma-delimited list (no spaces)

**Note:** A list is not allowed in the name parameter of any state. Use the features parameter if you want to pass the features as a list

- **features** *(Optional[list]*) -- A list of features to remove. If this is passed it will be used instead of the name parameter.

  New in version 2018.3.0.

- **remove_payload** *(Optional[bool]*) -- True will cause the feature to be removed from the side-by-side store. To install the feature in the future you will need to specify the source.

- **restart** *(Optional[bool]*) -- Restarts the computer when uninstall is complete if required by the role/feature uninstall. Default is False

**Note:** Some features require a reboot after uninstall. If so the feature will not be completely uninstalled until the server is restarted.

**Example**

Do not use the role or feature names mentioned in the PKGMGR documentation. To get a list of available roles and features run the following command:

```shell
salt <minion_name> win_servermanager.list_available
```

Use the name in the right column of the results.

```python
# Uninstall the IIS Web Server Role (Web-Server)
IIS-WebserverRole:
    win_servermanager.removed:
        - name: Web-Server

# Uninstall multiple features, reboot if required
uninstall_multiple_features:
    win_servermanager.removed:
        - features:
            - RemoteAccess
            - XPX-Viewer
            - SNMP-Service
            - restart: True
```
23.19.324 salt.states.win_smtp_server

Module for managing IIS SMTP server configuration on Windows servers.

salt.states.win_smtp_server.active_log_format(name, log_format, server='SmtpSvc/1')
Manage the active log format for the SMTP server.
Parameters
- log_format (str) -- The log format name.
- server (str) -- The SMTP server name.

Example of usage:

```python
smtp-log-format:
  win_smtp_server.active_log_format:
    - log_format: Microsoft IIS Log File Format
```

salt.states.win_smtp_server.connection_ip_list(name, addresses=None, grant_by_default=False, server='SmtpSvc/1')
Manage IP list for SMTP connections.
Parameters
- addresses (str) -- A dictionary of IP + subnet pairs.
- grant_by_default (bool) -- Whether the addresses should be a blacklist or whitelist.
- server (str) -- The SMTP server name.

Example of usage for creating a whitelist:

```python
smtp-connection-whitelist:
  win_smtp_server.connection_ip_list:
    - addresses: 127.0.0.1: 255.255.255.255
      172.16.1.98: 255.255.255.255
      172.16.1.99: 255.255.255.255
    - grant_by_default: False
```

Example of usage for creating a blacklist:

```python
smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses: 172.16.1.100: 255.255.255.255
      172.16.1.101: 255.255.255.255
    - grant_by_default: True
```

Example of usage for allowing any source to connect:

```python
smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses: {}
    - grant_by_default: True
```

salt.states.win_smtp_server.relay_ip_list(name, addresses=None, server='SmtpSvc/1')
Manage IP list for SMTP relay connections.

Due to the unusual way that Windows stores the relay IPs, it is advisable to retrieve the existing list you wish to set from a pre-configured server.

For example, setting '127.0.0.1' as an allowed relay IP through the GUI would generate an actual relay IP list similar to the following:
Note: Setting the list to None corresponds to the restrictive 'Only the list below' GUI parameter with an empty access list configured, and setting an empty list/tuple corresponds to the more permissive 'All except the list below' GUI parameter.

Parameters

- **addresses** *(str)* -- A list of the relay IPs. The order of the list is important.
- **server** *(str)* -- The SMTP server name.

Example of usage:

```python
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    addresses:
      - 24.0.0.128
      - 32.0.0.128
      - 60.0.0.128
      - 1.0.0.0
      - 76.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 1.0.0.0
      - 1.0.0.0
      - 2.0.0.0
      - 2.0.0.0
      - 4.0.0.0
      - 0.0.0.0
      - 76.0.0.128
      - 0.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 255.255.255.255
      - 127.0.0.1
```

Example of usage for disabling relaying:

```python
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    addresses: None
```

Example of usage for allowing relaying from any source:

```python
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    addresses: []
```

salt.states.win_smtp_server.server_setting(name, settings=None, server='SmtpSvc/1')
Ensure the value is set for the specified setting.
Parameters

- **settings** *(str)* -- A dictionary of the setting names and their values.
- **server** *(str)* -- The SMTP server name.

Example of usage:

```python
smtp-settings:
    win_smtp_server.server_setting:
        - settings:
            LogType: 1
            LogFilePeriod: 1
            MaxMessageSize: 16777216
            MaxRecipients: 10000
            MaxSessionSize: 16777216
```

23.19.325 salt.states.win_snmp

Module for managing SNMP service settings on Windows servers.

```python
salt.states.win_snmp.agent_settings(name, contact, location, services=None)
```

Manage the SNMP sysContact, sysLocation, and sysServices settings.

Parameters

- **contact** *(str)* -- The SNMP contact.
- **location** *(str)* -- The SNMP location.
- **services** *(str)* -- A list of selected services.

Example of usage:

```python
snmp-agent-settings:
    win_snmp.agent_settings:
        - contact: Test Contact
        - location: Test Location
        - services:
            - Physical
            - Internet
```

```python
salt.states.win_snmp.auth_traps_enabled(name, status=True)
```

Manage the sending of authentication traps.

Parameters **status** *(bool)* -- The enabled status.

Example of usage:

```python
snmp-auth-traps:
    win_snmp.auth_traps_enabled:
        - status: True
```

```python
salt.states.win_snmp.community_names(name, communities=None)
```

Manage the SNMP accepted community names and their permissions.

Parameters **communities** *(str)* -- A dictionary of SNMP communities and permissions.

Example of usage:

```python
snmp-community-names:
    win_snmp.community_names:
        - communities:
```

(continues on next page)
23.19.326 salt.states.win_system

Management of Windows system information

New in version 2014.1.0.

This state is used to manage system information such as the computer name and description.

salt.states.win_system.computer_desc(name)
    Manage the computer's description field
    name The desired computer description

salt.states.win_system.computer_name(name)
    Manage the computer's name
    name The desired computer name

salt.states.win_system.hostname(name)
    New in version 2016.3.0.
    Manage the hostname of the computer
    name The hostname to set

salt.states.win_system.join_domain(name, username=None, password=None, account_ou=None, account_exists=False, restart=False)
    Checks if a computer is joined to the Domain. If the computer is not in the Domain, it will be joined.
    Parameters
        • name (str) -- The name of the Domain.
        • username (str) -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user.
        • password (str) -- Password of the account to add the computer to the Domain.
        • account_ou (str) -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=departm_432,dc=my-company,dc=com.
        • account_exists (bool) -- Needs to be set to True to allow re-using an existing computer account.
        • restart (bool) -- Needs to be set to True to restart the computer after a successful join.
    Example:

    join_to_domain:
    system.join_domain:
        - name: mydomain.local.com
        - username: myaccount@mydomain.local.com
        - password: mysecretpassword
        - restart: True

    (continued from previous page)
salt.states.win_system.reboot(name, message=None, timeout=5, force_close=True, in_seconds=False, only_on_pending_reboot=True)

Reboot the computer

Parameters

- **message**(str) -- An optional message to display to users. It will also be used as a comment in the event log entry.
  
The default value is None.
- **timeout**(int) -- The number of minutes or seconds before a reboot will occur. Whether this number represents minutes or seconds depends on the value of `in_seconds`.
  
The default value is 5.
- **in_seconds**(bool) -- If this is True, the value of `timeout` will be treated as a number of seconds. If this is False, the value of `timeout` will be treated as a number of minutes.
  
The default value is False.
- **force_close**(bool) -- If this is True, running applications will be forced to close without warning. If this is False, running applications will not get the opportunity to prompt users about unsaved data.
  
The default value is True.
- **only_on_pending_reboot**(bool) -- If this is True, the reboot will only occur if the system reports a pending reboot. If this is False, the reboot will always occur.
  
The default value is True.

salt.states.win_system.shutdown(name, message=None, timeout=5, force_close=True, reboot=False, in_seconds=False, only_on_pending_reboot=False)

Shutdown the computer

Parameters

- **message**(str) -- An optional message to display to users. It will also be used as a comment in the event log entry.
  
The default value is None.
- **timeout**(int) -- The number of minutes or seconds before a shutdown will occur. Whether this number represents minutes or seconds depends on the value of `in_seconds`.
  
The default value is 5.
- **in_seconds**(bool) -- If this is True, the value of `timeout` will be treated as a number of seconds. If this is False, the value of `timeout` will be treated as a number of minutes.
  
The default value is False.
- **force_close**(bool) -- If this is True, running applications will be forced to close without warning. If this is False, running applications will not get the opportunity to prompt users about unsaved data.
  
The default value is True.
- **reboot**(bool) -- If this is True, the computer will restart immediately after shutting down. If False the system flushes all caches to disk and safely powers down the system.
  
The default value is False.
- **only_on_pending_reboot**(bool) -- If this is True, the shutdown will only occur if the system reports a pending reboot. If this is False, the shutdown will always occur.
The default value is False.

\[
\texttt{salt.states.win_system.} \texttt{workgroup(name)}
\]

New in version 3001.

Manage the workgroup of the computer

**Parameters** name (str) -- The workgroup to set

**Example:**

```
set workgroup:
  system.workgroup:
    - name: local
```

23.19.327 salt.states.win_wua

Installation of Windows Updates using the Windows Update Agent

New in version 2017.7.0.

Salt can manage Windows updates via the "wua" state module. Updates can be installed and removed. Update management declarations are as follows:

For installation:

```
# Install a single update using the KB
KB3194343:
  wua.installed

# Install a single update using the name parameter
install_update:
  wua.installed:
    - name: KB3194343

# Install multiple updates using the updates parameter and a combination of
# KB number and GUID
install_updates:
  wua.installed:
    - updates:
      - KB3194343
      - bb1dbb26-3fb6-45fd-bb05-e3c8e379195c
```

For removal:

```
# Remove a single update using the KB
KB3194343:
  wua.removed

# Remove a single update using the name parameter
remove_update:
  wua.removed:
    - name: KB3194343

# Remove multiple updates using the updates parameter and a combination of
# KB number and GUID
remove_updates:
  wua.removed:
    - updates:
```

(continues on next page)
salt.states.win_wua.installed(name, updates=None)

Ensure Microsoft Updates are installed. Updates will be downloaded if needed.

Parameters

- name (str) -- The identifier of a single update to install.
- updates (list) -- A list of identifiers for updates to be installed. Overrides name.
  Default is None.

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you're installing the correct update.

Warning: Using a partial KB number or a partial Title could result in more than one update being installed.

Returns A dictionary containing the results of the update

Return type dict

CLI Example:

```
# using a GUID
install_update:
  wua.installed:
    - name: 28cf1b09-2b1a-458c-9bd1-971d1b26b211

# using a KB
install_update:
  wua.installed:
    - name: KB3194343

# using the full Title
install_update:
  wua.installed:
    - name: Security Update for Adobe Flash Player for Windows 10 Version 1607(R)
      →(for x64-based Systems) (KB3194343)

# Install multiple updates
install_updates:
  wua.installed:
    - updates:
      - KB3194343
      - 28cf1b09-2b1a-458c-9bd1-971d1b26b211
```

salt.states.win_wua.removed(name, updates=None)

Ensure Microsoft Updates are uninstalled.

Parameters

- name (str) -- The identifier of a single update to uninstall.
- updates (list) -- A list of identifiers for updates to be removed. Overrides name.
  Default is None.

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you're uninstalling the correct update.
Warning: Using a partial KB number or a partial Title could result in more than one update being removed.

Returns A dictionary containing the results of the removal
Return type dict

CLI Example:

```sh
# using a GUID
uninstall_update:
  wua.removed:
    - name: 28cf1b09-2b1a-458c-9bd1-971d1b26b211

# using a KB
uninstall_update:
  wua.removed:
    - name: KB3194343

# using the full Title
uninstall_update:
  wua.removed:
    - name: Security Update for Adobe Flash Player for Windows 10 Version 1607\n      → (for x64-based Systems) (KB3194343)

# Install multiple updates
uninstall_updates:
  wua.removed:
    - updates:
      - KB3194343
      - 28cf1b09-2b1a-458c-9bd1-971d1b26b211
```

`salt.states.win_wua.uptodate(name, software=True, drivers=False, skip_hidden=False, skip_mandatory=False, skip_reboot=True, categories=None, severities=None)`

Ensure Microsoft Updates that match the passed criteria are installed. Updates will be downloaded if needed.

This state allows you to update a system without specifying a specific update to apply. All matching updates will be installed.

Parameters

- **name (str)** -- The name has no functional value and is only used as a tracking reference
- **software (bool)** -- Include software updates in the results (default is True)
- **drivers (bool)** -- Include driver updates in the results (default is False)
- **skip_hidden (bool)** -- Skip updates that have been hidden. Default is False.
- **skip_mandatory (bool)** -- Skip mandatory updates. Default is False.
- **skip_reboot (bool)** -- Skip updates that require a reboot. Default is True.
- **categories (list)** -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:

- Critical Updates
- Definition Updates
- Drivers (make sure you set drivers=True)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

- **severities** *(list)* -- Specify the severities to include. Must be passed as a list. All severities returned by default.

Severities include the following:
- Critical
- Important

Returns A dictionary containing the results of the update

Return type *dict*

CLI Example:

```bash
# Update the system using the state defaults
update_system:
  wua.uptodate

# Update the drivers
update_drivers:
  wua.uptodate:
    - software: False
    - drivers: True
    - skip_reboot: False

# Apply all critical updates
update_critical:
  wua.uptodate:
    - severities:
      - Critical
```

### 23.19.328 salt.states.win_wusa

Microsoft Updates (KB) Management

This module provides the ability to enforce KB installations from files (.msu), without WSUS or Windows Update

New in version 2018.3.4.

salt.states.win_wusa.**installed**(name, source)

Ensure an update is installed on the minion

Parameters

- **name** *(str)* -- Name of the Windows KB ("KB123456")
- **source** *(str)* -- Source of .msu file corresponding to the KB

Example:

```
KB123456:
  wusa.installed:
    - source: salt://kb123456.msu
```

salt.states.win_wusa.**uninstalled**(name)

Ensure an update is uninstalled from the minion

Parameters **name** *(str)* -- Name of the Windows KB ("KB123456")

Example:
23.19.329  salt.states.winrepo

Manage Windows Package Repository

\[
\text{salt.states.winrepo.}\text{genrepo(}\text{name, force=False, allow_empty=False}\text{)}
\]

Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)

If \textit{force} is True no checks will be made and the repository will be generated if \textit{allow_empty} is True then the state will not return an error if there are 0 packages,

\textbf{Note:} This state only loads on minions that have the \textit{roles: salt-master} grain set.

Example:

\[
\text{winrepo:}
\begin{align*}
\text{winrepo}.\text{genrepo}
\end{align*}
\]

23.19.330  salt.states.wordpress

This state module is used to manage Wordpress installations

\textbf{depends} wp binary from http://wp-cli.org/

\[
\text{salt.states.wordpress.}\text{activated(}\text{name, path, user}\text{)}
\]

Activate wordpress plugins

\textit{name} name of plugin to activate
\textit{path} path to wordpress installation
\textit{user} user who should own the files in the wordpress installation

\begin{tabular}{|c|}
\hline
\textbf{HyperDB:} \\
\textit{wordpress.activated:} \\
\hspace{1cm} - \textit{path}: /var/www/html \\
\hspace{1cm} - \textit{user}: apache \\
\hline
\end{tabular}

\[
\text{salt.states.wordpress.}\text{deactivated(}\text{name, path, user}\text{)}
\]

Deactivate wordpress plugins

\textit{name} name of plugin to deactivate
\textit{path} path to wordpress installation
\textit{user} user who should own the files in the wordpress installation

\begin{tabular}{|c|}
\hline
\textbf{HyperDB:} \\
\textit{wordpress.deactivated:} \\
\hspace{1cm} - \textit{path}: /var/www/html \\
\hspace{1cm} - \textit{user}: apache \\
\hline
\end{tabular}

\[
\text{salt.states.wordpress.}\text{installed(}\text{name, user, admin_user, admin_password, admin_email, title, url}\text{)}
\]

Run the initial setup of wordpress

\textit{name} path to the wordpress installation
\textit{user} user that owns the files for the wordpress installation
admin_user  username for wordpress website administrator user
admin_password  password for wordpress website administrator user
admin_email  email for wordpress website administrator user
title  title for the wordpress website
url  url for the wordpress website

```
/var/www/html:
wordpress.installed:
  - title: Daniel's Awesome Blog
  - user: apache
  - admin_user: dwallace
  - admin_email: dwallace@example.com
  - admin_password: password123
  - url: https://blog.dwallace.com
```

23.19.331 salt.states.x509

Manage X509 Certificates

New in version 2015.8.0.

depends  M2Crypto

This module can enable managing a complete PKI infrastructure including creating private keys, CAs, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.

Here is a simple example scenario. In this example ca is the ca server, and www is a web server that needs a certificate signed by ca.

For remote signing, peers must be permitted to remotely call the sign_remote_certificate function.

/etc/salt/master.d/peer.conf

```
peer:
  .*
    - x509.sign_remote_certificate
```

/srv/salt/top.sls

```
base:
  '*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine where it can be easily retrieved by other minions.

/srv/salt/ca.sls

```
/etc/salt/minion.d/x509.conf:
file.managed:
  - source: salt://x509.conf
```

(continues on next page)
```
restart-salt-minion:
    cmd.run:
        - name: 'salt-call service.restart salt-minion'
        - bg: True
        - onchanges:
            - file: /etc/salt/minion.d/x509.conf

/etc/pki:
    file.directory

/etc/pki/issued_certs:
    file.directory

/etc/pki/ca.key:
    x509.private_key_managed:
        - bits: 4096
        - backup: True

/etc/pki/ca.crt:
    x509.certificate_managed:
        - signing_private_key: /etc/pki/ca.key
        - CN: ca.example.com
        - C: US
        - ST: Utah
        - L: Salt Lake City
        - basicConstraints: "critical CA:true"
        - keyUsage: "critical cRLSign, keyCertSign"
        - subjectKeyIdentifier: hash
        - authorityKeyIdentifier: keyid,issuer:always
        - days_valid: 3650
        - days_remaining: 0
        - backup: True
        - require:
            - file: /etc/pki
```

The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.

```
/srv/salt/x509.conf
```

```
mine_functions:
    x509.get_pem_entries: [/etc/pki/ca.crt]

x509_signing_policies:
    www:
        - minions: 'www'
        - signing_private_key: /etc/pki/ca.key
        - signing_cert: /etc/pki/ca.crt
        - C: US
        - ST: Utah
        - L: Salt Lake City
        - basicConstraints: "critical CA:false"
        - keyUsage: "critical keyEncipherment"
        - subjectKeyIdentifier: hash
        - authorityKeyIdentifier: keyid,issuer:always
        - days_valid: 90
        - copypath: /etc/pki/issued_certs/
```
This state will instruct all minions to trust certificates signed by our new CA. Using Jinja to strip newlines from the text avoids dealing with newlines in the rendered YAML, and the `sign_remote_certificate` state will handle properly formatting the text before writing the output.

/srv/salt/cert.sls

```yaml
/usr/local/share/ca-certificates:
  file.directory

/usr/local/share/ca-certificates/intca.crt:
  x509.pem_managed:
    - text: {{ salt['mine.get'](['ca', 'x509.get_pem_entries'])['ca'][0] }}/etc/pki/ca.crt | replace('
', '') }}
```

This state creates a private key then requests a certificate signed by ca according to the www policy.

/srv/salt/www.sls

```yaml
/etc/pki/www.crt:
  x509.private_keyManaged:
    - name: /etc/pki/www.key
    - bits: 4096
    - backup: True

/etc/pki/www.crt:
  x509.certificateManaged:
    - ca_server: ca
    - signing_policy: www
    - public_key: /etc/pki/www.key
    - CN: www.example.com
    - days_remaining: 30
    - backup: True
```

This other state creates a private key then requests a certificate signed by ca according to the www policy but adds a strict date range for the certificate to be considered valid.

/srv/salt/www-time-limited.sls

```yaml
/etc/pki/www-time-limited.crt:
  x509.certificateManaged:
    - ca_server: ca
    - signing_policy: www
    - public_key: /etc/pki/www-time-limited.key
    - CN: www.example.com
    - not_before: 2019-05-05 00:00:00
    - not_after: 2020-05-05 14:30:00
    - backup: True
```

```
salt.states.x509.certificateManaged(name, days_remaining=90, append_certs=None, **kwargs)

Manage a Certificate

name Path to the certificate
days_remaining [90] Recreate the certificate if the number of days remaining on it are less than this number. The value should be less than days_valid, otherwise the certificate will be recreated every time the state is run. A value of 0 disables automatic renewal.
append_certs: A list of certificates to be appended to the managed file. They must be valid PEM files, otherwise an error will be thrown.
kwargs: Any arguments supported by x509.create_certificate or file.managed are supported.
```
not_before: Initial validity date for the certificate. This date must be specified in the format '%Y-%m-%d %H:%M:%S'.

New in version 3001.

not_after: Final validity date for the certificate. This date must be specified in the format '%Y-%m-%d %H:%M:%S'.

New in version 3001.

Examples:

```
/etc/pki/ca.crt:
  x509.certificate_managed:
    - signing_private_key: /etc/pki/ca.key
    - CN: ca.example.com
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:true"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 3650
    - days_remaining: 0
    - backup: True

/etc/ssl/www.crt:
  x509.certificate_managed:
    - ca_server: pki
    - signing_policy: www
    - public_key: /etc/ssl/www.key
    - CN: www.example.com
    - days_valid: 90
    - days_remaining: 30
    - backup: True
```

salt.states.x509.crl_managed(name, signing_private_key, signing_private_key_passphrase=None, signing_cert=None, revoked=None, days_valid=100, digest='', days_remaining=30, include_expired=False, **kwargs)

Manage a Certificate Revocation List

name Path to the certificate

signing_private_key The private key that will be used to sign the CRL. This is usually your CA's private key.

signing_private_key_passphrase Passphrase to decrypt the private key.

signing_cert The certificate of the authority that will be used to sign the CRL. This is usually your CA's certificate.

revoked A list of certificates to revoke. Must include either a serial number or a the certificate itself. Can optionally include the revocation date and notAfter date from the certificate. See example below for details.

days_valid [100] The number of days the certificate should be valid for.

digest The digest to use for signing the CRL. This has no effect on versions of pyOpenSSL less than 0.14.

days_remaining [30] The CRL should be automatically recreated if there are less than days_remaining days until the CRL expires. Set to 0 to disable automatic renewal.

include_expired [False] If True, include expired certificates in the CRL.

kwargs Any arguments supported by file.managed are supported.

Example:

```
/etc/pki/ca.crl:
```

(continues on next page)
x509.crl_managed:
- signing_private_key: /etc/pki/myca.key
- signing_cert: /etc/pki/myca.crt
- revoked:
  - compromised_web_key:
    - certificate: /etc/pki/certs/badweb.crt
    - revocation_date: 2015-03-01 00:00:00
    - reason: keyCompromise
  - terminated_vpn_user:
    - serial_number: D6:D2:DC:D8:4D:5C:C0:F4
    - not_after: 2016-01-01 00:00:00
    - revocation_date: 2015-02-25 00:00:00
    - reason: cessationOfOperation

salt.states.x509.csr_managed(name, **kwargs)
Manage a Certificate Signing Request
name: Path to the CSR
properties: The properties to be added to the certificate request, including items like subject, extensions and public key. See above for valid properties.
kwargs: Any arguments supported by file.managed are supported.
Example:

/etc/pki/mycert.csr:
 x509.csr_managed:
  - private_key: /etc/pki/mycert.key
  - CN: www.example.com
  - C: US
  - ST: Utah
  - L: Salt Lake City
  - keyUsage: 'critical dataEncipherment'

salt.states.x509.pem_managed(name, text, backup=False, **kwargs)
Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.
name: The path to the file to manage
text: The PEM formatted text to write.
kwargs: Any arguments supported by file.managed are supported.
salt.states.x509.private_key_managed(name, bits=2048, passphrase=None, cipher='aes_128_cbc', new=False, overwrite=False, verbose=True, **kwargs)
Manage a private key’s existence.
name: Path to the private key
bits: Key length in bits. Default 2048.
passphrase: Passphrase for encrypting the private key.
cipher: Cipher for encrypting the private key.
new: Always create a new key. Defaults to False. Combining new with prereq can allow key rotation whenever a new certificate is generated.
overwrite: Overwrite an existing private key if the provided passphrase cannot decrypt it.
verbose: Provide visual feedback on stdout, dots while key is generated. Default is True.

New in version 2016.11.0.
kwargs: Any kwargs supported by file.managed are supported.
Example:
The JINJA templating in this example ensures a private key is generated if the file doesn’t exist and that a new private key is generated whenever the certificate that uses it is to be renewed.
23.19.332  salt.states.xml

XML Manager

State management of XML files

salt.states.xml.value_present(name, xpath, value, **kwargs)

New in version 3000.

Manages a given XML file

name [string] The location of the XML file to manage, as an absolute path.
xpath [string] xpath location to manage
value [string] value to ensure present

```yaml
ensure_value_true:
  xml.value_present:
    - name: /tmp/test.xml
    - xpath: ./playwright[@id='1']
    - value: William Shakespeare
```

23.19.333  salt.states.xmpp

Sending Messages over XMPP

New in version 2014.1.0.

This state is useful for firing messages during state runs, using the XMPP protocol

```yaml
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

salt.states.xmpp.send_msg(name, recipient, profile)

Send a message to an XMPP user

```yaml
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

name The message to send to the XMPP user
salt.states.xmpp.send_msg_multi(name, profile, recipients=None, rooms=None)
Send a message to an list of recipients or rooms

server-warning-message:
xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipients:
        - admins@xmpp.example.com/salt
    - rooms:
        - qa@conference.xmpp.example.com

name  The message to send to the XMPP user

23.19.334  salt.states.zabbix_action

New in version 2017.7.
Management of Zabbix Action object over Zabbix API.

codeauthor  Jakub Sliva <jakub.sliva@ultimum.io>
salt.states.zabbix_action.absent(name, **kwargs)
Makes the Zabbix Action to be absent (either does not exist or delete it).
Parameters
- name -- Zabbix Action name
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

zabbix-action-absent:
    zabbix_action.absent:
        - name: Action name

salt.states.zabbix_action.present(name, params, **kwargs)
Creates Zabbix Action object or if differs update it according defined parameters
Parameters
- name -- Zabbix Action name
- params -- Definition of the Zabbix Action
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

If there is a need to get a value from current zabbix online (e.g. id of a hostgroup you want to put a discovered system into), put a dictionary with two keys "query_object" and "query_name" instead of the value. In this example we want to get object id of hostgroup named "Virtual machines" and "Databases".

zabbix-action-present:
    zabbix_action.present:
        - name: VMs
        - params:
23.19.335 salt.states.zabbix_host

Management of Zabbix hosts.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>
salt.states.zabbix_host.absent(name, **kwargs)
Ensures that the host does not exists, eventually deletes host.

New in version 2016.3.0.

Param name: technical name of the host

Parameters

- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

TestHostWithInterfaces:
zabbix_host.absent

salt.states.zabbix_host.assign_templates(host, templates, **kwargs)
Ensures that templates are assigned to the host.

New in version 2017.7.0.

Parameters

- host -- technical name of the host
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
add_zabbix_templates_to_host:
  zabbix_host.assign_templates:
    - host: TestHost
    - templates:
      - "Template OS Linux"
      - "Template App MySQL"
```

salt.states.zabbix_host.present(host, groups, interfaces, **kwargs)

Ensures that the host exists, eventually creates new host. NOTE: please use argument visible_name instead of name to not mess with name from salt sls. This function accepts all standard host properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host

New in version 2016.3.0.

Parameters

- host -- technical name of the host
- groups -- groupids of host groups to add the host to
- interfaces -- interfaces to be created for the host
- proxy_host -- Optional proxy name or proxyid to monitor host
- inventory -- Optional list of inventory names and values
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- visible_name -- Optional - string with visible name of the host, use 'visible_name' instead of 'name' parameter to not mess with value supplied from Salt sls file.

```python
create_test_host:
  zabbix_host.present:
    - host: TestHostWithInterfaces
    - proxy_host: 12345
    - groups:
      - 5
      - 6
      - 7
    - interfaces:
      - test1.example.com:
        - ip: '192.168.1.8'
        - type: 'Agent'
        - port: 92
      - testing2_create:
        - ip: '192.168.1.9'
        - dns: 'test2.example.com'
        - type: 'agent'
        - main: false
      - testovaci1_ipmi:
        - ip: '192.168.100.111'
        - type: 'ipmi'
    - inventory:
      - alias: some alias
      - asset_tag: jlm3937
```
23.19.336 salt.states.zabbix_hostgroup

Management of Zabbix host groups.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_hostgroup.absent(name, **kwargs)
Ensures that the host group does not exist, eventually delete host group.
New in version 2016.3.0.
Parameters
  • name -- name of the host group
  • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  • _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  • _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
delete_testing_host_group:
  zabbix_hostgroup.absent:
    - name: 'My hostgroup name'
```

salt.states.zabbix_hostgroup.present(name, **kwargs)
Ensures that the host group exists, eventually creates new host group.
New in version 2016.3.0.
Parameters
  • name -- name of the host group
  • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  • _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  • _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
create_testing_host_group:
  zabbix_hostgroup.present:
    - name: 'My hostgroup name'
```

23.19.337 salt.states.zabbix_mediatype

Management of Zabbix mediatypes.

codeauthor Raymond Kuiper <qix@the-wired.net>

salt.states.zabbix_mediatype.absent(name, **kwargs)
 Ensures that the mediatype does not exist, eventually deletes the mediatype.
Parameters
  • name -- name of the mediatype
  • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  • _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  • _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
salt.states.zabbix_mediatype.present(name, mediatype, **kwargs)
Creates new mediatype. NOTE: This function accepts all standard mediatype properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/3.0/manual/api/reference/host/object#host_inventory

Parameters
- name -- name of the mediatype
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

make_new_mediatype:
zabbix_mediatype.present:
  - name: 'Email'
  - mediatype: 0
  - smtp_server: smtp.example.com
  - smtp_hello: zabbix.example.com
  - smtp_email: zabbix@example.com

23.19.338 salt.states.zabbix_template

New in version 2017.7.
Management of Zabbix Template object over Zabbix API.

codeauthor Jakub Sliva <jakub.sliva@ultimum.io>
salt.states.zabbix_template.absent(name, **kwargs)
Makes the Zabbix Template to be absent (either does not exist or delete it).

Parameters
- name -- Zabbix Template name
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

zabbix-template-absent:
zabbix_template.absent:
  - name: Ceph OSD

salt.states.zabbix_template.is_present(name, **kwargs)
Check if Zabbix Template already exists.

Parameters
- name -- Zabbix Template name
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
salt.states.zabbix_template.present(name, params, static_host_list=True, **kwargs)

Creates Zabbix Template object or if differs update it according defined parameters. See Zabbix API documentation.

Zabbix API version: >3.0

Parameters

- **name** -- Zabbix Template name
- **params** -- Additional parameters according to Zabbix API documentation
- **static_host_list** -- If hosts assigned to the template are controlled only by this state or can be also assigned externally
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

---

**Note:** If there is a need to get a value from current zabbix online (e.g. ids of host groups you want the template to be associated with), put a dictionary with two keys "query_object" and "query_name" instead of the value. In this example we want to create template named "Testing Template", assign it to hostgroup Templates, link it to two ceph nodes and create a macro.

---

**Note:** IMPORTANT NOTE: Objects (except for template name) are identified by name (or by other key in some exceptional cases) so changing name of object means deleting old one and creating new one with new ID ‼!

---

**Note:** NOT SUPPORTED FEATURES:

- linked templates
- trigger dependencies
- groups and group prototypes for host prototypes

---

SLS Example:

```
zabbix-template-present:
  zabbix_template.present:
    - name: Testing Template
      # Do not touch existing assigned hosts
      # True will detach all other hosts than defined here
      - static_host_list: False
      - params:
        - description: Template for Ceph nodes
```
groups:
  # groups must already exist
  # template must be at least in one hostgroup
  - groupid:
    query_object: hostgroup
    query_name: Templates

macros:
  - macro: "\{${CEPH_CLUSTER_NAME}\"
    value: ceph

hosts:
  # hosts must already exist
  - hostid:
    query_object: host
    query_name: ceph-osd-01
  - hostid:
    query_object: host
    query_name: ceph-osd-02

# templates:
# Linked templates - not supported by state module but can be linked\n\n  manually (will not be touched)

applications:
  - name: Ceph OSD

items:
  - name: Ceph OSD avg fill item
    key_: ceph.osd_avg_fill
  type: 2
  value_type: 0
  delay: 60
  units: '%'
  description: 'Average fill of OSD'

applications:
  - applicationid:
    query_object: application
    query_name: Ceph OSD

triggers:
  - description: "Ceph OSD filled more that 90%"
    expression: "\{\{{'\}'\}Testing Template:ceph.osd_avg_fill.last()\{\{{'\}'\}\}}\} > 90"

priority: 4

discoveries:
  - name: Mounted filesystem discovery
    key_: vfs.fs.discovery
    type: 0
    delay: 60

itemprototypes:
  - name: Free disk space on {{'#'}}FSNAME
    key_: vfs.fs.size[{{'#'}}FSNAME,free]
    type: 0
    value_type: 3
    delay: 60
  applications:
    - applicationid:
      query_object: application
      query_name: Ceph OSD

triggerprototypes:
- **description**: "Free disk space is less than 20\% on volume \{\{FSNAME\}\}"  
  \(\Rightarrow\{\{FSNAME,free\}\}\text{last()}\{\{\}'\}\}<20"

**expression**: "\{\{Testing Template:vfs.fs.size\{\{FSNAME\}'\}\}{{'}'}}<20"

**graphs**:

- **name**: Ceph OSD avg fill graph  
  \(\Rightarrow\) width: 900  
  height: 200  
  graphtype: 0  
  gitems:

- **color**: F63100  
  itemid:

- **query_object**: item  
  **query_name**: Ceph OSD avg fill item

**screens**:

- **name**: Ceph  
  hsize: 1  
  vsize: 1  
  screenitems:

- **x**: 0  
  **y**: 0  
  resourcetype: 0  
  resourceid:

- **query_object**: graph  
  **query_name**: Ceph OSD avg fill graph

---

### 23.19.339 `salt.states.zabbix_user`

Management of Zabbix users.

**codeauthor** Jiri Kotlin <jiri.kotlin@ultimum.io>

**salt.states.zabbix_user.absent**(*name*, **kwargs)

Ensures that the user does not exist, eventually delete user.

New in version 2016.3.0.

**Parameters**

- **name** -- user alias  
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module’s docstring)  
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module’s docstring)  
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module’s docstring)

```bash
George:
zabbix_user.absent
```

**salt.states.zabbix_user.admin_password_present**(*name*, *password=None*, **kwargs)

Initial change of Zabbix Admin password to password taken from one of the sources (only the most prioritized one):

1. 'password' parameter  
2. '_connection_password' parameter  
3. pillar 'zabbix.password' setting
1) Tries to log in as Admin with password found in state password parameter or _connection_password or pillar or default zabbix password in this precise order, if any of them is present.
2) If one of above passwords matches, it tries to change the password to the most prioritized one.
3) If not able to connect with any password then it fails.

Parameters

- `name` -- Just a name of state
- `password` -- Optional - desired password for Admin to be set
- `_connection_user` -- Optional - Ignored in this state (always assumed 'Admin')
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
# password taken from pillar or _connection_password
zabbix-admin-password:
    zabbix_user.admin_password_present

# directly set password
zabbix-admin-password:
    zabbix_user.admin_password_present:
        - password: SECRET_PASS
```

salt.states.zabbix_user.present(`alias`, `passwd`, `usrgrps`, `medias=None`, `password_reset=False`, **kwargs)

Ensures that the user exists, eventually creates new user. NOTE: use argument firstname instead of name to not mess values with name from salt sls.

New in version 2016.3.0.

Parameters

- `alias` -- user alias
- `passwd` -- user's password
- `usrgrps` -- user groups to add the user to
- `medias` -- Optional - user's medias to create
- `password_reset` -- whether or not to reset password at update
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- `firstname` -- string with firstname of the user, use 'firstname' instead of 'name' parameter to not mess with value supplied from Salt sls file.

```python
make_user:
    zabbix_user.present:
        alias: George
        passwd: donottellanyonE@456x
        password_reset: True
        usrgrps:
            - 13
            - 7
        medias:
            me@example.com:
                mediatype: mail
                period: '1-7,00:00-24:00'
```

(continues on next page)
- severity: NIWAHD
- make_jabber:
  - active: true
  - mediatype: jabber
  - period: '1-5,08:00-19:00'
  - sendto: jabbera@example.com
- text_me_morning_disabled:
  - active: false
  - mediatype: sms
  - period: '1-5,09:30-10:00'
  - severity: D
  - sendto: '+42032132588568'

23.19.340 salt.states.zabbix_usergroup

Management of Zabbix user groups.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_usergroup.absent(name, **kwargs)

Ensures that the user group does not exist, eventually delete user group.

New in version 2016.3.0.

Parameters

- name -- name of the user group
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
delete_thai_monks_usrgrp:
  zabbix_usergroup.absent:
    - name: 'Thai monks'
```

salt.states.zabbix_usergroup.present(name, **kwargs)

Creates new user group. NOTE: This function accepts all standard user group properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.0/manual/appendix/api/usergroup/definitions#user_group

New in version 2016.3.0.

Parameters

- name -- name of the user group
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
make_new_thai_monks_usergroup:
  zabbix_usergroup.present:
    - name: 'Thai monks'
```
23.19.341 salt.states.zabbix_usermacro

Management of Zabbix usermacros. :codeauthor: Raymond Kuiper <qix@the-wired.net>

salt.states.zabbix_usermacro.absent(name, hostid=None, **kwargs)

Ensures that the mediatype does not exist, eventually deletes the mediatype.

Parameters

- **name** -- name of the usermacro
- **hostid** -- id's of the hosts to apply the usermacro on, if missing a global usermacro is assumed.
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
def delete_usermacro:
    zabbix_usermacro.absent:
    - name: '{SNMP_COMMUNITY}'
```

salt.states.zabbix_usermacro.present(name, value, hostid=None, **kwargs)

Creates a new usermacro.

Parameters

- **name** -- name of the usermacro
- **value** -- value of the usermacro
- **hostid** -- id's of the hosts to apply the usermacro on, if missing a global usermacro is assumed.
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
def override_host_usermacro:
    zabbix_usermacro.present:
    - name: '{SNMP_COMMUNITY}''
    - value: 'public'
    - hostid: 21
```
23.19.342 salt.states.zabbix_valuemap

New in version 2017.7.
Management of Zabbix Valuemap object over Zabbix API.

codeauthor Jakub Sliva <jakub.sliva@ultimum.io>
salt.states.zabbix_valuemap.absent(name, **kwargs)

Makes the Zabbix Value map to be absent (either does not exist or delete it).

Parameters

- **name** -- Zabbix Value map name
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
zabbix-valuemap-absent:
  zabbix_valuemap.absent:
    - name: Value map name
```

salt.states.zabbix_valuemap.present(name, params, **kwargs)

Creates Zabbix Value map object or if differs update it according defined parameters

Parameters

- **name** -- Zabbix Value map name
- **params** -- Definition of the Zabbix Value map
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)

        newvalue: two
```

23.19.343 salt.states.zcbuildout

Management of zc.buildout

This module is inspired from minitage's buildout maker (https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py)

New in version 2016.3.0.
Note: This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present

Available Functions

- built

```python
installed1
    buildout.installed:
        - name: /path/to/buildout

installed2
    buildout.installed:
        - name: /path/to/buildout
        - parts:
            - a
            - b
        - python: /path/to/pythonpath/bin/python
        - unless: /bin/test_something_installed
        - onlyif: /bin/test_else_installed
```

salt.states.zcbuildout.installed(name, config='buildout.cfg', quiet=False, parts=None, user=None, env=(), buildout_ver=None, test_release=False, distribute=None, new_st=None, offline=False, newest=False, python='/builds/saltstack/open/docs/builddocs/venv/bin/python3', debug=False, verbose=False, unless=None, onlyif=None, use_vt=False, loglevel='debug', **kwargs)

Install buildout in a specific directory

It is a thin wrapper to modules.buildout.buildout

name directory to execute in

quiet
do not output console & logs

config buildout config to use (default: buildout.cfg)

parts specific buildout parts to run

user user used to run buildout as

New in version 2014.1.4.

env environment variables to set when running

buildout_ver force a specific buildout version (1 | 2)

test_release buildout accept test release

new_st Forcing use of setuptools >= 0.7

distribute use distribute over setuptools if possible

offline does buildout run offline

python python to use

dequg run buildout with -D debug flag

onlyif Only execute cmd if statement on the host return 0

unless Do not execute cmd if statement on the host return 0

newest run buildout in newest mode

distribut3 run buildout in verbose mode (-vvvvv)

use_vt Use the new salt VT to stream output [experimental]

loglevel loglevel for buildout commands
23.19.344 salt.states.zenoss

State to manage monitoring in Zenoss.

New in version 2016.3.0.

This state module depends on the 'zenoss' Salt execution module.

Allows for setting a state of minions in Zenoss using the Zenoss API. Currently Zenoss 4.x and 5.x are supported.

```yaml
enable_monitoring:
  zenoss.monitored:
    - name: web01.example.com
    - device_class: /Servers/Linux
    - collector: localhost
    - prod_state: 1000

salt.states.zenoss.monitored(name, device_class=None, collector='localhost', prod_state=None)

Ensure a device is monitored. The 'name' given will be used for Zenoss device name and should be resolvable.
```

23.19.345 salt.states.zfs

States for managing zfs datasets

maintainer Jorge Schrauwen <sjorge@blackdot.be>
maturity new
depends salt.utils.zfs, salt.modules.zfs
platform smartos, illumos, solaris, freebsd, linux

New in version 2016.3.0.

Changed in version 2018.3.1: Big refactor to remove duplicate code, better type conversions and improved consistency in output.

```yaml
test/shares/yuki:
  zfs.filesystem_present:
    - create_parent: true
    - properties:
      quota: 16G

test/iscsi/haruhi:
  zfs.volume_present:
    - create_parent: true
    - volume_size: 16M
    - sparse: true
    - properties:
      readonly: on

test/shares/yuki@frozen:
```

(continues on next page)
zfs.snapshot_present

moka_origin:
  zfs.hold_present:
    - snapshot: test/shares/yuki@frozen

test/shares/moka:
  zfs.filesystem_present:
    - cloned_from: test/shares/yuki@frozen

test/shares/moka@tsukune:
  zfs.snapshot_absent

salt.states.zfs.bookmark_absent(name, force=False, recursive=False)
  ensure bookmark is absent on the system
  name [string] name of snapshot
  force [boolean] try harder to destroy the dataset (zfs destroy -f)
  recursive [boolean] also destroy all the child datasets (zfs destroy -r)

salt.states.zfs.bookmark_present(name, snapshot)
  ensure bookmark exists
  name [string] name of bookmark
  snapshot [string] name of snapshot

salt.states.zfs.filesystem_absent(name, force=False, recursive=False)
  ensure filesystem is absent on the system
  name [string] name of filesystem
  force [boolean] try harder to destroy the dataset (zfs destroy -f)
  recursive [boolean] also destroy all the child datasets (zfs destroy -r)

  Warning: If a volume with name exists, this state will succeed without destroying the volume specified by name. This module is dataset type sensitive.

salt.states.zfs.filesystem_present(name, create_parent=False, properties=None, cloned_from=None)
  ensure filesystem exists and has properties set
  name [string] name of filesystem
  create_parent [boolean] creates all the non-existing parent datasets. any property specified on the command line using the -o option is ignored.
  cloned_from [string] name of snapshot to clone
  properties [dict] additional zfs properties (-o)

  Note: cloned_from is only use if the filesystem does not exist yet, when cloned_from is set after the filesystem exists it will be ignored.

  Note: Properties do not get cloned, if you specify the properties in the state file they will be applied on a subsequent run.

salt.states.zfs.hold_absent(name, snapshot, recursive=False)
  ensure hold is absent on the system
  name [string] name of hold
  snapshot [string] name of snapshot
**Recursive** [boolean] recursively releases a hold with the given tag on the snapshots of all descendent file systems.

**salt.states.zfs.hold_present** *(name, snapshot, recursive=False)*

- ensure hold is present on the system
- **name** [string] name of holdt
- **snapshot** [string] name of snapshot
- **recursive** [boolean] recursively add hold with the given tag on the snapshots of all descendent file systems.

**salt.states.zfs.promoted** *(name)*

- ensure a dataset is not a clone
- **name** [string] name of filesystem or volume

**Warning:** only one dataset can be the origin, if you promote a clone the original will now point to the promoted dataset

**salt.states.zfs.scheduled_snapshot** *(name, prefix, recursive=True, schedule=None)*

- maintain a set of snapshots based on a schedule
- **name** [string] name of filesystem or volume
- **prefix** [string] prefix for the snapshots e.g. ‘test’ will result in snapshots being named ‘test-yyyymmdd_hhmm’
- **recursive** [boolean] create snapshots for all children also
- **schedule** [dict] dict holding the schedule, the following keys are available (minute, hour, day, month, and year) by default all are set to 0 the value indicated the number of snapshots of that type to keep around.

**Warning:** snapshots will only be created and pruned every time the state runs. a schedule must be setup to automatically run the state. this means that if you run the state daily the hourly snapshot will only be made once per day!

Changed in version 2018.3.0: switched to localtime from gmtime so times now take into account time zones.

**salt.states.zfs.snapshot_absent** *(name, force=False, recursive=False)*

- ensure snapshot is absent on the system
- **name** [string] name of snapshot
- **force** [boolean] try harder to destroy the dataset (zfs destroy -f)
- **recursive** [boolean] also destroy all the child datasets (zfs destroy -r)

**salt.states.zfs.snapshot_present** *(name, recursive=False, properties=None)*

- ensure snapshot exists and has properties set
- **name** [string] name of snapshot
- **recursive** [boolean] recursively create snapshots of all descendent datasets
- **properties** [dict] additional zfs properties (-o)

**salt.states.zfs.volume_absent** *(name, force=False, recursive=False)*

- ensure volume is absent on the system
- **name** [string] name of volume
- **force** [boolean] try harder to destroy the dataset (zfs destroy -f)
- **recursive** [boolean] also destroy all the child datasets (zfs destroy -r)

**Warning:** If a filesystem with name exists, this state will succeed without destroying the filesystem specified by name. This module is dataset type sensitive.

**salt.states.zfs.volume_present** *(name, volume_size, sparse=False, create_parent=False, properties=None, cloned_from=None)*

- ensure volume exists and has properties set
name  [string] name of volume
volume_size  [string] size of volume
sparse  [boolean] create sparse volume
create_parent  [boolean] creates all the non-existing parent datasets. any property specified on the command line using the -o option is ignored.
cloned_from  [string] name of snapshot to clone
properties  [dict] additional zfs properties (-o)

Note: cloned_from is only use if the volume does not exist yet, when cloned_from is set after the volume exists it will be ignored.

Note: Properties do not get cloned, if you specify the properties in the state file they will be applied on a subsequent run.

volume_size is considered a property, so the volume's size will be corrected when the properties get updated if it differs from the original volume.

The sparse parameter is ignored when using cloned_from.

23.19.346  salt.states.zk_concurrency

Control concurrency of steps within state execution using zookeeper

depends  kazoo
configuration  See salt.modules.zookeeper for setup instructions.

This module allows you to "wrap" a state's execution with concurrency control. This is useful to protect against all hosts executing highstate simultaneously if your services don't all HUP restart. The common way of protecting against this is to run in batch mode, but that doesn't protect from another person running the same batch command (and thereby having 2x the number of nodes deploying at once).

This module will block while acquiring a slot, meaning that however the command gets called it will coordinate with zookeeper to ensure that no more than max_concurrency steps are executing with a single path.

acquire_lock:
  zk_concurrency.lock:
    - name: /trafficeserver
    - zk_hosts: 'zookeeper:2181'
    - max_concurrency: 4
    - prereq:
      - service: trafficeserver

trafficserver:
  service.running:
    - watch:
      - file: /etc/trafficserver/records.config

/etc/trafficserver/records.config:
  file.managed:
    - source: salt://records.config

release_lock:
  zk_concurrency.unlock:

(continues on next page)
This example would allow the file state to change, but would limit the concurrency of the trafficserver service restart to 4.

```
salt.states.zk_concurrency.lock(name, zk_hosts=None, identifier=None, max_concurrency=1, timeout=None, ephemerallease=False, profile=None, scheme=None, username=None, password=None, default_acl=None)
```

Block state execution until you are able to get the lock (or hit the timeout)

```
salt.states.zk_concurrency.min_party(name, zk_hosts, min_nodes, blocking=False, profile=None, scheme=None, username=None, password=None, default_acl=None)
```

Ensure that there are `min_nodes` in the party at `name`, optionally blocking if not available.

```
salt.states.zk_concurrency.unlock(name, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False, profile=None, scheme=None, username=None, password=None, default_acl=None)
```

Remove lease from semaphore.

23.19.347 salt.states.zone

Management of Solaris Zones

maintainer Jorge Schrauwen <sjorge@blackdot.be>
maturity new
depends salt.modules.zoneadm, salt.modules.zonecfg
platform solaris
New in version 2017.7.0.

Below are some examples of how to use this state. Lets start with creating a zone and installing it.

```
omipkg1_configuration:
  zone.present:
    - name: omipkg1
      - brand: ipkg
      - zonepath: /zones/omipkg1
      - properties:
        - autoboot: true
        - ip-type: exclusive
        - cpu-shares: 50
      - resources:
        - attr:
          - name: owner
            - value: Jorge Schrauwen
            - type: string
          - attr:
            - name: description
              - value: OmniOS ipkg zone for testing
              - type: string
            - capped-memory:
```
A zone without network access is not very useful. We could update the zone.present state in the example above to add a network interface or we could use a separate state for this.

```
    omipkg1_network:
        zone.resource_present:
            - name: omipkg1
              resource_type: net
              resource_selector_property: mac-addr
              resource_selector_value: "02:08:20:a2:a3:10"
              physical: znic1
              require:
                - zone: omipkg1_configuration
```

Since this is a single tenant system having the owner attribute is pointless. Let's remove that attribute.

---

**Note:** The following state run the omipkg1_configuration state will add it again! If the entire configuration is managed it would be better to add resource_prune and optionally the resource_selector_property properties to the resource.

```
    omipkg1_strip_owner:
        zone.resource_present:
            - name: omipkg1
              resource_type: attr
              resource_selector_property: name
              resource_selector_value: owner
              require:
                - zone: omipkg1_configuration
```

Let's bump the zone's CPU shares a bit.

---

**Note:** The following state run the omipkg1_configuration state will set it to 50 again. Update the entire zone configuration is managed you should update it there instead.

```
    omipkg1_more_cpu:
        zone.property_present:
            - name: omipkg1
              property: cpu-shares
              value: 100
```

Or we can remove the limit altogether!
Note: The following state run the omipkg1_configuration state will set it to 50 again. Update the entire zone configuration is managed you should set the property to None (nothing after the :) instead.

```yaml
omipkg1_no_cpu:
  zonel.property_absent:
    - name: omipkg1
    - property: cpu-shares

salt.states.zone.absent(name, uninstall=False)
  Ensure a zone is absent
  name [string] name of the zone
  uninstall [boolean] when true, uninstall instead of detaching the zone first.

salt.states.zone.attached(name, force=False)
  Ensure zone is attached
  name [string] name of the zone
  force [boolean] force attach the zone

salt.states.zone.booted(name, single=False)
  Ensure zone is booted
  name [string] name of the zone
  single [boolean] boot in single usermode

salt.states.zone.detached(name)
  Ensure zone is detached
  name [string] name of the zone

salt.states.zone.export(name, path, replace=False)
  Export a zones configuration
  name [string] name of the zone
  path [string] path of file to export too.
  replace [boolean] replace the file if it exists

salt.states.zone.halted(name, graceful=True)
  Ensure zone is halted
  name [string] name of the zone
  graceful [boolean] use shutdown instead of halt if true

salt.states.zone.import_(name, path, mode='import', nodataset=False, brand_opts=None)
  Import a zones configuration
  name [string] name of the zone
  path [string] path of the configuration file to import
  mode [string] either import, install, or attach
  nodataset [boolean] do not create a ZFS file system
  brand_opts [boolean] brand specific options to pass

Note: The mode argument can be set to import, install, or attach. import: will only import the configuration install: will import and then try to install the zone attach: will import and then try to attach of the zone

```yaml
omipkg1:
  zonel.import:
    - path: /foo/bar/baz
```
salt.states.zone.installed(name, nodataset=False, brand_opts=None)

Ensure zone is installed
name [string] name of the zone
nodataset [boolean] do not create a ZFS file system
brand_opts [boolean] brand specific options to pass

salt.states.zone.present(name, brand, zonepath, properties=None, resources=None)

Ensure a zone with certain properties and resources
name [string] name of the zone
brand [string] brand of the zone
zonepath [string] path of the zone
properties [list of key-value pairs] dict of properties
resources [list of key-value pairs] dict of resources

Note: If the zone does not exist it will not be installed. You can use the `zone.installed` state for this.

Note:
Default resource selectors:
- fs: dir
- net: mac-addr
- device: match
- rctl: name
- attr: name
- dataset: name
- admin: user

Warning: Properties and resource will not be removed when they are absent from the state!
For properties, simple set them to `None`.
For resources, add the `resource_prune` property and set it to `True`. Also specify the `resource_selector_property` if the default is not the one you want.

salt.states.zone.property_absent(name, property)

Ensure property is absent
name [string] name of the zone
property [string] name of property

Note: This does a zoneacfg clear call. So the property may be reset to a default value! Does has the side effect of always having to be called.

salt.states.zone.property_present(name, property, value)

Ensure property has a certain value
name [string] name of the zone
property [string] name of property
value [string] value of property

salt.states.zone.resource_absent(name, resource_type, resource_selector_property, resource_selector_value)

Ensure resource is absent
name [string] name of the zone
resource_type [string] type of resource
resource_selector_property [string] unique resource identifier
resource_selector_value [string] value for resource selection

**Warning:** Both resource_selector_property and resource_selector_value must be provided, some properties like `name` are already reserved by salt in there states.

**Note:** You can set both resource_selector_property and resource_selector_value to None for resources that do not require them.

```python
salt.states.zone.resource_present(name, resource_type, resource_selector_property, resource_selector_value, **kwargs)
```

Ensure resource exists with provided properties

- name [string] name of the zone
- resource_type [string] type of resource
- resource_selector_property [string] unique resource identifier
- resource_selector_value [string] value for resource selection
- kwargs [string|int|...] resource properties

**Warning:** Both resource_selector_property and resource_selector_value must be provided, some properties like name are already reserved by salt in states.

**Note:** You can set both resource_selector_property and resource_selector_value to None for resources that do not require them.

```python
salt.states.zone.uninstalled(name)
```

Ensure zone is uninstalled

- name [string] name of the zone

### 23.19.348 salt.states.zookeeper

**depends** kazoo

**configuration** See `salt.modules.zookeeper` for setup instructions.

**ACLS**

For more information about ACLs, please checkout the kazoo documentation.

http://kazoo.readthedocs.io/en/latest/api/security.html#kazoo.security.make_digest_acl

The following options can be included in the acl dictionary:

- **param username** Username to use for the ACL.
- **param password** A plain-text password to hash.
- **param write** Write permission.
- **type write** bool
- **param create** Create permission.
type create  bool

param delete  Delete permission.

type delete  bool

param admin  Admin permission.

type admin  bool

param all  All permissions.

type all  bool

salt.states.zookeeper.absent(name, version=-1, recursive=False, profile=None, hosts=None, scheme=None, username=None, password=None, default_acl=None)

Make sure znode is absent

name  path to znode

version  Specify the version which should be deleted Default: -1 (always match)

recursive  Boolean to indicate if children should be recursively deleted Default: False

profile  Configured Zookeeper profile to authenticate with (Default: None)

hosts  Lists of Zookeeper Hosts (Default: '127.0.0.1:2181')

scheme  Scheme to authenticate with (Default: 'digest')

username  Username to authenticate (Default: None)

password  Password to authenticate (Default: None)

default_acl  Default acls to assign if a node is created in this connection (Default: None)

```
defdelete znode:
    zookeeper.absent:
        - name: /test
        - recursive: True
```

salt.states.zookeeper.acls(name, acls, version=-1, profile=None, hosts=None, scheme=None, username=None, password=None, default_acl=None)

Update acls on a znode

name  path to znode

acls  list of acl dictionaries to set on znode

version  Specify the version which should be deleted Default: -1 (always match)

profile  Configured Zookeeper profile to authenticate with (Default: None)

hosts  Lists of Zookeeper Hosts (Default: '127.0.0.1:2181')

scheme  Scheme to authenticate with (Default: 'digest')

username  Username to authenticate (Default: None)

password  Password to authenticate (Default: None)

default_acl  Default acls to assign if a node is created in this connection (Default: None)

```
update acls:
    zookeeper.acls:
        - name: /test/name
        - acls:
            - username: daniel
              password: test
              all: True
            - username: gtmanfred
              password: test
              all: True
```

salt.states.zookeeper.present(name, value, acls=None, ephemeral=False, sequence=False, makepath=False, version=-1, profile=None, hosts=None, scheme=None, username=None, password=None, default_acl=None)

23.19. state modules 4115
Make sure znode is present in the correct state with the correct acls

- **name**: path to znode
- **value**: value znode should be set to
- **acls**: list of acl dictionaries to set on znode (make sure the ones salt is connected with are included) Default: None

**ephemeral** Boolean to indicate if ephemeral znode should be created Default: False

**sequence** Boolean to indicate if znode path is suffixed with a unique index Default: False

**makepath** Boolean to indicate if the parent paths should be created Default: False

**version** For updating, specify the version which should be updated Default: -1 (always match)

**profile** Configured Zookeeper profile to authenticate with (Default: None)

**hosts** Lists of Zookeeper Hosts (Default: '127.0.0.1:2181)

**scheme** Scheme to authenticate with (Default: 'digest')

**username** Username to authenticate (Default: None)

**password** Password to authenticate (Default: None)

**default_acl** Default acls to assign if a node is created in this connection (Default: None)

```
add znode:
    zookeeper.present:
        - name: /test/name
        - value: gtmanfred
        - makepath: True

update znode:
    zookeeper.present:
        - name: /test/name
        - value: daniel
        - acls:
            - username: daniel
              password: test
              read: true
            - username: gtmanfred
              password: test
              read: true
              write: true
              create: true
              delete: true
              admin: true
        - makepath: True
```

23.19.349 salt.states.zpool

States for managing zpools

- **maintainer**: Jorge Schrauwen <sjorge@blackdot.be>
- **maturity**: new
- **depends**: salt.utils.zfs, salt.modules.zpool
- **platform**: smartos, illumos, solaris, freebsd, linux

New in version 2016.3.0.

Changed in version 2018.3.1: Big refactor to remove duplicate code, better type conversions and improved consistency in output.
oldpool:
  zpool.absent:
    - export: true

newpool:
  zpool.present:
    - config:
      - import: false
      - force: true
    - properties:
      - comment: salty storage pool
    - layout:
      - mirror:
        - /dev/disk0
        - /dev/disk1
      - mirror:
        - /dev/disk2
        - /dev/disk3

partitionpool:
  zpool.present:
    - config:
      - import: false
      - force: true
    - properties:
      - comment: disk partition salty storage pool
      - ashift: '12'
      - feature@lz4_compress: enabled
    - filesystem_properties:
      - compression: lz4
      - atime: on
      - relatime: on
    - layout:
      - /dev/disk/by-uuid/3e43ce94-77af-4f52-a91b-6cdbb0b0f41b

simplepool:
  zpool.present:
    - config:
      - import: false
      - force: true
    - properties:
      - comment: another salty storage pool
    - layout:
      - /dev/disk0
      - /dev/disk1

**Warning:** The layout will never be updated, it will only be used at time of creation. It's a whole lot of work to figure out if a devices needs to be detached, removed, etc. This is best done by the sysadmin on a case per case basis.

Filesystem properties are also not updated, this should be managed by the zfs state module.

salt.states.zpool.absent(name, export=False, force=False)
ensure storage pool is absent on the system
name [string] name of storage pool
export [boolean] export instead of destroy the zpool if present
force [boolean] force destroy or export

salt.states.zpool.present(name, properties=None, filesystem_properties=None, layout=None, config=None)

ensure storage pool is present on the system
name [string] name of storage pool
properties [dict] optional set of properties to set for the storage pool
filesystem_properties [dict] optional set of filesystem properties to set for the storage pool (creation only)
layout: dict disk layout to use if the pool does not exist (creation only)
config [dict] fine grain control over this state

Note:
The following configuration properties can be toggled in the config parameter.
  • import (true) - try to import the pool before creating it if absent
  • import_dirs (None) - specify additional locations to scan for devices on import (comma-separated)
  • device_dir (None, SunOS=/dev/dsk, Linux=/dev) - specify device directory to prepend for none absolute device paths
  • force (false) - try to force the import or creation

Note: It is no longer needed to give a unique name to each top-level vdev, the old layout format is still supported but no longer recommended.

- mirror:
  - /tmp/vdisk3
  - /tmp/vdisk2
- mirror:
  - /tmp/vdisk0
  - /tmp/vdisk1

The above yaml will always result in the following zpool create:

zpool create mypool mirror /tmp/vdisk3 /tmp/vdisk2 mirror /tmp/vdisk0 /tmp/vdisk1

Warning: The legacy format is also still supported but not recommended, because ID’s inside the layout dict must be unique they need to have a suffix.

mirror-0:
  /tmp/vdisk3
  /tmp/vdisk2
mirror-1:
  /tmp/vdisk0
  /tmp/vdisk1

Warning: Pay attention to the order of your dict!

- mirror:
  - /tmp/vdisk0
  - /tmp/vdisk1
  - /tmp/vdisk2

The above will result in the following zpool create:
zpool create mypool mirror /tmp/vdisk0 /tmp/vdisk1 /tmp/vdisk2

Creating a 3-way mirror! While you probably expect it to be mirror root vdev with 2 devices + a root vdev of 1 device!

### 23.20.1 salt.thorium.add

Used to manage the thorium register. The thorium register is where compound values are stored and computed, such as averages etc.

New in version 2016.11.0.

```python
depends statistics PyPi module
```

```python
calc.add(name, num, minimum=0, maximum=0, ref=None)
```

Adds together the num most recent values. Requires a list.

**USAGE:**

```python
foo:
calc.add:
  - name: myregentry
  - num: 5
```

```python
calc(name, num, oper, minimum=0, maximum=0, ref=None)
```

Perform a calculation on the num most recent values. Requires a list. Valid values for `oper` are:

- `add`: Add last num values together
- `mul`: Multiple last num values together
- `mean`: Calculate mean of last num values
- `median`: Calculate median of last num values
• median_low: Calculate low median of last num values
• median_high: Calculate high median of last num values
• median_grouped: Calculate grouped median of last num values
• mode: Calculate mode of last num values

USAGE:

```
foo:
  calc.calc:
    - name: myregentry
    - num: 5
    - oper: mean
```

salt.thorium.calc.mean(name, num, minimum=0, maximum=0, ref=None)
Calculates the mean of the num most recent values. Requires a list.

USAGE:

```
foo:
  calc.mean:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.median(name, num, minimum=0, maximum=0, ref=None)
Calculates the mean of the num most recent values. Requires a list.

USAGE:

```
foo:
  calc.median:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.median_grouped(name, num, minimum=0, maximum=0, ref=None)
Calculates the grouped mean of the num most recent values. Requires a list.

USAGE:

```
foo:
  calc.median_grouped:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.median_high(name, num, minimum=0, maximum=0, ref=None)
Calculates the high mean of the num most recent values. Requires a list.

USAGE:

```
foo:
  calc.median_high:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.median_low(name, num, minimum=0, maximum=0, ref=None)
Calculates the low mean of the num most recent values. Requires a list.

USAGE:

```
foo:
  calc.median_low:
```
Salt Documentation, Release 3003.1

(continued from previous page)

- name: myregentry
- num: 5

salt.thorium.calc.mode\(\text{name, num, minimum=0, maximum=0, ref=None}\)
Calculates the mode of the num most recent values. Requires a list.

 USAGE:

```
foo:
  calc.mode:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.mul\(\text{name, num, minimum=0, maximum=0, ref=None}\)
Multiplies together the num most recent values. Requires a list.

 USAGE:

```
foo:
  calc.mul:
    - name: myregentry
    - num: 5
```

23.20.2 salt.thorium.check

The check Thorium state is used to create gateways to commands, the checks make it easy to make states that watch registers for changes and then just succeed or fail based on the state of the register, this creates the pattern of having a command execution get gated by a check state via a requisite.

salt.thorium.check.contains\(\text{name, value, count_lt=None, count_lte=None, count_eq=None, count_gte=None, count_gt=None, count_ne=None}\)
Only succeed if the value in the given register location contains the given value

 USAGE:

```
foo:
  check.contains:
    - value: itni
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.eq\(\text{name, value}\)
Only succeed if the value in the given register location is equal to the given value

 USAGE:

```
foo:
  check.eq:
    - value: 42
run_remote_ex:
```

(continues on next page)
local.cmd:
  - tgt: '*'
  - func: test.ping
  - require:
    - check: foo

salt.thorium.check.event(name)
Checks for a specific event match and returns result True if the match happens

usage:

salt/foo/*/bar:
  check.event

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: salt/foo/*/bar

salt.thorium.check.gt(name, value)
Only succeed if the value in the given register location is greater than the given value

usage:

foo:
  check.gt:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo

salt.thorium.check.gte(name, value)
Only succeed if the value in the given register location is greater or equal than the given value

usage:

foo:
  check.gte:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo

salt.thorium.check.len_eq(name, value)
Only succeed if the length of the given register location is equal to the given value

usage:
foo:
  check.len_eq:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
    - check: foo

salt.thorium.check.len_gt(name, value)
Only succeed if length of the given register location is greater than the given value.

USAGE:

foo:
  check.len_gt:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
    - check: foo

salt.thorium.check.len_gte(name, value)
Only succeed if the length of the given register location is greater or equal than the given value.

USAGE:

foo:
  check.len_gte:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
    - check: foo

salt.thorium.check.len_lt(name, value)
Only succeed if the length of the given register location is less than the given value.

USAGE:

foo:
  check.len_lt:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
    - check: foo
salt.thorium.check.**len_lte**(name, value)
Only succeed if the length of the given register location is less than or equal the given value

**USAGE:**

```yaml
foo:
  check.len_lte:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.**len_ne**(name, value)
Only succeed if the length of the given register location is not equal to the given value.

**USAGE:**

```yaml
foo:
  check.len_ne:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.**lt**(name, value)
Only succeed if the value in the given register location is less than the given value

**USAGE:**

```yaml
foo:
  check.lt:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.**lte**(name, value)
Only succeed if the value in the given register location is less than or equal the given value

**USAGE:**

```yaml
foo:
  check.lte:
    - value: 42
run_remote_ex:
  local.cmd:
```

(continues on next page)
salt.thorium.check.ne(name, value)
  Only succeed if the value in the given register location is not equal to the given value

Usage:

```
foo:
  check.ne:
    - value: 42
```

23.20.3 salt.thorium.file

 Writes matches to disk to verify activity, helpful when testing

Normally this is used by giving the name of the file (without a path) that the data will be saved to. If for instance you use foo as the name:

```
foo:
  file.save
```

Then the file will be saved to:

```
<salt_cachedir>/thorium/saves/foo
```

You may also provide an absolute path for the file to be saved to:

```
/tmp/foo.save:
  file.save
```

Files will be saved in JSON format. However, JSON does not support set()’s. If you are saving a register entry that contains a `set()`, then it will fail to save to JSON format. However, you may pass data through a filter which makes it JSON compliant:

```
foo:
  file.save:
    filter: True
```

Be warned that if you do this, then the file will be saved, but not in a format that can be re-imported into Python.

salt.thorium.file.save(name, filter=False)
  Save the register to <salt cachedir>/thorium/saves/<name>, or to an absolute path.
  If an absolute path is specified, then the directory will be created non-recursively if it doesn’t exist.

Usage:
23.20.4 salt.thorium.key

The key Thorium State is used to apply changes to the accepted/rejected/pending keys

New in version 2016.11.0.

```
salt.thorium.key.timeout(name, delete=0, reject=0)
```

If any minion's status is older than the timeout value then apply the given action to the timed out key. This example will remove keys to minions that have not checked in for 300 seconds (5 minutes)

```
statreg:
   status.reg

clean_keys:
   key.timeout:
      - require:
      - status: statreg
      - delete: 300
```

23.20.5 salt.thorium.local

Run remote execution commands via the local client

```
salt.thorium.local.cmd(name, tgt, func, arg=(), tgt_type='glob', ret='', kwarg=None, **kwargs)
```

Execute a remote execution command

```
run_remote_ex:
   local.cmd:
      - tgt: '*'
      - func: test.ping

run_remote_ex:
   local.cmd:
      - tgt: '*'
      - func: test.sleep
      - arg:
        - 30

run_remote_ex:
   local.cmd:
      - tgt: '*'
      - func: test.sleep
      - kwarg:
        - length: 30
```
23.20.6 salt.thorium.reg

Used to manage the thorium register. The thorium register is where compound values are stored and computed, such as averages etc.

**salt.thorium.reg.clear**(name)

Clear the namespace from the register

**USAGE:**

```
clearns:
  reg.clear:
    - name: myregister
```

**salt.thorium.reg.delete**(name)

Delete the namespace from the register

**USAGE:**

```
deletens:
  reg.delete:
    - name: myregister
```

**salt.thorium.reg.list**(name, add, match, stamp=False, prune=0)

Add the specified values to the named list

If `stamp` is True, then the timestamp from the event will also be added if `prune` is set to an integer higher than 0, then only the last `prune` values will be kept in the list.

**USAGE:**

```
foo:
  reg.list:
    - add: bar
    - match: my/custom/event
    - stamp: True
```

**salt.thorium.reg.mean**(name, add, match)

Accept a numeric value from the matched events and store a running average of the values in the given register. If the specified value is not numeric it will be skipped

**USAGE:**

```
foo:
  reg.mean:
    - add: data_field
    - match: my/custom/event
```

**salt.thorium.reg.set**(name, add, match)

Add a value to the named set

**USAGE:**

```
foo:
  reg.set:
    - add: bar
    - match: my/custom/event
```
23.20.7 salt.thorium.runner

React by calling asynchronous runners

```
salt.thorium.runner.cmd(name, func=None, arg=(), **kwargs)
```

Execute a runner asynchronously:

```python
def run_cloud():
    runner.cmd:
    - func: cloud.create
    - arg:
        - my-ec2-config
        - myinstance
```

```python
def run_cloud():
    runner.cmd:
    - func: cloud.create
    - kwargs:
        provider: my-ec2-config
        instances: myinstance
```

23.20.8 salt.thorium.status

This thorium state is used to track the status beacon events and keep track of the active status of minions

New in version 2016.11.0.

```
salt.thorium.status.reg(name)
```

Activate this register to turn on a minion status tracking register, this register keeps the current status beacon data and the time that each beacon was last checked in.

23.20.9 salt.thorium.timer

Allow for flow based timers. These timers allow for a sleep to exist across multiple runs of the flow

```
salt.thorium.timer.hold(name, seconds)
```

Wait for a given period of time, then fire a result of True, requiring this state allows for an action to be blocked for evaluation based on time

```
def hold_on_a_moment():
    timer.hold:
    - seconds: 30
```
23.20.10 salt.thorium.wheel

React by calling asynchronous runners

```python
salt.thorium.wheel.cmd(name, fun=None, arg=(), **kwargs)
```

Execute a runner asynchronous:

```bash
run_cloud:
wheel.cmd:
  - fun: key.delete
  - match: minion_id
```

23.21 token modules

<table>
<thead>
<tr>
<th>localfs</th>
<th>Stores eauth tokens in the filesystem of the master.</th>
</tr>
</thead>
<tbody>
<tr>
<td>rediscluster</td>
<td>Provide token storage in Redis cluster.</td>
</tr>
</tbody>
</table>

23.21.1 salt.tokens.localfs

Stores eauth tokens in the filesystem of the master. Location is configured by the master config option 'token_dir'

```python
salt.tokens.localfs.get_token(opts, tok)
```

Fetch the token data from the store.

**Parameters**
- `opts` -- Salt master config options
- `tok` -- Token value to get

**Returns**
Token data if successful. Empty dict if failed.

```python
globaltokens.localfs.list_tokens(opts)
```

List all tokens in the store.

**Parameters**
- `opts` -- Salt master config options

**Returns**
List of dicts (tokens)

```python
salt.tokens.localfs.mk_token(opts, tdata)
```

Mint a new token using the config option hash_type and store tdata with 'token' attribute set to the token.

This module uses the hash of random 512 bytes as a token.

**Parameters**
- `opts` -- Salt master config options
- `tdata` -- Token data to be stored with 'token' attribute of this dict set to the token.

**Returns**
tdata with token if successful. Empty dict if failed.

```python
globaltokens.localfs.rm_token(opts, tok)
```

Remove token from the store.

**Parameters**
- `opts` -- Salt master config options
- `tok` -- Token to remove

**Returns**
Empty dict if successful. None if failed.
23.21.2 salt.tokens.rediscluster

Provide token storage in Redis cluster.

To get started simply start a redis cluster and assign all hashslots to the connected nodes. Add the redis hostname and port to master configs as eauth_redis_host and eauth_redis_port. Default values for these configs are as follow:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eauth_redis_host</td>
<td>localhost</td>
</tr>
<tr>
<td>eauth_redis_port</td>
<td>6379</td>
</tr>
</tbody>
</table>

depends

- redis-py-cluster Python package

salt.tokens.rediscluster.get_token(opts, tok)

Fetch the token data from the store.

Parameters

- **opts** -- Salt master config options
- **tok** -- Token value to get

Returns

Token data if successful. Empty dict if failed.

salt.tokens.rediscluster.list_tokens(opts)

List all tokens in the store.

Parameters **opts** -- Salt master config options

Returns

List of dicts (token_data)

salt.tokens.rediscluster.mk_token(opts, tdata)

Mint a new token using the config option hash_type and store tdata with 'token' attribute set to the token. This module uses the hash of random 512 bytes as a token.

Parameters

- **opts** -- Salt master config options
- **tdata** -- Token data to be stored with 'token' attribute of this dict set to the token.

Returns

tdata with token if successful. Empty dict if failed.

salt.tokens.rediscluster.rm_token(opts, tok)

Remove token from the store.

Parameters

- **opts** -- Salt master config options
- **tok** -- Token to remove

Returns

Empty dict if successful. None if failed.

23.22 master tops modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobbler</td>
<td>Cobbler Tops</td>
</tr>
<tr>
<td>ext_nodes</td>
<td>External Nodes Classifier</td>
</tr>
<tr>
<td>mongo</td>
<td>Read tops data from a mongodb collection</td>
</tr>
<tr>
<td>reclass_adapter</td>
<td>Read tops data from a reclass database</td>
</tr>
<tr>
<td>saltclass</td>
<td>Saltclass Configuration</td>
</tr>
<tr>
<td>varstack_top</td>
<td>Use Varstack to provide tops data</td>
</tr>
</tbody>
</table>
23.22.1 salt.tops.cobbler

Cobbler Tops

Cobbler Tops is a master tops subsystem used to look up mapping information from Cobbler via its API. The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```yaml
master_tops:
  cobbler: {}
cobbler.url: https://example.com/cobbler_api # default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

Module Documentation

**salt.tops.cobbler.top(***kwargs)**

Look up top data in Cobbler for a minion.

23.22.2 salt.tops.ext_nodes

External Nodes Classifier

The External Nodes Classifier is a master tops subsystem that retrieves mapping information from major configuration management systems. One of the most common external nodes classifiers system is provided by Cobbler and is called cobbler-ext-nodes.

The cobbler-ext-nodes command can be used with this configuration:

```yaml
master_tops:
  ext_nodes: cobbler-ext-nodes
```

It is noteworthy that the Salt system does not directly ingest the data sent from the cobbler-ext-nodes command, but converts the data into information that is used by a Salt top file.

Any command can replace the call to 'cobbler-ext-nodes' above, but currently the data must be formatted in the same way that the standard 'cobbler-ext-nodes' does.

See (admittedly degenerate and probably not complete) example:

```yaml
classes:
  - basepackages
  - database
```

The above essentially is the same as a top.sls containing the following:

```yaml
base:
  '*':
    - basepackages
    - database
```

23.22. master tops modules
salt.tops.ext_nodes.top(**kwargs)
    Run the command configured

23.22.3 salt.tops.mongo

Read tops data from a mongodb collection

This module will load tops data from a mongo collection. It uses the node's id for lookups.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- `mongo.db` - The mongo database to connect to. Defaults to 'salt'.
- `mongo.host` - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- `mongo.port` - The port that the mongo database is running on. Defaults to 27017.
- `mongo.user` - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.
- `mongo.password` - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.

Configuring the Mongo Tops Subsystem

```
master_tops:
    mongo:
        collection: tops
        id_field: _id
        re_replace: ""
        re_pattern: \.example\.com
        states_field: states
        environment_field: environment
```

Module Documentation

salt.tops.mongo.top(**kwargs)
    Connect to a mongo database and read per-node tops data.

    Parameters
    - `collection`(*) -- The mongodb collection to read data from. Defaults to 'tops'.
    - `id_field`(*) -- The field in the collection that represents an individual minion id. Defaults to '_id'.
    - `re_pattern`(*) -- If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If `None`, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to `None`.
    - `re_replace`(*) -- Use as the replacement value in node ids matched with `re_pattern`. Defaults to ".". Feel free to use backreferences here.
    - `states_field`(*) -- The name of the field providing a list of states.
• **environment_field**(*) -- The name of the field providing the environment. Defaults to environment.

### 23.22.4 salt.tops.reclass_adapter

Read tops data from a reclass database

This `master_tops` plugin provides access to the `reclass` database, such that state information (top data) are retrieved from `reclass`.

You can find more information about `reclass` at [http://reclass.pantsfullofunix.net](http://reclass.pantsfullofunix.net).

To use the plugin, add it to the `master_tops` list in the Salt master config and tell `reclass` by way of a few options how and where to find the inventory:

```yaml
master_tops:
  reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause `reclass` to read the inventory from YAML files in `/srv/salt/nodes` and `/srv/salt/classes`.

If you are also using `reclass` as `ext_pillar` plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for `ext_pillar` and `master_tops`):

```yaml
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass
```

If you want to run `reclass` from source, rather than installing it, you can either let the master know via the `PYTHONPATH` environment variable, or by setting the configuration option, like in the example above.

`salt.tops.reclass_adapter.top(**kwargs)`

Query `reclass` for the top data (states of the minions).

### 23.22.5 salt.tops.saltclass

Saltclass Configuration

```yaml
master_tops:
  saltclass:
    path: /srv/saltclass
```

### 23.22. master tops modules

- `salt.tops.reclass_adapter`
- `salt.tops.saltclass`
Description

This module clones the behaviour of reclass (http://reclass.pantsfullofunix.net/), without the need of an external app, and add several features to improve flexibility. Saltclass lets you define your nodes from simple yaml files (.yml) through hierarchical class inheritance with the possibility to override pillars down the tree.

Features

- Define your nodes through hierarchical class inheritance
- Reuse your reclass datas with minimal modifications
  - applications => states
  - parameters => pillars
- Use Jinja templating in your yaml definitions
- Access to the following Salt objects in Jinja
  - __opts__
  - __salt__
  - __grains__
  - __pillars__
  - minion_id
- Chose how to merge or override your lists using ^ character (see examples)
- Expand variables ${} with possibility to escape them if needed ${} (see examples)
- Ignores missing node/class and will simply return empty without breaking the pillar module completely - will be logged

An example subset of datas is available here: http://git.mauras.ch/salt/saltclass/src/master/examples

<table>
<thead>
<tr>
<th>Terms usable in yaml files</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classes</td>
<td>A list of classes that will be processed in order</td>
</tr>
<tr>
<td>states</td>
<td>A list of states that will be returned by master_tops function</td>
</tr>
<tr>
<td>pillars</td>
<td>A yaml dictionary that will be returned by the ext_pillar function</td>
</tr>
<tr>
<td>environment</td>
<td>Node saltenv that will be used by master_tops</td>
</tr>
</tbody>
</table>

A class consists of:
- zero or more parent classes
- zero or more states
- any number of pillars

A child class can override pillars from a parent class. A node definition is a class in itself with an added environment parameter for saltenv definition.
Class names

Class names mimic salt way of defining states and pillar files. This means that `default.users` class name will correspond to one of these:

- `<saltclass_path>/classes/default/users.yml`
- `<saltclass_path>/classes/default/users/init.yml`

Saltclass file hierarchy

A saltclass tree would look like this:

```
<saltclass_path>
  └── classes
      ├── app
      │   └── borgbackup.yml
      │       └── ssh
      │           └── server.yml
      └── default
          └── init.yml
      └── roles
          ├── app.yml
          │   └── nginx
          │       └── init.yml
          │       └── server.yml
          └── subsidiaries
              ├── gnv.yml
              │   └── gnv.node1.yml
              └── qls.yml
                  └── qls.node1.yml
                      └── qls.node2.yml
              └── zrh.yml
                  └── zrh.node1.yml
                      └── zrh.node2.yml
                      └── zrh.node3.yml
```
Saltclass Examples

<saltclass_path>/nodes/lausanne/qls.node1.yml

```yaml
environment: base

classes:
  {% for class in ['default'] %}
    - {{ class }}
  {%- endfor %}
  - subsidiaries{{{ __grains__["id"].split('.')[0] }}}
```

<saltclass_path>/classes/default/init.yml

```yaml
classes:
  - default.users
  - default.motd

states:
  - openssh

pillars:
  default:
    network:
      dns:
        srv1: 192.168.0.1
        srv2: 192.168.0.2
        domain: example.com
      ntp:
        srv1: 192.168.10.10
        srv2: 192.168.10.20

<saltclass_path>/classes/subsidiaries/gnv.yml

```yaml
pillars:
  default:
    network:
      sub: Geneva
      dns:
        srv1: 10.20.0.1
        srv2: 10.20.0.2
        srv3: 192.168.1.1
        domain: gnv.example.com
    users:
      adm1:
        uid: 1210
        gid: 1210
        gecos: 'Super user admin1'
        homedir: /srv/app/adm1
      adm3:
        uid: 1203
        gid: 1203
        gecos: 'Super user adm
```
Variable expansions

Escaped variables are rendered as is: `\${test}`

Missing variables are rendered as is: `\${net:dns:srv2}`

```
pillars:
  app:
  config:
    dns:
      srv1: \${default:network:dns:srv1}
      srv2: \${net:dns:srv2}
    uri: https://application.domain/call?\${test}
  prod_parameters:
    - p1
    - p2
    - p3
  pkg:
    - app-core
    - app-backend
```

List override

Not using `^` as the first entry will simply merge the lists

```
pillars:
  app:
    pkg:
      - ^
      - app-frontend
```

Note: Known limitation

Currently you can't have both a variable and an escaped variable in the same string as the escaped one will not be correctly rendered - `\${xx}` will stay as is instead of being rendered as `\${xx}'

```
salt.tops.saltclass.top(**kwargs)
    Compile tops

23.22.6 salt.tops.varstack_top
```

Use Varstack to provide tops data

This `master_tops` plugin provides access to the varstack hierarchical yaml files, so you can use varstack as a full external node classifier and store state information (top data) in it.
Configuring Varstack

To use varstack as a master top external node classifier, install varstack as documented. Then, add to your master's configuration:

```yaml
master_tops:
  varstack: /path/to/the/config/file/varstack.yaml
```

Varstack will then use /path/to/the/config/file/varstack.yaml (usually /etc/varstack.yaml) to determine which configuration data to return as adapter information. From there you can take a look at the README of varstack to learn how this file is evaluated. The ENC part will just return the 'states' dictionary for the node.

Ie, if my.fqdn.yaml file contains:

```yaml
---
states:
  - sudo
  - openssh
  - apache
  - salt.minion
```

these will be returned as `{'base': ['sudo', 'openssh', 'apache', 'salt.minion']}` and managed by salt as if given from a top.sls file.

```python
salt.tops.varstack_top.top(**kwargs)
Query varstack for the top data (states of the minions).
```

23.23 wheel modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Manage the master configuration file</td>
</tr>
<tr>
<td>error</td>
<td>Error generator to enable integration testing of salt wheel error handling</td>
</tr>
<tr>

<tr>
<td>minions</td>
<td>Wheel system wrapper for connected minions</td>
</tr>
<tr>
<td>pillar_roots</td>
<td>The pillar_roots wheel module is used to manage files under the pillar roots directories on the master server.</td>
</tr>
</tbody>
</table>

23.23.1 salt.wheel.config

Manage the master configuration file

```python
salt.wheel.config.apply(key, value)
Set a single key
```

**Note:** This will strip comments from your config file

```python
class.update_config(file_name, yaml_contents)
Update master config with yaml_contents.
```
Writes `yaml_contents` to a file named `file_name.conf` under the folder specified by `default_include`. This folder is named `master.d` by default. Please look at `include-configuration` for more information.

Example low data:

```python
data = {
    'username': 'salt',
    'password': 'salt',
    'fun': 'config.update_config',
    'file_name': 'gui',
    'yaml_contents': {'id': 1},
    'client': 'wheel',
    'eauth': 'pam',
}
```

```
salt.wheel.config.values()
Return the raw values of the config file
```

### 23.23.2 `salt.wheel.error`

Error generator to enable integration testing of salt wheel error handling

```
salt.wheel.error.error(name=None, message='')
If name is None Then return empty dict
Otherwise raise an exception with __name__ from name, message from message
```

```bash
salt-wheel error
salt-wheel error.error name="Exception" message="This is an error."
```

### 23.23.3 `salt.wheel.file_roots`

Read in files from the `file_root` and save files to the `file_root`

```
salt.wheel.file_roots.find(path, saltenv='base')
Return a dict of the files located with the given path and environment
```

```
salt.wheel.file_roots.list_env(saltenv='base')
Return all of the file paths found in an environment
```

```
salt.wheel.file_roots.list_roots()
Return all of the files names in all available environments
```

```
salt.wheel.file_roots.read(path, saltenv='base')
Read the contents of a text file, if the file is binary then
```

```
salt.wheel.file_roots.write(data, path, saltenv='base', index=0)
Write the named file, by default the first file found is written, but the index of the file can be specified to write to a lower priority file root
```

### 23.23. wheel modules

4139
23.23.4 salt.wheel.key

Wheel system wrapper for the Salt key system to be used in interactions with the Salt Master programmatically.

The key module for the wheel system is meant to provide an internal interface for other Salt systems to interact with the Salt Master. The following usage examples assume that a WheelClient is available:

```python
import salt.config
import salt.wheel

opts = salt.config.master_config('/etc/salt/master')
wheel = salt.wheel.WheelClient(opts)
```

Note that importing and using the WheelClient must be performed on the same machine as the Salt Master and as the same user that runs the Salt Master, unless external_auth is configured and the user is authorized to execute wheel functions.

The function documentation starts with the wheel reference from the code sample above and use the WheelClient functions to show how they can be called from a Python interpreter.

The wheel key functions can also be called via a salt command at the CLI using the saltutil execution module.

salt.wheel.key.accept(match, include_rejected=False, include_denied=False)

Accept keys based on a glob match. Returns a dictionary.

match The glob match of keys to accept.

include_rejected To include rejected keys in the match along with pending keys, set this to True. Defaults to False.

include_denied To include denied keys in the match along with pending keys, set this to True. Defaults to False.

```python
>>> wheel.cmd('key.accept', ['minion1'])
{'minions': ['minion1']}
```

salt.wheel.key.accept_dict(match, include_rejected=False, include_denied=False)

Accept keys based on a dict of keys. Returns a dictionary.

match The dictionary of keys to accept.

include_rejected To include rejected keys in the match along with pending keys, set this to True. Defaults to False.

include_denied To include denied keys in the match along with pending keys, set this to True. Defaults to False.

New in version 2016.3.4.

Example to move a list of keys from the minions_pre (pending) directory to the minions (accepted) directory:

```python
>>> wheel.cmd('key.accept_dict',
{   'minions_pre': ['jerry', 'stuart', 'bob'],
},
)
{'minions': ['jerry', 'stuart', 'bob']}
```

salt.wheel.key.delete(match)

Delete keys based on a glob match. Returns a dictionary.

```python
```
match  The glob match of keys to delete.

```python
>>> wheel.cmd_async({'fun': 'key.delete', 'match': 'minion1'})
{'jid': '20160826201244808521', 'tag': 'salt/wheel/20160826201244808521'}
```

**salt.wheel.key.delete_dict**(match)
Delete keys based on a dict of keys. Returns a dictionary.

match  The dictionary of keys to delete.

```python
>>> wheel.cmd_async({'fun': 'key.delete_dict', 'match': {'minions': ['jerry', 'stuart', 'bob'],}})
{'jid': '20160826201244808521', 'tag': 'salt/wheel/20160826201244808521'}
```

**salt.wheel.key.finger**(match, hash_type=None)
Return the matching key fingerprints. Returns a dictionary.

match  The key for with to retrieve the fingerprint.
hash_type  The hash algorithm used to calculate the fingerprint

```python
>>> wheel.cmd('key.finger', ['minion1'])
```

**salt.wheel.key.finger_master**(hash_type=None)
Return the fingerprint of the master's public key

hash_type  The hash algorithm used to calculate the fingerprint

```python
>>> wheel.cmd('key.finger_master')
```

**salt.wheel.key.gen**(id_=None, keysize=2048)
Generate a key pair. No keys are stored on the master. A key pair is returned as a dict containing pub and priv keys. Returns a dictionary containing the pub and priv keys with their generated values.

id_  Set a name to generate a key pair for use with salt. If not specified, a random name will be specified.
keysize  The size of the key pair to generate. The size must be 2048, which is the default, or greater. If set to a value less than 2048, the key size will be rounded up to 2048.

```python
>>> wheel.cmd('key.gen')
{'pub': '-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBC
...
BBPfamX9gGPQtpN9e8HwCzXjQhmg80rcU10WHw09SDWLOlnW+ueTwugEOpPtVniQIDAQAB
-----END PUBLIC KEY-----',
'priv': '-----BEGIN RSA PRIVATE KEY-----

MIIEpAIBAAKCAQEA42Kf+w9XeZWgguzv...
QH3/w74X1+WT8lx4R2KGLYB1h+bCCFEQ/Zvcu4xp4bI0PtSKozEQ===
-----END RSA PRIVATE KEY-----'}
```

**salt.wheel.key.gen_accept**(id_, keysize=2048, force=False)
Generate a key pair then accept the public key. This function returns the key pair in a dict, only the public key is preserved on the master. Returns a dictionary.

id_  The name of the minion for which to generate a key pair.
keysize  The size of the key pair to generate. The size must be 2048, which is the default, or greater. If set to a value less than 2048, the key size will be rounded up to 2048.
force If a public key has already been accepted for the given minion on the master, then the gen_accept function will return an empty dictionary and not create a new key. This is the default behavior. If force is set to True, then the minion’s previously accepted key will be overwritten.

```python
>>> wheel.cmd('key.gen_accept', ['foo'])
{'pub': '-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBC
...
BBPfamX9gGPQTpN9e8HwcZjXQnmg8orcUl10WHw09SDWLOlnW+ueTWugE0pT\niqIDAQAB
-----END PUBLIC KEY-----',
'priv': '-----BEGIN RSA PRIVATE KEY-----
MIIEpAIBAAKCAQEA42Kf+w9XeZwgguzv...
QH3/W74X1+WTBlx4R2KGLYBiH+bccFEQ/Zvcu4Xp4bIOPtRkozE=\n-----END RSA PRIVATE KEY-----'}
```

We can now see that the `foo` minion’s key has been accepted by the master:

```python
>>> wheel.cmd('key.list', ['accepted'])
{'minions': ['foo', 'minion1', 'minion2', 'minion3']}
```

### salt.wheel.key.gen_keys(keydir=None, keyname=None, keysize=None, user=None)
Generate minion RSA keypair

### salt.wheel.key.gen_signature(priv, pub, signature_path, auto_create=False, keysize=None)
Generate master public-key-signature

### salt.wheel.key.key_str(match)
Return information about the key. Returns a dictionary.

match The key to return information about.

```python
>>> wheel.cmd('key.key_str', ['minion1'])
{'minions': {'minion1': '-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0B...
-----END PUBLIC KEY-----'}}
```

### salt.wheel.key.list_(match)
List all the keys under a named status. Returns a dictionary.

match The type of keys to list. The pre, un, and unaccepted options will list unaccepted/unsigned keys. acc or accepted will list accepted/signed keys. rej or rejected will list rejected keys. Finally, all will list all keys.

```python
>>> wheel.cmd('key.list', ['accepted'])
{'minions': ['minion1', 'minion2', 'minion3']}
```

### salt.wheel.key.list_all()
List all the keys. Returns a dictionary containing lists of the minions in each salt-key category, including minions, minions_rejected, minions_denied, etc. Returns a dictionary.

```python
>>> wheel.cmd('key.list_all')
{'local': ['master.pem', 'master.pub'], 'minions_rejected': [], 'minions_denied': [], 'minions_pre': [], 'minions': ['minion1', 'minion2', 'minion3']}
```

### salt.wheel.key.master_key_str()
Returns master's public key. Returns a dictionary

```python
>>> wheel.cmd('key.master_key_str')
{'local': {'master.pub': '-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0B
(continues on next page)
salt.wheel.key.name_match(match)
List all the keys based on a glob match

salt.wheel.key.reject(match, include_accepted=False, include_denied=False)
Reject keys based on a glob match. Returns a dictionary.
match  The glob match of keys to reject.
include_accepted  To include accepted keys in the match along with pending keys, set this to True. Defaults to False.
include_denied  To include denied keys in the match along with pending keys, set this to True. Defaults to False.

>>> wheel.cmd_async({'fun': 'key.reject', 'match': 'minion1'})
{'jid': '20160826201244808521', 'tag': 'salt/wheel/20160826201244808521'}

salt.wheel.key.reject_dict(match, include_accepted=False, include_denied=False)
Reject keys based on a dict of keys. Returns a dictionary.
match  The dictionary of keys to reject.
include_accepted  To include accepted keys in the match along with pending keys, set this to True. Defaults to False.
include_denied  To include denied keys in the match along with pending keys, set this to True. Defaults to False.

New in version 2016.3.4.

>>> wheel.cmd_async({'fun': 'key.reject_dict',
                'match': {
                    'minions': ['jerry', 'stuart', 'bob'],
                }},
                {'jid': '20160826201244808521', 'tag': 'salt/wheel/20160826201244808521'}

23.23.5 salt.wheel.minions

Wheel system wrapper for connected minions

salt.wheel.minions.connected()
  List all connected minions on a salt-master

23.23.6 salt.wheel.pillar_roots

The pillar_roots wheel module is used to manage files under the pillar roots directories on the master server.

salt.wheel.pillar_roots.find(path, saltenv='base')
  Return a dict of the files located with the given path and environment

salt.wheel.pillar_roots.list_env(saltenv='base')
  Return all of the file paths found in an environment

salt.wheel.pillar_roots.list_roots()
  Return all of the files names in all available environments

salt.wheel.pillar_roots.read(path, saltenv='base')
  Read the contents of a text file, if the file is binary then

salt.wheel.pillar_roots.write(data, path, saltenv='base', index=0)
  Write the named file, by default the first file found is written, but the index of the file can be specified to write to a lower priority file root
24.1 Python client API

Salt provides several entry points for interfacing with Python applications. These entry points are often referred to as *Client() APIs. Each client accesses different parts of Salt, either from the master or from a minion. Each client is detailed below.

See also:

There are many ways to access Salt programmatically.

Salt can be used from CLI scripts as well as via a REST interface.

See Salt's outputter system to retrieve structured data from Salt as JSON, or as shell-friendly text, or many other formats.

See the state.event runner to utilize Salt's event bus from shell scripts.

Salt's netapi module provides access to Salt externally via a REST interface. Review the netapi module documentation for more information.

24.1.1 Salt's opts dictionary

Some clients require access to Salt's opts dictionary. (The dictionary representation of the master or minion config files.)

A common pattern for fetching the opts dictionary is to defer to environment variables if they exist or otherwise fetch the config from the default location.

```
salt.config.client_config(path, env_var='SALT_CLIENT_CONFIG', defaults=None)
```

Load Master configuration data

Usage:

```
import salt.config
master_opts = salt.config.client_config('/etc/salt/master')
```

Returns a dictionary of the Salt Master configuration file with necessary options needed to communicate with a locally-running Salt Master daemon. This function searches for client specific configurations and adds them to the data from the master configuration.

This is useful for master-side operations like LocalClient.
Salt Documentation, Release 3003.1

salt.config.minion_config(path, env_var='SALT_MINION_CONFIG', defaults=None, cache_minion_id=False, ignore_config_errors=True, minion_id=None, role='minion')

Reads in the minion configuration file and sets up special options

This is useful for Minion-side operations, such as the Caller class, and manually running the loader interface.

```python
import salt.config
minion_opts = salt.config.minion_config('/etc/salt/minion')
```

24.1.2 Salt’s Loader Interface

Modules in the Salt ecosystem are loaded into memory using a custom loader system. This allows modules to have conditional requirements (OS, OS version, installed libraries, etc) and allows Salt to inject special variables (__salt__, __opts__, etc).

Most modules can be manually loaded. This is often useful in third-party Python apps or when writing tests. However, some modules require and expect a full, running Salt system underneath. Notably modules that facilitate master-to-minion communication such as the mine, publish, and peer execution modules. The error KeyError: 'master_uri' is a likely indicator for this situation. In those instances use the Caller class to execute those modules instead.

Each module type has a corresponding loader function.

salt.loader.minion_mods(opts=None, context=None, utils=None, whitelist=None, initial_load=False, loaded_base_name=None, notify=False, static_modules=None, proxy=None)

Load execution modules

Returns a dictionary of execution modules appropriate for the current system by evaluating the __virtual__() function in each module.

Parameters

- `opts (dict)` -- The Salt options dictionary
- `context (dict)` -- A Salt context that should be made present inside generated modules in __context__
- `utils (dict)` -- Utility functions which should be made available to Salt modules in __utils__. See utils_dirs in salt.config for additional information about configuration.
- `whitelist (list)` -- A list of modules which should be whitelisted.
- `initial_load (bool)` -- Deprecated flag! Unused.
- `loaded_base_name (str)` -- A string marker for the loaded base name.
- `notify (bool)` -- Flag indicating that an event should be fired upon completion of module loading.

```python
import salt.config
import salt.loader
__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
__opts__['grains'] = __grains__
__utils__ = salt.loader.utils(__opts__)
__salt__ = salt.loader.minion_mods(__opts__, __utils__)
__salt__['test.ping']()
```

salt.loader.raw_mod(opts, name, functions, mod='modules')

Returns a single module loaded raw and bypassing the __virtual__ function

```python
import salt.config
import salt.loader
__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
__opts__['grains'] = __grains__
__utils__ = salt.loader.utils(__opts__)
__salt__ = salt.loader.minion_mods(__opts__, __utils__)
__salt__['test.ping']()
```
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion

testmod = salt.loader.raw_mod(__opts__, 'test', None)

import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion

statemods = salt.loader.states(__opts__, None, None)

import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion

__grains__ = salt.loader.grains(__opts__)

print __grains__[\'id\']

import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion

grainfuncs = salt.loader.grain_funcs(__opts__)

24.1.3 Salt’s Client Interfaces

LocalClient

class salt.client.LocalClient(c_path='/etc/salt/master', mopts=None, skip_perm_errors=False, io_loop=None, keep_loop=False, auto_reconnect=False, listen=False)

The interface used by the salt CLI tool on the Salt Master

LocalClient is used to send a command to Salt minions to execute execution modules and return the results to the Salt Master.
Importing and using `LocalClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. (Unless `external_auth` is configured and authentication credentials are included in the execution).

**Note:** The `LocalClient` uses a Tornado IOLoop, this can create issues when using the `LocalClient` inside an existing IOLoop. If creating the `LocalClient` in partnership with another IOLoop either create the IOLoop before creating the `LocalClient`, or when creating the IOLoop use `io.loop.current()` which will return the ioloop created by `LocalClient`.

```python
import salt.client

local = salt.client.LocalClient()
local.cmd('*', 'test.fib', [10])
```

Synchronously execute a command on targeted minions

```python
local.cmd(tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', jid='', full_return=False, kwarg=None, **kwargs)
```

Parameters

- **tgt** (*string or list*) -- Which minions to target for the execution. Default is shell glob. Modified by the `tgt_type` option.
- **fun** (*string or list of strings*) -- The module and function to call on the specified minions of the form module.function. For example `test.ping` or `grains.items`.

**Compound commands** Multiple functions may be called in a single publish by passing a list of commands. This can dramatically lower overhead and speed up the application communicating with Salt.

```python
local.cmd('*', ['grains.items', 'sys.doc', 'cmd.run'], ['uptime'], ['whoami'], kwarg={'foo': 'bar'})
```

With extra keyword arguments for the command function to be run:

```python
local.cmd('test.arg', ['arg1', 'arg2'], kwarg={'foo': 'bar'})
```

Compound commands can be used for multiple executions in a single publish. Function names and function arguments are provided in separate lists but the index values must correlate and an empty list must be used if no arguments are required.
arg list must correlate by index meaning a function that does not take arguments must still have a corresponding empty list at the expected index.

- **arg(list or list-of-lists)** -- A list of arguments to pass to the remote function. If the function takes no arguments `arg` may be omitted except when executing a compound command.

- **timeout** -- Seconds to wait after the last minion returns but before all minions return.

- **tgt_type** -- The type of tgt. Allowed values:
  - `glob` - Bash glob completion - Default
  - `pcre` - Perl style regular expression
  - `list` - Python list of hosts
  - `grain` - Match based on a grain comparison
  - `grain_pcre` - Grain comparison with a regex
  - `pillar` - Pillar data comparison
  - `pillar_pcre` - Pillar data comparison with a regex
  - `nodegroup` - Match on nodegroup
  - `range` - Use a Range server for matching
  - `compound` - Pass a compound match string
  - `ipcidr` - Match based on Subnet (CIDR notation) or IPv4 address.

  Changed in version 2017.7.0: Renamed from `expr_form` to `tgt_type`

- **ret** -- The returner to use. The value passed can be single returner, or a comma delimited list of returners to call in order on the minions

- **kwarg** -- A dictionary with keyword arguments for the function.

- **full_return** -- Output the job return only (default) or the full return including exit code and other job metadata.

- **kwargs** -- Optional keyword arguments. Authentication credentials may be passed when using `external_auth`.

  For example: `local.cmd('*', 'test.ping', username='saltdev', password='saltdev', eauth='pam').` Or: `local.cmd('*', 'test.ping', token='5871821ea51754fdcea8153c1c745433')`

Returns A dictionary with the result of the execution, keyed by minion ID. A compound command will return a sub-dictionary keyed by function name.

**cmd_async**

Asynchronously send a command to connected minions

The function signature is the same as `cmd()` with the following exceptions.

Returns A job ID or 0 on failure.

```
>>> local.cmd_async('*','test.sleep', [300])
'20131219215921857715'
```

**cmd_batch**

Iteratively execute a command on subsets of minions at a time

The function signature is the same as `cmd()` with the following exceptions.

Parameters **batch** -- The batch identifier of systems to execute on

Returns A generator of minion returns

```
>>> returns = local.cmd_batch('*','state.highstate', batch='10%')
>>> for ret in returns:
...    print(ret)
{[jerry]: {...}}
```

(continues on next page)
cmd_iter (tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', kwarg=None, **kwargs)
Yields the individual minion returns as they come in

The function signature is the same as cmd() with the following exceptions.

Normally cmd_iter() does not yield results for minions that are not connected. If you want it to return results for disconnected minions set expect_minions=True in kwarg.

**Returns**

A generator yielding the individual minion returns

```python
>>> ret = local.cmd_iter('*\', 'test.ping')
>>> for i in ret:
...     print(i)
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
{'stewart': {'ret': True}}
```

cmd_iter_no_block (tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', show_jid=False, verbose=False, kwarg=None, **kwargs)
Yields the individual minion returns as they come in, or None when no returns are available.

The function signature is the same as cmd() with the following exceptions.

**Returns**

A generator yielding the individual minion returns, or None when no returns are available. This allows for actions to be injected in between minion returns.

```python
>>> ret = local.cmd_iter_no_block('*\', 'test.ping')
>>> for i in ret:
...     print(i)
None
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
None
{'stewart': {'ret': True}}
```

cmd_subset (tgt, fun, arg=(), tgt_type='glob', ret='', kwarg=None, subset=3, cli=False, progress=False, full_return=False, **kwargs)
Execute a command on a random subset of the targeted systems

The function signature is the same as cmd() with the following exceptions.

**Parameters**

- **subset** -- The number of systems to execute on
- **cli** -- When this is set to True, a generator is returned, otherwise a dictionary of the minion returns is returned

```python
>>> SLC.cmd_subset('*\', 'test.ping', subset=1)
{'jerry': True}
```

get_cli_returns (jid, minions, timeout=None, tgt='*', tgt_type='glob', verbose=False, show_jid=False, kwarg=None, **kwargs)
Starts a watcher looking at the return data for a specified JID

**Returns**

all of the information for the JID

get_event_iter_returns (jid, minions, timeout=None)
Gather the return data from the event system, break hard when timeout is reached.
run_job(tgt, fun, arg=(), tgt_type='glob', ret='', timeout=None, jid='', kwarg=None, **kwargs)

Asynchronously send a command to connected minions

Prep the job directory and publish a command to any targeted minions.

Returns A dictionary of (validated) pub_data or an empty dictionary on failure. The pub_data contains the job ID and a list of all minions that are expected to return data.

>>> local.run_job('*', 'test.sleep', [300])
{'jid': '20131219215650131543', 'minions': ['jerry']}

Salt Caller

class salt.client.Caller(c_path='/etc/salt/minion', mopts=None)

Caller is the same interface used by the salt-call command-line tool on the Salt Minion.

Changed in version 2015.8.0: Added the cmd method for consistency with the other Salt clients. The existing function and sminion.functions interfaces still exist but have been removed from the docs.

Importing and using Caller must be done on the same machine as a Salt Minion and it must be done using the same user that the Salt Minion is running as.

Usage:

```python
import salt.client
caller = salt.client.Caller()
caller.cmd('test.ping')
```

Note, a running master or minion daemon is not required to use this class. Running salt-call --local simply sets file_client to 'local'. The same can be achieved at the Python level by including that setting in a minion config file.

New in version 2014.7.0: Pass the minion config as the mopts dictionary.

```python
import salt.client
import salt.config
__opts__ = salt.config.minion_config('/etc/salt/minion')
__opts__['file_client'] = 'local'
caller = salt.client.Caller(mopts=__opts__)
```

```
caller.cmd('test.arg', 'Foo', 'Bar', baz='Baz')

caller.cmd('event.send', 'myco/myevent/something',
    data={'foo': 'Foo'}, with_env=['GIT_COMMIT'], with_grains=True)
```
Salt Proxy Caller

```python
class salt.client.ProxyCaller(c_path='/etc/salt_proxy', mopts=None)
```

ProxyCaller is the same interface used by the `salt-call` with the args `--proxyid <proxyid>` command-line tool on the Salt Proxy Minion.

Importing and using `ProxyCaller` must be done on the same machine as a Salt Minion and it must be done using the same user that the Salt Minion is running as.

Usage:

```python
import salt.client
caller = salt.client.Caller()
caller.cmd('test.ping')
```

Note, a running master or minion daemon is not required to use this class. Running `salt-call --local` simply sets `file_client` to 'local'. The same can be achieved at the Python level by including that setting in a minion config file.

```python
import salt.client
import salt.config
__opts__ = salt.config.proxy_config('/etc/salt_proxy', minion_id='quirky_edison')
__opts__['file_client'] = 'local'
caller = salt.client.ProxyCaller(mopts=__opts__)
```

Note: To use this for calling proxies, the `is_proxy` functions requires that `--proxyid` be an argument on the commandline for the script this is used in, or that the string `proxy` is in the name of the script.

```python
cmd(fun, *args, **kwargs)
    Call an execution module with the given arguments and keyword arguments
    caller.cmd('test.arg', 'Foo', 'Bar', baz='Baz')
    caller.cmd('event.send', 'myco/myevent/something',
               data={'foo': 'Foo'}, with_env=['GIT_COMMIT'], with_grains=True)
```

RunnerClient

```python
class salt.runner.RunnerClient(opts, context=None)
```

The interface used by the `salt-run` CLI tool on the Salt Master

It executes `runner modules` which run on the Salt Master.

Importing and using RunnerClient must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as.

Salt’s `external_auth` can be used to authenticate calls. The eauth user must be authorized to execute runner modules: `@runner`. Only the `master_call()` below supports eauth.

```python
asynchronous(fun, low, user='UNKNOWN', pub=None, local=True)
    Execute the function in a multiprocess and return the event tag to use to watch for the return
    cmd(fun=None, pub_data=None, kwarg=None, print_event=True, full_return=False)
    Execute a function
    cmd_async(low)
    Execute a runner function asynchronously; eauth is respected
```
This function requires that `external_auth` is configured and the user is authorized to execute runner functions: (@runner).

```
runner.eauth_async({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})
```

**cmd_sync** (*low, timeout=None, full_return=False*)
Execute a runner function synchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized to execute runner functions: (@runner).

```
runner.eauth_sync({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})
```

**WheelClient**

```python
class salt.wheel.WheelClient(ops=None)
```
An interface to Salt's wheel modules

**Wheel modules** interact with various parts of the Salt Master.

Importing and using `WheelClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. Unless `external_auth` is configured and the user is authorized to execute wheel functions: (@wheel).

Usage:

```python
import salt.config
import salt.wheel
opts = salt.config.master_config('/etc/salt/master')
wheel = salt.wheel.WheelClient(opts)
```

**asynchronous** (*fun, low, user='UNKNOWN', pub=None, local=True*)
Execute the function in a multiprocess and return the event tag to use to watch for the return

**cmd** (*fun, arg=None, pub_data=None, kwarg=None, print_event=True, full_return=False*)
Execute a function

```python
>>> wheel.cmd('key.finger', ['jerry'])
```

**cmd_async** (*low*)
Execute a function asynchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized

```python
>>> wheel.cmd_async({
    'fun': 'key.finger',
    'match': 'jerry',
})
```
cmd_sync

Execute a wheel function synchronously; eauth is respected

```python
>>> wheel.cmd_sync({
    'fun': 'key.finger',
    'match': 'jerry',
    'eauth': 'auto',
    'username': 'saltdev',
    'password': 'saltdev',
})
```

CloudClient

class salt.cloud.CloudClient(path=None, opts=None, config_dir=None, pillars=None)
The client class to wrap cloud interactions

action

Execute a single action via the cloud plugin backend

Examples:

```python
client.action(fun='show_instance', names=['myinstance'])
client.action(fun='show_image', provider='my-ec2-config',
              kwargs={'image': 'ami-10314d79'})
```

create

Create the named VMs, without using a profile

Example:

```python
client.create(provider='my-ec2-config', names=['myinstance'],
              image='ami-1624987f', size='t1.micro', ssh_username='ec2-user',
              securitygroup='default', delvol_on_destroy=True)
```

destroy

Destroy the named VMs

eextra_action

Perform actions with block storage devices

Example:

```python
client.extra_action(names=['myblock'], action='volume_create',
                    provider='my-nova', kwargs={'voltype': 'SSD', 'size': 1000})
```
client = salt.cloud.CloudClient(path='/etc/salt/cloud')
client.profile('do_512_git', names=['minion01'],)

query_type='list_nodes'
Query basic instance information

select_query(query_type='list_nodes_select')
Query select instance information
SSHClient

```python
class salt.client.ssh.client.SSHClient(c_path='/etc/salt/master', mopts=None, disable_custom_roster=False)
```

Create a client object for executing routines via the salt-ssh backend

New in version 2015.5.0.

```python
def cmd(tgt, fun, arg=(), timeout=None, tgt_type='glob', kwarg=None, **kwargs)
    Execute a single command via the salt-ssh subsystem and return all routines at once
    New in version 2015.5.0.
```

```python
def cmd_iter(tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', kwarg=None, **kwargs)
    Execute a single command via the salt-ssh subsystem and return a generator
    New in version 2015.5.0.
```

24.2 netapi modules

24.2.1 Introduction to netapi modules

netapi modules provide API-centric access to Salt. Usually externally-facing services such as REST or WebSockets, XMPP, XMLRPC, etc.

In general netapi modules bind to a port and start a service. They are purposefully open-ended. A single module can be configured to run as well as multiple modules simultaneously.

netapi modules are enabled by adding configuration to your Salt Master config file and then starting the `salt-api` daemon. Check the docs for each module to see external requirements and configuration settings.

Communication with Salt and Salt satellite projects is done using Salt’s own Python API. A list of available client interfaces is below.

salt-api

Prior to Salt’s 2014.7.0 release, netapi modules lived in the separate sister projected `salt-api`. That project has been merged into the main Salt project.

See also:

* [The full list of netapi modules](#)
**local** (*args, **kwargs*)

Run execution modules synchronously

See `salt.client.LocalClient.cmd()` for all available parameters.

Sends a command from the master to the targeted minions. This is the same interface that Salt's own CLI uses. Note the `arg` and `kwarg` parameters are sent down to the minion(s) and the given function, `fun`, is called with those parameters.

Returns Returns the result from the execution module

**local_async** (*args, **kwargs*)

Run execution modules asynchronously

Wraps `salt.client.LocalClient.run_job()`.

Returns job ID

**local_subset** (*args, **kwargs*)

Run execution modules against subsets of minions

New in version 2016.3.0.

Wraps `salt.client.LocalClient.cmd_subset()`

**runner** (`fun`, `timeout=None`, `full_return=False`, **kwargs**)

Run runner modules <all-salt.runners> synchronously

Wraps `salt.runner.RunnerClient.cmd_sync()`.

Note that runner functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the runner module

**runner_async** (`fun`, **kwargs**)

Run runner modules <all-salt.runners> asynchronously

Wraps `salt.runner.RunnerClient.cmd_async()`.

Note that runner functions must be called using keyword arguments. Positional arguments are not supported.

Returns event data and a job ID for the executed function.

**ssh** (*args, **kwargs*)

Run salt-ssh commands synchronously

Wraps `salt.client.ssh.client.SSHClient.cmd_sync()`.

Returns Returns the result from the salt-ssh command

**wheel** (`fun`, **kwargs**)

Run wheel modules synchronously

Wraps `salt.wheel.WheelClient.master_call()`.

Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the wheel module

**wheel_async** (`fun`, **kwargs**)

Run wheel modules asynchronously

Wraps `salt.wheel.WheelClient.master_call()`.

Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the wheel module
Writing netapi modules

`netapi` modules, put simply, bind a port and start a service. They are purposefully open-ended and can be used to present a variety of external interfaces to Salt, and even present multiple interfaces at once.

See also:

The full list of netapi modules

Configuration

All `netapi` configuration is done in the *Salt master config* and takes a form similar to the following:

```yaml
rest_cherrypy:
  port: 8000
  debug: True
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

The `__virtual__` function

Like all module types in Salt, `netapi` modules go through Salt's loader interface to determine if they should be loaded into memory and then executed.

The `__virtual__` function in the module makes this determination and should return `False` or a string that will serve as the name of the module. If the module raises an `ImportError` or any other errors, it will not be loaded.

The `start` function

The `start()` function will be called for each `netapi` module that is loaded. This function should contain the server loop that actually starts the service. This is started in a multiprocess.

Multiple instances

New in version 2016.11.0.

`rest_cherrypy` and `rest_tornado` support running multiple instances by copying and renaming entire directory of those. To start the copied multiple `netapi` modules, add configuration blocks for the copied `netapi` modules in the Salt Master config. The name of each added configuration block must match with the name of each directory of the copied `netapi` module.

Inline documentation

As with the rest of Salt, it is a best-practice to include liberal inline documentation in the form of a module docstring and docstrings on any classes, methods, and functions in your `netapi` module.
Loader “magic” methods

The loader makes the \_\_opts\_\_ data structure available to any function in a netapi module.
CHAPTER TWENTYFIVE

ARCHITECTURE

If you are used to configuration management tools that require you to plan down to the last detail before you install anything, you are probably wondering why this section doesn’t appear before the installation instructions. With Salt, you can switch to a high availability architecture at any time, and add additional components to scale your deployment as you go.

Since a single Salt master can manage thousands of systems, we usually recommend that you start by deploying a single Salt master, and then modifying your deployment as needed for redundancy, geographical distribution, and scale.

25.1 High Availability Features in Salt

Salt supports several features for high availability and fault tolerance. Brief documentation for these features is listed alongside their configuration parameters in Configuration file examples.

25.1.1 Multimaster

Salt minions can connect to multiple masters at one time by configuring the master configuration parameter as a YAML list of all the available masters. By default, all masters are "hot", meaning that any master can direct commands to the Salt infrastructure.

In a multimaster configuration, each master must have the same cryptographic keys, and minion keys must be accepted on all masters separately. The contents of file_roots and pillar_roots need to be kept in sync with processes external to Salt as well.

A tutorial on setting up multimaster with "hot" masters is here:

Multimaster Tutorial

25.1.2 Multimaster with Failover

Changing the master_type parameter from str to failover will cause minions to connect to the first responding master in the list of masters. Every master_alive_interval seconds the minions will check to make sure the current master is still responding. If the master does not respond, the minion will attempt to connect to the next master in the list. If the minion runs out of masters, the list will be recycled in case dead masters have been restored. Note that master_alive_interval must be present in the minion configuration, or else the recurring job to check master status will not get scheduled.

Failover can be combined with PKI-style encrypted keys, but PKI is NOT REQUIRED to use failover.

Multimaster with PKI and Failover is discussed in this tutorial
master_type: failover can be combined with master_shuffle: True to spread minion connections across all masters (one master per minion, not each minion connecting to all masters). Adding Salt Syndics into the mix makes it possible to create a load-balanced Salt infrastructure. If a master fails, minions will notice and select another master from the available list.

### 25.1.3 Syndic

Salt's Syndic feature is a way to create differing infrastructure topologies. It is not strictly an HA feature, but can be treated as such.

With the syndic, a Salt infrastructure can be partitioned in such a way that certain masters control certain segments of the infrastructure, and "Master of Masters" nodes can control multiple segments underneath them.

Syndics are covered in depth in *Salt Syndic*.

### 25.1.4 Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Syndics are covered in depth in *Salt Syndic*.

### 25.2 Salt Syndic

The most basic or typical Salt topology consists of a single Master node controlling a group of Minion nodes. An intermediate node type, called Syndic, when used offers greater structural flexibility and scalability in the construction of Salt topologies than topologies constructed only out of Master and Minion node types.

A Syndic node can be thought of as a special passthrough Minion node. A Syndic node consists of a salt-syndic daemon and a salt-master daemon running on the same system. The salt-master daemon running on the Syndic node controls a group of lower level Minion nodes and the salt-syndic daemon connects higher level Master node, sometimes called a Master of Masters.

The salt-syndic daemon relays publications and events between the Master node and the local salt-master daemon. This gives the Master node control over the Minion nodes attached to the salt-master daemon running on the Syndic node.

#### 25.2.1 Configuring the Syndic

To setup a Salt Syndic you need to tell the Syndic node and its Master node about each other. If your Master node is located at 10.10.0.1, then your configurations would be:

On the Syndic node:

```
# /etc/salt/master
syndic_master: 10.10.0.1  # may be either an IP address or a hostname
```

```
# /etc/salt/minion

# id is shared by the salt-syndic daemon and a possible salt-minion daemon
```

(continues on next page)
On the Master node:

```
# /etc/salt/master
order_masters: True
```

The `syndic_master` option tells the Sydnic node where to find the Master node in the same way that the `master` option tells a Minion node where to find a Master node.

The `id` option is used by the `salt-syndic` daemon to identify with the Master node and if unset will default to the hostname or IP address of the Sydnic just as with a Minion.

The `order_masters` option configures the Master node to send extra information with its publications that is needed by Sydnic nodes connected directly to it.

Note: Each Sydnic must provide its own `file_roots` directory. Files will not be automatically transferred from the Master node.

### 25.2.2 Configuring the Sydnic with Multimaster

New in version 2015.5.0.

Sydnic with Multimaster lets you connect a sydnic to multiple masters to provide an additional layer of redundancy in a sydnic configuration.

Higher level masters should first be configured in a multimaster configuration. See Multimaster Tutorial.

On the sydnic, the `syndic_master` option is populated with a list of the higher level masters.

Since each sydnic is connected to each master, jobs sent from any master are forwarded to minions that are connected to each sydnic. If the `master_id` value is set in the master config on the higher level masters, job results are returned to the master that originated the request in a best effort fashion. Events/jobs without a `master_id` are returned to any available master.

### 25.2.3 Running the Sydnic

The `salt-syndic` daemon is a separate process that needs to be started in addition to the `salt-master` daemon running on the Sydnic node. Starting the `salt-syndic` daemon is the same as starting the other Salt daemons.

The Master node in many ways sees the Sydnic as an ordinary Minion node. In particular, the Master will need to accept the Sydnic’s Minion key as it would for any other Minion.

On the Sydnic node:

```
# salt-syndic
or
# service salt-syndic start
```

On the Master node:

```
# salt-key -a my_syndic
```
The Master node will now be able to control the Minion nodes connected to the Syndic. Only the Syndic key will be listed in the Master node's key registry but this also means that key activity between the Syndic's Minions and the Syndic does not encumber the Master node. In this way, the Syndic's key on the Master node can be thought of as a placeholder for the keys of all the Minion and Syndic nodes beneath it, giving the Master node a clear, high level structural view on the Salt cluster.

On the Master node:

```
# salt-key -L
Accepted Keys:  
my_syndic  
Denied Keys:  
Unaccepted Keys:  
Rejected Keys:  

# salt '*' test.version
minion_1:  
    2018.3.4  
minion_2:  
    2018.3.4  
minion_4:  
    2018.3.4  
minion_3:  
    2018.3.4  
```

25.2.4 Topology

A Master node (a node which is itself not a Syndic to another higher level Master node) must run a salt-master daemon and optionally a salt-minion daemon.

A Syndic node must run salt-syndic and salt-master daemons and optionally a salt-minion daemon.

A Minion node must run a salt-minion daemon.

When a salt-master daemon issues a command, it will be received by the Syndic and Minion nodes directly connected to it. A Minion node will process the command in the way it ordinarily would. On a Syndic node, the salt-syndic daemon will relay the command to the salt-master daemon running on the Syndic node, which then propagates the command to the Minions and Syndics connected to it.

When events and job return data are generated by salt-minion daemons, they are aggregated by the salt-master daemon they are connected to, which salt-master daemon then relays the data back through its salt-syndic daemon until the data reaches the Master or Syndic node that issued the command.

25.2.5 Syndic wait

syndic_wait is a master configuration file setting that specifies the number of seconds the Salt client should wait for additional syndics to check in with their lists of expected minions before giving up. This value defaults to 5 seconds.

The syndic_wait setting is necessary because the higher-level master does not have a way of knowing which minions are below the syndics. The higher-level master has its own list of expected minions and the masters below them have their own lists as well, so the Salt client does not how long to wait for all returns. The syndic_wait option allows time for all minions to return to the Salt client.
Note: To reduce the amount of time the CLI waits for Minions to respond, install a Minion on the Syndic or tune the value of the `syndic_wait` configuration.

While it is possible to run a Syndic without a Minion installed on the same system, it is recommended, for a faster CLI response time, to do so. Without a Minion installed on the Syndic node, the timeout value of `syndic_wait` increases significantly - about three-fold. With a Minion installed on the Syndic, the CLI timeout resides at the value defined in `syndic_wait`.

Note: If you have a very large infrastructure or many layers of Syndics, you may find that the CLI doesn’t wait long enough for the Syndics to return their events. If you think this is the case, you can set the `syndic_wait` value in the Master configs on the Master or Syndic nodes from which commands are executed. The default value is 5, and should work for the majority of deployments.

In order for a Master or Syndic node to return information from Minions that are below their Syndics, the CLI requires a short wait time in order to allow the Syndics to gather responses from their Minions. This value is defined in the `syndic_wait` config option and has a default of five seconds.

### 25.2.6 Syndic config options

These are the options that can be used to configure a Syndic node. Note that other than `id`, Syndic config options are placed in the Master config on the Syndic node.

- **id**: Syndic id (shared by the `salt-syndic` daemon with a potential `salt-minion` daemon on the same system)
- **syndic_master**: Master node IP address or hostname
- **syndic_master_port**: Master node ret_port
- **syndic_log_file**: path to the logfile (absolute or not)
- **syndic_pidfile**: path to the pidfile (absolute or not)
- **syndic_wait**: time in seconds to wait on returns from this syndic

### 25.2.7 Minion Data Cache

Beginning with Salt 2016.11.0, the **Pluggable Minion Data Cache** was introduced. The minion data cache contains the Salt Mine data, minion grains, and minion pillar information cached on the Salt Master. By default, Salt uses the `localfs` cache module, but other external data stores can be used instead.

Using a pluggable minion cache modules allows for the data stored on a Salt Master about Salt Minions to be replicated on other Salt Masters the Minion is connected to. Please see the `Minion Data Cache` documentation for more information and configuration examples.
MINION DATA CACHE

New in version 2016.11.0.

The Minion data cache contains the Salt Mine data, minion grains and minion pillar information cached on the Salt Master. By default, Salt uses the localfs cache module to save the data in a msgpack file on the Salt Master.

26.1 Pluggable Data Cache

While the default Minion data cache is the localfs cache, other external data stores can also be used to store this data such as the consul module. To configure a Salt Master to use a different data store, the cache setting needs to be established:

```yaml
[cache]
  consul
```

The pluggable data cache streamlines using various Salt topologies such as a Multi-Master or Salt Syndics configuration by allowing the data stored on the Salt Master about a Salt Minion to be available to other Salt Syndics or Salt Masters that a Salt Minion is connected to.

Additional minion data cache modules can be easily created by modeling the custom data store after one of the existing cache modules.

See cache modules for a current list.

26.2 Configuring the Minion Data Cache

The default localfs Minion data cache module doesn't require any configuration. External data cache modules with external data stores such as Consul require a configuration setting in the master config.

Here's an example config for Consul:

```yaml
[consul]
  host: 127.0.0.1
  port: 8500
  token: None
  scheme: http
  consistency: default
  dc: dc1
  verify: True

[cache]
  consul
```
New in version 2018.3.0.  
Changed in version 3000.  

---

**Note:** This functionality is under development and could be changed in the future releases  

Many times it is useful to store the results of a command during the course of an execution. Salt Slots are designed to allow you to store this information and use it later during the *highstate* or other job execution.  

Slots extend the state syntax and allows you to do things right before the state function is executed. So you can make a decision in the last moment right before a state is executed.

## 27.1 Execution functions  

---

**Note:** Using execution modules return data as a state values is a first step of Slots development. Other functionality is under development.  

Slots allow you to use the return from a remote-execution function as an argument value in states.  

Slot syntax looks close to the simple python function call.  

```python
__slot__:salt:<module>.<function>(<args>, ..., <kwargs...>, ...)
```

For the 3000 release, this syntax has been updated to support parsing functions which return dictionaries and for appending text to the slot result.  

```python
__slot__:salt:<module>.<function>(<args>..., <kwargs...>, ...).dictionary ~ append
```

There are some specifics in the syntax coming from the execution functions nature and a desire to simplify the user experience. First one is that you don’t need to quote the strings passed to the slots functions. The second one is that all arguments handled as strings.  

Here is a simple example:

```yaml
copy-some-file:
  file.copy:
    - name: __slot__:salt:test.echo(text=/tmp/some_file)
    - source: __slot__:salt:test.echo(/etc/hosts)
```
This will execute the `test.echo` execution functions right before calling the state. The functions in the example will return `/tmp/some_file` and `/etc/hosts` strings that will be used as a target and source arguments in the state function `file.copy`.

Here is an example of result parsing and appending:

```
file-in-user-home:
  file.copy:
    - name: __slot__:salt:user.info(someuser).home ~ /subdirectory
    - source: salt://somefile
```
This section contains details on the Windows Package Manager, and specific information you need to use Salt on Windows.

28.1 Windows Package Manager

28.1.1 Introduction

The Windows Package Manager provides a software repository and a package manager similar to what is provided by `yum` and `apt` on Linux. This tool enables the installation of software on remote Windows systems.

The repository contains a collection of software definition files. A software definition file is a YAML/JINJA file with an `.sls` file extension. It contains all the information Salt needs to install a software package on a Windows system, including the download location of the installer, required command-line switches for silent install, etc.

Software definition files can be hosted in one or more Git repositories. The default repository is hosted on GitHub by SaltStack. It is maintained by SaltStack and the Salt community and contains software definition files for many common Windows packages. Anyone is welcome to submit a pull request to this repo to add new software definitions. The default github repository is:

- `salt-winrepo-ng`

The Windows Package Manager is used the same way as other package managers Salt is aware of. For example:

- The `pkg.installed` and similar states work on Windows.
- The `pkg.install` and similar module functions work on Windows.

High level differences to `yum` and `apt` are:

- The repository metadata (SLS files) can be managed through either Salt or git
- Packages can be downloaded from within the Salt repository, a git repository or from HTTP(S) or FTP URLs
- No dependencies are managed. Dependencies between packages need to be managed manually
Requirements

If using the a software definition files hosted on a Git repo, the following libraries are required:

- GitPython 0.3 or later
- or
- pygit2 0.20.3 with libgit 0.20.0 or later

28.1.2 Quick Start

You can get up and running with winrepo pretty quickly just using the defaults. Assuming no changes to the default configuration (ie, file_roots) run the following commands on the master:

```bash
salt-run winrepo.update_git_repos
salt * pkg.refresh_db
salt * pkg.install firefox_x64
```

On a masterless minion run the following:

```bash
salt-call --local winrepo.update_git_repos
salt-call --local pkg.refresh_db
salt-call --local pkg.install firefox_x64
```

These commands clone the default winrepo from github, update the winrepo database on the minion, and install the latest version of Firefox.

28.1.3 Configuration

The Github repository (winrepo) is synced to the file_roots in a location specified by the winrepo_dir_ng setting in the config. The default value of winrepo_dir_ng is as follows:

- Linux master: /srv/salt/win/repo-ng (salt://win/repo-ng)
- Masterless minion: C:\salt\srv\salt\win\repo-ng (salt://win/repo-ng)

Master Configuration

The following are settings are available for configuring the winrepo on the master:

- winrepo_dir
- winrepo_dir_ng
- winrepo_remotes
- winrepo_remotes_ng
- winrepo_branch
- winrepo_provider
- winrepo_ssl_verify

See here for detailed information on all master config options for winrepo.
**winrepo_dir**

*winrepo_dir* (str)

This setting is maintained for backwards compatibility with legacy minions. It points to the location in the `file_roots` where the winrepo files are kept. The default is: `/srv/salt/win/repo`

**winrepo_dir_ng**

*winrepo_dir_ng* (str)

The location in the `file_roots` where the winrepo files are kept. The default is `/srv/salt/win/repo-ng`.

**Warning:** You can change the location of the winrepo directory. However, it must always be set to a path that is inside the `file_roots`. Otherwise the software definition files will be unreachable by the minion.

**Important:** A common mistake is to change the `file_roots` setting and fail to update the `winrepo_dir_ng` and `winrepo_dir` settings so that they are inside the `file_roots`.

**winrepo_remotes**

*winrepo_remotes* (list)

This setting is maintained for backwards compatibility with legacy minions. It points to the legacy git repo. The default is a list containing a single URL:

https://github.com/saltstack/salt-winrepo

The legacy repo can be disabled by setting it to an empty list in the master config.

```
winrepo_remotes: []
```

**winrepo_remotes_ng**

*winrepo_remotes_ng* (list)

This setting tells the `winrepo.upgate_git_repos` command where the next generation winrepo is hosted. This a list of URLs to multiple git repos. The default is a list containing a single URL:

https://github.com/saltstack/salt-winrepo-ng
**winrepo_refspecs**

*winrepo_refspecs* (list)

Specify what references to fetch from remote repositories. The default is `['+refs/heads/*:refs/remotes/origin/*', '+refs/tags/*:refs/tags/*']`

**winrepo_branch**

*winrepo_branch* (str)

The branch of the git repo to checkout. The default is `master`

**winrepo_provider**

*winrepo_provider* (str)

The provider to be used for winrepo. Default is `pygit2`. Falls back to `gitpython` when `pygit2` is not available.

**winrepo_ssl_verify**

*winrepo_ssl_verify* (bool)

Ignore SSL certificate errors when contacting remote repository. Default is `False`

**Master Configuration (pygit2)**

The following configuration options only apply when the `winrepo_provider` option is set to `pygit2`.

- **winrepo_insecure_auth**
- **winrepo_passphrase**
- **winrepo_password**
- **winrepo_privkey**
- **winrepo_pubkey**
- **winrepo_user**

**winrepo_insecure_auth**

*winrepo_insecure_auth* (bool)

Used only with `pygit2` provider. Whether or not to allow insecure auth. Default is `False`
**winrepo_passphrase**

*winrepo_passphrase* (str)

Used only with *pygit2* provider. Used when the SSH key being used to authenticate is protected by a passphrase. Default is ''

**winrepo_privkey**

*winrepo_privkey* (str)

Used only with *pygit2* provider. Used with *winrepo_pubkey* to authenticate to SSH remotes. Default is ''

**winrepo_pubkey**

*winrepo_pubkey* (str)

Used only with *pygit2* provider. Used with *winrepo_privkey* to authenticate to SSH remotes. Default is ''

**winrepo_user**

*winrepo_user* (str)

Used only with *pygit2* provider. Used with *winrepo_password* to authenticate to HTTPS remotes. Default is ''

**winrepo_password**

*winrepo_password* (str)

Used only with *pygit2* provider. Used with *winrepo_user* to authenticate to HTTPS remotes. Default is ''

**Minion Configuration**

Refreshing the package definitions can take some time, these options were introduced to allow more control of when it occurs. These settings apply to all minions whether in masterless mode or not.

- *winrepo_cache_expire_max*
- *winrepo_cache_expire_min*
- *winrepo_cachefile*
- *winrepo_source_dir*
**winrepo_cache_expire_max**

*winrepo_cache_expire_max* (int)

Sets the maximum age in seconds of the winrepo metadata file to avoid it becoming stale. If the metadata file is older than this setting it will trigger a `pkg.refresh_db` on the next run of any `pkg` module function that requires the metadata file. Default is 604800 (1 week).

Software package definitions are automatically refreshed if stale after `winrepo_cache_expire_max`. Running a highstate normal forces the refresh of the package definition and generation of the metadata, unless the metadata is younger than `winrepo_cache_expire_max`.

**winrepo_cache_expire_min**

*winrepo_cache_expire_min* (int)

Sets the minimum age in seconds of the winrepo metadata file to avoid refreshing too often. If the metadata file is older than this setting the metadata will be refreshed unless you pass `refresh: False` in the state. Default is 1800 (30 min).

**winrepo_cachefile**

*winrepo_cachefile* (str)

The file name of the winrepo cache file. The file is placed at the root of `winrepo_dir_ng`. Default is `winrepo.p`.

**winrepo_source_dir**

*winrepo_source_dir* (str)

The location of the .sls files on the Salt file server. This allows for using different environments. Default is `salt:/win/repo-ng/`.

**Warning:** If the default for `winrepo_dir_ng` is changed, this setting may need to changed on each minion. The default setting for `winrepo_dir_ng` is `/srv/salt/win/repo-ng`. If that were changed to `/srv/salt/new/repo-ng` then the `winrepo_source_dir` would need to be changed to `salt://new/repo-ng`.

**Masterless Minion Configuration**

The following are settings are available for configuring the winrepo on a masterless minion:

- `winrepo_dir`
- `winrepo_dir_ng`
- `winrepo_remotes`
- `winrepo_remotes_ng`

See [here](#) for detailed information on all minion config options for winrepo.
**winrepo_dir**

*winrepo_dir* (str)

This setting is maintained for backwards compatibility with legacy minions. It points to the location in the `file_roots` where the winrepo files are kept. The default is: `C:salt\srv\salt\win\repo`

**winrepo_dir_ng**

*winrepo_dir_ng* (str)

The location in the `file_roots` where the winrepo files are kept. The default is `C:salt\srv\salt\win\repo-ng`.

**Warning:** You can change the location of the winrepo directory. However, it must always be set to a path that is inside the `file_roots`. Otherwise the software definition files will be unreachable by the minion.

**Important:** A common mistake is to change the `file_roots` setting and fail to update the `winrepo_dir_ng` and `winrepo_dir` settings so that they are inside the `file_roots`. You might also want to verify `winrepo_source_dir` on the minion as well.

**winrepo_remotes**

*winrepo_remotes* (list)

This setting is maintained for backwards compatibility with legacy minions. It points to the legacy git repo. The default is a list containing a single URL:

https://github.com/saltstack/salt-winrepo

The legacy repo can be disabled by setting it to an empty list in the minion config.

```
winrepo_remotes: []
```

**winrepo_remotes_ng**

*winrepo_remotes_ng* (list)

This setting tells the `winrepo.upgate_git_repos` command where the next generation winrepo is hosted. This a list of URLs to multiple git repos. The default is a list containing a single URL:

https://github.com/saltstack/salt-winrepo-ng
28.1.4 Initialization

Populate the Local Repository

The SLS files used to install Windows packages are not distributed by default with Salt. Use the `winrepo.update_git_repos` runner to initialize the repository in the location specified by `winrepo_dir_ng` in the master config. This will pull the software definition files down from the git repository.

```
salt-run winrepo.update_git_repos
```

If running a minion in masterless mode, the same command can be run using `salt-call`. The repository will be initialized in the location specified by `winrepo_dir_ng` in the minion config.

```
salt-call --local winrepo.update_git_repos
```

These commands will also sync down the legacy repo to maintain backwards compatibility with legacy minions. See Legacy Minions

The legacy repo can be disabled by setting it to an empty list in the master or minion config.

```
winrepo_remotes: []
```

Generate the Metadata File (Legacy)

This step is only required if you are supporting legacy minions. In current usage the metadata file is generated on the minion in the next step, Update the Minion Database. For legacy minions the metadata file is generated on the master using the `winrepo.genrepo` runner.

```
salt-run winrepo.genrepo
```

Update the Minion Database

Run `pkg.refresh_db` on each of your Windows minions to synchronize the package repository to the minion and build the package database.

```
# From the master
salt -G 'os:windows' pkg.refresh_db

# From the minion in masterless mode
salt-call --local pkg.refresh_db
```

The above command returns the following summary denoting the number of packages that succeeded or failed to compile:

```
local:
    --------
        failed:
            0
        success:
            301
        total:
            301
```
Note: This command can take a few minutes to complete as the software definition files are copied to the minion and the database is generated.

Note: Use \texttt{pkg.refresh\_db} when developing new Windows package definitions to check for errors in the definitions against one or more Windows minions.

28.1.5 Usage

After completing the configuration and initialization steps, you are ready to manage software on your Windows minions.

Note: The following example commands can be run from the master using \texttt{salt} or on a masterless minion using \texttt{salt\_call}

List Installed Packages

You can get a list of packages installed on the system using \texttt{pkg.list\_pkgs}.

\begin{verbatim}
# From the master
salt -G 'os:windows' pkg.list\_pkgs

# From the minion in masterless mode
salt\_call --local pkg.list\_pkgs
\end{verbatim}

This will return all software installed on the system whether it is managed by Salt or not as shown below:

\begin{verbatim}
local:  
 Frhed 1.6.0:  
  1.6.0
 GNU Privacy Guard:  
  2.2.16
 Gpg4win (3.1.9):  
  3.1.9
 git:  
  2.17.1.2
 nsis:  
  3.03
 python3\_x64:  
  3.7.4150.0
 salt-minion-py3:  
  2019.2.3
\end{verbatim}

You can tell by how the software name is displayed which software is managed by Salt and which software is not. When Salt finds a match in the winrepo database it displays the short name as defined in the software definition file. It is usually a single-word, lower-case name. All other software names will be displayed with the full name as they are shown in Add/Remove Programs. So, in the return above, you can see that Git (git), Nullsoft Installer (nsis), Python 3.7 (python3\_x64) and Salt (salt-minion-py3) all have a corresponding software definition file. The others do not.
List Available Versions

You can query the available version of a package using `pkg.list_available` and passing the name of the software:

```
# From the master
salt winminion pkg.list_available firefox_x64

# From the minion in masterless mode
salt-call --local pkg.list_available firefox_x64
```

The above command will return the following:

```
winminion:
  - 69.0
  - 69.0.1
  - 69.0.2
  - 69.0.3
  - 70.0
  - 70.0.1
  - 71.0
  - 72.0
  - 72.0.1
  - 72.0.2
  - 73.0
  - 73.0.1
  - 74.0
```

As you can see, there are many versions of Firefox available for installation. You can refer to a software package by its name or its full_name surrounded by quotes.

**Note:** From a Linux master it is OK to use single-quotes. However, the cmd shell on Windows requires you to use double-quotes when wrapping strings that may contain spaces. Powershell seems to accept either one.

Install a Package

You can install a package using `pkg.install`:

```
# From the master
salt winminion pkg.install 'firefox_x64'

# From the minion in masterless mode
salt-call --local pkg.install "firefox_x64"
```

The above will install the latest version of Firefox.

```
# From the master
salt winminion pkg.install 'firefox_x64' version=74.0

# From the minion in masterless mode
salt-call --local pkg.install "firefox_x64" version=74.0
```

The above will install version 74.0 of Firefox.

If a different version of the package is already installed it will be replaced with the version in the winrepo (only if the package itself supports live updating).
You can also specify the full name:

```bash
# From the master
salt winminion pkg.install 'Mozilla Firefox 17.0.1 (x86 en-US)'

# From the minion in masterless mode
salt-call --local pkg.install "Mozilla Firefox 17.0.1 (x86 en-US)"
```

### Remove a Package

You can uninstall a package using `pkg.remove`:

```bash
# From the master
salt winminion pkg.remove firefox_x64

# From the minion in masterless mode
salt-call --local pkg.remove firefox_x64
```

## 28.1.6 Software Definition Files

A software definition file is a YAML/JINJA2 file that contains all the information needed to install a piece of software using Salt. It defines information about the package to include version, full name, flags required for the installer and uninstaller, whether or not to use the Windows task scheduler to install the package, where to download the installation package, etc.

### Directory Structure and Naming

The files are stored in the location designated by the `winrepo_dir_ng` setting. All files in this directory that have a `.sls` file extension are considered software definition files. The files are evaluated to create the metadata file on the minion.

You can maintain standalone software definition files that point to software on other servers or on the internet. In this case the file name would be the short name of the software with the `.sls` extension, ie `firefox.sls`.

You can also store the binaries for your software together with their software definition files in their own directory. In this scenario, the directory name would be the short name for the software and the software definition file would be inside that directory and named `init.sls`.

Look at the following example directory structure on a Linux master assuming default config settings:

```
srv/
    |--salt/
        |--win/
            |--repo-ng/
                |--custom_defs/
                    |--ms_office_2013_x64/
                        |--access.en-us/
                        |--excel.en-us/
                        |--outlook.en-us/
                        |--powerpoint.en-us/
                        |--word.en-us/
                        |--init.sls
                        |--setup.dll
                        |--setup.exe
```

(continues on next page)
In the above directory structure, the user has created the custom_defs directory in which to store their custom software definition files. In that directory you see a folder for MS Office 2013 that contains all the installer files along with a software definition file named init.sls. The user has also created two more standalone software definition files: openssl.sls and zoom.sls.

The salt-winrepo-ng directory is created by the winrepo.update_git_repos command. This folder contains the clone of the git repo designated by the winrepo_remotes_ng config setting.

**Warning:** It is recommended that the user not modify the files in the salt-winrepo-ng directory as it will break future runs of winrepo.update_git_repos.

**Warning:** It is recommended that the user not place any custom software definition files in the salt-winrepo-ng directory. The winrepo.update_git_repos command wipes out the contents of the salt-winrepo-ng directory each time it is run. Any extra files stored there will be lost.

### Writing Software Definition Files

A basic software definition file is really easy to write if you already know some basic things about your software:

- The full name as shown in Add/Remove Programs
- The exact version number as shown in Add/Remove Programs
- How to install your software silently from the command line

The software definition file itself is just a data structure written in YAML. The top level item is a short name that Salt will use to reference the software. There can be only one short name in the file and it must be unique across all software definition files in the repo. This is the name that will be used to install/remove the software. It is also the name that will appear when Salt finds a match in the repo when running pkg.list_pkgs.

The next indentation level is the version number. There can be many of these, but they must be unique within the file. This is also displayed in pkg.list_pkgs.

The last indentation level contains the information Salt needs to actually install the software. Available parameters are:
- **full_name**: The full name as displayed in Add/Remove Programs
- **installer**: The location of the installer binary
- **install_flags**: The flags required to install silently
- **uninstaller**: The location of the uninstaller binary
- **uninstall_flags**: The flags required to uninstall silently
- **msiexec**: Use msiexec to install this package
- **allusers**: If this is an MSI, install to all users
- **cache_dir**: Cache the entire directory in the installer URL (`salt://`)
- **cache_file**: Cache a single file in the installer URL (`salt://`)
- **use_scheduler**: Launch the installer using the task scheduler
- **source_hash**: The hash sum for the installer

Usage of these parameters is demonstrated in the following examples and discussed in more detail below. To understand these examples you'll need a basic understanding of Jinja. The following links have some basic tips and best practices for working with Jinja in Salt:

Understanding Jinja

Jinja

**Example: Basic**

Take a look at this basic, pure YAML example for a software definition file for Firefox:

```yaml
firefox_x64:
  '74.0':
    full_name: Mozilla Firefox 74.0 (x64 en-US)
    installer: 'https://download-installer.cdn.mozilla.net/pub/firefox/releases/74.0/
               win64/en-US/Firefox%20Setup%2074.0.exe'
    install_flags: '/S'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
  '73.0.1':
    full_name: Mozilla Firefox 73.0.1 (x64 en-US)
    installer: 'https://download-installer.cdn.mozilla.net/pub/firefox/releases/73.0.1/
               win64/en-US/Firefox%20Setup%2073.0.1.exe'
    install_flags: '/S'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
```

You can see the first item is the short name for the software, in this case `firefox_x64`. It is the first line in the definition. The next line is indented two spaces and contains the software version. The lines following the version are indented two more spaces and contain all the information needed to install the Firefox package.

**Important**: The package name must be unique to all other packages in the software repository. The `full_name` combined with the version must also be unique. They must also match exactly what is shown in Add/Remove Programs (`appwiz.cpl`).
**Important:** The version number must be enclosed in quotes, otherwise the YAML parser will remove trailing zeros. For example, `74.0` will just become `74`.

As you can see in the example above, a software definition file can define multiple versions for the same piece of software. These are denoted by putting the next version number at the same indentation level as the first with its software definition information indented below it.

### Example: Jinja

When there are tens or hundreds of versions available for a piece of software definition file can become quite large. This is a scenario where Jinja can be helpful. Consider the following software definition file for Firefox using Jinja:

```yaml
{% set lang = salt['config.get']('firefox:pkg:lang', 'en-US') %}

firefox_x64:
  {% for version in ['74.0', '73.0', '72.0.2', '72.0.1', '72.0', '71.0', '70.0.1', '70.0', '69.0.3', '69.0.2', '69.0.1'] %}

    '{{ version }}':
      full_name: 'Mozilla Firefox {{ version }} (x64 {{ lang }})'
      installer: 'https://download-installer.cdn.mozilla.net/pub/firefox/releases/{{ version }}/win64/{{ lang }}/FirefoxSetup.exe'
      install_flags: '/S'
      uninstaller: '%ProgramFiles%\Mozilla Firefox\uninstall\helper.exe'
      uninstall_flags: '/S'
  {%- endfor %}
```

In this example we are able to generate a software definition file that defines how to install 12 versions of Firefox. We use Jinja to create a list of available versions. That list is in a `for` loop where each version is placed in the `version` variable. The version is inserted everywhere there is a `{{ version }}` marker inside the `for` loop.

You’ll notice that there is a single variable (`lang`) defined at the top of the software definition. Because these files are going through the Salt renderer many Salt modules are exposed via the `salt` keyword. In this case it is calling the `config.get` function to get a language setting that can be placed in the minion config. If it is not there, it defaults to `en-US`.

### Example: Latest

There are some software vendors that do not provide access to all versions of their software. Instead they provide a single URL to what is always the latest version. In some cases the software keeps itself up to date. One example of this is the Google Chrome web browser.

Chrome

To handle situations such as these, set the version to `latest`. Here’s an example:

```yaml
chrome:
  latest:
    full_name: 'Google Chrome'
    installer: 'https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi'
    install_flags: '/qn /norestart'
```

(continues on next page)
uninstaller: 'https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi'
uninstall_flags: '/qn /norestart'
msiexec: True

The above example shows us two things. First it demonstrates the usage of `latest` as the version. In this case Salt will install the version of Chrome at the URL and report that version.

The second thing to note is that this is installing software using an MSI. You can see that `msiexec` is set to `True`.

**Example: MSI Patch**

When the `msiexec` parameter is set to `True` it uses the `/i` option for installs and the `/x` option for uninstalls. This is problematic when trying to install an MSI patch which requires the `/p` option. You can't combine the `/i` and `/p` options. So how do you apply a patch to installed software in winrepo using an `.msp` file?

One wiley contributor came up with the following solution to this problem by using the `%cd%` environment variable. Consider the following software definition file:

```yaml
MyApp:
  '1.0':
    full_name: MyApp
    installer: 'salt://win/repo-ng/MyApp/MyApp.1.0.msi'
    install_flags: '/qn /norestart'
    uninstaller: '{B5B5868F-23BA-297A-917D-0DF345TF5764}'
    uninstall_flags: '/qn /norestart'
    msiexec: True
  '1.1':
    full_name: MyApp
    installer: 'salt://win/repo-ng/MyApp/MyApp.1.0.msi'
    install_flags: '/qn /norestart /update "%cd%\MyApp.1.1.msp"'
    uninstaller: '{B5B5868F-23BA-297A-917D-0DF345TF5764}'
    uninstall_flags: '/qn /norestart'
    msiexec: True
    cache_file: salt://win/repo/MyApp/MyApp.1.1.msp
```

There are a few things to note about this software definition file. First, is the solution we are trying to solve, that of applying a patch. Version 1.0 just installs the application using the 1.0 MSI defined in the `installer` parameter. There is nothing special in the `install_flags` and nothing is cached.

Version 1.1 uses the same installer, but uses the `cache_file` option to specify a single file to cache. In order for this to work the MSP file needs to be in the same directory as the MSI file on the `file_roots`.

The final step to getting this to work is to add the additional `/update` flag to the `install_flags` parameter. Add the path to the MSP file using the `%cd%` environment variable. `%cd%` resolves to the current working directory which is the location in the minion cache where the installer file is cached.

See issue #32780 for more details.

This same approach could be used for applying MST files for MSIs and answer files for other types of .exe based installers.
Parameters

These are the parameters that can be used to generate a software definition file. These parameters are all placed under the version in the software definition file:

Example usage can be found on the github repo

**full_name (str)**

This is the full name for the software as shown in "Programs and Features" in the control panel. You can also get this information by installing the package manually and then running pkg.list_pkgs. Here's an example of the output from pkg.list_pkgs:

```
salt 'test-2008' pkg.list_pkgs
test-2008
----------
  7-Zip 9.20 (x64 edition):
    9.20.00.0
  Mozilla Firefox 74.0 (x64 en-US)
    74.0
  Mozilla Maintenance Service:
    74.0
  salt-minion-py3:
    3001
```

Notice the Full Name for Firefox: Mozilla Firefox 74.0 (x64 en-US). That's exactly what should be in the full_name parameter in the software definition file.

If any of the software installed on the machine matches the full name defined in one of the software definition files in the repository the package name will be returned. The example below shows the pkg.list_pkgs for a machine that has Mozilla Firefox 74.0 installed and a software definition for that version of Firefox.

```
test-2008:
----------
  7zip:
    9.20.00.0
  Mozilla Maintenance Service:
    74.0
  firefox_x64:
    74.0
  salt-minion-py3:
    3001
```

**Important:** The version number and full_name need to match the output from pkg.list_pkgs exactly so that the installation status can be verified by the state system.

**Note:** It is still possible to successfully install packages using pkg.install, even if the full_name or the version number don't match exactly. The module will complete successfully, but continue to display the full name in pkg.list_pkgs. If this is happening, verify that the full_name and the version match exactly what is displayed in Add/Remove Programs.

**Tip:** To force Salt to display the full name when there's already an existing package definition file on the system, you
can pass a bogus saltenv parameter to the command like so: pkg.list_pkgs saltenv=NotARealEnv

Tip: It's important use pkg.refresh_db to check for errors and ensure the latest package definition is on any minion you’re testing new definitions on.

**installer (str)**

This is the path to the binary (.exe, .msi) that will install the package. This can be a local path or a URL. If it is a URL or a Salt path (salt://), the package will be cached locally and then executed. If it is a path to a file on disk or a file share, it will be executed directly.

**Note:** When storing software in the same location as the winrepo it is usually best practice to place each installer in its own directory rather than in the root of winrepo.

Best practice is to create a sub folder named after the package. That folder will contain the software definition file named init.sls. The binary installer should be stored in that directory as well if you’re hosting those files on the file_roots.

pkg.refresh_db will process all .sls files in all sub directories in the winrepo_dir_ng directory.

**install_flags (str)**

This setting contains any flags that need to be passed to the installer to make it perform a silent install. These can often be found by adding /? or /h when running the installer from the command-line. A great resource for finding these silent install flags is the WPKG project wiki:

**Warning:** Salt will appear to hang if the installer is expecting user input. So it is imperative that the software have the ability to install silently.

**uninstaller (str)**

This is the path to the program used to uninstall this software. This can be the path to the same exe or msi used to install the software. Exe uninstallers are pretty straight forward. MSIs, on the other hand, can be handled a couple different ways. You can use the GUID for the software to uninstall or you can use the same MSI used to install the software.

You can usually find uninstall information in the registry:

- Software\Microsoft\Windows\CurrentVersion\Uninstall
- Software\WOW6432Node\Microsoft\Windows\CurrentVersion\Uninstall

Here's an example using the GUID to uninstall software.

7zip:

```
'9.20.00.0':
  full_name: 7-Zip 9.20 (x64 edition)
  installer: salt://win/repo-ng/7zip/7z920-x64.msi
```

(continues on next page)
Here’s an example using the same MSI used to install the software:

```plaintext
7zip:
'9.20.00.0':
  full_name: 7-Zip 9.20 (x64 edition)
  installer: salt://win/repo-ng/7zip/7z920-x64.msi
  install_flags: '/qn /norestart'
  uninstaller: salt://win/repo-ng/7zip/7z920-x64.msi
  uninstall_flags: '/qn /norestart'
  msiexec: True
```

**uninstall_flags (str)**

This setting contains any flags that need to be passed to the uninstaller to make it perform a silent uninstall. These can often be found by adding `/?` or `/h` when running the uninstaller from the command-line. A great resource for finding these silent install flags the WPKG project wiki:

**Warning:** Salt will appear to hang if the uninstaller is expecting user input. So it is imperative that the software have the ability to uninstall silently.

**msiexec (bool, str)**

This tells Salt to use `msiexec /i` to install the package and `msiexec /x` to uninstall. This is for `.msi` installations only.

Possible options are:

- True
- False (default)
- the path to `msiexec.exe` on your system

```plaintext
7zip:
'9.20.00.0':
  full_name: 7-Zip 9.20 (x64 edition)
  installer: salt://win/repo/7zip/7z920-x64.msi
  install_flags: '/qn /norestart'
  uninstaller: salt://win/repo/7zip/7z920-x64.msi
  uninstall_flags: '/qn /norestart'
  msiexec: 'C:\Windows\System32\msiexec.exe'
```
allusers (bool)

This parameter is specific to .msi installations. It tells msiexec to install the software for all users. The default is True.

cache_dir (bool)

This setting requires the software to be stored on the file_roots and only applies to URLs that begin with salt:// /. If True the entire directory where the installer resides will be recursively cached. This is useful for installers that depend on other files in the same directory for installation.

Warning: Be aware that all files and directories in the same location as the installer file will be copied down to the minion. If you place your software definition file in the root of winrepo (/srv/salt/win/repo-ng) and it contains cache_dir: True the entire contents of winrepo will be cached to the minion. Therefore, it is best practice to place your installer files in a subdirectory if they are to be stored in winrepo.

Here's an example using cache_dir:

```
sqlexpress:
  '12.0.2000.8':
    full_name: Microsoft SQL Server 2014 Setup (English)
    installer: 'salt://win/repo/sqlexpress/setup.exe'
    install_flags: '/ACTION=install /IACCEPTSQLSERVERLICENSETERMS /Q'
    cache_dir: True
```

cache_file (str)

This setting requires the file to be stored on the file_roots and only applies to URLs that begin with salt:// /. It indicates a single file to copy down for use with the installer. It is copied to the same location as the installer. Use this over cache_dir if there are many files in the directory and you only need a specific file and don’t want to cache additional files that may reside in the installer directory.

use_scheduler (bool)

If set to True, Windows will use the task scheduler to run the installation. A one-time task will be created in the task scheduler and launched. The return to the minion will be that the task was launched successfully, not that the software was installed successfully.

Note: This is used by the software definition for Salt itself. The first thing the Salt installer does is kill the Salt service, which then kills all child processes. If the Salt installer is launched via Salt, then the installer itself is killed leaving Salt on the machine but not running. Use of the task scheduler allows an external process to launch the Salt installation so its processes aren’t killed when the Salt service is stopped.
source_hash (str)

This tells Salt to compare a hash sum of the installer to the provided hash sum before execution. The value can be formatted as `<hash_algorithm>=<hash_sum>`, or it can be a URI to a file containing the hash sum.

For a list of supported algorithms, see the [hashlib documentation](#).

Here's an example using `source_hash`:

```yaml
messageanalyzer:
  '4.0.7551.0':
    full_name: 'Microsoft Message Analyzer'
    installer: 'salt://win/repo/messageanalyzer/MessageAnalyzer64.msi'
    install_flags: '/quiet /norestart'
    uninstaller: '{1CC02C23-8FCD-487E-860C-311EC0A0C933}'
    uninstall_flags: '/quiet /norestart'
    msiexec: True
    source_hash: 'sha1=62875ff451f13b10a8ff988f2943e76a4735d3d4'
```

Not Implemented

The following parameters are often seen in the software definition files hosted on the Git repo. However, they are not implemented and have no effect on the installation process.

```yaml
param bool reboot Not implemented
param str locale Not implemented
```

### 28.1.7 Managing Windows Software on a Standalone Windows Minion

The Windows Software Repository functions similarly in a standalone environment, with a few differences in the configuration.

To replace the winrepo runner that is used on the Salt master, an execution module exists to provide the same functionality to standalone minions. The functions are named the same as the ones in the runner, and are used in the same way; the only difference is that `salt-call` is used instead of `salt-run`:

```bash
salt-call winrepo.update_git_repos
salt-call pkg.refresh_db
```

After executing the previous commands the repository on the standalone system is ready for use.

### 28.1.8 Troubleshooting

**My software installs correctly but pkg.installed says it failed**

If you have a package that seems to install properly, but Salt reports a failure then it is likely you have a version or `full_name` mismatch.

Check the exact `full_name` and `version` as shown in Add/Remove Programs (`appwiz.cpl`). Use `pkg.list_pkgs` to check that the `full_name` and `version` exactly match what is installed. Make sure the software definition file has the exact value for `full_name` and that the version matches exactly.

Also, make sure the version is wrapped in single quotes in the software definition file.
Changes to sls files not being picked up

You may have recently updated some of the software definition files on the repo. Ensure you have refreshed the database on the minion.

```
salt winminion pkg.refresh_db
```

How Success and Failure are Reported by pkg.installed

The install state/module function of the Windows package manager works roughly as follows:

1. Execute `pkg.list_pkgs` to get a list of software currently on the machine
2. Compare the requested version with the installed version
3. If versions are the same, report no changes needed
4. Install the software as described in the software definition file
5. Execute `pkg.list_pkgs` to get a new list of software currently on the machine
6. Compare the requested version with the new installed version
7. If versions are the same, report success
8. If versions are different, report failure

Winrepo Upgrade Issues

To minimize potential issues, it is a good idea to remove any winrepo git repositories that were checked out by the legacy (pre-2015.8.0) winrepo code when upgrading the master to 2015.8.0 or later. Run `winrepo.update_git_repos` to clone them anew after the master is started.

28.1.9 pygit2/GitPython Support for Maintaining Git Repos

The `winrepo.update_git_repos` runner now makes use of the same underlying code used by the `Git Fileserver Backend` and `Git External Pillar` to maintain and update its local clones of git repositories. If a compatible version of either `pygit2` (0.20.3 and later) or `GitPython` (0.3.0 or later) is installed, Salt will use it instead of the old method (which invokes the `git.latest` state).

Note: If compatible versions of both `pygit2` and `GitPython` are installed, then Salt will prefer `pygit2`. To override this behavior use the `winrepo_provider` configuration parameter:

```
winrepo_provider: gitpython
```

The `winrepo` execution module (discussed above in the `Managing Windows Software on a Standalone Windows Minion` section) does not yet officially support the new `pygit2/GitPython` functionality, but if either `pygit2` or `GitPython` is installed into Salt’s bundled Python then it should work. However, it should be considered experimental at this time.
28.1.10 Accessing Authenticated Git Repos (pygit2)

Support for pygit2 added the ability to access authenticated git repositories and to set per-remote config settings. An example of this would be the following:

```yaml
winrepo_remotes:
    - https://github.com/saltstack/salt-winrepo.git
    - git@github.com:myuser/myrepo.git:
        - pubkey: /path/to/key.pub
        - privkey: /path/to/key
        - passphrase: myaw3s0m3pa$$phr4$3
    - https://github.com/myuser/privaterepo.git:
        - user: mygithubuser
        - password: CorrectHorseBatteryStaple
```

Note: Per-remote configuration settings work in the same fashion as they do in gitfs, with global parameters being overridden by their per-remote counterparts. For instance, setting `winrepo_passphrase` would set a global passphrase for winrepo that would apply to all SSH-based remotes, unless overridden by a `passphrase` per-remote parameter.

See [here](#) for more a more in-depth explanation of how per-remote configuration works in gitfs. The same principles apply to winrepo.

28.1.11 Maintaining Git Repos

A `clean` argument has been added to the `winrepo.update_git_repos` runner. When `clean` is `True` it will tell the runner to dispose of directories under the `winrepo_dir`/`winrepo_dir` which are not explicitly configured. This prevents the need to manually remove these directories when a repo is removed from the config file. To clean these old directories, just pass `clean=True`:

```bash
salt-run winrepo.update_git_repos clean=True
```

If a mix of git and non-git Windows Repo definition files are being used, then this should *not* be used, as it will remove the directories containing non-git definitions.

28.1.12 Name Collisions Between Repos

Collisions between repo names are now detected. The `winrepo.update_git_repos` runner will not proceed if any are detected. Consider the following configuration:

```yaml
winrepo_remotes:
    - https://foo.com/bar/baz.git
    - https://mydomain.tld/baz.git
    - https://github.com/foobar/baz
```

The `winrepo.update_git_repos` runner will refuse to update repos here, as all three of these repos would be checked out to the same directory. To work around this, a per-remote parameter called `name` can be used to resolve these conflicts:

```yaml
winrepo_remotes:
    - https://foo.com/bar/baz.git
    - https://mydomain.tld/baz.git:
```

(continues on next page)
28.1.13 Legacy Minions

The Windows Package Manager was upgraded with breaking changes starting with Salt 2015.8.0. To maintain backwards compatibility Salt continues to support older minions.

The breaking change was to generate the winrepo database on the minion instead of the master. This allowed for the use of Jinja in the software definition files. It enabled the use of pillar, grains, execution modules, etc. during compile time. To support this new functionality, a next-generation (ng) repo was created.

See the Changes in Version 2015.8.0 for details.

On prior versions of Salt, or legacy minions, the winrepo database was generated on the master and pushed down to the minions. Any grains exposed at compile time would have been those of the master and not the minion.

The repository for legacy minions is named salt-winrepo and is located at:

- https://github.com/saltstack/salt-winrepo

Legacy Configuration

Winrepo settings were changed with the introduction of the Next Generation (ng) of winrepo.

Legacy Master Config Options

There were three options available for a legacy master to configure winrepo. Unless you’re running a legacy master as well, you shouldn’t need to configure any of these.

- win_gitrepos
- win_repo
- win_repo_mastercachefile

win_gitrepos: (list)

A list of URLs to github repos. Default is a list with a single URL:

- https://github.com/saltstack/salt-winrepo.git

win_repo: (str)

The location on the master to store the winrepo. The default is /srv/salt/win/repo.

win_repo_mastercachefile: (str) The location on the master to generate the winrepo database file. The default is /srv/salt/win/repo/winrep.p
Legacy Minion Config Options

There is only one option available to configure a legacy minion for winrepo.

- **win_repo_cachefile**

  *win_repo_cachefile*: (str)

  The location on the Salt file server to obtain the winrepo database file. The default is `salt://win/repo/winrepo.p`

  **Note:** If the location of the `winrepo.p` file is not in the default location on the master, the `win_repo_cachefile` setting will need to be updated to reflect the proper location on each minion.

Legacy Quick Start

You can get up and running with winrepo pretty quickly just using the defaults. Assuming no changes to the default configuration (ie, `file_roots`) run the following commands on the master:

```
salt-run winrepo.update_git_repos
salt-run winrepo.genrepo
salt * pkg.refresh_db
salt * pkg.install firefox
```

These commands clone the default winrepo from github, generate the metadata file, push the metadata file down to the legacy minion, and install the latest version of Firefox.

Legacy Initialization

Initializing the winrepo for a legacy minion is similar to that for a newer minion. There is an added step in that the metadata file needs to be generated on the master prior to refreshing the database on the minion.

Populate the Local Repository

The SLS files used to install Windows packages are not distributed by default with Salt. So, the first step is to clone the repo to the master. Use the `winrepo.update_git_repos` runner initialize the repository in the location specified by `winrepo_dir` in the master config. This will pull the software definition files down from the git repository.

```
salt-run winrepo.update_git_repos
```

Generate the Metadata File

The next step is to create the metadata file for the repo (`winrepo.p`). The metadata file is generated on the master using the `winrepo.genrepo` runner.

```
salt-run winrepo.genrepo
```

**Note:** You only need to do this if you need to support legacy minions.
Update the Minion Database

Run `pkg.refresh_db` on each of your Windows minions to copy the metadata file down to the minion.

```bash
# From the master
salt -G 'os:windows' pkg.refresh_db
```

Changes in Version 2015.8.0+

Git repository management for the Windows Software Repository changed in version 2015.8.0, and several master/minion config parameters were renamed for consistency.

For a complete list of the new winrepo config options, see [here](#) for master config options, and [here](#) for configuration options for masterless Windows minions.

**pygit2/GitPython Support**

On the master, the `winrepo.update_git_repos` runner was updated to use either `pygit2` or `GitPython` to checkout the git repositories containing repo data. If `pygit2` or `GitPython` is installed, existing winrepo git checkouts should be removed after upgrading to 2015.8.0. Then they should be cloned again by running `winrepo.update_git_repos`.

If neither `GitPython` nor `pygit2` are installed, Salt will fall back to pre-existing behavior for `winrepo.update_git_repos`, and a warning will be logged in the master log.

**Note:** Standalone Windows minions do not support the new `GitPython/pygit2` functionality, and will instead use the `git.latest` state to keep repositories up-to-date. More information on how to use the Windows Software Repo on a standalone minion can be found [here](#).

**Config Parameters Renamed**

Many of the legacy winrepo configuration parameters changed in version 2015.8.0 to make them more consistent. Below are the parameters which changed for version 2015.8.0:

**Master Config**

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>win_repo</code></td>
<td><code>winrepo_dir</code></td>
</tr>
<tr>
<td><code>win_repo_mastercache</code></td>
<td><code>winrepo_dir</code></td>
</tr>
<tr>
<td><code>win_repo_mastercache</code></td>
<td><code>winrepo_remotes</code></td>
</tr>
</tbody>
</table>

**Note:** The `winrepo_dir_ng` and `winrepo_remotes_ng` settings were introduced in 2015.8.0 for working with the next generation repo.

See [here](#) for detailed information on all master config options for the Windows Repo.

**Minion Config**

28.1. Windows Package Manager
### 28.2 Windows-specific Behaviour

Salt is capable of managing Windows systems, however due to various differences between the operating systems, there are some things you need to keep in mind.

This document will contain any quirks that apply across Salt or generally across multiple module functions. Any Windows-specific behavior for particular module functions will be documented in the module function documentation. Therefore this document should be read in conjunction with the module function documentation.

#### 28.2.1 Group parameter for files

Salt was originally written for managing Unix-based systems, and therefore the file module functions were designed around that security model. Rather than trying to shoehorn that model on to Windows, Salt ignores these parameters and makes non-applicable module functions unavailable instead.

One of the commonly ignored parameters is the `group` parameter for managing files. Under Windows, while files do have a 'primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Because of this, any file module functions that typically require a group, do not under Windows. Attempts to directly use file module functions that operate on the group (e.g. `file.chgrp`) will return a pseudo-value and cause a log message to appear. No group parameters will be acted on.

If you do want to access and change the 'primary group' property and understand the implications, use the `file.get_pgid` or `file.get_pgroup` functions or the `pgroup` parameter on the `file.chown` module function.

#### 28.2.2 Dealing with case-insensitive but case-preserving names

Windows is case-insensitive, but however preserves the case of names and it is this preserved form that is returned from system functions. This causes some issues with Salt because it assumes case-sensitive names. These issues generally occur in the state functions and can cause bizarre looking errors.

To avoid such issues, always pretend Windows is case-sensitive and use the right case for names, e.g. specify `user=Administrator` instead of `user=administrator`.

Follow issue #11801 for any changes to this behavior.
28.2.3 Dealing with various username forms

Salt does not understand the various forms that Windows usernames can come in, e.g. username, mydomain\username, username@mydomain.tld can all refer to the same user. In fact, Salt generally only considers the raw username value, i.e. the username without the domain or host information.

Using these alternative forms will likely confuse Salt and cause odd errors to happen. Use only the raw username value in the correct case to avoid problems.

Follow issue #11801 for any changes to this behavior.

28.2.4 Specifying the None group

Each Windows system has built-in _None_ group. This is the default 'primary group' for files for users not on a domain environment.

Unfortunately, the word _None_ has special meaning in Python - it is a special value indicating 'nothing', similar to null or nil in other languages.

To specify the None group, it must be specified in quotes, e.g. ./salt '*' file.chgrp C:\path\to\file "'None'".

28.2.5 Symbolic link loops

Under Windows, if any symbolic link loops are detected or if there are too many levels of symlinks (defaults to 64), an error is always raised.

For some functions, this behavior is different to the behavior on Unix platforms. In general, avoid symlink loops on either platform.
29.1 Overview

In its most typical use, Salt is a software application in which clients, called "minions" can be commanded and controlled from a central command server called a "master".

Commands are normally issued to the minions (via the master) by calling a client script simply called, 'salt'.

Salt features a pluggable transport system to issue commands from a master to minions. The default transport is ZeroMQ.

29.2 Salt Client

29.2.1 Overview

The salt client is run on the same machine as the Salt Master and communicates with the salt-master to issue commands and to receive the results and display them to the user.

The primary abstraction for the salt client is called 'LocalClient'.

When LocalClient wants to publish a command to minions, it connects to the master by issuing a request to the master's ReqServer (TCP: 4506)

The LocalClient system listens to responses for its requests by listening to the master event bus publisher (master_event_pub.ipc).

29.3 Salt Master

29.3.1 Overview

The salt-master daemon runs on the designated Salt master and performs functions such as authenticating minions, sending, and receiving requests from connected minions and sending and receiving requests and replies to the 'salt' CLI.
### 29.3.2 Moving Pieces

When a Salt master starts up, a number of processes are started, all of which are called 'salt-master' in a process-list but have various role categories.

Among those categories are:

- Publisher
- EventPublisher
- MWorker

#### 29.3.3 Publisher

The Publisher process is responsible for sending commands over the designated transport to connected minions. The Publisher is bound to the following:

- TCP: port 4505
- IPC: publish_pull.ipc

Each salt minion establishes a connection to the master Publisher.

#### 29.3.4 EventPublisher

The EventPublisher publishes master events out to any event listeners. It is bound to the following:

- IPC: master_event_pull.ipc
- IPC: master_event_pub.ipc

#### 29.3.5 MWorker

Worker processes manage the back-end operations for the Salt Master.

The number of workers is equivalent to the number of 'worker_threads' specified in the master configuration and is always at least one.

Workers are bound to the following:

- IPC: workers.ipc

#### 29.3.6 ReqServer

The Salt request server takes requests and distributes them to available MWorker processes for processing. It also receives replies back from minions.

The ReqServer is bound to the following:

- TCP: 4506
- IPC: workers.ipc

Each salt minion establishes a connection to the master ReqServer.
29.3.7 Job Flow

The Salt master works by always publishing commands to all connected minions and the minions decide if the command is meant for them by checking themselves against the command target.

The typical lifecycle of a salt job from the perspective of the master might be as follows:

1) A command is issued on the CLI. For example, ‘salt my_minion test.version’.

2) The ‘salt’ command uses LocalClient to generate a request to the salt master by connecting to the ReqServer on TCP:4506 and issuing the job.

3) The salt-master ReqServer sees the request and passes it to an available MWorker over workers.ipc.

4) A worker picks up the request and handles it. First, it checks to ensure that the requested user has permissions to issue the command. Then, it sends the publish command to all connected minions. For the curious, this happens in ClearFuncs.publish().

5) The worker announces on the master event bus that it is about to publish a job to connected minions. This happens by placing the event on the master event bus (master_event_pull.ipc) where the EventPublisher picks it up and distributes it to all connected event listeners on master_event_pub.ipc.

6) The message to the minions is encrypted and sent to the Publisher via IPC on publish_pull.ipc.

7) Connected minions have a TCP session established with the Publisher on TCP port 4505 where they await commands. When the Publisher receives the job over publish_pull, it sends the jobs across the wire to the minions for processing.

8) After the minions receive the request, they decrypt it and perform any requested work, if they determine that they are targeted to do so.

9) When the minion is ready to respond, it publishes the result of its job back to the master by sending the encrypted result back to the master on TCP 4506 where it is again picked up by the ReqServer and forwarded to an available MWorker for processing. (Again, this happens by passing this message across workers.ipc to an available worker.)

10) When the MWorker receives the job it decrypts it and fires an event onto the master event bus (master_event_pull.ipc). (Again for the curious, this happens in AESFuncs._return().

11) The EventPublisher sees this event and re-publishes it on the bus to all connected listeners of the master event bus (on master_event_pub.ipc). This is where the LocalClient has been waiting, listening to the event bus for minion replies. It gathers the job and stores the result.

12) When all targeted minions have replied or the timeout has been exceeded, the salt client displays the results of the job to the user on the CLI.

29.4 Salt Minion

29.4.1 Overview

The salt-minion is a single process that sits on machines to be managed by Salt. It can either operate as a stand-alone daemon which accepts commands locally via ‘salt-call’ or it can connect back to a master and receive commands remotely.

When starting up, salt minions connect back to a master defined in the minion config file. They connect to two ports on the master:

- TCP: 4505 This is the connection to the master Publisher. It is on this port that the minion receives jobs from the master.
• **TCP: 4506** This is the connection to the master ReqServer. It is on this port that the minion sends job results back to the master.

### 29.4.2 Event System

Similar to the master, a salt-minion has its own event system that operates over IPC by default. The minion event system operates on a push/pull system with IPC files at minion_event_<unique_id>_pub.ipc and minion_event_<unique_id>_pull.ipc.

The astute reader might ask why have an event bus at all with a single-process daemon. The answer is that the salt-minion may fork other processes as required to do the work without blocking the main salt-minion process and this necessitates a mechanism by which those processes can communicate with each other. Secondarily, this provides a bus by which any user with sufficient permissions can read or write to the bus as a common interface with the salt minion.

### 29.4.3 Minion Job Flow

When a salt minion starts up, it attempts to connect to the Publisher and the ReqServer on the salt master. It then attempts to authenticate and once the minion has successfully authenticated, it simply listens for jobs.

Jobs normally come either come from the 'salt-call' script run by a local user on the salt minion or they can come directly from a master.

The job flow on a minion, coming from the master via a 'salt' command is as follows:

1) A master publishes a job that is received by a minion as outlined by the master's job flow above. 2) The minion is polling its receive socket that's connected to the master Publisher (TCP 4505 on master). When it detects an incoming message, it picks it up from the socket and decrypts it. 3) A new minion process or thread is created and provided with the contents of the decrypted message. The _thread_return() method is provided with the contents of the received message. 4) The new minion thread is created. The _thread_return() function starts up and actually calls out to the requested function contained in the job. 5) The requested function runs and returns a result. [Still in thread.] 6) The result of the function that's run is encrypted and returned to the master's ReqServer (TCP 4506 on master). [Still in thread.] 7) Thread exits. Because the main thread was only blocked for the time that it took to initialize the worker thread, many other requests could have been received and processed during this time.

### 29.5 A Note on ClearFuncs vs. AESFuncs

A common source of confusion is determining when messages are passed in the clear and when they are passed using encryption. There are two rules governing this behaviour:

1) ClearFuncs is used for intra-master communication and during the initial authentication handshake between a minion and master during the key exchange. 2) AESFuncs is used everywhere else.
29.6 Changelog

With the addition of SEP 01 the keepachangelog format was introduced into our CHANGELOG.md file. The Salt project is using the towncrier tool to manage the CHANGELOG.md file. The reason this tool was added to manage the changelog was because we were previously managing the file manually and it would cause many merge conflicts. This tool allows us to add changelog entries into separate files and before a release we simply need to run towncrier --version=<version> for it to compile the changelog correctly.

29.6.1 How do I add a changelog entry

To add a changelog entry you will need to add a file in the changelog directory. The file name should follow the syntax <issue #>.<type>.

The types are in alignment with keepachangelog:

- removed: any features that have been removed
- deprecated: any features that will soon be removed
- changed: any changes in current existing features
- fixed: any bug fixes
- added: any new features added

For example if you are fixing a bug for issue number #1234 your filename would look like this: changelog/1234.fixed.

The contents of the file should contain a summary of what you are fixing. If there is a legitimate reason to not include an issue number with a given contribution you can add the PR number as the file name (<PR #>.<type>).

If your PR does not align with any of the types, then you do not need to add a changelog entry.

29.6.2 How to generate the changelog

This step is only used when we need to generate the changelog right before releasing. You should NOT run towncrier on your PR, unless you are preparing the final PR to update the changelog before a release.

You can run the towncrier tool directly or you can use nox to help run the command and ensure towncrier is installed in a virtual environment. The instructions below will detail both approaches.

If you want to see what output towncrier will produce before generating the change log you can run towncrier in draft mode:

towncrier --draft --version=3001

nox -e 'changelog(draft=True) -- 3000.1

Version will need to be set to whichever version we are about to release. Once you are confident the draft output looks correct you can now generate the changelog by running:

towncrier --version=3001

nox -e 'changelog(draft=False) -- 3000.1

After this is run towncrier will automatically remove all the files in the changelog directory.
29.7 Contributing

So you want to contribute to the Salt project? Excellent! You can help in a number of ways:

- Using Salt and opening well-written bug reports.
- Joining a working group.
- Answering questions on irc, the community Slack, the salt-users mailing list, Server Fault, or r/saltstack on Reddit.
- Fixing bugs.
- Enhancing the documentation.
- Providing workarounds, patches, or other code without tests.
- Telling other people about problems you solved using Salt.

If you’d like to update docs or fix an issue, you’re going to need the Salt repo. The best way to contribute is using Git.

29.7.1 Environment Setup

To hack on Salt or the docs you’re going to need to set up your development environment. If you already have a workflow that you’re comfortable with, you can use that, but otherwise this is an opinionated guide for setting up your dev environment. Follow these steps and you’ll end out with a functioning dev environment and be able to submit your first PR.

This guide assumes at least a passing familiarity with Git, a common version control tool used across many open source projects, and is necessary for contributing to Salt. For an introduction to Git, watch Salt Docs Clinic - Git For the True Beginner. Because of its widespread use, there are many resources for learning more about Git. One popular resource is the free online book Learn Git in a Month of Lunches.

29.7.2 pyenv, Virtual Environments, and You

We recommend pyenv, since it allows installing multiple different Python versions, which is important for testing Salt across all the versions of Python that we support.

On Linux

Install pyenv:

```bash
$ git clone https://github.com/pyenv/pyenv.git ~/.pyenv
$ export PATH="${HOME}/.pyenv/bin":$PATH
$ git clone https://github.com/pyenv/pyenv-virtualenv.git $(pyenv root)/plugins/pyenv-virtualenv
```
On Mac

Install pyenv using brew:

```
brew update
brew install pyenv
brew install pyenv-virtualenv
```

Now add pyenv to your `.bashrc`:

```
echo 'export PATH=\"$HOME/.pyenv/bin:$PATH\"' >> ~/.bashrc
pyenv init 2>&1 ~/.bashrc
pyenv virtualenv-init 2>&1 ~/.bashrc
```

For other shells, see the pyenv instructions.

Go ahead and restart your shell. Now you should be able to install a new version of Python:

```
pyenv install 3.7.0
```

If that fails, don’t panic! You’re probably just missing some build dependencies. Check out pyenv common build problems.

Now that you’ve got your version of Python installed, you can create a new virtual environment with this command:

```
pyenv virtualenv 3.7.0 salt
```

Then activate it:

```
pyenv activate salt
```

Sweet! Now you’re ready to clone Salt so you can start hacking away! If you get stuck at any point, check out the resources at the beginning of this guide. IRC and Slack are particularly helpful places to go.

Get The Source!

Salt uses the fork and clone workflow for Git contributions. See Using the Fork-and-Branch Git Workflow for how to implement it. But if you just want to hurry and get started you can go ahead and follow these steps:

Clones are so shallow. Well, this one is anyway:

```
git clone --depth=1 --origin salt https://github.com/saltstack/salt.git
```

This creates a shallow clone of Salt, which should be fast. Most of the time that’s all you’ll need, and you can start building out other commits as you go. If you really want all 108,300+ commits you can just run `git fetch --unshallow`. Then go make a sandwich because it’s gonna be a while.

You’re also going to want to head over to GitHub and create your own fork of Salt. Once you’ve got that set up you can add it as a remote:

```
git remote add yourname <YOUR SALT REMOTE>
```

If you use your name to refer to your fork, and salt to refer to the official Salt repo you’ll never get upstream or origin confused.

Note: Each time you start work on a new issue you should fetch the most recent changes from `salt/upstream`. 29.7. Contributing 4205
**pre-commit and nox Setup**

Here at Salt we use pre-commit and nox to make it easier for contributors to get quick feedback, for quality control, and to increase the chance that your merge request will get reviewed and merged. Nox enables us to run multiple different test configurations, as well as other common tasks. You can think of it as Make with superpowers. Pre-commit does what it sounds like: it configures some Git pre-commit hooks to run black for formatting, isort for keeping our imports sorted, and pylint to catch issues like unused imports, among others. You can easily install them in your virtualenv with:

```
python -m pip install pre-commit nox
pre-commit install
```

**Warning:** Currently there is an issue with the pip-tools-compile pre-commit hook on Windows. The details around this issue are included here: [https://github.com/saltstack/salt/issues/56642](https://github.com/saltstack/salt/issues/56642). Please ensure you export SKIP=pip-tools-compile to skip pip-tools-compile.

Now before each commit, it will ensure that your code at least *looks* right before you open a pull request. And with that step, it’s time to start hacking on Salt!

### 29.7.3 Salt Issues

**Create Your Own**

Perhaps you’ve come to this guide because you found a problem in Salt, and you’ve diagnosed the cause. Maybe you need some help figuring out the problem. In any case, creating quality bug reports is a great way to contribute to Salt even if you lack the skills, time, or inclination to fix it yourself. If that’s the case, head on over to Salt’s issue tracker on GitHub.

Creating a **good** report can take a little bit of time - but every minute you invest in making it easier for others to reproduce and understand your issue is time well spent. The faster someone can understand your issue, the faster it will be able to get fixed correctly.

The thing that every issue needs goes by many names, but one at least as good as any other is MCVE - Minimum Complete Verifiable Example.

In a nutshell:

- **Minimum:** All of the extra information has been removed. Will 2 or 3 lines of master/minion config still exhibit the behavior?

- **Complete:** Minimum also means complete. If your example is missing information, then it’s not complete. Salt, Python, and OS versions are all bits of information that make your example complete. Have you provided the commands that you ran?

- **Verifiable:** Can someone take your report and reproduce it?

Slow is smooth, and smooth is fast - it may feel like you’re taking a long time to create your issue if you’re creating a proper MCVE, but a MCVE eliminates back and forth required to reproduce/verify the issue so someone can actually create a fix.
Pick An Issue

If you don’t already have an issue in mind, you can search for help wanted issues. If you also search for good first issue then you should be able to find some issues that are good for getting started contributing to Salt. Documentation issues are also good starter issues. When you find an issue that catches your eye (or one of your own), it’s a good idea to comment on the issue and mention that you’re working on it. Good communication is key to collaboration - so if you don’t have time to complete work on the issue, just leaving some information about when you expect to pick things up again is a great idea!

29.7.4 Hacking Away

Salt, Tests, Documentation, and You

Before approving code contributions, Salt requires:

- documentation
- meaningful passing tests
- correct code

Documentation fixes just require correct documentation.

What If I Don’t Write Tests or Docs?

If you aren’t into writing documentation or tests, we still welcome your contributions! But your PR will be labeled Needs Testcase and Help Wanted until someone can get to write the tests/documentation. Of course, if you have a desire but just lack the skill we are more than happy to collaborate and help out! There’s the documentation working group and the testing working group. We also regularly stream our test clinic live on Twitch every Tuesday afternoon and Thursday morning, Central Time. If you’d like specific help with tests, bring them to the clinic. If no community members need help, you can also just watch tests written in real time.

Documentation

Salt uses both docstrings, as well as normal reStructuredText files in the salt/doc folder for documentation. Since we use nox, you can build your docs and view them in your browser with this one-liner:

```bash
python -m nox -e 'docs-html(compress=False, clean=False)'; cd doc/_build/html; python -m webbrowser http://localhost:8000/contents.html; python -m http.server
```

The first time this will take a while because there are a lot of modules. Maybe you should go grab some dessert if you already finished that sandwich. But once Sphinx is done building the docs, python should launch your default browser with the URL http://localhost:8000/contents.html. Now you can navigate to your docs and ensure your changes exist. If you make changes, you can simply run this:

```bash
cd ~/.; python -m nox -e 'docs-html(compress=False, clean=False)'; cd doc/_build/html; python -m http.server
```

And then refresh your browser to get your updated docs. This one should be quite a bit faster since Sphinx won’t need to rebuild everything.

If your change is a docs-only change, you can go ahead and commit/push your code and open a PR. You can indicate that it’s a docs-only change by adding [Documentation] to the title of your PR. Otherwise you’ll want to write some tests and code.
Running Development Salt

Note: If you run into any issues in this section, check the Troubleshooting section.

If you’re going to hack on the Salt codebase you’re going to want to be able to run Salt locally. The first thing you need to do is install Salt as an editable pip install:

```
python -m pip install -e .
```

This will let you make changes to Salt without having to re-install it.

After all of the dependencies and Salt are installed, it’s time to set up the config for development. Typically Salt runs as root, but you can specify which user to run as. To configure that, just copy the master and minion configs. We have .gitignore setup to ignore the local/ directory, so we can put all of our personal files there.

```
mkdir -p local/etc/salt/
```

Create a master config file as local/etc/salt/master:

```
cat <<EOF >local/etc/salt/master
user: $(whoami)
root_dir: $PWD/local/
publish_port: 55505
ret_port: 55506
EOF
```

And a minion config as local/etc/salt/minion:

```
cat <<EOF >local/etc/salt/minion
user: $(whoami)
root_dir: $PWD/local/
master: localhost
id: saltdev
master_port: 55506
EOF
```

Now you can start your Salt master and minion, specifying the config dir.

```
salt-master --config-dir=local/etc/salt/ --log-level=debug --daemon
salt-minion --config-dir=local/etc/salt/ --log-level=debug --daemon
```

Now you should be able to accept the minion key:

```
salt-key -c local/etc/salt -Ay
```

And check that your master/minion are communicating:

```
salt -c local/etc/salt \* test.version
```

Rather than running test.version from your master, you can run it from the minion instead:

```
salt-call -c local/etc/salt test.version
```

Note that you’re running salt-call instead of salt, and you’re not specifying the minion (\*), but if you’re running the dev version then you still will need to pass in the config dir. Now that you’ve got Salt running, you can hack away on the Salt codebase!

If you need to restart Salt for some reason, if you’ve made changes and they don’t appear to be reflected, this is one option:
If you’d rather not use `kill`, you can have a couple of terminals open with your salt virtualenv activated and omit the `--daemon` argument. Salt will run in the foreground, so you can just use `ctrl+c` to quit.

**Test First? Test Last? Test Meaningfully!**

You can write tests first or tests last, as long as your tests are meaningful and complete! Typically the best tests for Salt are going to be unit tests. Testing is a whole topic on its own, but you may also want to write functional or integration tests. You’ll find those in the `salt/tests` directory.

When you’re thinking about tests to write, the most important thing to keep in mind is, “What, exactly, am I testing?” When a test fails, you should know:

- What, specifically, failed?
- Why did it fail?
- As much as possible, what do I need to do to fix this failure?

If you can’t answer those questions then you might need to refactor your tests.

When you’re running tests locally, you should make sure that if you remove your code changes your tests are failing. If your tests aren’t failing when you haven’t yet made changes, then it’s possible that you’re testing the wrong thing.

But whether you adhere to TDD/BDD, or you write your code first and your tests last, ensure that your tests are meaningful.

**Running Tests**

As previously mentioned, we use `nox`, and that’s how we run our tests. You should have it installed by this point but if not you can install it with this:

```
python -m pip install nox
```

Now you can run your tests:

```
python -m nox -e "pytest-3.7(coverage=False)" -- tests/unit/cli/test_batch.py
```

It’s a good idea to install `espeak` or use `say` on Mac if you’re running some long-running tests. You can do something like this:

```
python -m nox -e "pytest-3.7(coverage=False)" -- tests/unit/cli/test_batch.py; espeak "Tests done, woohoo!"
```

That way you don’t have to keep monitoring the actual test run.
Changelog and Commit!

When you write your commit message you should use imperative style. Do this:

Add frobnosticate capability

Don’t do this:

Added frobnosticate capability

But that advice is backwards for the changelog. We follow the keepachangelog approach for our changelog, and use towncrier to generate it for each release. As a contributor, all that means is that you need to add a file to the salt/changelog directory, using the `<issue #>.<type>` format. For instance, if you fixed issue 123, you would do:

```
echo "Made sys.doc inform when no minions return" > changelog/123.fixed
```

And that’s all that would go into your file. When it comes to your commit message, it’s usually a good idea to add other information, such as

- What does a reviewer need to know about the change that you made?
- If someone isn’t an expert in this area, what will they need to know?

This will also help you out, because when you go to create the PR it will automatically insert the body of your commit messages.

29.7.5 PR Time!

Once you’ve done all your dev work and tested locally, you should check out our PR guidelines. After you read that page, it’s time to open a new PR. Fill out the PR template - you should have updated or created any necessary docs, and written tests if you’re providing a code change. When you submit your PR, we have a suite of tests that will run across different platforms to help ensure that no known bugs were introduced.

Now What?

You’ve made your changes, added documentation, opened your PR, and have passing tests... now what? When can you expect your code to be merged?

When you open your PR, a reviewer will get automatically assigned. If your PR is submitted during the week you should be able to expect some kind of communication within that business day. If your tests are passing and we’re not in a code freeze, ideally your code will be merged that day. If you haven’t heard from your assigned reviewer, ping them on GitHub, irc, or Community Slack.

It’s likely that your reviewer will leave some comments that need addressing - it may be a style change, or you forgot a changelog entry, or need to update the docs. Maybe it’s something more fundamental - perhaps you encountered the rare case where your PR has a much larger scope than initially assumed.

Whatever the case, simply make the requested changes (or discuss why the requests are incorrect), and push up your new commits. If your PR is open for a significant period of time it may be worth rebasing your changes on the most recent changes to Salt. If you need help, the previously linked Git resources will be valuable.

But if, for whatever reason, you’re not interested in driving your PR to completion then just note that in your PR. Something like, “I’m not interested in writing docs/tests, I just wanted to provide this fix - someone else will need to complete this PR.” If you do that then we’ll add a “Help Wanted” label and someone will be able to pick up the PR, make the required changes, and it can eventually get merged in.

In any case, now that you have a PR open, congrats! You’re a Salt developer! You rock!
29.7.6 Troubleshooting

\texttt{zmq.core.error.ZMQError}

Once the minion starts, you may see an error like the following:

\begin{verbatim}
zmq.core.error.ZMQError: ipc path "/path/to/your/virtualenv/var/run/salt/minion/minion_event_7824dc
 is longer than 107 characters (sizeof(sockaddr_un.sun_path)).
\end{verbatim}

This means that the path to the socket the minion is using is too long. This is a system limitation, so the only workaround is to reduce the length of this path. This can be done in a couple different ways:

1. Create your virtualenv in a path that is short enough.
2. Edit the \texttt{conf_minion:sock_dir} minion config variable and reduce its length. Remember that this path is relative to the value you set in \texttt{conf_minion:root_dir}.

**NOTE:** The socket path is limited to 107 characters on Solaris and Linux, and 103 characters on BSD-based systems.

\textbf{No permissions to access ...}

If you forget to pass your config path to any of the \texttt{salt*} commands, you might see

\begin{verbatim}
No permissions to access "/var/log/salt/master", are you running as the correct user?
\end{verbatim}

Just pass \texttt{-c local/etc/salt} (or whatever you named it)

\textbf{File descriptor limit}

You might need to raise your file descriptor limit. You can check it with:

\begin{verbatim}
ulimit -n
\end{verbatim}

If the value is less than 3072, you should increase it with:

\begin{verbatim}
ulimit -n 3072
# For c-shell:
limit descriptors 3072
\end{verbatim}

\textbf{Pygit2 or other dependency install fails}

You may see some failure messages when installing requirements. You can directly access your nox environment and possibly install pygit (or other dependency) that way. When you run nox, you’ll see a message like this:

\begin{verbatim}
nox > Re-using existing virtual environment at .nox/pytest-parametrized-3-crypto-none- transport-zeromq-coverage-false.
\end{verbatim}

For this, you would be able to install with:

\begin{verbatim}
.NOX/pytest-parametrized-3-crypto-none-transport-zeromq-coverage-false/bin/python -m pip install pygit2
\end{verbatim}
29.8 Deprecating Code

Salt should remain backwards compatible, though sometimes, this backwards compatibility needs to be broken because a specific feature and/or solution is no longer necessary or required. At first one might think, let me change this code, it seems that it’s not used anywhere else so it should be safe to remove. Then, once there’s a new release, users complain about functionality which was removed and they where using it, etc. This should, at all costs, be avoided, and, in these cases, that specific code should be deprecated.

In order to give users enough time to migrate from the old code behavior to the new behavior, the deprecation time frame should be carefully determined based on the significance and complexity of the changes required by the user.

Salt feature releases are based on the Periodic Table. Any new features going into the master branch will be named after the next element in the Periodic Table. For example, Magnesium was the feature release name associated with the v3002 tag. At that point in time, any new features going into the master branch, after v3002 was tagged, were part of the Aluminium feature release.

A deprecation warning should be in place for at least two major releases before the deprecated code and its accompanying deprecation warning are removed. More time should be given for more complex changes. For example, if the current release under development is 3001, the deprecated code and associated warnings should remain in place and warn for at least Aluminium.

To help in this deprecation task, salt provides salt.utils.versions.warn_until. The idea behind this helper function is to show the deprecation warning to the user until salt reaches the provided version. Once that provided version is equaled salt.utils.versions.warn_until will raise a RuntimeError making salt stop its execution. This stoppage is unpleasant and will remind the developer that the deprecation limit has been reached and that the code can then be safely removed.

Consider the following example:

```python
def some_function(bar=False, foo=None):
    if foo is not None:
        salt.utils.versions.warn_until(
            "Aluminium",
            "The 'foo' argument has been deprecated and its "
            "functionality removed, as such, its usage is no longer "
            "required."
        )
```

Development begins on Aluminium, or v3003, after the v3002 tag is applied to the master branch. Once this occurs, all uses of the warn_until function targeting Aluminium, along with the code they are warning about should be removed from the code.

29.9 Python 2 Deprecation FAQ

FAQ

- Python 2 Deprecation FAQ
  - Why are we deprecating Python 2?
  - Was this announced/decided before making the change?
  - Can I contribute Python 2 code?
What if my OS does not include Python 3 packages? Or, how do I upgrade from Salt on Python 2 to Salt on Python 3?

- On Modern Platforms
- On Other Platforms
  - Build Your Own
    - `pop-build` distributions
- Will you support a Python 3 master with an older Python 2 minion?
- Will you support Python 2 master with a new Python 3 minion?
- How does this impact Salt-SSH support?
- What is your plan for removing Python 2 code?
- Will Salt continue to package for Python 2?

### 29.9.1 Why are we deprecating Python 2?

Python 2.7.18 was the final release of Python2, released in April 2020. At this point, Python 2 will no longer receive any unpaid support. The Python core developers are focusing their efforts on improving and enhancing Python 3. Additionally, many libraries that Salt depends on have also dropped Python 2 support.

To take advantage of continued support and improvements, Salt is joining the ranks of projects that are dropping legacy Python support in favor of Python 3.

### 29.9.2 Was this announced/decided before making the change?

SEP 5 was approved in April, 2019.

### 29.9.3 Can I contribute Python 2 code?

For several years, Salt has been a Python 2/3 codebase, requiring Python 3 support for all contributions. The only changes contributors can expect to this process is that we will now accept Python 3-only code changes.

While there is a significant subset of Python that is compatible with both Python 3 and legacy Python, changes requiring `six` or otherwise removing Python 3-only code will not be accepted.

### 29.9.4 What if my OS does not include Python 3 packages? Or, how do I upgrade from Salt on Python 2 to Salt on Python 3?

There are several options to upgrade to Python 3.
On Modern Platforms

At this point, most modern Linux distributions have Python 3 packages. Ubuntu 20.04 LTS has moved to Python 3.8 as its default system Python.

On Other Platforms

Build Your Own

If your current distribution does not have Python 3 it’s pretty simple to use Salt to build and distribute Python 3 on your own. Installing Python 3 and pip installing Salt gives you the most control over your distribution.

**pop-build distributions**

Another approach is to use the pop-build distribution of Salt. With the Sodium release we will begin releasing packages for Salt using pop-build, in tandem with our normal build process. The pop-build distribution will contain Salt, Python, and any necessary dependencies, which will make it trivial to have a completely supported version of Salt.

29.9.5 Will you support a Python 3 master with an older Python 2 minion?

Yes! Our policy of keeping newer masters backwards compatible with at least the most recent minion version is not changing. You should be able to run modern Salt Masters on Python 3 with slightly older minions running on legacy Python. Of course, if you want your minions to be able to take advantage of the newest features in Salt, upgrading to Python 3 will be necessary.

29.9.6 Will you support Python 2 master with a new Python 3 minion?

In keeping with our existing policy, we make no guarantees about older masters with newer minions. It may work, but breakages are common and should be expected.

29.9.7 How does this impact Salt-SSH support?

Salt-SSH will need Python 3 on the target minions. We will be upgrading Salt-SSH to provide instructions or recommendations on adding Python3 if it is not detected.

29.9.8 What is your plan for removing Python 2 code?

Legacy Python code will be gradually removed from the Salt codebase.

While we could remove most of it at once, that introduces a high level of risk. Instead, beginning with the Sodium (v3001) release, Salt will simply drop support for Python 2. PRs will no longer be required to support Python 2 before merging.

Over time, as modules are changed, six and other legacy Python syntax will be removed. It may be at some point in the future it becomes necessary to remove the last vestiges of legacy Python from Salt, but currently the plan is to take a more measured approach.
29.9.9 Will Salt continue to package for Python 2?

No. Beginning with Sodium (v3001), Salt will no longer release packages for, or support Python 2.

29.10 Installing Salt for development

Clone the repository using:

```
git clone https://github.com/saltstack/salt
```

**Note:** tags

Just cloning the repository is enough to work with Salt and make contributions. However, fetching additional tags from git is required to have Salt report the correct version for itself. To do this, first add the git repository as an upstream source:

```
git remote add upstream https://github.com/saltstack/salt
```

Fetching tags is done with the git 'fetch' utility:

```
git fetch --tags upstream
```

Create a new `virtualenv`:

```
virtualenv /path/to/your/virtualenv
```

Avoid making your `virtualenv path too long`.

On Arch Linux, where Python 3 is the default installation of Python, use the `virtualenv2` command instead of `virtualenv`.

On Gentoo you must use `--system-site-packages` to enable pkg and portage_config functionality

**Note:** Using system Python modules in the virtualenv

To use already-installed python modules in virtualenv (instead of having pip download and compile new ones), run `virtualenv --system-site-packages` Using this method eliminates the requirement to install the salt dependencies again, although it does assume that the listed modules are all installed in the system PYTHONPATH at the time of virtualenv creation.

**Note:** Python development package

Be sure to install python-devel package in order to install required Python modules. In Debian/Ubuntu run `sudo apt-get install -y python-dev`. In RedHat based system install `python-devel`

Activate the virtualenv:

```
source /path/to/your/virtualenv/bin/activate
```

Install Salt (and dependencies) into the virtualenv:
pip install pyzmq PyYAML pycrypto msgpack jinja2 psutil futures tornado
pip install -e ./salt  # the path to the salt git clone from above

Note: Installing psutil
Python header files are required to build this module, otherwise the pip install will fail. If your distribution separates binaries and headers into separate packages, make sure that you have the headers installed. In most Linux distributions which split the headers into their own package, this can be done by installing the python-dev or python-devel package. For other platforms, the package will likely be similarly named.

Note: Installing dependencies on macOS.
You can install needed dependencies on macOS using homebrew or macports. See macOS Installation

Warning: Installing on RedHat-based Distros
If installing from pip (or from source using setup.py install), be advised that the yum-utils package is needed for Salt to manage packages on RedHat-based systems.

29.10.1 Running a self-contained development version

During development it is easiest to be able to run the Salt master and minion that are installed in the virtualenv you created above, and also to have all the configuration, log, and cache files contained in the virtualenv as well.

The /path/to/your/virtualenv referenced multiple times below is also available in the variable $VIRTUAL_ENV once the virtual environment is activated.

Copy the master and minion config files into your virtualenv:

mkdir -p /path/to/your/virtualenv/etc/salt/pki/{master,minion}
cp ./salt/conf/master ./salt/conf/minion /path/to/your/virtualenv/etc/salt/

Edit the master config file:

1. Uncomment and change the user: root value to your own user.
2. Uncomment and change the root_dir: / value to point to /path/to/your/virtualenv.
3. Uncomment and change the pki_dir: /etc/salt/pki/master value to point to /path/to/your/virtualenv/etc/salt/pki/master
4. If you are running version 0.11.1 or older, uncomment, and change the pidfile: /var/run/salt-master.pid value to point to /path/to/your/virtualenv/salt-master.pid.
5. If you are also running a non-development version of Salt you will have to change the publish_port and ret_port values as well.

Edit the minion config file:

1. Repeat the edits you made in the master config for the user and root_dir values as well as any port changes.
2. Uncomment and change the pki_dir: /etc/salt/pki/minion value to point to /path/to/your/virtualenv/etc/salt/pki/minion
If you are running version 0.11.1 or older, uncomment, and change the `pidfile` value to point to `/path/to/your/virtualenv/salt-minion.pid`.

Uncomment and change the `master:` value to point at `localhost`.

Uncomment and change the `id:` value to something descriptive like "saltdev". This isn't strictly necessary but it will serve as a reminder of which Salt installation you are working with.

If you have changed the `ret_port` value in the master config because you are also running a non-development version of Salt, then you will have to change the `master_port` value in the minion config to match.

---

**Note:** Using `salt-call` with a Standalone Minion

If you plan to run `salt-call` with this self-contained development environment in a masterless setup, you should invoke `salt-call` with `-c /path/to/your/virtualenv/etc/salt` so that salt can find the minion config file. Without the `-c` option, Salt finds its config files in `/etc/salt`.

Start the master and minion, accept the minion's key, and verify your local Salt installation is working:

```bash
cd /path/to/your/virtualenv
salt-master -c ./etc/salt -d
salt-minion -c ./etc/salt -d
salt-key -c ./etc/salt -L
salt-key -c ./etc/salt -A
salt -c ./etc/salt '*' test.version
```

Running the master and minion in debug mode can be helpful when developing. To do this, add `-l debug` to the calls to `salt-master` and `salt-minion`. If you would like to log to the console instead of to the log file, remove the `-d`.

**Note:** Too long socket path?

Once the minion starts, you may see an error like the following:

```
zmq.core.error.ZMQError: ipc path "/path/to/your/virtualenv/var/run/salt/minion/minion_event_7824dc567a2f6755939af78b96249f_pub.ipc" is longer than 107 characters (sizeof(sockaddr_un.sun_path)).
```

This means that the path to the socket the minion is using is too long. This is a system limitation, so the only workaround is to reduce the length of this path. This can be done in a couple different ways:

1. Create your virtualenv in a path that is short enough.
2. Edit the `sock_dir` minion config variable and reduce its length. Remember that this path is relative to the value you set in `root_dir`.

**NOTE:** The socket path is limited to 107 characters on Solaris and Linux, and 103 characters on BSD-based systems.

**Note:** File descriptor limits

Ensure that the system open file limit is raised to at least 2047:

```
# check your current limit
ulimit -n

# raise the limit. persists only until reboot
```

(continues on next page)
Changing Default Paths

Instead of updating your configuration files to point to the new root directory and having to pass the new configuration directory path to all of Salt’s CLI tools, you can explicitly tweak the default system paths that Salt expects:

```bash
GENERATE_SALT_SYSPATHS=1 pip install --global-option='--salt-root-dir=/path/to/your/
virtualenv/'
   -e ./salt  # the path to the salt git clone from above
```

You can now call all of Salt’s CLI tools without explicitly passing the configuration directory.

Additional Options

If you want to distribute your virtualenv, you probably don’t want to include Salt’s clone .git/ directory, and, without it, Salt won’t report the accurate version. You can tell setup.py to generate the hardcoded version information which is distributable:

```bash
GENERATE_SALT_SYSPATHS=1 WRITE_SALT_VERSION=1 pip install --global-option='--salt-
root-dir=/path/to/your/virtualenv/'
   -e ./salt  # the path to the salt git clone from above
```

Instead of passing those two environmental variables, you can just pass a single one which will trigger the other two:

```bash
MIMIC_SALT_INSTALL=1 pip install --global-option='--salt-root-dir=/path/to/your/
virtualenv/'
   -e ./salt  # the path to the salt git clone from above
```

This last one will grant you an editable salt installation with hardcoded system paths and version information.

29.10.2 Installing Salt from the Python Package Index

If you are installing using easy_install, you will need to define a USE_SETUPTOOLS environment variable, otherwise dependencies will not be installed:

```bash
USE_SETUPTOOLS=1 easy_install salt
```
29.10.3 Editing and previewing the documentation

You need `sphinx-build` command to build the docs. In Debian/Ubuntu this is provided in the `python-sphinx` package. Sphinx can also be installed to a virtualenv using pip:

```
pip install Sphinx==1.3.1
```

Change to salt documentation directory, then:

```
cd doc; make html
```

- This will build the HTML docs. Run `make` without any arguments to see the available make targets, which include `html`, `man`, and `text`.
- The docs then are built within the `docs/_build/` folder. To update the docs after making changes, run `make` again.
- The docs use reStructuredText for markup. See a live demo at http://rst.ninjs.org/.
- The help information on each module or state is culled from the python code that runs for that piece. Find them in `salt/modules/` or `salt/states/`.
- To build the docs on Arch Linux, the `python2-sphinx` package is required. Additionally, it is necessary to tell `make` where to find the proper `sphinx-build` binary, like so:

```
make SPHINXBUILD=sphinx-build2 html
```

- To build the docs on RHEL/CentOS 6, the `python-sphinx10` package must be installed from EPEL, and the following `make` command must be used:

```
make SPHINXBUILD=sphinx-build html
```

Once you've updated the documentation, you can run the following command to launch a simple Python HTTP server to see your changes:

```
cd _build/html; python -m SimpleHTTPServer
```

29.10.4 Running unit and integration tests

Run the test suite with following command:

```
./setup.py test
```

See [here](#) for more information regarding the test suite.

29.10.5 Issue and Pull Request Labeling System

SaltStack uses several labeling schemes to help facilitate code contributions and bug resolution. See the [Labels and Milestones](#) documentation for more information.
29.11 GitHub Labels and Milestones

SaltStack uses several label categories, as well as milestones, to triage incoming issues and pull requests in the GitHub issue tracker. Labels are used to sort issues by type, priority, severity, status, functional area, functional group, and targeted release and pull requests by status, functional area, functional group, type of change, and test status. Milestones are used to indicate whether an issue is fully triaged or is scheduled to be fixed by SaltStack in an upcoming sprint.

29.11.1 Milestones

All issues are assigned to a milestone, whereas pull requests are almost never assigned to a milestone as the mean lifetime of pull requests is short enough that there is no need to track them temporally.

SaltStack uses milestones to indicate which issues are blocked on submitter or upstream actions, are approved, or are scheduled to be fixed or implemented in an upcoming sprint. If an issue is not attached to a sprint milestone, you are welcome to work on it at your own desire and convenience. If it is attached to a sprint milestone and you have already begun working on it or have a solution in mind or have other ideas related to the issue, you are encouraged to coordinate with the assignee via the GitHub issue tracker to create the best possible solution or implementation.

- **Approved** - The issue has been validated and has all necessary information.
- **Blocked** - The issue is waiting on actions by parties outside of SaltStack, such as receiving more information from the submitter or resolution of an upstream issue. This milestone is usually applied in conjunction with the labels **Info Needed**, **Question**, **Expected Behavior**, **Won't Fix For Now**, or **Upstream Bug**.

29.11.2 Labels

Labels are used to sort and describe issues and pull requests. Some labels are usually reserved for one or the other, though most labels may be applied to both.

New issues will receive at least one label and a milestone, and new pull requests will receive at least one label. Except for the **functional area** and **functional group** label categories, issues will generally receive only up to one label per category.

**Type**

Issues are categorized into one of several types. Type labels are almost never used for pull requests. GitHub treats pull requests like issues in many ways, so a pull request could be considered an issue with an implicit **Pull Request** type label applied.

- **Feature** - The issue is a request for new functionality including changes, enhancements, refactors, etc.
- **Bug** - The issue documents broken, incorrect, or confusing behavior. This label is always accompanied by a **severity label**.
- **Duplicate** - The issue is a duplicate of another feature request or bug report.
- **Upstream Bug** - The issue is a result of an upstream issue.
- **Question** - The issue is more of a question than a request for new features or a report of broken features, but can sometimes lead to further discussion or changes of confusing or incongruous behavior or documentation.
- **Expected Behavior** - The issue is a bug report of intended functionality.
Priority

An issue's priority is relative to its functional area. If a bug report, for example, about gitfs indicates that all users of gitfs will encounter this bug, then a P1 label will be applied, even though users who are not using gitfs will not encounter the bug. If a feature is requested by many users, it may be given a high priority.

- P1 - The issue will be seen by all users.
- P2 - The issue will be seen by most users.
- P3 - The issue will be seen by about half of users.
- P4 - The issue will not be seen by most users. Usually the issue is a very specific use case or corner case.

Severity

Severity labels are almost always only applied to issues labeled Bug.

- Blocker - The issue is blocking an impending release.
- Critical - The issue causes data loss, crashes or hangs salt processes, makes the system unresponsive, etc.
- High Severity - The issue reports incorrect functionality, bad functionality, a confusing user experience, etc.
- Medium Severity - The issue reports cosmetic items, formatting, spelling, colors, etc.

Functional Area

Many major components of Salt have corresponding GitHub labels. These labels are applied to all issues and pull requests as is reasonably appropriate. They are useful in organizing issues and pull requests according to the source code relevant to issues or the source code changed by pull requests.

- Execution Module
- File Servers
- Grains
- Multi-Master
- Packaging Related to packaging of Salt, not Salt's support for package management.
- Pillar
- RAET
- Returners
- Runners
- SPM
- Salt-API
- Salt-Cloud
- Salt-SSH
- Salt-Syndic
- State Module
- Tests
Functional Group

These labels sort issues and pull requests according to the internal SaltStack engineering teams.

- **Core** - The issue or pull request relates to code that is central or existential to Salt itself.
- **Platform** - The issue or pull request relates to support and integration with various platforms like traditional operating systems as well as containers, platform-based utilities like filesystems, command schedulers, etc., and system-based applications like web servers, databases, etc.
- **RIoT** - The issue or pull request relates to support and integration with various abstract systems like cloud providers, hypervisors, API-based services, etc.
- **Console** - The issue or pull request relates to the SaltStack enterprise console.
- **Documentation** - The issue or pull request relates to documentation.

Status

Status labels are used to define and track the state of issues and pull requests. Not all potential statuses correspond to a label, but some statuses are common enough that labels have been created for them. If an issue has not been moved beyond the **Blocked** milestone, it is very likely that it will only have a status label.

- **Cannot Reproduce** - The issue is a bug and has been reviewed by a SaltStack engineer, but it cannot be replicated with the provided information and context. Those involved with the bug will need to work through additional ideas until the bug can be isolated and verified.
- **Confirmed** - The issue is a bug and has been confirmed by a SaltStack engineer, who often documents a minimal working example that reproduces the bug.
- **Fixed Pending Verification** - The issue is a bug and has been fixed by one or more pull requests, which should link to the issue. Closure of the issue is contingent upon confirmation of resolution from the submitter. If the submitter reports a negative confirmation, this label is removed. If no response is given after a few weeks, then the issue will be assumed fixed and closed.
- **Info Needed** - The issue needs more information before it can be verified and resolved. For a feature request this may include a description of the use cases. Almost all bug reports need to include at least the versions of salt and its dependencies, the system type and version, commands used, debug logs, error messages, and relevant configs.
- **Pending Changes** - The pull request needs additional changes before it can be merged.
- **Pending Discussion** - The issue or pull request needs more discussion before it can be closed or merged. The status of the issue or pull request is not clear or apparent enough for definite action to be taken, or additional input from SaltStack, the submitter, or another party has been requested.

If the issue is not a pull request, once the discussion has arrived at a cogent conclusion, this label will be removed and the issue will be accepted. If it is a pull request, the results of the discussion may require additional changes and thus, a **Pending Changes** label.

- **won't-fix** - The issue is legitimate, but it is not something the Salt core team is currently able or willing to fix or implement. Issues having this label may be revisited in the future, or solved by a Salt community member.
Test Status

These labels relate to the status of the automated tests that run on pull requests.

- **has-failing-test** - The PR currently has one or more failing tests that prevent the PR from being merged.
- **Needs Testcase** - The PR has code changes, but lack any automated tests. These PRs need automated tests written before they may be merged.

Other

These labels indicate miscellaneous issue types or statuses that are common or important enough to be tracked and sorted with labels.

- **Awesome** - The pull request implements an especially well crafted solution, or a very difficult but necessary change.
- **Help Wanted** - The issue appears to have a simple solution. Issues having this label should be a good starting place for new contributors to Salt.
- **Regression** - The issue is a bug that breaks functionality known to work in previous releases.
- **Story** - The issue is used by a SaltStack engineer to track progress on multiple related issues in a single place.
- **Stretch** - The issue is an optional goal for the current sprint but may not be delivered.
- **ZD** - The issue is related to a Zendesk customer support ticket.
- **<Release>** - The issue is scheduled to be implemented by `<Release>`. See here for a discussion of Salt's release codenames.

29.12 Logging Internals

TODO

29.13 Package Providers

This page contains guidelines for writing package providers.

29.13.1 Package Functions

One of the most important features of Salt is package management. There is no shortage of package managers, so in the interest of providing a consistent experience in `pkg` states, there are certain functions that should be present in a package provider. Note that these are subject to change as new features are added or existing features are enhanced.
**list_pkgs**

This function should declare an empty dict, and then add packages to it by calling `pkg_resource.add_pkg`, like so:

```python
__salt__("pkg_resource.add_pkg")(ret, name, version)
```

The last thing that should be done before returning is to execute `pkg_resource.sort_pkglist`. This function does not presently do anything to the return dict, but will be used in future versions of Salt.

```python
__salt__("pkg_resource.sort_pkglist")(ret)
```

`list_pkgs` returns a dictionary of installed packages, with the keys being the package names and the values being the version installed. Example return data:

```json
{"foo": "1.2.3-4", "bar": "5.6.7-8"}
```

**latest_version**

Accepts an arbitrary number of arguments. Each argument is a package name. The return value for a package will be an empty string if the package is not found or if the package is up-to-date. The only case in which a non-empty string is returned is if the package is available for new installation (i.e. not already installed) or if there is an upgrade available.

If only one argument was passed, this function return a string, otherwise a dict of name/version pairs is returned. This function must also accept **kwargs, in order to receive the fromrepo and repo keyword arguments from pkg states. Where supported, these arguments should be used to find the install/upgrade candidate in the specified repository. The fromrepo kwarg takes precedence over repo, so if both of those kwargs are present, the repository specified in fromrepo should be used. However, if repo is used instead of fromrepo, it should still work, to preserve backwards compatibility with older versions of Salt.

**version**

Like latest_version, accepts an arbitrary number of arguments and returns a string if a single package name was passed, or a dict of name/value pairs if more than one was passed. The only difference is that the return values are the currently-installed versions of whatever packages are passed. If the package is not installed, an empty string is returned for that package.

**upgrade_available**

Deprecated and destined to be removed. For now, should just do the following:

```python
def myfunc():
    return __salt__("pkg.latest_version")(name) != ""
```
install

The following arguments are required and should default to None:

1. name (for single-package pkg states)
2. pkgs (for multiple-package pkg states)
3. sources (for binary package file installation)

The first thing that this function should do is call `pkg_resource.parse_targets` (see below). This function will convert the SLS input into a more easily parsed data structure. `pkg_resource.parse_targets` may need to be modified to support your new package provider, as it does things like parsing package metadata which cannot be done for every package management system.

```
pkg_params, pkg_type = __salt__["pkg_resource.parse_targets"](name, pkgs, sources)
```

Two values will be returned to the `install` function. The first of them will be a dictionary. The keys of this dictionary will be package names, though the values will differ depending on what kind of installation is being done:

- If `name` was provided (and `pkgs` was not), then there will be a single key in the dictionary, and its value will be `None`. Once the data has been returned, if the `version` keyword argument was provided, then it should replace the `None` value in the dictionary.

- If `pkgs` was provided, then `name` is ignored, and the dictionary will contain one entry for each package in the `pkgs` list. The values in the dictionary will be `None` if a version was not specified for the package, and the desired version if specified. See the Multiple Package Installation Options section of the `pkg.installed` state for more info.

- If `sources` was provided, then `name` is ignored, and the dictionary values will be the path/URI for the package.

The second return value will be a string with two possible values: repository or file. The `install` function can use this value (if necessary) to build the proper command to install the targeted package(s).

Both before and after the installing the target(s), you should run `list_pkgs` to obtain a list of the installed packages. You should then return the output of `salt.utils.data.compare_dicts()`:

```
def myfunc():
    return salt.utils.data.compare_dicts(old, new)
```

remove

Removes the passed package and return a list of the packages removed.

29.13.2 Package Repo Functions

There are some functions provided by `pkg` which are specific to package repositories, and not to packages themselves. When writing modules for new package managers, these functions should be made available as stated below, in order to provide compatibility with the `pkgrepo` state.

All repo functions should accept a `basedir` option, which defines which directory repository configuration should be found in. The default for this is dictated by the repo manager that is being used, and rarely needs to be changed.

```
basedir = "/etc/yum.repos.d"
__salt__["pkg.list_repos"](basedir)
```
list_repos

Lists the repositories that are currently configured on this system.

```
__salt__['pkg.list_repos']()
```

Returns a dictionary, in the following format:

```
{'reponame': 'config_key_1': 'config value 1',
 'config_key_2': 'config value 2',
 'config_key_3': ['list item 1 (when appropriate)',
 'list item 2 (when appropriate)']}
```

get_repo

Displays all local configuration for a specific repository.

```
__salt__['pkg.get_repo'](repo="myrepo")
```

The information is formatted in much the same way as list_repos, but is specific to only one repo.

```
{'config_key_1': 'config value 1',
 'config_key_2': 'config value 2',
 'config_key_3': ['list item 1 (when appropriate)',
 'list item 2 (when appropriate)']}
```

del_repo

Removes the local configuration for a specific repository. Requires a `repo` argument, which must match the locally configured name. This function returns a string, which informs the user as to whether or not the operation was a success.

```
__salt__['pkg.del_repo'](repo="myrepo")
```

mod_repo

Modify the local configuration for one or more option for a configured repo. This is also the way to create new repository configuration on the local system; if a repo is specified which does not yet exist, it will be created.

The options specified for this function are specific to the system; please refer to the documentation for your specific repo manager for specifics.

```
__salt__['pkg.mod_repo'](repo="myrepo", url="http://myurl.com/repo")
```
29.13.3 Low-Package Functions

In general, the standard package functions as describes above will meet your needs. These functions use the system’s native repo manager (for instance, yum or the apt tools). In most cases, the repo manager is actually separate from the package manager. For instance, yum is usually a front-end for rpm, and apt is usually a front-end for dpkg. When possible, the package functions that use these package managers directly should do so through the low package functions.

It is normal and sane for pkg to make calls to lowpkg, but lowpkg must never make calls to pkg. This is affects functions which are required by both pkg and lowpkg, but the technique in pkg is more performant than what is available to lowpkg. When this is the case, the lowpkg function that requires that technique must still use the lowpkg version.

list_pkgs

Returns a dict of packages installed, including the package name and version. Can accept a list of packages; if none are specified, then all installed packages will be listed.

```
installed = __salt__['lowpkg.list_pkgs']('foo', 'bar')
```

Example output:

```
{
    "foo": "1.2.3-4",  "bar": "5.6.7-8"
}
```

verify

Many (but not all) package management systems provide a way to verify that the files installed by the package manager have or have not changed. This function accepts a list of packages; if none are specified, all packages will be included.

```
installed = __salt__['lowpkg.verify']('httpd')
```

Example output:

```
{
    "/etc/httpd/conf/httpd.conf": {
        "mismatch": ["size", "md5sum", "mtime"],
        "type": "config",
    }
}
```

def_list

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

```
installed = __salt__['lowpkg.file_list']('httpd', 'apache')
```

This function does not return which files belong to which packages; all files are returned as one giant list (hence the file_list function name. However, This information is still returned inside of a dict, so that it can provide any errors to the user in a sane manner.
file_dict

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

```
installed = __salt__['lowpkg.file_dict']('httpd', 'apache', 'kernel')
```

Unlike `file_list`, this function will break down which files belong to which packages. It will also return errors in the same manner as `file_list`.

```json
{
    "errors": ["package apache is not installed"],
    "packages": {
        "httpd": ["/etc/httpd", "/etc/httpd/conf", "...SNIP..."],
        "kernel": ["/boot/.vmlinuz-2.6.32-279.el6.x86_64.hmac",
        "/boot/System.map-2.6.32-279.el6.x86_64",
        "...SNIP...",
        ],
    },
}
```

## 29.14 Pull Requests

Salt is a large software project with many developers working together. We encourage all Salt users to contribute new features, bug fixes and documentation fixes. For those who haven't contributed to a large software project before we encourage you to consider the following questions when preparing a pull request.

This isn’t an exhaustive list and these aren’t necessarily hard and fast rules, but these are things we consider when reviewing a pull request.

- Does this change work on all platforms? In cases where it does not, is an appropriate and easy-to-understand reason presented to the user? Is it documented as-such? Have we thought about all the possible ways this code might be used and accounted as best we can for them?
- Will this code work on versions of all Python we support? Will it work on future versions?
- Are Python reserved keywords used? Are variables named in a way that will make it easy for the next person to understand what’s going on?
- Does this code present a security risk in any way? What is the worst possible thing that an attacker could do with this code? If dangerous cases are possible, is it appropriate to document them? If so, has this been done? Would this change pass muster with a professional security audit? Is it obvious to a person using this code what the risks are?
- Is it readable? Does it conform to our [style guide](#)? Is the code documented such that the next person who comes along will be able to read and understand it? Most especially, are edge-cases documented to avoid regressions? Will it be immediately evident to the next person who comes along why this change was made?
• If appropriate, has the person who wrote the code which is being modified been notified and included in the process?

• What are the performance implications of this change? Is there a more efficient way to structure the logic and if so, does making the change balance itself against readability in a sensible way? Do the performance characteristics of the code change based on the way it is being invoked (i.e., through an API or various command-line tools.) Will it be easy to profile this change if it might be a problem?

• Are caveats considered and documented in the change?

• Will the code scale? More critically, will it scale in both directions? Salt runs in data-centers and on Raspberry Pi installations in the Sahara. It needs to work on big servers and tiny devices.

• Is appropriate documentation written both in public-facing docs and in-line? How will the user know how to use this? What will they do if it doesn't work as expected? Is this something a new user will understand? Can a user know all they need to about this functionality by reading the public docs?

• Is this a change in behavior? If so, is it in the appropriate branch? Are deprecation warnings necessary? Have those changes been fully documented? Have we fully thought through what implications a change in behavior might have?

• How has the code been tested? If appropriate are there automated tests which cover this? Is it likely to regress? If so, how has the potential of that regression been mitigated? What is the plan for ensuring that this code works going forward?

• If it's asynchronous code, what is the potential for a race condition?

• Is this code an original work? If it's borrowed from another project or found online are the appropriate licensing/attribution considerations handled?

• Is the reason for the change fully explained in the PR? If not for review, this is necessary so that somebody in the future can go back and figure out why it was necessary.

• Is the intended behavior of the change clear? How will that behavior be known to future contributors and to users?

• Does this code handle errors in a reasonable way? Have we gone back through the stack as much as possible to make sure that an error cannot be raised that we do not account for? Are errors tested for as well as proper functionality?

• If the code relies on external libraries, do we properly handle old versions of them? Do we require a specific version and if so is this version check implemented? Is the library available on the same platforms that module in question claims to support? If the code was written and tested against a particular library, have we documented that fact?

• Can this code freeze/hang/crash a running daemon? Can it stall a state run? Are there infinite loops? Are appropriate timeouts implemented?

• Is the function interface well documented? If argument types can not be inferred by introspection, are they documented?

• Are resources such as file-handles cleaned-up after they are used?

• Is it possible that a reference-cycle exists between objects that will leak memory?

• Has the code been linted and does it pass all tests?

• Does the change fully address the problem or is it limited to a small surface area? By this, I mean that it should be clear that the submitter has looked for other cases in the function or module where the given case might also be addressed. If additional changes are necessary are they documented in the code as a FIXME or the PR and in Github as an issue to be tracked?

• Will the code throw errors/warnings/stacktraces to the console during normal operation?
• Has all the debugging been removed?
• Does the code log any sensitive data? Does it show sensitive data in process lists? Does it store sensitive data
to disk and if so, does it do so in a secure manner? Are there potential race conditions in between writing the
data to disk and setting the appropriate permissions?
• Is it clear from the solution that the problem is well-understood? How can somebody who has never seen the
problem feel confident that this proposed change is the best one?
• What’s hard-coded that might not need to be? Are we making sensible decisions for the user and allowing
them to tune and change things where appropriate?
• Are utility functions used where appropriate? Does this change re-implement something we already have
code for?
• Is the right thing being fixed? There are cases where it’s appropriate to fix a test and cases where it’s appropriate
to fix the code that’s under test. Which is best for the user? Is this change a shortcut or a solution that will be
solid in the months and years to come?
• How will this code react to changes elsewhere in the code base? What is it coupled to and have we fully
thought through how best to present a coherent interface to consumers of a given function or method?
• Does this PR try to fix too many bugs/problems at once?
• Should this be split into multiple PRs to make them easier to test and reason about?

29.15 Pull Request Requirements

The following outlines what is required before a pull request can be merged into the salt project. For each of these
requirements, an exception can be made that requires 3 approvals before merge. The exceptions are detailed more
below.

29.15.1 All PR requirements

• Approval Required: approval review from core team member OR 1 approval review from captain of working
group
• Cannot merge your own PR until 1 reviewer approves from defined list above that is not the author.
• All Tests Pass

29.15.2 Bug Fix PR requirements

• Test Coverage: regression test written to cover bug fix. Contributors only need to write test coverage for their
specific changes.
• Point to the issue the PR is resolving. If there is not an issue one will need to be created.
29.15.3 Feature PR requirements

- Test Coverage: tests written to cover new feature. Contributors only need to write test coverage for their specific changes.
- Add .. versionadded:: <release> to module’s documentation. If you are not certain which release your fix will be included in you can include TBD and the PR reviewer will let you know the correct name of the release you need to update to the versionadded.

29.15.4 Exceptions to all requirements

As previously stated, all of the above requirements can be bypassed with 3 approvals. PR’s that do not require tests include:

- documentation
- cosmetic changes (for example changing from log.debug to log.trace)
- fixing tests
- pylint
- changes outside of the salt directory

29.16 Reporting Bugs

Salt uses GitHub to track open issues and feature requests.

To file a bug, please navigate to the new issue page for the Salt project.

In an issue report, please include the following information:

- The output of salt --versions-report from the relevant machines. This can also be gathered remotely by using salt <my_tgt> test.versions_report.
- A description of the problem including steps taken to cause the issue to occur and the expected behaviour.
- Any steps taken to attempt to remediate the problem.
- Any configuration options set in a configuration file that may be relevant.
- A reproduceable test case. This may be as simple as an SLS file that illustrates a problem or it may be a link to a repository that contains a number of SLS files that can be used together to re-produce a problem. If the problem is transitory, any information that can be used to try and reproduce the problem is helpful.
- [Optional] The output of each salt component (master/minion/CLI) running with the -ldebug flag set.

Note: Please be certain to scrub any logs or SLS files for sensitive data!
29.17 Salt Topology

Salt is based on a powerful, asynchronous, network topology using ZeroMQ. Many ZeroMQ systems are in place to enable communication. The central idea is to have the fastest communication possible.

29.17.1 Servers

The Salt Master runs 2 network services. First is the ZeroMQ PUB system. This service by default runs on port 4505 and can be configured via the publish_port option in the master configuration.

Second is the ZeroMQ REP system. This is a separate interface used for all bi-directional communication with minions. By default this system binds to port 4506 and can be configured via the ret_port option in the master.

29.17.2 PUB/SUB

The commands sent out via the salt client are broadcast out to the minions via ZeroMQ PUB/SUB. This is done by allowing the minions to maintain a connection back to the Salt Master and then all connections are informed to download the command data at once. The command data is kept extremely small (usually less than 1K) so it is not a burden on the network.

29.17.3 Return

The PUB/SUB system is a one way communication, so once a publish is sent out the PUB interface on the master has no further communication with the minion. The minion, after running the command, then sends the command’s return data back to the master via the ret_port.

29.18 Developing Salt Tutorial

This tutorial assumes you have:

- a web browser
- a GitHub account (<my_account>)
- a command line (CLI)
- git
- a text editor

29.18.1 Fork

In your browser, navigate to the saltstack/salt GitHub repository.

Click on Fork (https://github.com/saltstack/salt/#fork-destination-box).

Note: If you have more than one GitHub presence, for example if you are a member of a team, GitHub will ask you into which area to clone Salt. If you don’t know where, then select your personal GitHub account.
29.18.2 Clone

In your CLI, navigate to the directory into which you want clone the Salt codebase and submit the following command:

```bash
$ git clone https://github.com/<my_account>/salt.git
```

where `<my_account>` is the name of your GitHub account. After the clone has completed, add SaltStack as a second remote and fetch any changes from `upstream`.

```bash
$ cd salt
$ git remote add upstream https://github.com/saltstack/salt.git
$ git fetch upstream
```

For this tutorial, we will be working off from the `master` branch, which is the default branch for the SaltStack GitHub project. This branch needs to track `upstream/master` so that we will get all upstream changes when they happen.

```bash
$ git checkout master
$ git branch --set-upstream-to upstream/master
```

29.18.3 Fetch

Fetch any `upstream` changes on the `master` branch and sync them to your local copy of the branch with a single command:

```bash
$ git pull --rebase
```

**Note:** For an explanation on `pull vs pull --rebase` and other excellent points, see [this article](#) by Mislav Marohnić.

29.18.4 Branch

Now we are ready to get to work. Consult the sprint beginner bug list and select an execution module whose `__virtual__` function needs to be updated. I'll select the `alternatives` module.

Create a new branch off from `master`. Be sure to name it something short and descriptive.

```bash
$ git checkout -b virt_ret
```

29.18.5 Edit

Edit the file you have selected, and verify that the changes are correct.

```bash
$ vim salt/modules/alternatives.py
$ git diff
```

```bash
diff --git a/salt/modules/alternatives.py b/salt/modules/alternatives.py
index 1653e5f..30c0a59 100644
--- a/salt/modules/alternatives.py
+++ b/salt/modules/alternatives.py
```

(continues on next page)
commit

Stage and commit the changes. Write a descriptive commit summary, but try to keep it less than 50 characters. Review your commit.

```bash
$ git add salt/modules/alternatives.py
$ git commit -m 'modules.alternatives: __virtual__ return err msg'
$ git show
```

Note: If you need more room to describe the changes in your commit, run `git commit` (without the `-m`, `message`, `option`) and you will be presented with an editor. The first line is the commit summary and should still be 50 characters or less. The following paragraphs you create are free form and will be preserved as part of the commit.

Push

Push your branch to your GitHub account. You will likely need to enter your GitHub username and password.

```bash
$ git push origin virt_ret
Username for 'https://github.com': <my_account>
Password for 'https://<my_account>@github.com':
```

Note: If authentication over https does not work, you can alternatively setup ssh keys. Once you have done this, you may need add the keys to your git repository configuration

```bash
$ git config ssh.key ~/.ssh/<key_name>
```

where `<key_name>` is the file name of the private key you created.
29.18.8 Merge

In your browser, navigate to the new pull request page on the saltstack/salt GitHub repository and click on compare across forks. Select <my_account> from the list of head forks and the branch you are wanting to merge into master (virt_ret in this case).

When you have finished reviewing the changes, click Create pull request.

If your pull request contains only a single commit, the title and comment will be taken from that commit’s summary and message, otherwise the branch name is used for the title. Edit these fields as necessary and click Create pull request.

Note: Although these instructions seem to be the official pull request procedure on github’s website, here are two alternative methods that are simpler.

• If you navigate to your clone of salt, https://github.com/<my_account>/salt, depending on how old your branch is or how recently you pushed updates on it, you may be presented with a button to create a pull request with your branch.

• I find it easiest to edit the following URL:

  https://github.com/saltstack/salt/compare/master...<my_account>:virt_ret

29.18.9 Resources

GitHub offers many great tutorials on various aspects of the git- and GitHub-centric development workflow:

https://help.github.com/

There are many topics covered by the Salt Developer documentation:

https://docs.saltstack.com/en/latest/topics/development/index.html

The contributing documentation presents more details on specific contributing topics:

https://docs.saltstack.com/en/latest/topics/development/contributing.html

29.19 Modular Systems

When first working with Salt, it is not always clear where all of the modular components are and what they do. Salt comes loaded with more modular systems than many users are aware of, making Salt very easy to extend in many places.

The most commonly used modular systems are execution modules and states. But the modular systems extend well beyond the more easily exposed components and are often added to Salt to make the complete system more flexible.
Interactive Debugging

Sometimes debugging with `print()` and extra logs sprinkled everywhere is not the best strategy. IPython is a helpful debug tool that has an interactive python environment which can be embedded in python programs.

First the system will require IPython to be installed.

```bash
# Debian
apt-get install ipython

# Arch Linux
pacman -Syu ipython2

# RHEL/CentOS (via EPEL)
yum install python-ipython
```

Now, in the troubling python module, add the following line at a location where the debugger should be started:

```python
test = "test123"
import IPython
IPython.embed_kernel()
```

After running a Salt command that hits that line, the following will show up in the log file:

```
[CRITICAL] To connect another client to this kernel, use:
[IPKernelApp] --existing kernel-31271.json
```

Now on the system that invoked `embed_kernel`, run the following command from a shell:

```
# NOTE: use ipython2 instead of ipython for Arch Linux
ipython console --existing
```

This provides a console that has access to all the vars and functions, and even supports tab-completion.

```python
print(test)
test123
```

To exit IPython and continue running Salt, press `Ctrl-d` to logout.

**Special Module Contents**

These are things that may be defined by the module to influence various things.
__virtual__

__virtual_aliases__

__virtualname__

__init__

Called before __virtual__() 

__proxyenabled__

grains and proxy modules

__proxyenabled__ as a list containing the names of the proxy types that the module supports.

__load__

__func_alias__

__outputter__

Dunder Dictionaries

Salt provides several special "dunder" dictionaries as a convenience for Salt development. These include __opts__, __context__, __salt__, and others. This document will describe each dictionary and detail where they exist and what information and/or functionality they provide.

The following dunder dictionaries are always defined, but may be empty

• __context__
• __grains__
• __pillar__
• __opts__

__opts__

Defined in: All modules

The __opts__ dictionary contains all of the options passed in the configuration file for the master or minion.

---

Note: In many places in salt, instead of pulling raw data from the __opts__ dict, configuration data should be pulled from the salt get functions such as config.get, aka __salt__['config.get']('foo:bar') The get functions also allow for dict traversal via the : delimiter. Consider using get functions whenever using __opts__ or __pillar__ and __grains__ (when using grains for configuration data)

---

The configuration file data made available in the __opts__ dictionary is the configuration data relative to the running daemon. If the modules are loaded and executed by the master, then the master configuration data is
available, if the modules are executed by the minion, then the minion configuration is available. Any additional information passed into the respective configuration files is made available

__salt__

Defined in: Auth, Beacons, Engines, Execution, Executors, Outputters, Pillars, Proxies, Renderers, Returners, Runners, SDB, SSH Wrappers, State, Thorium

__salt__ contains the execution module functions. This allows for all functions to be called as they have been set up by the salt loader.

```python
__salt__['cmd.run']('fdisk -l')
__salt__['network.ip_addrs']()
```

Note: When used in runners or outputters, __salt__ references other runner/outputter modules, and not execution modules.

__grains__

Filled in for: Execution, Pillar, Renderer, Returner, SSH Wrapper, State.

The __grains__ dictionary contains the grains data generated by the minion that is currently being worked with. In execution modules, state modules and returners this is the grains of the minion running the calls, when generating the external pillar the __grains__ is the grains data from the minion that the pillar is being generated for.

While __grains__ is defined for every module, it's only filled in for some.

__pillar__

Filled in for: Execution, Renderer, Returner, SSH Wrapper, State

The __pillar__ dictionary contains the pillar for the respective minion.

While __pillar__ is defined for every module, it's only filled in for some.

__ext_pillar__

Filled in for: Pillar

The __ext_pillar__ dictionary contains the external pillar modules.
**__context__**

During a state run the `__context__` dictionary persists across all states that are run and then is destroyed when the state ends.

When running an execution module `__context__` persists across all module executions until the modules are refreshed; such as when `saltutil.sync_all` or `state.apply` are executed.

A great place to see how to use `__context__` is in the `cp.py` module in `salt/modules/cp.py`. The fileclient authenticates with the master when it is instantiated and then is used to copy files to the minion. Rather than create a new fileclient for each file that is to be copied down, one instance of the fileclient is instantiated in the `__context__` dictionary and is reused for each file. Here is an example from `salt/modules/cp.py`:

```python
if not "cp.fileclient" in __context__:
    __context__["cp.fileclient"] = salt.fileclient.get_file_client(__opts__)
```

---

**Note:** Because `__context__` may or may not have been destroyed, always be sure to check for the existence of the key in `__context__` and generate the key before using it.

---

**__utils__**

Defined in: Cloud, Engine, Execution, File Server, Grain, Pillar, Proxy, Roster, Runner, SDB, State

**__proxy__**

Defined in: Beacon, Engine, Execution, Executor, Proxy, Renderer, Returner, State, Util

**__runner__**

Defined in: Engine, Roster, Thorium

**Note:** When used in engines, it should be called `__runners__` (plural)

---

**__executors__**

Defined in: Executor

**__ret__**

Defined in: Proxy
29.19.2 Configuration Options

A number of configuration options can affect the load process. This is a quick list of them:

- `autoload_dynamic_modules (Minion)`
- `cython_enable (Minion, Master)`
- `disable_modules (Minion)`
- `disable_returners (Minion)`
- `enable_zip_modules (Minion)`
- `extension_modules (Master)`
- `extmod_whitelist (Minion, Master)`
- `extmod_blacklist (Minion, Master)`
- `whitelist_modules (Minion)`
- `grains_dirs (Minion)`
- `module_dirs (Minion, Master)`
- `outputter_dirs (Minion, Master)`
- `providers (Minion)`
- `render_dirs (Minion)`
- `returner_dirs (Minion)`
- `runner_dirs (Master)`
- `states_dirs (Master)`
- `states_dirs (Minion)`
- `utils_dirs (Minion)`
29.19.3 Loading Modules

Modules come primarily from several sources:

- The Salt package itself
- The Salt File Server
- The extmods directory
- Secondary packages installed

Using one source to override another is not supported.

The Salt Package

Salt itself ships with a large number of modules. These are part of the Salt package itself and don't require the user to do anything to use them. (Although a number of them have additional dependencies and/or configuration.)

The Salt File Server

The user may add modules by simply placing them in special directories in their fileserver. The name of the directory inside of the file server is the directory name prepended by underscore, such as:

- _grains
- _modules
- _states

Modules must be synced before they can be used. This can happen a few ways, discussed below.

Note: Using saltenv besides base may not work in all contexts.

Sync Via States

The minion configuration contains an option autoload_dynamic_modules which defaults to True. This option makes the state system refresh all dynamic modules when states are run. To disable this behavior set autoload_dynamic_modules to False in the minion config.

When dynamic modules are autoloaded via states, only the modules defined in the same saltenvs as the states currently being run.

Sync Via the saltutil Module

The saltutil module has a number of functions that can be used to sync all or specific dynamic modules. The saltutil.sync_* execution functions and runner functions can be used to sync modules to minions and the master, respectively.
The extmods Directory

Any files placed in the directory set by extension_modules settings (minion, master, default /var/cache/salt/*/extmods) can also be loaded as modules. Note that these directories are also used by the saltutil.sync_* functions (mentioned above) and files may be overwritten.

Secondary Packages

Third-party packages may also add modules to Salt if they are installed in the same system and Python environment as the Salt Minion or Master.

This is done via setuptools entry points:

```python
setup(
    # ...
    entry_points={"salt.loader": ["module_dirs=spirofs.loader:module"],
    # ...
)
```

Note that these are not synced from the Salt Master to the Minions. They must be installed independently on each Minion.

29.19.4 Module Types

The specific names used by each loading method above are as follows. See sections below for a short summary of each of these systems.

<table>
<thead>
<tr>
<th>Module Type</th>
<th>Salt Package Name</th>
<th>FS/Directory Name</th>
<th>Entry Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auth</td>
<td>salt.auth(index)</td>

</tr>
</tbody>
</table>

**Note:** While it is possible to import modules directly with the import statement, it is strongly recommended that the appropriate *dunder dictionary* is used to access them instead. This is because a number of factors affect module names, module selection, and module overloading.

### Auth

The auth module system allows for external authentication routines to be easily added into Salt. The *auth* function needs to be implemented to satisfy the requirements of an auth module. Use the pam module as an example.

See *External Authentication System* for more about authentication in Salt.

### Beacon

- **Writing Beacons**

Beacons are polled by the Salt event loop to monitor non-salt processes. See *Beacons* for more information about the beacon system.

### Cache

The minion cache is used by the master to store various information about minions. See *Minion Data Cache* for more information.

*1 These modules cannot be loaded from the Salt File Server.*
Cloud

Cloud modules are backend implementations used by Salt Cloud.

Engine

Engines are open-ended services managed by the Salt daemon (both master and minion). They may interact with event loop, call other modules, or a variety of non-salt tasks. See Salt Engines for complete details.

Execution

Execution modules make up the core of the functionality used by Salt to interact with client systems. The execution modules create the core system management library used by all Salt systems, including states, which interact with minion systems.

Execution modules are completely open ended in their execution. They can be used to do anything required on a minion, from installing packages to detecting information about the system. The only restraint in execution modules is that the defined functions always return a JSON serializable object.

Executor

Executors control how execution modules get called. The default is to just call them, but this can be customized.

File Server

The file server module system is used to create file server backends used by the Salt Master. These modules need to implement the functions used in the fileserver subsystem. Use the gitfs module as an example.

See File Server Backends for more information.

Grains

- Writing Grains

Grain modules define extra routines to populate grains data. All defined public functions will be executed and MUST return a Python dict object. The dict keys will be added to the grains made available to the minion.

See Grains for more.

Log Handler
