"return": "Welcome"}
post()
Send one or more Salt commands (lowstates) in the request body

POST /

Request Headers
• X-Auth-Token -- a session token from SaltAuthHandler.
• Accept -- the desired response format.
• Content-Type -- the format of the request body.

Response Headers
• Content-Type -- the format of the response body; depends on the Accept request header.

Status Codes
• 200 OK -- success
• 401 Unauthorized -- authentication required
• 406 Not Acceptable -- requested Content-Type not available

*lowstate* data describing Salt commands must be sent in the request body.

Example request:
```
curl -si https://localhost:8000 \
   -H "Accept: application/x-yaml" \
   -H "X-Auth-Token: d40d1e1e" \
   -d client=local \ 
   -d tgt='*' \
   -d fun='test.ping' \ 
   -d arg
```

POST / HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
X-Auth-Token: d40d1e1e
Content-Length: 36
Content-Type: application/x-www-form-urlencoded

fun=test.ping&arg&client=local&tgt=*

Example response:
Responses are an in-order list of the lowstate's return data. In the event of an exception running a command the return will be a string instead of a mapping.

```
HTTP/1.1 200 OK
Content-Length: 200
Allow: GET, HEAD, POST
Content-Type: application/x-yaml

return:
- ms-0: true
  ms-1: true
  ms-2: true
  ms-3: true
  ms-4: true
```

multiple commands
Note that if multiple `lowstate` structures are sent, the Salt API will execute them in serial, and will not stop execution upon failure of a previous job. If you need to have commands executed in order and stop on failure please use compound-command-execution.

/\login

class salt.netapi.rest_tornado.saltnado.SaltAuthHandler(*args, **kwargs)
Handler for login requests

get()
All logins are done over post, this is a parked endpoint

GET /\login
Status Codes
• 401 Unauthorized -- authentication required
• 406 Not Acceptable -- requested Content-Type not available

Example request:

curl -i localhost:8000/login

GET /login HTTP/1.1
Host: localhost:8000
Accept: application/json

Example response:

HTTP/1.1 401 Unauthorized
Content-Type: application/json
Content-Length: 58

{"status": "401 Unauthorized", "return": "Please log in"}

post()
Authenticate against Salt's eauth system

POST /\login
Request Headers
• X-Auth-Token -- a session token from SaltAuthHandler.
• Accept -- the desired response format.
• Content-Type -- the format of the request body.

Form Parameters
• eauth -- the eauth backend configuried for the user
• username -- username
• password -- password

Status Codes
• 200 OK -- success
• 400 Bad Request -- bad request
• 401 Unauthorized -- authentication required
• 406 Not Acceptable -- requested Content-Type not available
• 500 Internal Server Error -- internal server error

Example request:
curl -si localhost:8000/login \
   -H "Accept: application/json" \
   -d username='saltuser' \
   -d password='saltpass' \
   -d eauth='pam'

POST / HTTP/1.1
Host: localhost:8000
Content-Length: 42
Content-Type: application/x-www-form-urlencoded
Accept: application/json

username=saltuser&password=saltpass&eauth=pam

Example response:

HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {
   "token": "6d1b722e",
   "start": 1363805943.776223,
   "expire": 1363849143.776224,
   "user": "saltuser",
   "eauth": "pam",
   "perms": [
      "grains.*",
      "status.*",
      "sys.*",
      "test.*"
   ]
}}

/minions

class salt.netapi.rest_tornado.saltnado.MinionSaltAPIHandler(*args, **kwargs)
   A convenience endpoint for minion related functions

def get(mid=None)
   A convenience URL for getting lists of minions or getting minion details

   GET /minions/(mid)

   Request Headers
   - X-Auth-Token -- a session token from SaltAuthHandler.
   - Accept -- the desired response format.

   Status Codes
   - 200 OK -- success
   - 401 Unauthorized -- authentication required
• 406 Not Acceptable -- requested Content-Type not available

Example request:

curl -i localhost:8000/minions/ms-3

GET /minions/ms-3 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 129005
Content-Type: application/x-yaml

return:
- ms-3:
   grains.items:
      ...

post()
Start an execution command and immediately return the job id

**POST /minions**

Request Headers

- X-Auth-Token -- a session token from SaltAuthHandler.
- Accept -- the desired response format.
- Content-Type -- the format of the request body.

Response Headers

- Content-Type -- the format of the response body; depends on the Accept request header.

Status Codes

- 200 OK -- success
- 401 Unauthorized -- authentication required
- 406 Not Acceptable -- requested Content-Type not available

lowstate data describing Salt commands must be sent in the request body. The client option will be set to local_async().

Example request:

curl -ssS localhost:8000/minions
   -H "Accept: application/x-yaml"
   -d tgt='*' 
   -d fun='status.diskusage'

POST /minions HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 26
Content-Type: application/x-www-form-urlencoded

tgt=*&fun=status.diskusage

Example response:
HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]

/jobs

class salt.netapi.rest_tornado.saltnado.JobsSaltAPIHandler(*args, **kwargs)

A convenience endpoint for job cache data

get(jid=None)

A convenience URL for getting lists of previously run jobs or getting the return from a single job

GET /jobs/ (jid)
List jobs or show a single job from the job cache.

Status Codes
- 200 OK -- success
- 401 Unauthorized -- authentication required
- 406 Not Acceptable -- requested Content-Type not available

Example request:
curl -i localhost:8000/jobs

GET /jobs HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- '20121130104633606931':
  Arguments:
  - '3'
  Function: test.fib
  Target: jerry
  Target-type: glob

Example request:
curl -i localhost:8000/jobs/20121130104633606931

GET /jobs/20121130104633606931 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:
Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

info:
- Arguments:
  - '3'
    Function: test.fib
  Minions:
  - jerry
    Target: '*'
    Target-type: glob
    User: saltdev
    jid: '20121130104633606931'
return:
- jerry:
  - - 0
  - 1
  - 1
  - 2
  - 6.9141387939453125e-06

/run

class salt.netapi.rest_tornado.saltenado.RunSaltAPIHandler(*args, **kwargs)

Endpoint to run commands without normal session handling

post()

Run commands bypassing the normal session handling

POST /run

This entry point is primarily for "one-off" commands. Each request must pass full Salt authentication credentials. Otherwise this URL is identical to the root URL (/).

lowstate data describing Salt commands must be sent in the request body.

Status Codes

- 200 OK -- success
- 401 Unauthorized -- authentication required
- 406 Not Acceptable -- requested Content-Type not available

Example request:

curl -sS localhost:8000/run \
  -H 'Accept: application/x-yaml' \
  -d client='local' \
  -d tgt='*' \
  -d fun='test.ping' \
  -d username='saltdev' \
  -d password='saltdev' \
  -d eauth='pam'
POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

client=local&tgt=*&fun=test.ping&username=saltdev&password=saltdev&
eauth=pam

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
  - ms-0: true
  - ms-1: true
  - ms-2: true
  - ms-3: true
  - ms-4: true

/events

class salt.netapi.rest_tornado.saltenado.EventsSaltAPIHandler(*args,**kwargs)
  Expose the Salt event bus
  
  The event bus on the Salt master exposes a large variety of things, notably when executions are started on the
  master and also when minions ultimately return their results. This URL provides a real-time window into a
  running Salt infrastructure.

  See also:
  Events & Reactor

get()
  An HTTP stream of the Salt master event bus
  
  This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.

  GET /events

  Status Codes
  - 200 OK -- success
  - 401 Unauthorized -- authentication required
  - 406 Not Acceptable -- requested Content-Type not available

  Example request:

curl -NsS localhost:8000/events

GET /events HTTP/1.1
Host: localhost:8000

Example response:
HTTP/1.1 200 OK
Connection: keep-alive
Cache-Control: no-cache
Content-Type: text/event-stream;charset=utf-8
retry: 400
data: {'tag': '', 'data': {'minions': ['ms-4', 'ms-3', 'ms-2', 'ms-1 
→', 'ms-0']}}
data: {'tag': '20130802115730568475', 'data': {'jid': 
→'20130802115730568475', 'return': True, 'retcode': 0, 'success':True, 'cmd': '_return', 'fun': 'test.ping', 'id': 'ms-1'}}

The event stream can be easily consumed via JavaScript:

```javascript
<!-- Note, you must be authenticated! -->
var source = new EventSource('/events');
source.onopen = function() { console.debug('opening');
source.onerror = function(e) { console.debug('error!', e );
source.onmessage = function(e) { console.debug(e.data) };

Or using CORS:

```javascript
var source = new EventSource('/events', {withCredentials: true});
``` 

Some browser clients lack CORS support for the EventSource() API. Such clients may instead pass the X-Auth-Token value as an URL parameter:

curl -NsS localhost:8000/events/6d1b722e

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the data: and tag: prefixes will need to be removed manually before attempting to unserialize the JSON.

curl's -N flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

curl -NsS localhost:8000/events | \
   while IFS= read -r line ; do 
     echo $line
   done

Here is an example of using awk to filter events based on tag:

curl -NsS localhost:8000/events | \
   awk 'BEGIN { RS=""; FS="\n" } 
     $1 ~ /^tag: salt\//job\/[0-9]+\//[0-9]+$/ { print $0 } ,

   tag: salt/job/20140112010149808995/new
   data: {"tag": "salt/job/20140112010149808995/new", "data": {"tgt_type 
→": "glob", "jid": "20140112010149808995", "tgt": "jerry", "_stamp 
→": "2014-01-12_01:01:49.809617", "user": "shouse", "arg": [], "fun
```
(continues on next page)
"test.ping", "minions": ["jerry"]}

tag: 20140112010149808995
data: {"tag": "20140112010149808995", "data": {"fun_args": [], "jid
"": "20140112010149808995", "return": true, "retcode": 0, "success
"": true, "cmd": "_return", "_stamp": "2014-01-12_01:01:49.819316", 
"fun": "test.ping", "id": "jerry"}}

## /hook

class salt.netapi.rest_tornado.saltnado.WebhookSaltAPIHandler(*args, **kwargs)

A generic web hook entry point that fires an event on Salt's event bus

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub web hooks.

**Note:** Be mindful of security

Salt's Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

This is a generic interface and securing it is up to you!

This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

The event data is taken from the request body. The `Content-Type` header is respected for the payload.

The event tag is prefixed with `salt/netapi/hook` and the URL path is appended to the end. For example, a POST request sent to `/hook/mycompany/myapp/mydata` will produce a Salt event with the tag `salt/netapi/hook/mycompany/myapp/mydata`.

The following is an example `.travis.yml` file to send notifications to Salt of successful test runs:

```
language: python
script: python -m unittest tests
after_success:
  - 'curl -sS http://saltapi-url.example.com:8000/hook/travis/build/
    -success -d branch="${TRAVIS_BRANCH}" -d commit="${TRAVIS_COMMIT}"'
```

See also:

* [Events](#events)
* [Reactor](#reactor)

**post**(tag_suffix=None)

Fire an event in Salt with a custom event tag and data

### POST /hook

**Status Codes**

- 200 OK -- success
- 401 Unauthorized -- authentication required
- 406 Not Acceptable -- requested Content-Type not available
- 413 Request Entity Too Large -- request body is too large

Example request:
curl -sS localhost:8000/hook -d foo='Foo!' -d bar='Bar!'

POST /hook HTTP/1.1
Host: localhost:8000
Content-Length: 16
Content-Type: application/x-www-form-urlencoded

foo=Foo&bar=Bar!

Example response:

HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL `http://localhost:8000/hook/mycompany/build/success` which contains the result of a build and the SHA of the version that was built as JSON. That would then produce the following event in Salt that could be used to kick off a deployment via Salt's Reactor:

Event fired at Fri Feb 14 17:40:11 2014
*************************
Tag: salt/netapi/hook/mycompany/build/success
Data:
{'_stamp': '2014-02-14_17:40:11.440996',
'headers': {
  'X-My-Secret-Key': 'F0fAgoQjIT@W',
  'Content-Length': '37',
  'Content-Type': 'application/json',
  'Host': 'localhost:8000',
  'Remote-Addr': '127.0.0.1'},
'post': {'revision': 'aa22a3c4b2e7', 'result': True}}

Salt’s Reactor could listen for the event:

reactor:
  - 'salt/netapi/hook/mycompany/build/*'
  - /srv/reactor/react_ci_builds.sls

And finally deploy the new build:

{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}

{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
deploy_my_app:
  cmd.state.sls:
    - tgt: 'application*'
    - arg:
      - myapp.deploy
    - kwarg:

(continues on next page)
25.11.5 rest_wsgi

A minimalist REST API for Salt

This `rest_wsgi` module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety.

All authentication is done through Salt’s external auth system.

Usage

- All requests must be sent to the root URL (/).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.

See also:

`rest_cherrypy`

The `rest_cherrypy` module is more full-featured, production-ready, and has built-in security features.

Deployment

The `rest_wsgi` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

Using a WSGI-compliant web server

This module may be run via any WSGI-compliant production server such as Apache with mod_wsgi or Nginx with FastCGI.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.

salt-api using a development-only server

If run directly via the salt-api daemon it uses the `wsgiref.simple_server()` that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. This server does not use encryption; please note that raw Salt authentication credentials must be sent with every HTTP request.

Running this module via salt-api is not recommended!

In order to start this module via the salt-api daemon the following must be put into the Salt master config:
rest_wsgi:
  port: 8001

Usage examples

**POST /**

Example request for a basic `test.ping`:

```
% curl -sS -i \
   -H 'Content-Type: application/json' \
   -d '[["eauth":"pam","username":"saltdev","password":"saltdev",\n          "client":"local","tgt":"*","fun":"test.ping"]]' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [["ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, \n             "ms--0": true]]}
```

Example request for an asynchronous `test.ping`:

```
% curl -sS -i \
   -H 'Content-Type: application/json' \
   -d '[["eauth":"pam","username":"saltdev","password":"saltdev",\n          "client":"local_async","tgt":"*","fun":"test.ping"]]' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 103
Content-Type: application/json

{"return": [{"jid": "20130412192112593739", "minions": ["ms--4", "ms--3", \n            "ms--2", "ms--1", "ms--0"]}]}
```

Example request for looking up a job ID:

```
% curl -sS -i \
   -H 'Content-Type: application/json' \
   -d '[["eauth":"pam","username":"saltdev","password":"saltdev",\n          "client":"runner","fun":"jobs.lookup_jid","jid":"20130412192112593739"]]' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{}  
```

(continues on next page)
form lowstate
    A list of lowstate data appropriate for the client interface you are calling.

status 200
    success

status 401
    authentication required

25.12.1 salt.output.dson

Display return data in DSON format

This outputer is intended for demonstration purposes. Information on the DSON spec can be found [here](#).

This outputer requires Dogeon (installable via pip)

```python
salt.output.dson.output(data, **kwargs)
```

Print the output data in JSON
25.12.2 salt.output.highstate

Outputer for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outputer to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outputer. These values can be set in the master config to change the output of the salt command or set in the minion config to change the output of the salt-call command.

state_verbose:

By default stateVerbose is set to True, setting this to False will instruct the highstate outputer to omit displaying anything in green, this means that nothing with a result of True and no changes will not be printed

state_output:

The highstate outputer has six output modes, full, terse, mixed, changes and filter

- The default is set to full, which will display many lines of detailed information for each executed chunk.
- If terse is used, then the output is greatly simplified and shown in only one line.
- If mixed is used, then terse output will be used unless a state failed, in which case full output will be used.
- If changes is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
- If filter is used, then either or both of two different filters can be used: exclude or terse.
  - for exclude, state.highstate expects a list of states to be excluded (or None) followed by True for terse output or False for regular output. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance: exclude=True,
  - for terse, state.highstate expects simply True or False.

These can be set as such from the command line, or in the Salt config as state_output_exclude or state_output_terse, respectively.

The output modes have one modifier:

full_id, terse_id, mixed_id, changes_id and filter_id If _id is used, then the corresponding form will be used, but the value for name will be drawn from the state ID. This is useful for cases where the name value might be very long and hard to read.

state_tabular:

If state_output uses the terse output, set this to True for an aligned output format. If you wish to use a custom format, this can be set to a string.

state_output_pct:

Set state_output_pct to True in order to add "Success %" and "Failure %" to the "Summary" section at the end of the highstate output.

state_compress_ids:

Set state_compress_ids to True to aggregate information about states which have multiple "names" under the same state ID in the highstate output. This is useful in combination with the terse_id value set in the state_output option when states are using the names state parameter.

Example usage:

If state_output: filter is set in the configuration file:
salt '!' state.highstate exclude=None,True

means to exclude no states from the highstate and turn on terse output.

salt twd state.highstate exclude=problemstate1,problemstate2,False

means to exclude states problemstate1 and problemstate2 from the highstate, and use regular output.

Example output for the above highstate call when top.sls defines only one other state to apply to minion twd:

twd:

Summary for twd
-------------
Succeeded: 1 (changed=1)
Failed: 0
-------------
Total states run: 1

Example output with no special settings in configuration files:

myminion:

ID: test.ping
Function: module.run
Result: True
Comment: Module function test.ping executed
Changes:

ret:
True

Summary for myminion
-------------
Succeeded: 1
Failed: 0
-------------
Total: 0

salt.output.highstate.output(data, **kwargs)

The HighState Outputer is only meant to be used with the state.highstate function, or a function that returns highstate return data.

25.12.3 salt.output.json_out

Display return data in JSON format

configuration

The output format can be configured in two ways: Using the --out-indent CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the output-indent setting in the Master or Minion configuration file with one of the following values:
• Null: put each minion return on a single line.

• pretty: use four-space indents and sort the keys.

• An integer: specify the indentation level.

Salt’s outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many can not. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```
{
    "dave": {
        "en0": {
            "hwaddr": "02:b0:26:32:4c:69",
            ...
        }
    }
}
{
    "jerry": {
        "en0": {
            "hwaddr": "02:26:ab:0d:9b:0d",
            ...
        }
    }
}
{
    "kevin": {
        "en0": {
            "hwaddr": "02:6d:7f:ce:9f:ee",
            ...
        }
    }
}
{
    "mike": {
        "en0": {
            "hwaddr": "02:48:a2:4b:70:a0",
            ...
        }
    }
}
{
    "phill": {
        "en0": {
            "hwaddr": "02:1d:cc:a2:33:55",
            ...
        }
    }
}
{
    "stuart": {
        "en0": {
            "hwaddr": "02:9a:e0:ea:9e:3c",
            ...
        }
    }
}
```

CLI Example:

```
salt '*' foo.bar --out=json
```

```
salt.output.json_out.output(data, **kwargs)
    Print the output data in JSON
```

### 25.12.4 salt.output.key

Display salt-key output

The `salt-key` command makes use of this outputter to format its output.

```
salt.output.key.output(data, **kwargs)
    Read in the dict structure generated by the salt key API methods and print the structure.
```

### 25.12.5 salt.output.nested

Recursively display nested data

This is the default outputter for most execution functions.

Example output:

```
myminion:
    ______
    foo:
        ______
        bar:
            baz
dictionary:
        ______
        abc:
            123
```

(continues on next page)
def:
    456
list:
    - Hello
    - World

class salt.output.nested.NestDisplay(retcode=0)
    Manage the nested display contents
display(ret, indent, prefix, out)
    Recursively iterate down through data structures to determine output
ustring(indent, color, msg, prefix='', suffix='', endc=None)
salt.output.nested.output(ret, **kwargs)
    Display ret data

25.12.6 salt.output.newline_values_only

Display values only, separated by newlines

New in version 2015.5.0.
This outputer is designed for Salt CLI return data. It will do the following to the return dict:

1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion’s values are separated by newlines.

This results in a single string of return data containing all the values from the various minions.

Warning: As noted above, this outputer will discard the minion ID. If the minion ID is important, then an outputer that returns the full return dictionary in a parsable format (such as json, pprint, or yaml) may be more suitable.

Example 1

salt '*' foo.bar --out=newline_values_only

Input

```{  
    'myminion': ['127.0.0.1', '10.0.0.1'],
    'second-minion': ['127.0.0.1', '10.0.0.2']
}```
Output

127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2

Example 2

salt '//*[@data-testid]:' foo.bar --out=newline_values_only

Input

```
{
    'myminion': 8,
    'second-minion': 10
}
```

Output

```
8
10
```

```
salt.output.newline_values_only.output(data, **kwargs)
    Display modified ret data
```

25.12.7  salt.output.no_out_quiet

Display no output

No output is produced when this outputter is selected

CLI Example:

```
salt '/*' foo.bar --out=quiet
```

```
salt.output.no_out_quiet.output(ret, **kwargs)
    Don't display data. Used when you only are interested in the return.
```
25.12.8 salt.output.no_return

Display output for minions that did not return

This outtputter is used to display notices about which minions failed to return when a salt function is run with -v or --verbose. It should not be called directly from the CLI.

Example output:

```
virtucentos:
  Minion did not return
```

```py
class salt.output.no_return.NestDisplay
    Create generator for nested output
display(ret, indent, prefix, out)
    Recursively iterate down through data structures to determine output
salt.output.no_return.output(ret, **kwargs)
    Display ret data
```

25.12.9 salt.output.overstatestage

Display clean output of an overstate stage

This outtputter is used to display Orchestrate Runner stages, and should not be called directly.

```
salt.output.overstatestage.output(data, **kwargs)
    Format the data for printing stage information from the overstate system
```

25.12.10 salt.output.pony

Display Pony output data structure

```
depends
  • ponysay CLI program
```

Display output from a pony. Ponies are better than cows because everybody wants a pony.

Example output:

```
< {'local': True} >
-----------------
```

(continues on next page)
CLI Example:

```
salt '*' foo.bar --out=pony
```

```
salt.output.pony.output(data, **kwargs)
```

Mane function

---

### 25.12.11 salt.output.pprint_out

**Python pretty-print (pprint)**

The python pretty-print system was once the default outerrer. It simply passes the return data through to `pprint.pformat` and prints the results.

CLI Example:

```
salt '*' foo.bar --out=pprint
```

Example output:

```python
{'saltmine': {'foo': {'bar': 'baz',
                     'dictionary': {'abc': 123, 'def': 456},
                     'list': ['Hello', 'World']}}}
```

```
salt.output.pprint_out.output(data, **kwargs)
```

Print out via pretty print
25.12.12  salt.output.profile

Display profiling data in a table format

Show profile data for returners that would normally show a highstate output.

CLI Example:

```shell
salt '*!' state.apply something --out=profile
```

Attempt to output the returns of state.sls and state.highstate as a table of names, modules and durations that looks somewhat like the following:

<table>
<thead>
<tr>
<th>name</th>
<th>mod.fun</th>
<th>duration (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-fail-unless-stmt</td>
<td>other.function</td>
<td>-1.0000</td>
</tr>
<tr>
<td>old-minion-config</td>
<td>grains.list_present</td>
<td>1.1200</td>
</tr>
<tr>
<td>salt-data</td>
<td>group.present</td>
<td>48.3800</td>
</tr>
<tr>
<td>/etc/salt/minion</td>
<td>file.managed</td>
<td>63.1450</td>
</tr>
</tbody>
</table>

To get the above appearance, use settings something like these:

```python
out.table.separate_rows: False
out.table.justify: left
out.table.delim: ''
out.table.prefix: ''
out.table.suffix: ''
```

```python
salt.output.profile.output(data, **kwargs)
```

Display the profiling data in a table format.

25.12.13  salt.output.progress

Display return data as a progress bar

```python
salt.output.progress.output(ret, bar, **kwargs)
```

Update the progress bar

```python
salt.output.progress.progress_iter(progress)
```

Initialize and return a progress bar iter

25.12.14  salt.output.raw

Display raw output data structure

This ouputter simply displays the output as a python data structure, by printing a string representation of it. It is similar to the `pprint` ouputter, only the data is not nicely formatted/indented.

This was the original outputter used by Salt before the outputter system was developed.

CLI Example:

```shell
salt '*!' foo.bar --out=raw
```
Example output:

```
salt 'x' foo.bar --out=raw
{'myminion': {'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}}
```

```python
salt.output.raw.output(data, **kwargs)
    Rather basic....
```

25.12.15 salt.output.table_out

Display output in a table format

New in version 2017.7.0.

The table outputter displays a sequence of rows as table.

Example output:

```
edge01.bjm01:
--------
comment:  
out:  
--------
| Active | Interface | Last Move | Mac       | Moves | Static |
| Vlan   |           |           |           |       |        |
| True   | ae1.900   | 0.0       | 40:A6:77:5A:50:01 | 0     | False |
| 111    |           |           |           |       |        |
| True   | ae1.111   | 0.0       | 64:16:8D:32:26:58 | 0     | False |
| 111    |           |           |           |       |        |
| True   | ae1.111   | 0.0       | 8C:60:4F:73:2D:57 | 0     | False |
| 111    |           |           |           |       |        |
| True   | ae1.111   | 0.0       | 8C:60:4F:73:2D:7C | 0     | False |
| 111    |           |           |           |       |        |
| True   | ae.1222   | 0.0       | 8C:60:4F:73:2D:57 | 0     | False |
| 222    |           |           |           |       |        |
| True   | ae1.222   | 0.0       | F4:0F:1B:76:9D:97 | 0     | False |
| 222    |           |           |           |       |        |
```

(continues on next page)
CLI Example:

code
salt '*' foo.bar --out=table
endcode

```
class salt.output.table_out.TableDisplay(has_header=True, row_delimiter='-', delim='|',
                                         justify='center', separate_rows=True, prefix='|', suffix='|
                                         ', width=50, wrapfunc=None)
```

Manage the table display content.

```python
display(ret, indent, out, rows_key=None, labels_key=None)
```

Display table(s).

```python
display_rows(rows, labels, indent)
```

Prepares row content and displays.

```python
prepare_rows(rows, indent, has_header)
```

Prepare rows content to be displayed.

```python
ustring(indent, color, msg, prefix='', suffix='', endc=None)
```

Build the unicode string to be displayed.

```python
wrap_onspace(text)
```

When the text inside the column is longer then the width, will split by space and continue on the next line.

```
salt.output.table_out.output(ret, **kwargs)
```

Display the output as table.

Parameters

- **nested_indent** (*) -- integer, specify the left alignment.
- **has_header** (*) -- boolean specifying if header should be displayed. Default: True.
- **row_delimiter** (*) -- character to separate rows. Default: `-`.
- **delim** (*) -- character to separate columns. Default: " | ".
- **justify** (*) -- text alignment. Default: center.
- **separate_rows** (*) -- boolean specifying if row separator will be displayed between consecutive rows. Default: True.
- **prefix** (*) -- character at the beginning of the row. Default: " | ".
- **suffix** (*) -- character at the end of the row. Default: " | ".
- **width** (*) -- column max width. Default: 50.
- **rows_key** (*) -- display the rows under a specific key.
- **labels_key** (*) -- use the labels under a certain key. Otherwise will try to use the dictionary keys (if any).
- **title** (*) -- display title when only one table is selected (using the rows_key argument).
25.12.16 salt.output.txt

Simple text outputter

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

CLI Example:

```
salt '*' foo.bar --out=txt
```

```
salt.output.txt.output(data, **kwargs)
```

Output the data in lines, very nice for running commands

25.12.17 salt.output.virt_query

virt.query outputter

Used to display the output from the virt.query runner.

```
salt.output.virt_query.output(data, **kwargs)
```

Display output for the salt-run virt.query function

25.12.18 salt.output.yaml_out

Display return data in YAML format

This outputter defaults to printing in YAML block mode for better readability.

CLI Example:

```
salt '*' foo.bar --out=yaml
```

Example output:

```
saltmine:
  foo:
    bar: baz
  dictionary:
    abc: 123
    def: 456
  list:
    - Hello
    - World
```

```
salt.output.yaml_out.output(data, **kwargs)
```

Print out YAML using the block mode

25.12. output modules
# 25.13 pillar modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmd_json</td>
<td>Execute a command and read the output as JSON.</td>
</tr>
<tr>
<td>cmd_yaml</td>
<td>Execute a command and read the output as YAML.</td>
</tr>
<tr>
<td>cmd_yamlex</td>
<td>Execute a command and read the output as YAMLEX.</td>
</tr>
<tr>
<td>cobbler</td>
<td>A module to pull data from Cobbler via its API into the Pillar dictionary</td>
</tr>
<tr>
<td>confidant</td>
<td>An external pillar module for getting credentials from confidant.</td>
</tr>
<tr>
<td>consul_pillar</td>
<td>Use Consul K/V as a Pillar source with values parsed as YAML.</td>
</tr>
<tr>
<td>csvpillar</td>
<td>Store key/value pairs in a CSV file</td>

</tbody>
</table>

25.13.1 salt.pillar.cmd_json

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion's Pillar data.

Configuring the CMD_JSON ext_pillar

Set the following Salt config to setup cmd json result as external pillar source:

```
ext_pillar:
- cmd_json: 'echo {"arg":"value"}'
```

This will run the command `echo {arg: value}` on the master.

Module Documentation

`salt.pillar.cmd_json.ext_pillar(minion_id, pillar, command)`

Execute a command and read the output as JSON

25.13.2 salt.pillar.cmd_yaml

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data

`salt.pillar.cmd_yaml.ext_pillar(minion_id, pillar, command)`

Execute a command and read the output as YAML
**25.13.3 salt.pillar.cmd_yamlex**

Execute a command and read the output as YAMLEX.

The YAMLEX data is then directly overlaid onto the minion’s Pillar data

```
salt.pillar.cmd_yamlex.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAMLEX

**25.13.4 salt.pillar.cobbler**

A module to pull data from Cobbler via its API into the Pillar dictionary

**Configuring the Cobbler ext_pillar**

The same cobbler parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
ext_pillar:
  - cobbler:
      key: cobbler # Nest results within this key. By default, values are not nested.
      only: [parameters] # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api #default is http://localhost/
cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

**Module Documentation**

```
salt.pillar.cobbler.ext_pillar(minion_id, pillar, key=None, only=())
```

Read pillar data from Cobbler via its API.

**25.13.5 salt.pillar.confidant**

An external pillar module for getting credentials from confidant.

**Configuring the Confidant module**

The module can be configured via ext_pillar in the minion config:

```
ext_pillar:
  - confidant:
      profile:
        # The URL of the confidant web service url: 'https://confidant-production.example.com'
        # The context to use for KMS authentication auth_context: from: example-production-iad to: confidant-production-iad user_type: service # The KMS master key to use for authentication auth_key: "alias/authnz" # Cache file for KMS auth token token_cache_file:
```
/run/confidant/confidant_token # The duration of the validity of a token, in minutes token_duration: 60 # key, keyid and region can be defined in the profile, but it's generally best to use IAM roles or environment variables for AWS auth. keyid: 98nh9h908h09kjjk key: jhf908gyeghehe0he0g8h0u0j0n0n09hj09h0 region: us-east-1

depends
confidant-common, confidant-client

Module Documentation

salt.pillar.confidant.ext_pillar(minion_id, pillar, profile=None)
Read pillar data from Confidant via its API.

25.13.6 salt.pillar.consul_pillar

Use Consul K/V as a Pillar source with values parsed as YAML

depends
• python-consul

In order to use an consul server, a profile must be created in the master configuration file:

```yaml
my_consul_config:
  consul.host: 127.0.0.1
  consul.port: 8500
  consul.token: b6376760-a8bb-edd5-fcda-33bc13bfc556
  consul.scheme: http
  consul.consistency: default
  consul.dc: dev
  consul.verify: True
```

All parameters are optional.

The consul.token requires python-consul >= 0.4.7.

If you have a multi-datacenter Consul cluster you can map your pillar.env entries to your data centers by providing a dictionary of mappings in consul.dc field:

```yaml
my_consul_config:
  consul.dc:
    dev: us-east-1
    prod: us-west-1
```

In the example above we specifying static mapping between Pillar environments and data centers: the data for dev and prod Pillar environments will be fetched from us-east-1 and us-west-1 datacenter respectively.

In fact when consul.dc is set to dictionary keys are processed as regular expressions (that can capture named parameters) and values are processed as string templates as per PEP 3101.

```yaml
my_consul_config:
  consul.dc:
    ^dev-.*$: dev-datacenter
    ^(?P<region>\w+) prod$: prod-datacenter-{region}
```

25.13. pillar modules
This example maps all Pillar environments starting with `dev-` to `dev-datacenter` whereas Pillar environment like `eu-prod` will be mapped to `prod-datacenter-eu`.

Before evaluation patterns are sorted by length in descending order.

If Pillar environment names correspond to data center names a single pattern can be used:

```python
my_consul_config:
    consul.dc:
        ^((?P<env>.*))$: '{env}'
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified:

```yaml
ext_pillar:
    - consul: my_consul_config
ext_pillar:
    - consul: my_consul_config root=salt
```

Using these configuration profiles, multiple consul sources may also be used:

```yaml
ext_pillar:
    - consul: my_consul_config
    - consul: my_other_consul_config
```

Either the `minion_id`, or the `role`, or the `environment` grain may be used in the `root` path to expose minion-specific information stored in consul.

```yaml
ext_pillar:
    - consul: my_consul_config root=salt/%(minion_id)s
    - consul: my_consul_config root=salt/%(role)s
    - consul: my_consul_config root=salt/%(environment)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
    - consul: my_consul_config root=salt-shared
    - consul: my_other_consul_config root=salt-private/%(minion_id)s
```

If using the `role` or `environment` grain in the consul key path, be sure to define it using `/etc/salt/grains`, or similar:

```yaml
role: my-minion-role
environment: dev
```

It's possible to lock down where the pillar values are shared through minion targeting. Note that double quotes " are required around the target value and cannot be used inside the matching statement. See the section on Compound Matchers for more examples.

```yaml
ext_pillar:
    - consul: my_consul_config root=salt target="L@salt.example.com and\n      G@osarch:x86_64"
```

The data from Consul can be merged into a nested key in Pillar.

```yaml
ext_pillar:
    - consul: my_consul_config pillar_root=consul_data
```
By default, keys containing YAML data will be deserialized before being merged into Pillar. This behavior can be disabled by setting `expand_keys` to `false`.

```yaml
ext_pillar:
  - consul: my_consul_config expand_keys=false
```

```python
salt.pillar.consul_pillar.consul_fetch(client, path)
    Query consul for all keys/values within base path
salt.pillar.consul_pillar.ext_pillar(minion_id, pillar, conf)
    Check consul for all data
salt.pillar.consul_pillar.fetch_tree(client, path, expand_keys)
    Grab data from consul, trim base path and remove any keys which are folders. Take the remaining data and send it to be formatted in such a way as to be used as pillar data.
salt.pillar.consul_pillar.get_conn(opts, profile)
    Return a client object for accessing consul
salt.pillar.consul_pillar.pillar_format(ret, keys, value, expand_keys)
    Perform data formatting to be used as pillar data and merge it with the current pillar data

25.13.7 salt.pillar.csvpillar

Store key/value pairs in a CSV file

New in version 2016.11.0.

Example configuration:

```yaml
ext_pillar:
  - csv: /path/to/file.csv

# or

ext_pillar:
  - csv:
    path: /path/to/file.csv
    namespace: 'subkey'
    fieldnames:
      - col1
      - col2
      - col2
```

The first column must be minion IDs and the first row must be dictionary keys. E.g.:

<table>
<thead>
<tr>
<th>id</th>
<th>role</th>
<th>env</th>
</tr>
</thead>
<tbody>
<tr>
<td>jerry</td>
<td>web</td>
<td>prod</td>
</tr>
<tr>
<td>stuart</td>
<td>web</td>
<td>stage</td>
</tr>
<tr>
<td>dave</td>
<td>web</td>
<td>qa</td>
</tr>
<tr>
<td>phil</td>
<td>db</td>
<td>prod</td>
</tr>
<tr>
<td>kevin</td>
<td>db</td>
<td>stage</td>
</tr>
<tr>
<td>mike</td>
<td>db</td>
<td>qa</td>
</tr>
</tbody>
</table>
Will produce the following Pillar values for a minion named "jerry":

```
{
    'role': 'web',
    'env': 'prod',
}
```

```
salt.pillar.csvpillar.ext_pillar(mid, pillar, path, idkey='id', namespace=None, fieldnames=None, restkey=None, restval=None, dialect='excel')
```

Read a CSV into Pillar

Parameters

- **path**(str) -- Absolute path to a CSV file.
- **idkey**(str) -- (Optional) The column name of minion IDs.
- **namespace**(str) -- (Optional) A pillar key to namespace the values under.
- **fieldnames**(list) -- (Optional) if the first row of the CSV is not column names they may be specified here instead.

### 25.13.8 salt.pillar.digicert

Digicert Pillar Certificates

This module will only return pillar data if the digicert runner module has already been used to create certificates.

To configure this module, set **digicert** to True in the **ext_pillar** section of your master configuration file:

```
ext_pillar:
  - digicert: True
```

```
salt.pillar.digicert.ext_pillar(minion_id, pillar, conf)
```

Return an existing set of certificates

### 25.13.9 salt.pillar.django_orm

Generate Pillar data from Django models through the Django ORM

**maintainer**

Micah Hausler <micah.hausler@gmail.com>

**maturity**

new

Configuring the django_orm ext_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project's requirements installed.

```
ext_pillar:
  - django_orm:
      pillar_name: my_application
      project_path: /path/to/project/
      settings_module: my_application.settings
      env_file: /path/to/env/file.sh
      # Optional: If your project is not using the system python,
```

(continues on next page)
# add your virtualenv path below.
env: /path/to/virtualenv/

django_app:

    # Required: the app that is included in INSTALLED_APPS
    my_application.clients:

        # Required: the model name
        Client:

            # Required: model field to use as the key in the rendered
            # Pillar. Must be unique; must also be included in the
            # `fields` list below.
            name: shortname

            # Optional:
            # See Django's QuerySet documentation for how to use .filter()
            filter: {‘kw’: ‘args’}

            # Required: a list of field names
            # List items will be used as arguments to the .values() method.
            # See Django's QuerySet documentation for how to use .values()
            fields:
                - field_1
                - field_2

This would return pillar data that would look like

```
my_application:
    my_application.clients:
        Client:
            client_1:
                field_1: data_from_field_1
                field_2: data_from_field_2
            client_2:
                field_1: data_from_field_1
                field_2: data_from_field_2
```

As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using ManyToManyFields will not currently work since the return from values() changes if a ManyToMany is present.

```
ext_pillar:
    - django_orm:
        pillar_name: djangotutorial
        project_path: /path/to/mysite
        settings_module: mysite.settings

        django_app:
            mysite.polls:
                Choices:
                    name: poll__question
```

(continues on next page)
fields:
- poll__question
- poll__id
- choice_text
- votes

Module Documentation

call.pillar django_orm.ext_pillar

Connect to a Django database through the ORM and retrieve model fields

Parameters

- pillar_name (str) -- The name of the pillar to be returned
- project_path (str) -- The full path to your Django project (the directory manage.py is in)
- settings_module (str) -- The settings module for your project. This can be found in your manage.py file
- django_app (str) -- A dictionary containing your apps, models, and fields
- env (str) -- The full path to the virtualenv for your Django project
- env_file (str) -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

25.13.10 call.pillar.ec2_pillar

Retrieve EC2 instance data for minions for ec2_tags and ec2_tags_list

The minion id must be the AWS instance-id or value in tag_match_key. For example set tag_match_key to Name to have the minion-id matched against the tag 'Name'. The tag contents must be unique. The value of tag_match_value can be 'uqdn' or 'asis'. if 'uqdn', then the domain will be stripped before comparison.

Additionally, the use_grain option can be set to True. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.

Note: If you are using use_grain: True in the configuration for this external pillar module, the minion must have metadata_server_grains enabled in the minion config file (see also here).

It is important to also note that enabling the use_grain option allows the minion to manipulate the pillar data returned, as described above.

The optional tag_list_key indicates which keys should be added to ec2_tags_list and be split by tag_list_sep (by default ;). If a tag key is included in tag_list_key it is removed from ec2_tags. If a tag does not exist it is still included as an empty list.

Note: As with any master configuration change, restart the salt-master daemon for changes to take effect.
This is a very simple pillar configuration that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

```python
tag_match_key: 'Name'
tag_match_value: 'asis'
tag_list_key:
- Role
tag_list_sep: ';'
use_grain: True
minion_ids:
- trusted-minion-1
- trusted-minion-2
- trusted-minion-3
```

Execute a command and read the output as YAML

25.13.11 salt.pillar.etcd_pillar

Use etcd data as a Pillar source

New in version 2014.7.0.

```yaml
depends
- python-etcd or etcd3-py
```

In order to use an etcd server, a profile must be created in the master configuration file:

```yaml
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

In order to choose whether to use etcd API v2 or v3, you can put the following configuration option in the same place as your etcd configuration. This option defaults to true, meaning you will use v2 unless you specify otherwise.

```yaml
etcd.require_v2: True
```

When using API v3, there are some specific options available to be configured within your etcd profile. They are defaulted to the following...

```yaml
etcd.encode_keys: False
etcd.encode_values: True
etcd.raw_keys: False
etcd.raw_values: False
etcd.unicode_errors: "surrogateescape"
```

etcd.encode_keys indicates whether you want to pre-encode keys using msgpack before adding them to etcd.

Note: If you set etcd.encode_keys to True, all recursive functionality will no longer work. This includes tree and ls and all other methods if you set recurse/recursive to True. This is due to the fact that when
encoding with msgpack, keys like /salt and /salt/stack will have differing byte prefixes, and etcd v3 searches recursively using prefixes.

etcd.encode_values indicates whether you want to pre-encode values using msgpack before adding them to etcd. This defaults to True to avoid data loss on non-string values wherever possible.

etcd.raw_keys determines whether you want the raw key or a string returned.

etcd.raw_values determines whether you want the raw value or a string returned.

etcd.unicode_errors determines what you policy to follow when there are encoding/decoding errors.

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```yaml
ext_pillar:
  - etcd: my_etcd_config

ext_pillar:
  - etcd: my_etcd_config root=/salt
```

Using these configuration profiles, multiple etcd sources may also be used:

```yaml
ext_pillar:
  - etcd: my_etcd_config
  - etcd: my_other_etcd_config
```

The minion_id may be used in the root path to expose minion-specific information stored in etcd.

```yaml
ext_pillar:
  - etcd: my_etcd_config root=/salt/%(minion_id)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
  - etcd: my_etcd_config root=/salt-shared
  - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s
```

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:

```
etcdctl set /salt-shared/mykey my_value
etcdctl set /salt-private/special_minion_id/mykey my_other_value
```

salt.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)

Check etcd for all data

### 25.13.12 salt.pillar.extra_minion_data_in_pillar

Add all extra minion data to the pillar.

```python
codeauthor
Alexandru.Bleotu@morganstanley.ms.com
```

One can filter on the keys to include in the pillar by using the include parameter. For subkeys the ‘:’ notation is supported (i.e. ‘key:subkey’) The keyword ‘<all>’ includes all keys.
Complete example in etc/salt/master

```yaml
ext_pillar:
  - extra_minion_data_in_pillar:
      include: *

ext_pillar:
  - extra_minion_data_in_pillar:
      include:
        - key1
        - key2:subkey2

ext_pillar:
  - extra_minion_data_in_pillar:
      include: <all>
```

```
salt.pillar.extra_minion_data_in_pillar.ext_pillar(minion_id, pillar, include, extra_minion_data=None)
```

## 25.13.13 salt.pillar.file_tree

The `file_tree` external pillar allows values from all files in a directory tree to be imported as Pillar data.

**Note:** This is an external pillar and is subject to the rules and constraints governing external pillars.

New in version 2015.5.0.

In this pillar, data is organized by either Minion ID or Nodegroup name. To setup pillar data for a specific Minion, place it in `<root_dir>/hosts/<minion_id>`. To setup pillar data for an entire Nodegroup, place it in `<root_dir>/nodegroups/<node_group>` where `<node_group>` is the Nodegroup's name.

### Example file_tree Pillar

#### Master Configuration

```yaml
ext_pillar:
  - file_tree:
      root_dir: /srv/ext_pillar
      follow_dir_links: False
      keep_newline: True
```

The `root_dir` parameter is required and points to the directory where files for each host are stored. The `follow_dir_links` parameter is optional and defaults to False. If `follow_dir_links` is set to True, this external pillar will follow symbolic links to other directories.

**Warning:** Be careful when using `follow_dir_links`, as a recursive symlink chain will result in unexpected results.

25.13. pillar modules 3555
Changed in version 2018.3.0: If `root_dir` is a relative path, it will be treated as relative to the `pillar_roots` of the environment specified by `pillarenv`. If an environment specifies multiple roots, this module will search for files relative to all of them, in order, merging the results.

If `keep_newline` is set to `True`, then the pillar values for files ending in newlines will keep that newline. The default behavior is to remove the end-of-file newline. `keep_newline` should be turned on if the pillar data is intended to be used to deploy a file using `contents_pillar` with a `file.managed` state.

Changed in version 2015.8.4: The `raw_data` parameter has been renamed to `keep_newline`. In earlier releases, `raw_data` must be used. Also, this parameter can now be a list of globs, allowing for more granular control over which pillar values keep their end-of-file newline. The globs match paths relative to the directories named for minion IDs and nodegroups underneath the `root_dir` (see the layout examples in the below sections).

```yaml
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      keep_newline:
        - files/testdir/*
```

**Note:** In earlier releases, this documentation incorrectly stated that binary files would not affect the `keep_newline` configuration. However, this module does not actually distinguish between binary and text files.

Changed in version 2017.7.0: Templating/rendering has been added. You can now specify a default render pipeline and a black- and whitelist of (dis)allowed renderers.

`template` must be set to `True` for templating to happen.

```yaml
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      render_default: jinja|yaml
      renderer_blacklist:
        - gpg
      renderer_whitelist:
        - jinja
        - yaml
      template: True
```

**Assigning Pillar Data to Individual Hosts**

To configure pillar data for each host, this external pillar will recursively iterate over `root_dir/hosts/id` (where `id` is a minion ID), and compile pillar data with each subdirectory as a dictionary key and each file as a value.

For example, the following `root_dir` tree:

```
./hosts/
./hosts/test-host/
./hosts/test-host/files/
./hosts/test-host/files/testdir/
./hosts/test-host/files/testdir/file1.txt
./hosts/test-host/files/testdir/file2.txt
./hosts/test-host/files/another-testdir/
./hosts/test-host/files/another-testdir/symlink-to-file1.txt
```
will result in the following pillar tree for minion with ID test-host:

```
test-host:  
    --------
    apache:  
        --------
        config.d:  
            --------
            00_important.conf:  
                <important_config important_setting="yes" />
            20_bob_extra.conf:  
                <bob_specific_cfg has_freeze_ray="yes" />
    corporate_app:  
        --------
        settings:  
            --------
            common_settings:  
                // This is the main settings file for the corporate  
                // internal web app  
                main_setting: probably
            bob_settings:  
                role: bob
```

**Note:** The leaf data in the example shown is the contents of the pillar files.

salt.pillar.file_tree.ext_pillar(minion_id, pillar, root_dir=None, follow_dir_links=False, debug=False, keep_newline=False, render_default=None, renderer_blacklist=None, renderer_whitelist=None, template=False)

Compile pillar data from the given root_dir specific to Nodegroup names and Minion IDs.

If a Minion's ID is not found at <root_dir>/host/<minion_id> or if it is not included in any Nodegroups named at <root_dir>/nodegroups/<node_group>, no pillar data provided by this pillar module will be available for that Minion.

Changed in version 2017.7.0: Templating/rendering has been added. You can now specify a default render pipeline and a black- and whitelist of (dis)allowed renderers.

**template** must be set to True for templating to happen.

```
ext_pillar:
    - file_tree:
        root_dir: /path/to/root/directory
        render_default: jinja|yaml
        renderer_blacklist:
            - gpg
        renderer_whitelist:
            - jinja
            - yaml
        template: True
```

Parameters
- **minion_id** -- The ID of the Minion whose pillar data is to be collected
- **pillar** -- Unused by the file_tree pillar module
- **root_dir** -- Filesystem directory used as the root for pillar data (e.g. /srv/ext_pillar)

  Changed in version 2018.3.0: If root_dir is a relative path, it will be treated as relative to the `pillar_roots` of the environment specified by `pillarenv`. If an environment specifies multiple roots, this module will search for files relative to all of them, in order, merging the results.

- **follow_dir_links** -- Follow symbolic links to directories while collecting pillar files. Defaults to False.

  **Warning**: Care should be exercised when enabling this option as it will follow links that point outside of root_dir.

  **Warning**: Symbolic links that lead to infinite recursion are not filtered.

- **debug** -- Enable debug information at log level debug. Defaults to False. This option may be useful to help debug errors when setting up the file_tree pillar module.

- **keep_newline** -- Preserve the end-of-file newline in files. Defaults to False. This option may either be a boolean or a list of file globs (as defined by the Python fnmatch package) for which end-of-file newlines are to be kept.

  keep_newline should be turned on if the pillar data is intended to be used to deploy a file using `contents_pillar` with a `file.managed` state.

  Changed in version 2015.8.4: The raw_data parameter has been renamed to keep_newline. In earlier releases, raw_data must be used. Also, this parameter can now be a list of globs, allowing for more granular control over which pillar values keep their end-of-file newline. The globs match paths relative to the directories named for Minion IDs and Nodegroup names underneath the root_dir.

  **ext_pillar**:
  ```
  - file_tree:
    root_dir: /srv/ext_pillar
    keep_newline:
      - apache/config.d/*
      - corporate_app/settings/*
  ```

  **Note**: In earlier releases, this documentation incorrectly stated that binary files would not affected by the keep_newline. However, this module does not actually distinguish between binary and text files.

- **render_default** -- Override Salt’s default global renderer for the file_tree pillar.

  ```
  render_default: jinja
  ```

- **renderer_blacklist** -- Disallow renderers for pillar files.

  ```
  renderer_blacklist:
    - json
  ```

- **renderer_whitelist** -- Allow renderers for pillar files.
renderer_whitelist:
- yaml
- jinja

- **template** -- Enable templating of pillar files. Defaults to `False`.

## 25.13.14 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

### Configuring the Foreman ext_pillar

Set the following Salt config to setup Foreman as external pillar source:

```yaml
ext_pillar:
- foreman:
  key: foreman # Nest results within this key
  only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar

foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```

The following options are optional:

- **foreman.api**: apiversion # default is 2 (1 is not supported yet)
- **foreman.verifyssl**: False # default is True
- **foreman.certfile**: /etc/ssl/certs/mycert.pem # default is None
- **foreman.keyfile**: /etc/ssl/private/mykey.pem # default is None
- **foreman.cafile**: /etc/ssl/certs/mycert.ca.pem # default is None
- **foreman.lookup_parameters**: True # default is True

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on [GitHub](https://github.com).

### Module Documentation

salt.pillar.foreman.**ext_pillar**(minion_id, pillar, key=None, only=())

Read pillar data from Foreman via its API.
25.13.15 salt.pillar.git_pillar

Use a git repository as a Pillar source

This external pillar allows for a Pillar top file and Pillar SLS files to be sourced from a git repository. However, since git_pillar does not have an equivalent to the pillar_roots parameter, configuration is slightly different. A Pillar top file is required to be in the git repository and must still contain the relevant environment, like so:

```
base:
  'x*':
    - foo
```

The branch/tag which maps to that environment must then be specified along with the repo's URL. Configuration details can be found below.

**Important:** Each branch/tag used for git_pillar must have its own top file. This is different from how the top file works when configuring States. The reason for this is that each git_pillar branch/tag is processed separately from the rest. Therefore, if the qa branch is to be used for git_pillar, it would need to have its own top file, with the qa environment defined within it, like this:

```
qa:
  'dev-*':
    - bar
```

Additionally, while git_pillar allows for the branch/tag to be overridden (see here), keep in mind that the top file must reference the actual environment name. It is common practice to make the environment in a git_pillar top file match the branch/tag name, but when remapping, the environment of course no longer matches the branch/tag, and the top file needs to be adjusted accordingly. When expected Pillar values configured in git_pillar are missing, this is a common misconfiguration that may be to blame, and is a good first step in troubleshooting.

Configuring git_pillar for Salt

Beginning with Salt version 2015.8.0, pygit2 is now supported in addition to GitPython. The requirements for GitPython and pygit2 are the same as for GitFS, as described here.

**Important:** git_pillar has its own set of global configuration parameters. While it may seem intuitive to use the global gitfs configuration parameters (gitfs_base, etc.) to manage git_pillar, this will not work. The main difference for this is the fact that the different components which use Salt's git backend code do not all function identically. For instance, in git_pillar it is necessary to specify which branch/tag to be used for git_pillar remotes. This is the reverse behavior from gitfs, where branches/tags make up your environments.

See here for documentation on the git_pillar configuration options and their usage.

Here is an example git_pillar configuration:

```
ext_pillar:
  - git:
    # Use 'prod' instead of the branch name 'production' as the environment
    production https://gitserver/git-pillar.git:
```

(continues on next page)
The main difference between this and the old way of configuring git_pillar is that multiple remotes can be configured under one git section under ext_pillar. More than one git section can be used, but it is not necessary. Remotes will be evaluated sequentially.

Per-remote configuration parameters are supported (similar to gitfs), and global versions of the git_pillar configuration parameters can also be set.

To remap a specific branch to a specific Pillar environment, use the env per-remote parameter:

```yaml
ext_pillar:
  - git:
      production https://gitserver/git-pillar.git:
        env: prod
```

If __env__ is specified as the branch name, then git_pillar will decide which branch to use based on the following criteria:

- If the minion has a pillarenv configured, it will use that pillar environment. (2016.11.2 and later)
- Otherwise, if the minion has an environment configured, it will use that environment.
- Otherwise, the master’s git_pillar_base will be used.

**Note:** The use of environment to choose the pillar environment dates from a time before the pillarenv parameter was added. In a future release, it will be ignored and either the minion’s pillarenv or the master’s git_pillar_base will be used.

Here’s an example of using __env__ as the git_pillar environment:

```yaml
ext_pillar:
  - git:
      __env__ https://gitserver/git-pillar.git:
        root: pillar
```

The corresponding Pillar top file would look like this:
"{{saltenv}}":
  '*: 
    - bar

With the addition of pygit2 support, git_pillar can now interact with authenticated remotes. Authentication works just like in gitfs (as outlined in the Git Fileserver Backend Walkthrough), only with the global authentication parameter names prefixed with git_pillar instead of gitfs (e.g. git_pillar_pubkey, git_pillar_privkey, git_pillar_passphrase, etc.).

Note: The name parameter can be used to further differentiate between two remotes with the same URL and branch. When using two remotes with the same URL, the name option is required.

How Multiple Remotes Are Handled

As noted above, multiple remotes can be included in the same git ext_pillar configuration. Consider the following:

```
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
ext_pillar:
  - etcd: my_etcd_config
  - git:
    - master https://mydomain.tld/foo.git:
      - root: pillar
    - master https://mydomain.tld/bar.git
    - master https://mydomain.tld/baz.git
    - dev https://mydomain.tld/qux.git
  - git:
    - master https://mydomain.tld/abc.git
    - dev https://mydomain.tld/123.git
```

To understand how pillar data from these repos will be compiled, it's important to know how Salt will process them. The following points should be kept in mind:

1. Each ext_pillar is called separately from the others. So, in the above example, the etcd ext_pillar will be evaluated first, with the first group of git_pillar remotes evaluated next (and merged into the etcd pillar data). Lastly, the second group of git_pillar remotes will be evaluated, and then merged into the ext_pillar data evaluated before it.

2. Within a single group of git_pillar remotes, each remote will be evaluated in order, with results merged together as each remote is evaluated.

Note: Prior to the 2017.7.0 release, remotes would be evaluated in a non-deterministic order.

3. By default, when a repo is evaluated, other remotes' which share its pillar environment will have their files made available to the remote being processed.

The first point should be straightforward enough, but the second and third could use some additional clarification. First, point #2. In the first group of git_pillar remotes, the top file and pillar SLS files in the foo remote will be evaluated first. The bar remote will be evaluated next, and its results will be merged into the pillar data compiled...
when the `foo` remote was evaluated. As the subsequent remotes are evaluated, their data will be merged in the same fashion.

But wait, don't these repositories belong to more than one pillar environments? Well, yes. The default method of generating pillar data compiles pillar data from all environments. This behavior can be overridden using a `pillarenv`. Setting a `pillarenv` in the minion config file will make that minion tell the master to ignore any pillar data from environments which don't match that pillarenv. A pillarenv can also be specified for a given minion or set of minions when running states, by using the `pillarenv` argument. The CLI pillarenv will override one set in the minion config file. So, assuming that a pillarenv of `base` was set for a minion, it would not get any of the pillar variables configured in the `qux` remote, since that remote is assigned to the `dev` environment. The only way to get its pillar data would be to specify a pillarenv of `dev`, which would mean that it would then ignore any items from the `base` pillarenv. A more detailed explanation of pillar environments can be found here.

Moving on to point #3, and looking at the example `ext_pillar` configuration, as the `foo` remote is evaluated, it will also have access to the files from the `bar` and `baz` remotes, since all three are assigned to the `base` pillar environment. So, if an SLS file referenced by the `foo` remotes's top file does not exist in the `foo` remote, it will be searched for in the `bar` remote, followed by the `baz` remote. When it comes time to evaluate the `bar` remote, SLS files referenced by the `bar` remote's top file will first be looked for in the `bar` remote, followed by `foo`, and `baz`, and when the `baz` remote is processed, SLS files will be looked for in `baz`, followed by `foo` and `bar`. This "failover" logic is called a directory overlay, and it is also used by `file_roots` and `:conf_minion\pillar_roots`. The ordering of which remote is checked for SLS files is determined by the order they are listed. First the remote being processed is checked, then the others that share the same environment are checked. However, before the 2017.7.0 release, since evaluation was unordered, the remote being processed would be checked, followed in no specific order by the other repos which share the same environment.

Beginning with the 2017.7.0 release, this behavior of git_pillar remotes having access to files in other repos which share the same environment can be disabled by setting `git_pillar_includes` to `False`. If this is done, then all git_pillar remotes will only have access to their own SLS files. Another way of ensuring that a git_pillar remote will not have access to SLS files from other git_pillar remotes which share the same pillar environment is to put them in a separate `git` section under `ext_pillar`. Look again at the example configuration above. In the second group of git_pillar remotes, the `abc` remote would not have access to the SLS files from the `foo`, `bar`, and `baz` remotes, and vice-versa.

**Mountpoints**

New in version 2017.7.0.

Assume the following pillar top file:

```yaml
base:
  'web*':
    - common
    - web.server.nginx
    - web.server.appdata
```

Now, assume that you would like to configure the `web.server.nginx` and `web.server.appdata` SLS files in separate repos. This could be done using the following `ext_pillar` configuration (assuming that `git_pillar_includes` has not been set to `False`):

```yaml
ext_pillar:
  - git:
      - master https://mydomain.tld/pillar-common.git
      - master https://mydomain.tld/pillar-nginx.git
      - master https://mydomain.tld/pillar-appdata.git
```
However, in order to get the files in the second and third git_pillar remotes to work, you would need to first create
the directory structure underneath it (i.e. place them underneath web/server/ in the repository). This also makes
it tedious to reorganize the configuration, as changing web.server.nginx to web.nginx in the top file would
require you to also move the SLS files in the pillar-nginx up a directory level.

For these reasons, much like gitfs, git_pillar now supports a "mountpoint" feature. Using the following ext_pillar
configuration, the SLS files in the second and third git_pillar remotes can be placed in the root of the git repository:

```yaml
ext_pillar:
  - git:
    - master https://mydomain.tld/pillar-common.git
    - master https://mydomain.tld/pillar-nginx.git:
      - mountpoint: web/server/
    - master https://mydomain.tld/pillar-appdata.git:
      - mountpoint: web/server/
```

Now, if the top file changed the SLS target from web.server.nginx, instead of reorganizing the git repository,
you would just need to adjust the mountpoint to web/ (and restart the salt-master daemon).

Note:

- Leading and trailing slashes on the mountpoints are optional.
- Use of the mountpoint feature requires that git_pillar_includes is not disabled.
- Content from mounted git_pillar repos can only be referenced by a top file in the same pillar environment.
- Salt versions prior to 2018.3.4 ignore the root parameter when mountpoint is set.

all_saltenvs

New in version 2018.3.4.

When __env__ is specified as the branch name, all_saltenvs per-remote configuration parameter overrides
the logic Salt uses to map branches/tags to pillar environments (i.e. pillarenvs). This allows a single branch/tag to
appear in all saltenvs. Example:

```yaml
ext_pillar:
  - git:
    - __env__ https://mydomain.tld/top.git
      all_saltenvs: master
    - __env__ https://mydomain.tld/pillar-nginx.git:
      mountpoint: web/server/
    - __env__ https://mydomain.tld/pillar-appdata.git:
      mountpoint: web/server/
```
**git_pillar_update_interval**

New in version 3000.

This option defines the default update interval (in seconds) for git_pillar remotes. The update is handled within the global loop, hence `git_pillar_update_interval` should be a multiple of `loop_interval`.

```
git_pillar_update_interval: 120
```

**fallback**

New in version 3001.

Setting `fallback` per-remote or global configuration parameter will map non-existing environments to a default branch. Example:

```
ext_pillar:
  - git:
      - __env__ https://mydomain.tld/top.git
        all_saltenvs: master
      - __env__ https://mydomain.tld/pillar-nginx.git:
        mountpoint: web/server/
        fallback: master
      - __env__ https://mydomain.tld/pillar-appdata.git:
        mountpoint: web/server/
        fallback: master
```

```
salt.pillar.git_pillar.ext_pillar(minion_id, pillar, *repos)
```

Checkout the ext_pillar sources and compile the resulting pillar SLS

### 25.13.16 salt.pillar.gpg

Decrypt pillar data through the builtin GPG renderer

In most cases, you'll want to make this the last external pillar used. For example, to pair with the builtin stack pillar you could do something like this:

```
ext_pillar:
  - stack: /path/to/stack.cfg
  - gpg: {}
```

Set `gpg_keydir` in your config to adjust the homedir the renderer uses.

```
salt.pillar.gpg.ext_pillar(minion_id, pillar, *args, **kwargs)
```

25.13. pillar modules
25.13.17  salt.pillar.hg_pillar

Use remote Mercurial repository as a Pillar source.
New in version 2015.8.0.
The module depends on the hglib python module being available. This is the same requirement as for hgfs_ so should not pose any extra hurdles.
This external Pillar source can be configured in the master config file as such:

```
ext_pillar:
  - hg: ssh://hg@example.co/user/repo
```

class salt.pillar.hg_pillar.Repo(repo_uri)

Deal with remote hg (mercurial) repository for Pillar

    close()

    Cleanup mercurial command server

    pull()

    update(branch='default')

    Ensure we are using the latest revision in the hg repository

salt.pillar.hg_pillar.ext_pillar(minion_id, pillar, repo, branch='default', root=None)

    Extract pillar from an hg repository

salt.pillar.hg_pillar.update(repo_uri)

    Execute an hg pull on all the repos

25.13.18  salt.pillar.hiera

Use hiera data as a Pillar source

salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)

    Execute hiera and return the data

25.13.19  salt.pillar.http_json

A module that adds data to the Pillar structure retrieved by an http request

Configuring the HTTP_JSON ext_pillar

Set the following Salt config to setup http json result as external pillar source:

```
ext_pillar:
  - http_json:
      url: http://example.com/api/minion_id
      namespace: 'subkey'
      username: username
      password: password
      header_dict: None
      auth: None
```
You can pass additional parameters, they will be added to the http.query call\n\n\nYou can pass additional parameters, they will be added to the http.query call **utils.http.query function**:  

**Changed in version 3006.0:** If namespace is defined, the data will be added under the specified subkeys in the Pillar structure.  

If the `with_grains` parameter is set, grain keys wrapped in can be provided (wrapped in <> brackets) in the url in order to populate pillar data based on the grain value.

```python
ext_pillar:
  - http_json:
      url: http://example.com/api/<nodename>
      with_grains: True
```

**Changed in version 2018.3.0:** If %s is present in the url, it will be automatically replaced by the minion_id:

```python
ext_pillar:
  - http_json:
      url: http://example.com/api/%s
```

### Module Documentation

**salt.pillar.http_json.ext_pillar**(*minion_id, pillar, url, with_grains=False, header_dict=None, auth=None, username=None, password=None, namespace=None*)

Read pillar data from HTTP response.

#### Parameters

- **url** (*str*) -- Url to request.  
- **with_grains** (*bool*) -- Whether to substitute strings in the url with their grain values.  
- **header_dict** (*dict*) -- Extra headers to send  
- **auth** -- special auth if needed  
- **username** (*str*) -- username for auth  
- **password** (*str*) -- password for auth  
- **namespace** (*str*) -- (Optional) A pillar key to namespace the values under. .. versionadded:: 3006.0

#### Returns

- A dictionary of the pillar data to add.

#### Return type

- **dict**
25.13.20  salt.pillar.http_yaml

A module that adds data to the Pillar structure retrieved by an http request

Configuring the HTTP_YAML ext_pillar

Set the following Salt config to setup an http endpoint as the external pillar source:

```
ext_pillar:
  - http_yaml:
      url: http://example.com/api/minion_id
      username: username
      password: password
      header_dict: None
      auth: None
```

You can pass additional parameters, they will be added to the http.query call `utils.http.query function`:

If the with_grains parameter is set, grain keys wrapped in can be provided (wrapped in <> brackets) in the url in order to populate pillar data based on the grain value.

```
ext_pillar:
  - http_yaml:
      url: http://example.com/api/<nodename>
      with_grains: True
```

Changed in version 2018.3.0: If %s is present in the url, it will be automatically replaced by the minion_id:

```
ext_pillar:
  - http_json:
      url: http://example.com/api/%s
```

Module Documentation

salt.pillar.http_yaml.ext_pillar(minion_id, pillar, url, with_grains=False, header_dict=None, auth=None, username=None, password=None)

Read pillar data from HTTP response.

Parameters
- url (`str`) -- Url to request.
- with_grains (`bool`) -- Whether to substitute strings in the url with their grain values.
- header_dict (`dict`) -- Extra headers to send
- username (`str`) -- username for auth
- password (`str`) -- password for auth
- auth -- special auth if needed

Returns
A dictionary of the pillar data to add.

Return type
`dict`
25.13.21 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

depends
certtool

salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)
Read in the generated libvirt keys

salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted', expiration_days='365')
Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions

25.13.22 salt.pillar.makostack

Simple and flexible YAML ext_pillar which can read pillar from within pillar.

New in version 2016.3.0.

This custom saltstack ext_pillar is a direct ripoff of the ‘stack’ ext_pillar, simply ported to use mako instead of jinja2 for templating.

It supports the following features:

- multiple config files that are mako templates with support for pillar, __grains__, __salt__, __opts__ objects.
- a config file renders as an ordered list of files. Unless absolute, the paths of these files are relative to the current config file - if absolute, they will be treated literally.
- this list of files are read in order as mako templates with support for stack, pillar, __grains__, __salt__, __opts__ objects.
- all these rendered files are then parsed as yaml.
- then all yaml dicts are merged in order, with support for the following, merging strategies: merge-first, merge-last, remove, and overwrite.
- stack config files can be matched based on pillar, grains, or opts values, which make it possible to support kind of self-contained environments.

Configuration in Salt

Like any other external pillar, its configuration takes place through the ext_pillar key in the master config file.

However, you can configure MakoStack in 3 different ways:
Single config file

This is the simplest option, you just need to set the path to your single MakoStack config file like below:

```
ext_pillar:
    - makostack: /path/to/stack.cfg
```

List of config files

You can also provide a list of config files:

```
ext_pillar:
    - makostack:
      - /path/to/stack1.cfg
      - /path/to/stack2.cfg
```

Select config files through grains|pillar|opts matching

You can also opt for a much more flexible configuration: MakoStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:

```
ext_pillar:
    - makostack:
      pillar:environment:
        dev: /path/to/dev/stack.cfg
        prod: /path/to/prod/stack.cfg
      grains:custom:grain:
        value:
          - /path/to/stack1.cfg
          - /path/to/stack2.cfg
      opts:custom:opt:
        value: /path/to/stack0.cfg
```

Grafting data from files to arbitrary namespaces

An extended syntax for config files permits defining "graft points" on a per-config-file basis. As an example, if the file foo.cfg would produce the following:

```
foo:
  - bar
  - baz
```

and you specified the cfg file as /path/to/foo.cfg:yummy:fur, the following would actually end up in pillar after all merging was complete:

```
yummy:
  fur:
    foo:
```
MakoStack configuration files

The config files that are referenced in the above `ext_pillar` configuration are mako templates which must render as a simple ordered list of yaml files that will then be merged to build pillar data.

Unless an absolute path name is specified, the path of these yaml files is assumed to be relative to the directory containing the MakoStack config file. If a path begins with '/', however, it will be treated literally and can be anywhere on the filesystem.

The following variables are available in mako templating of makostack configuration files:

- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-)  
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of mako to build your list of yaml files that will be merged in pillar data.

For example, you could have a MakoStack config file which looks like:

```
$ cat /path/to/stack/config.cfg
core.yml
osarchs/%{ __grains__['osarch'] }.yml
oscodenames/%{ __grains__['oscodename'] }.yml
% for role in pillar.get('roles', []):
  roles/%{ role }.yml
% endfor
minions/%{ minion_id }.yml
```

And the whole directory structure could look like:

```
$ tree /path/to/stack/
/path/to/stack/
  config.cfg
  core.yml
  osarchs/
    amd64.yml
    armhf.yml
  oscodenames/
    wheezy.yml
    jessie.yml
  roles/
    web.yml
    db.yml
  minions/
```

(continues on next page)
Overall process

In the above MakoStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and which pillar roles is ["db"], the following yaml files would be merged in order:

- core.yml
- osarchs/amd64.yml
- oscodenames/jessie.yml
- roles/db.yml
- minions/test-1-dev.yml

Before merging, every files above will be preprocessed as mako templates. The following variables are available in mako templating of yaml files:

- `stack`: the MakoStack pillar data object that has currently been merged (data from previous yaml files in MakoStack configuration)
- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-)  
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of mako to build your pillar data, and even use other pillar values that has already been merged by MakoStack (from previous yaml files in MakoStack configuration) through the `stack` variable.

Once a yaml file has been preprocessed by mako, we obtain a Python dict - let’s call it `yml_data` - then, MakoStack will merge this `yml_data` dict in the main `stack` dict (which contains already merged MakoStack pillar data). By default, MakoStack will deeply merge `yml_data` in `stack` (similarly to the `recurse` salt `pillar_source_merging_strategy`), but 3 merging strategies are currently available for you to choose (see next section).

Once every yaml files have been processed, the `stack` dict will contain your whole own pillar data, merged in order by MakoStack. So MakoStack `ext_pillar` returns the `stack` dict, the contents of which Salt takes care to merge in with all of the other pillars and finally return the whole pillar to the minion.

Merging strategies

The way the data from a new `yml_data` dict is merged with the existing `stack` data can be controlled by specifying a merging strategy. Right now this strategy can either be `merge-last` (the default), `merge-first`, `remove`, or `overwrite`.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the `overwrite` strategy (other strategies don't make sense in that case).

The merging strategy can be set by including a dict in the form of:
as the first item of the dict or list. This allows fine grained control over the merging process.

**merge-last (default) strategy**

If the merge-last strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the `recurrse salt pillar_source_merging_strategy`). This allows for extending previously defined data.

**merge-first strategy**

If the merge-first strategy is selected, then the content of dict or list variables are swapped between the yaml_data and stack objects before being merged recursively with the merge-last previous strategy.

**remove strategy**

If the remove strategy is selected, then content of dict or list variables in stack are removed only if the corresponding item is present in the yaml_data dict. This allows for removing items from previously defined data.

**overwrite strategy**

If the overwrite strategy is selected, then the content of dict or list variables in stack is overwritten by the content of yaml_data dict. So this allows one to overwrite variables from previous definitions.

**Merging examples**

Let's go through small examples that should clarify what's going on when a yaml_data dict is merged in the stack dict.

When you don't specify any strategy, the default merge-last strategy is selected:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td>users:</td>
<td>users:</td>
<td>users:</td>
</tr>
<tr>
<td>tom:</td>
<td>tom:</td>
<td>tom:</td>
</tr>
<tr>
<td>uid: 500</td>
<td>uid: 1000</td>
<td>uid: 1000</td>
</tr>
<tr>
<td>roles:</td>
<td>roles:</td>
<td>roles:</td>
</tr>
<tr>
<td>- sysadmin</td>
<td>- developer</td>
<td>- sysadmin</td>
</tr>
<tr>
<td>root:</td>
<td>mat:</td>
<td>root:</td>
</tr>
<tr>
<td>uid: 0</td>
<td>uid: 1001</td>
<td>uid: 0</td>
</tr>
</tbody>
</table>

Then you can select a custom merging strategy using the __ key in a dict:
<table>
<thead>
<tr>
<th>Stack</th>
<th>YAML Data</th>
<th>Stack (after merge)</th>
</tr>
</thead>
</table>
| users:  
  tom:   
    uid: 500  
    roles:  
      - sysadmin  
  root:  
    uid: 0 | users:  
  tom:   
    uid: 1000  
    roles:  
      - developer  
  mat:  
    uid: 1001 | users:  
  tom:   
    uid: 1000  
    roles:  
      - sysadmin  
      - developer  
  mat:  
    uid: 1001  
    root:  
      uid: 0 |
| users:  
  tom:   
    uid: 500  
    roles:  
      - sysadmin  
  root:  
    uid: 0 | users:  
  tom:   
    uid: 1000  
    roles:  
      - developer  
      - sysadmin  
  mat:  
    uid: 1001  
  root:  
    uid: 0 | users:  
  root:  
    uid: 0 |
| users:  
  tom:   
    uid: 500  
    roles:  
      - sysadmin  
  root:  
    uid: 0 | users:  
  tom:   
    uid: 1000  
    roles:  
      - developer  
  mat:  
    uid: 1001 | users:  
  tom:   
    uid: 1000  
    roles:  
      - developer  
  mat:  
    uid: 1001 |

You can also select a custom merging strategy using a `__` object in a list:
<table>
<thead>
<tr>
<th>USERS</th>
<th>YAML_DATA</th>
<th>STACK (AFTER MERGE)</th>
</tr>
</thead>
<tbody>
<tr>
<td>tom, root</td>
<td>- __: merge-last - mat</td>
<td>- tom, root - mat</td>
</tr>
<tr>
<td>tom, root</td>
<td>- __: merge-first - mat</td>
<td>- mat, tom, root</td>
</tr>
<tr>
<td>tom, root</td>
<td>- __: remove - mat - tom</td>
<td>- root</td>
</tr>
<tr>
<td>tom, root</td>
<td>- __: overwrite - mat</td>
<td>- mat</td>
</tr>
</tbody>
</table>

salt.pillar.makostack.ext_pillar(minion_id, pillar, *args, **kwargs)

25.13.23 salt.pillar.mongo

Read Pillar data from a mongodb collection

```
depends
    pymongo (for salt-master)
```

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as `salt.returners.mongo_future_return`. These variables go in your master config file.

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

Or single URI:

```
mongo.uri: URI
```
where uri is in the format:

```
mongodb://[username:password@]host1[:port1][,host2[:port2],...[, hostN[:portN]]]//[database][?options]]
```

Example:

```
mongodb://db1.example.net:27017/mydatabase
mongodb://db1.example.net:27017,db2.example.net:2500/?replicaSet=test
mongodb://db1.example.net:27017,db2.example.net:2500/?replicaSet=test&connectTimeoutMS=300000
```

More information on URI format can be found in [https://docs.mongodb.com/manual/reference/connection-string/](https://docs.mongodb.com/manual/reference/connection-string/)

### Configuring the Mongo ext_pillar

The Mongo ext_pillar takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```
ext_pillar:
    - mongo: {collection: vm, id_field: name, re_pattern: \.example\.com, fields: [customer_id, software, apache_vhosts]}
```

In the example above, we’ve decided to use the `vm` collection in the database to store the data. Minion ids are stored in the name field on documents in that collection. And, since minion ids are FQDNs in most cases, we’ll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the `customer_id`, `software`, and `apache_vhosts` fields, as that will contain the data we want for a given node. They will be available directly inside the pillar dict in your SLS templates.

### Module Documentation

```
salt.pillar.mongo.ext_pillar
(minion_id, pillar, collection='pillar', id_field='\_id', re_pattern=None,
 re_replace='', fields=None)
```

Connect to a mongo database and read per-node pillar information.

**Parameters**

- **collection** (*) -- The mongodb collection to read data from. Defaults to 'pillar'.
- **id_field** (*) -- The field in the collection that represents an individual minion id. Defaults to '_id'.
- **re_pattern** (*) -- If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If None, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to None.
- **re_replace** (*) -- Use as the replacement value in node ids matched with `re_pattern`. Defaults to `.`. Feel free to use backreferences here.
- **fields** (*) -- The specific fields in the document to use for the pillar data. If None, will use the entire document. If using the entire document, the `_id` field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to None.
25.13.24 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

This module is a concrete implementation of the sql_base ext_pillar for MySQL.

```
maturity
  new
depends
  python-mysqldb
platform
  all
```

Configuring the mysql ext_pillar

Use the 'mysql' key under ext_pillar for configuration of queries.

MySQL configuration of the MySQL returner is being used (mysql.db, mysql.user, mysql.pass, mysql.port, mysql.host) for database connection info.

Required python modules: MySQLdb

Complete example

```
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'
  port: 3306
  ssl:
    cert: /etc/mysql/client-cert.pem
    key: /etc/mysql/client-key.pem

ext_pillar:
  - mysql:
    fromdb:
      query: 'SELECT col1,col2,col3,col4,col5,col6,col7
               FROM some_random_table
               WHERE minion_pattern LIKE %s'
      depth: 5
      as_list: True
      with_lists: [1,3]
```

class salt.pillar.mysql.MySQLExtPillar

This class receives and processes the database rows from MySQL.

`extract_queries(args, kwargs)`

This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.
salt.pillar.mysql.ext_pillar(minion_id, pillar, *args, **kwargs)
   Execute queries against MySQL, merge and return as a dict

25.13.25 salt.pillar.nacl
Decrypt pillar data through the built-in NACL renderer
In most cases, you’ll want to make this the last external pillar used. For example, to pair with the built-in stack pillar you could do something like this:

```
nacl.config:
   keyfile: /root/.nacl

ext_pillar:
   stack: /path/to/stack.cfg
   nacl: {}
```

Set nacl.config in your config.
salt.pillar.nacl.ext_pillar(minion_id, pillar, *args, **kwargs)

25.13.26 salt.pillar.netbox
A module that adds data to the Pillar structure from a NetBox API.
New in version 2019.2.0.

Configuring the NetBox ext_pillar
To use this pillar, you must first create a token in your NetBox instance at http://netbox.example.com/user/api-tokens/(substituting the hostname of your NetBox instance)
The NetBox api_url and api_token must be set in the master config.
For example /etc/salt/master.d/netbox.conf:

```
ext_pillar:
   netbox:
      api_url: http://netbox.example.com/api/
      api_token: 123abc
```

The following options are optional, and determine whether or not the module will attempt to configure the proxy pillar data for use with the napalm proxy-minion:

```
proxy_return: True
proxy_username: admin
```

By default, this module will query the NetBox API for the platform associated with the device, and use the 'NAPALM driver' field to set the napalm proxy-minion driver. (Currently only 'napalm' is supported for drivertype.)
This module currently only supports the napalm proxy minion and assumes you will use SSH keys to authenticate to the network device. If password authentication is desired, it is recommended to create another proxy key in pillar_roots (or git_pillar) with just the passwd key and use salt.renderers.gpg to encrypt the value.
If you use more than one username for your devices, leave proxy_username unset, and set the username key in your pillar as well. If any additional options for the proxy setup are needed, they should also be configured in pillar_roots.

Other available configuration options:

- **site_details**: *True*
  Whether should retrieve details of the site the device belongs to.

- **site_prefixes**: *True*
  Whether should retrieve the prefixes of the site the device belongs to.

- **devices**: *True*
  New in version 3004.
  Whether should retrieve physical devices.

- **virtual_machines**: *False*
  New in version 3004.
  Whether should retrieve virtual machines.

- **interfaces**: *False*
  New in version 3004.
  Whether should retrieve the interfaces of the device.

- **interface_ips**: *False*
  New in version 3004.
  Whether should retrieve the IP addresses for interfaces of the device. (interfaces must be set to True as well)

- **api_query_result_limit**: *Use NetBox default*
  New in version 3004.
  An integer specifying how many results should be returned for each query to the NetBox API. Leaving this unset will use NetBox’s default value.

- **connected_devices**: *False*
  New in version 3006.0.
  Whether connected_devices key should be populated with device objects. If set to True it will force interfaces to also be true as a dependency

Note that each option you enable can have a detrimental impact on pillar performance, so use them with caution.

After configuring the pillar, you must restart the Salt master for the changes to take effect.

For example:

```
systemctl restart salt-master
```

To query perform a quick test of the pillar, you should refresh the pillar on the minion with the following:

```
salt minion1 saltutil.refresh_pillar
```

And then query the pillar:

```
salt minion1 pillar.items 'netbox'
```

Example output:
minion1:
  netbox:
    id: 511
    url: https://netbox.example.com/api/dcim/devices/511/
    name: minion1
    node_type: device

salt.pillar.netbox.ext_pillar(minion_id, pillar, *args, **kwargs)

Query NetBox API for minion data
25.13.27 salt.pillar.neutron

Use Openstack Neutron data as a Pillar source. Will list all networks listed inside of Neutron, to all minions.

New in version 2015.5.1.

depends

- python-neutronclient

A keystone profile must be used for the pillar to work (no generic keystone configuration here). For example:

```yaml
my_openstack_config:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'
```

After the profile is created, configure the external pillar system to use it.

```yaml
ext_pillar:
  - neutron: my_openstack_config
```

Using these configuration profiles, multiple neutron sources may also be used:

```yaml
ext_pillar:
  - neutron: my_openstack_config
  - neutron: my_other_openstack_config
```

By default, these networks will be returned as a pillar item called networks. In order to have them returned under a different name, add the name after the Keystone profile name:

```yaml
ext_pillar:
  - neutron: my_openstack_config neutron_networks
salt.pillar.neutron.ext_pillar(minion_id, pillar, conf)
```

Check neutron for all data

25.13.28 salt.pillar.nodegroups

Nodegroups Pillar

Introspection: to which nodegroups does my minion belong? Provides a pillar with the default name of nodegroups which contains a list of nodegroups which match for a given minion.

New in version 2016.11.0.
Command Line

```bash
salt-call pillar.get nodegroups
local:
  - class_infra
  - colo_sj
  - state_active
  - country_US
  - type_saltmaster
```

Configuring Nodegroups Pillar

```bash
extension_modules: /srv/salt/ext
ext_pillar:
  - nodegroups:
    pillar_name: 'nodegroups'
```

```python
salt.pillar.nodegroups.ext_pillar(minion_id, pillar, pillar_name='nodegroups')
```

A salt external pillar which provides the list of nodegroups of which the minion is a member.

**Parameters**

- `minion_id` -- used for compound matching nodegroups
- `pillar` -- provided by salt, but not used by nodegroups ext_pillar
- `pillar_name` -- optional name to use for the pillar, defaults to 'nodegroups'

**Returns**

a dictionary which is included by the salt master in the pillars returned to the minion

25.13.29 salt.pillar.pepa

Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.

Configuring Pepa

```bash
extension_modules: /srv/salt/ext
ext_pillar:
  - pepa:
    resource: host
      in pillars
      sequence: # Sequence used for hierarchical substitution
      substitution
        - hostname:
          name: input # Alias used for template directory
          base_only: True # Only use templates from Base
        - environment, i.e. no staging
          - default:
          - environment:
```

(continues on next page)
- **location.region:**
  - name: region
- **location.country:**
  - name: country
- **location.datacenter:**
  - name: datacenter
- **roles:**
- **osfinger:**
  - name: os
- **hostname:**
  - name: override
  - base_only: True
    - subkey: True
      # Create a sub-key in pillars, named after the resource in this case [host]
    - subkey_only: True
      # Only create a sub-key, and leave the top level untouched

**pepa_roots:**
- base: /srv/pepa/base
  # Path for base environment
- dev: /srv/pepa/base
  # Associate dev with base
- qa: /srv/pepa/qa
- prod: /srv/pepa/prod
  # Path for prod environment

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys may use '.' in the name
#pepa_delimiter: ...

# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
# environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
# saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug

#log_granular_levels:
# salt: warning
# salt.loaded.ext.pillar.pepa: debug

Pepa can also be used in Master-less SaltStack setup.
Command line

```

positional arguments:
  hostname          Hostname

optional arguments:
  -h, --help        show this help message and exit
  -c CONFIG, --config CONFIG  Configuration file
  -d, --debug       Print debug info
  -g GRAINS, --grains GRAINS  Input Grains as YAML
  -p PILLAR, --pillar PILLAR  Input Pillar as YAML
  -n, --no-color    No color output
  -v, --validate    Validate output
```

Templates

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

Example File: host/input/test_example_com.yaml

```
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..dhcp: False
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64
```

As you see in this example you can use Jinja directly inside the template.

Example File: host/region/amer.yaml

```
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
time..ntp..servers:
  - ntp1.amer.example.com
  - ntp2.amer.example.com
  - ntp3.amer.example.com
```

(continues on next page)
Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.

Example:

osfinger: Fedora-19

Would become:

fedora_19.yaml

Nested dictionaries

In order to create nested dictionaries as output you can use double dot ".." as a delimiter. You can change this using "pepa_delimiter" we choose double dot since single dot is already used by key names in some modules, and using ":" requires quoting in the YAML.

Example:

```
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
network..dns..options:
  - timeout:2
  - attempts:1
  - ndots:1
network..dns..search:
  - example.com
```

Would become:

```
network:
  dns:
    servers:
      - 10.0.0.1
      - 10.0.0.2
    options:
      - timeout:2
      - attempts:1
      - ndots:1
    search:
      - example.com
```
Operators

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can’t be changed.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge()</td>
<td>Merge list or hash</td>
</tr>
<tr>
<td>unset()</td>
<td>Unset key</td>
</tr>
<tr>
<td>immutable()</td>
<td>Set the key as immutable, so it can't be changed</td>
</tr>
<tr>
<td>imerge()</td>
<td>Set immutable and merge</td>
</tr>
<tr>
<td>iunset()</td>
<td>Set immutable and unset</td>
</tr>
</tbody>
</table>

Example:

```
network..dns..search..merge():
    - foobar.com
    - dummy.nl
owner..immutable(): Operations
host..printers..unset():
```

Validation

Since it’s very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pepa we use YAML, Jinja and Cerberus <https://github.com/nicolaiarocci/cerberus>.

Schema

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pepa templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

File Example: host/validation/network.yaml

```
network..dns..search:
    type: list
    allowed:
        - example.com

network..dns..options:
    type: list
    allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
    type: list
    schema:
        regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..gateway:
    type: string
```

(continues on next page)
regex: ^([0-9]{1,3}\.).{3}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}

network..interfaces..{{ interface }}..dhcp:
  type: boolean

25.13.30 salt.pillar.pillar_ldap

Use LDAP data as a Pillar source

This pillar module executes a series of LDAP searches. Data returned by these searches are aggregated, whereby data returned by later searches override data by previous searches with the same key.

The final result is merged with existing pillar data.

The configuration of this external pillar module is done via an external file which provides the actual configuration for the LDAP searches.
Configuring the LDAP ext_pillar

The basic configuration is part of the master configuration.

```yaml
ext_pillar:
  - pillar_ldap: /etc/salt/master.d/pillar_ldap.yaml
```

Note: When placing the file in the master.d directory, make sure its name doesn't end in .conf, otherwise the salt-master process will attempt to parse its content.

Warning: Make sure this file has very restrictive permissions, as it will contain possibly sensitive LDAP credentials!

The only required key in the master configuration is pillar_ldap pointing to a file containing the actual configuration.

Configuring the LDAP searches

The file is processed using Salt's Renderers <renderers> which makes it possible to reference grains within the configuration.

Warning: When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the 'id' grain which is verified through the minion's key/cert.

Map Mode

The it-admins configuration below returns the Pillar it-admins by:

- filtering for: members of the group it-admins - objects with objectclass=user
- returning the data of users, where each user is a dictionary containing the configured string or list attributes.

Configuration

```yaml
salt-users:
  server: ldap.company.tld
  port: 389
  tls: true
  dn: 'dc=company,dc=tld'
  binddn: 'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw: bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn: 'ou=users,dc=company,dc=tld'
```

(continues on next page)
filter: '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'

attrs:
  - cn
  - displayName
  - givenName
  - sn

lists:
  - memberOf

search_order:
  - salt-users

Result

```json
{
  'salt-users': [
    {
      'cn': 'cn=johndoe,ou=users,dc=company,dc=tld',
      'displayName': 'John Doe',
      'givenName': 'John',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team01,ou=groups,dc=company'
      ]
    },
    {
      'cn': 'cn=janedoe,ou=users,dc=company,dc=tld',
      'displayName': 'Jane Doe',
      'givenName': 'Jane',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team02,ou=groups,dc=company'
      ]
    }
  ]
}
```

salt.pillar.pillar_ldap.ext_pillar(minion_id, pillar, config_file)

Execute LDAP searches and return the aggregated data
25.13.31 salt.pillar.postgres

Retrieve Pillar data by doing a postgres query
New in version 2017.7.0.

maturity
new
depends
psycopg2
platform
all

Complete Example

```python
postgres:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - postgres:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
          FROM some_random_table
          WHERE minion_pattern LIKE %s'
        depth: 5
        as_list: True
        with_lists: [1, 3]

class salt.pillar.postgres.POSTGRESExtPillar
    This class receives and processes the database rows from POSTGRES.

    extract_queries(args, kwargs)
        This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.postgres.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against POSTGRES, merge and return as a dict

25.13.32 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data.

salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
    Execute an unmodified puppet_node_classifier and read the output as YAML
25.13.33  salt.pillar.reclass_adapter

Use the "reclass" database as a Pillar source

This ext_pillar plugin provides access to the reclass database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the ext_pillar list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```yaml
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):

```yaml
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass
```

If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.

```python
salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)
```

Obtain the Pillar data from reclass for the given minion_id.

25.13.34  salt.pillar.redismod

Read pillar data from a Redis backend

New in version 2014.7.0.

```python
depends
  - redis Python module (on master)
```
Salt Master Redis Configuration

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- **redis.db** - The Redis database to use. Defaults to 0.
- **redis.host** - The Redis host to connect to. Defaults to 'salt'.
- **redis.port** - The port that the Redis database is listening on. Defaults to 6379.
- **redis.password** - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

Configuring the Redis ext_pillar

```
ext_pillar:
  - redis: {function: key_value}
```

salt.pillar.redismod.ext_pillar(minion_id, pillar, function, **kwargs)
Grabs external pillar data based on configured function

salt.pillar.redismod.key_json(minion_id, pillar, pillar_key=None)
Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if pillar_key is not set.

```
pillar_key
  Pillar key to return data into
```

salt.pillar.redismod.key_value(minion_id, pillar, pillar_key='redis_pillar')
Looks for key in redis matching minion_id, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

```
pillar_key
  Pillar key to return data into
```

25.13.35 salt.pillar.rethinkdb_pillar

Provide external pillar data from RethinkDB

New in version 2018.3.0.

```
depends
  rethinkdb (on the salt-master)
```

salt master rethinkdb configuration

These variables must be configured in your master configuration file.

- **rethinkdb.host** - The RethinkDB server. Defaults to 'salt'
- **rethinkdb.port** - The port the RethinkDB server listens on. Defaults to '28015'
- **rethinkdb.database** - The database to connect to. Defaults to 'salt'
- **rethinkdb.username** - The username for connecting to RethinkDB. Defaults to ''
- **rethinkdb.password** - The password for connecting to RethinkDB. Defaults to ''
salt-master ext_pillar configuration

The ext_pillar function arguments are given in single line dictionary notation.

```python
ext_pillar:
    - rethinkdb: {table: ext_pillar, id_field: minion_id, field: pillar_root,
                  pillar_key: external_pillar}
```

In the example above the following happens.

- The salt-master will look for external pillars in the 'ext_pillar' table on the RethinkDB host
- The minion id will be matched against the 'minion_id' field
- Pillars will be retrieved from the nested field 'pillar_root'
- Found pillars will be merged inside a key called 'external_pillar'

Module Documentation

```python
salt.pillar.rethinkdb_pillar.ext_pillar(minion_id, pillar,
                                        table='pillar',
                                        id_field=None,
                                        field=None,
                                        pillar_key=None)
```

Collect minion external pillars from a RethinkDB database

Arguments:

- `table`: The RethinkDB table containing external pillar information. Defaults to 'pillar'
- `id_field`: Field in document containing the minion id. If blank then we assume the table index matches
  minion ids
- `field`: Specific field in the document used for pillar data, if blank then the entire document will be used
- `pillar_key`: The salt-master will nest found external pillars under this key before merging into the minion
  pillars. If blank, external pillars will be merged at top level

25.13.36 salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options

```python
ext_pillar:
    - s3:
        bucket: my.fancy.pillar.bucket
        keyid: KASKFJWAKJASJKDAJKSD
        key: ksladfDLKDALSFKSD93q032sdDasdfasdfsadkf
        multiple_env: False
        environment: base
        prefix: somewhere/overthere
        verify_ssl: True
        service_url: s3.amazonaws.com
        kms_keyid: 01234567-89ab-cdef-0123-4567890abcde
        s3_cache_expire: 30
        s3_sync_on_update: True
        path_style: False
        https_enable: True
```

25.13. pillar modules
The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to 'base'. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if multiple_env is True.

The `prefix` defaults to ''. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when multiple_env is True or False. Essentially it tells ext_pillar to look for your pillar data in a 'subdirectory' of your S3 bucket

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. *NOTE* If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to 's3.amazonaws.com'. It specifies the base url to use for accessing S3.

The `kms_keyid` parameter is optional. It specifies the ID of the Key Management Service (KMS) master key that was used to encrypt the object.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than jit.

The `https_enable` parameter defaults to True. It specifies whether to use path style requests or dns style requests

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<files>
```

Multiple environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<environment>/<files>
```

If you wish to define your pillar data entirely within S3 it's recommended that you use the `prefix=` parameter and specify one entry in ext_pillar for each environment rather than specifying multiple_env. This is due to issue #22471 (https://github.com/saltstack/salt/issues/22471)

```python
class salt.pillar.s3.S3Credentials(
    key, keyid, bucket, service_url, verify_ssl=True, kms_keyid=None,
    location=None, path_style=False, https_enable=True)
```

```python
salt.pillar.s3.ext_pillar(
    minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True,
    location=None, multiple_env=False, environment='base', prefix='",
    service_url=None, kms_keyid=None, s3_cache_expire=30,
    s3_sync_on_update=True, path_style=False, https_enable=True)
```

Execute a command and read the output as YAML
25.13.37  salt.pillar.saltclass

SaltClass Pillar Module

```
ext_pillar:
  - saltclass:
    path: /srv/saltclass
```

For additional configuration instructions, see the `saltclass` module

```
salt.pillar.saltclass.ext_pillar(minion_id, pillar, "args", **"kwargs")
```

Compile pillar data

25.13.38  salt.pillar.sql_base

Retrieve Pillar data by doing a SQL query

This module is not meant to be used directly as an ext_pillar. It is a place to put code common to PEP 249 compliant SQL database adapters. It exposes a python ABC that can be subclassed for new database providers.

```
maturity
  new

platform
  all
```

Theory of sql_base ext_pillar

Ok, here’s the theory for how this works...

- First, any non-keyword args are processed in order.
- Then, remaining keywords are processed.

We do this so that it’s backward compatible with older configs. Keyword arguments are sorted before being appended, so that they’re predictable, but they will always be applied last so overall it’s moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.
- A list has the first entry used as the query, the second as the pillar depth.
- A mapping uses the keys "query" and "depth" as the tuple

You can retrieve as many fields as you like, how they get used depends on the exact settings.

Configuring a sql_base ext_pillar

The sql_base ext_pillar cannot be used directly, but shares query configuration with its implementations. These examples use a fake 'sql_base' adapter, which should be replaced with the name of the adapter you are using.

A list of queries can be passed in
ext_pillar:
  - sql_base:
    - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    - "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"

Or you can pass in a mapping

ext_pillar:
  - sql_base:
    main: 
    - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    extras:
    - "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"

The query can be provided as a string as we have just shown, but they can be provided as lists

ext_pillar:
  - sql_base:
    - SELECT pillar,value FROM pillars WHERE minion_id = %s
    2

Or as a mapping

ext_pillar:
  - sql_base:
    - query:
      - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2

The depth defines how the dicts are constructed. Essentially if you query for fields a,b,c,d for each row you'll get:

- With depth 1: {a: {"b": b, "c": c, "d": d}}
- With depth 2: {a: {b: {"c": c, "d": d}}}
- With depth 3: {a: {b: {c: d}}}

Depth greater than 3 wouldn't be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

Then they are merged in a similar way to plain pillar data, in the order returned by the SQL database.

Thus subsequent results overwrite previous ones when they collide.

The ignore_null option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = 'default' AND minion_id != %s"
      depth: 2
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2
    ignore_null: True

If you specify as_list: True in the mapping expression it will convert collisions to lists.

If you specify with_lists: '..' in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string '1,3' will result in:
These columns define list grouping

```
{a: [
    {c: [
        {e: 1},
        {g: 2}
    ]}
],
 {h: [
    {j: 3, k: 4 }
 ]}
 ]}
```

The range for with_lists is 1 to number_of_fields, inclusive. Numbers outside this range are ignored.

If you specify `as_json: True` in the mapping expression and query only for single value, returned data are considered in JSON format and will be merged directly.

```
ext_pillar:
  - sql_base:
    - query: "SELECT json_pillar FROM pillars WHERE minion_id = %s"
      as_json: True
```

The processed JSON entries are recursively merged in a single dictionary. Additionnally if `as_list` is set to `True` the lists will be merged in case of collision.

For instance the following rows:

```
{"a": {"b": [1, 2]}, "c": 3} {"a": {"b": [1, 3]}, "d": 4}
```

will result in the following pillar with `as_list=False`

```
{"a": {"b": [1, 3], "c": 3, "d": 4}
```

and in with `as_list=True`

```
{"a": {"b": [1, 2, 3], "c": 3, "d": 4}
```

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your minion_id is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

Configuration of the connection depends on the adapter in use.

New in version 3005: The `as_json` parameter.
More complete example for MySQL (to also show configuration)

```yaml
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
            FROM some_random_table
            WHERE minion_pattern LIKE %s
        depth: 5
        as_list: True
        with_lists: [1,3]
```

class salt.pillar.sql_base.SqlBaseExtPillar

This class receives and processes the database rows in a database agnostic way.

```python
as_json = False
as_list = False
depth = 0

enter_root(root)
  Set self.focus for kwarg queries

extract_queries(args, kwargs)
  This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dict.

fetch(minion_id, pillar, *args, **kwargs)
  Execute queries, merge and return as a dict.

field_names = None

focus = None

ignore_null = False

num_fields = 0

process_fields(field_names, depth)
  The primary purpose of this function is to store the sql field list and the depth to which we process.

process_results(rows)
  This function takes a list of database results and iterates over, merging them into a dict form.

result = None

with_lists = None
```
25.13.39  salt.pillar.sqlcipher

Retrieve Pillar data by running a SQLCipher query

New in version 2016.3.0.

Python SQLCipher support is provided by the pysqlcipher Python package. You need this module installed to query Pillar data from a SQLCipher database.

This module is a concrete implementation of the sql_base ext_pillar for SQLCipher.

    maturity
    new
    depends
    pysqlcipher (for py2) or pysqlcipher3 (for py3)
    platform
    all

Configuring the sqlcipher ext_pillar

Use the 'sqlcipher' key under ext_pillar for configuration of queries.

SQLCipher database connection configuration requires the following values configured in the master config:

- `sqlcipher.database` - The SQLCipher database to connect to. Defaults to '/var/lib/salt/pillar-sqlcipher.db'.
- `sqlcipher.pass` - The SQLCipher database decryption password.
- `sqlcipher.timeout` - The connection timeout in seconds.

Example configuration

```
sqlcipher:
    database: '/var/lib/salt/pillar-sqlcipher.db'
    pass: strong_pass_phrase
    timeout: 5.0
```

Complete Example

```
sqlcipher:
    database: '/var/lib/salt/pillar-sqlcipher.db'
    pass: strong_pass_phrase
    timeout: 5.0

ext_pillar:
    - sqlcipher:
        fromdb:
            query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                    FROM some_random_table
                    WHERE minion_pattern LIKE ?'
            depth: 5
            as_list: True
            with_lists: [1,3]
```
class salt.pillar.sqlcipher.SQLCipherExtPillar
    This class receives and processes the database rows from SQLCipher.
salt.pillar.sqlcipher.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against SQLCipher, merge and return as a dict

25.13.40 salt.pillar.sqlite3

Retrieve Pillar data by doing a SQLite3 query
New in version 2015.8.0.
sqlite3 is included in the stdlib since Python 2.5.
This module is a concrete implementation of the sql_base ext_pillar for SQLite3.
    platform
        all

Configuring the sqlite3 ext_pillar

Use the 'sqlite3' key under ext_pillar for configuration of queries.
SQLite3 database connection configuration requires the following values configured in the master config:
Note, timeout is in seconds.

```python
sqlite3.database: /var/lib/salt/pillar.db
sqlite3.timeout: 5.0
```

Complete Example

```python
sqlite3:
    database: '/var/lib/salt/pillar.db'
    timeout: 5.0
ext_pillar:
    - sqlite3:
        fromdb:
            query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                    FROM some_random_table
                    WHERE minion_pattern LIKE ?'
            depth: 5
            as_list: True
            with_lists: [1,3]
```

class salt.pillar.sqlite3.SQLite3ExtPillar
    This class receives and processes the database rows from SQLite3.
salt.pillar.sqlite3.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against SQLite3, merge and return as a dict
25.13.41 salt.pillar.stack

Simple and flexible YAML ext_pillar which can read pillar from within pillar.

New in version 2016.3.0.

PillarStack is a custom saltstack ext_pillar which was inspired by varstack but is heavily based on Jinja2 for maximum flexibility.

It supports the following features:

• multiple config files that are jinja2 templates with support for pillar, __grains__, __salt__, __opts__ objects and pillarenv
• a config file renders as an ordered list of files (paths of these files are relative to the current config file)
• this list of files are read in ordered as jinja2 templates with support for stack, pillar, __grains__, __salt__, __opts__ objects and pillarenv
• all these rendered files are then parsed as yaml
• then all yaml dicts are merged in order with support for the following merging strategies: merge-first, merge-last, remove, and overwrite
• stack config files can be matched based on pillar, grains, or opts values, which make it possible to support kind of self-contained environments

Installation

PillarStack is already bundled with Salt since 2016.3.0 version so there is nothing to install from version 2016.3.0.

If you use an older Salt version or you want to override PillarStack with a more recent one, follow the installation procedure below.

Installing the PillarStack ext_pillar is as simple as dropping the stack.py file in the <extension_modules>/pillar directory (no external python module required), given that extension_modules is set in your salt-master configuration, see: https://docs.saltproject.io/en/latest/ref/configuration/master.html#extension-modules

Configuration in Salt

Like any other external pillar, its configuration takes place through the ext_pillar key in the master config file. However, you can configure PillarStack in 3 different ways:

Single config file

This is the simplest option, you just need to set the path to your single PillarStack config file like below:

```
ext_pillar:
  - stack: /path/to/stack.cfg
```
List of config files

You can also provide a list of config files:

```
ext_pillar:
  - stack:
    - /path/to/stack1.cfg
    - /path/to/stack2.cfg
```

Select config files through grains|pillar|opts matching

You can also opt for a much more flexible configuration: PillarStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:

```
ext_pillar:
  - stack:
    pillar:something:
      - bar: /path/to/bar/stack.cfg
      - foo: /path/to/foo/stack.cfg
    grains:custom:grain:
      - value:
        - /path/to/stack1.cfg
        - /path/to/stack2.cfg
    opts:custom:opt:
      - value: /path/to/stack0.cfg
    opts:saltenv:
      - dev: /path/to/dev/stack.cfg
      - __env__: /path/to/__env__/stack.cfg
```

PillarStack configuration files

The config files that are referenced in the above `ext_pillar` configuration are jinja2 templates which must render as a simple ordered list of yaml files that will then be merged to build pillar data.

The path of these yaml files must be relative to the directory of the PillarStack config file. These paths support unix style pathname pattern expansion through the Python glob module [https://docs.python.org/2/library/glob.html](https://docs.python.org/2/library/glob.html).

The following variables are available in jinja2 templating of PillarStack configuration files:

- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-) 
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your list of yaml files that will be merged in pillar data.

For example, you could have a PillarStack config file which looks like:
And the whole directory structure could look like:

```bash
$ tree /path/to/stack/
/path/to/stack/
  ├── config.cfg
  │   └── core.yml
  │       └── common/
  │           ├── xxx.yml
  │           └── yyy.yml
  │       └── osarchs/
  │           ├── amd64.yml
  │           └── armhf.yml
  │       └── oscodenames/
  │           ├── wheezy.yml
  │           └── jessie.yml
  │       └── roles/
  │           └── web.yml
  │       └── db.yml
  └── minions/
      ├── test-1-dev.yml
      └── test-2-dev.yml
```

**Overall process**

In the above PillarStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and which pillar `roles` is `"db"`, the following yaml files would be merged in order:

- `core.yml`
- `common/xxx.yml`
- `common/yyyy.yml`
- `osarchs/amd64.yml`
- `oscodenames/jessie.yml`
- `roles/db.yml`
- `minions/test-1-dev.yml`

Before merging, every files above will be preprocessed as Jinja2 templates. The following variables are available in Jinja2 templating of yaml files:
• **stack**: the PillarStack pillar data object that has currently been merged (data from previous `yaml` files in PillarStack configuration)

• **pillar**: the pillar data (as passed by Salt to our `ext_pillar` function)

• **minion_id**: the minion id ;-)  

• **__opts__**: a dictionary of mostly Salt configuration options

• **__grains__**: a dictionary of the grains of the minion making this pillar call

• **__salt__**: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your pillar data, and even use other pillar values that has already been merged by PillarStack (from previous `yaml` files in PillarStack configuration) through the **stack** variable.

Once a `yaml` file has been preprocessed by Jinja2, we obtain a Python dict - let’s call it **yaml_data** - then, PillarStack will merge this **yaml_data** dict in the main **stack** dict (which contains already merged PillarStack pillar data). By default, PillarStack will deeply merge **yaml_data** in **stack** (similarly to the **recurse salt pillar_source_merging_strategy**), but 3 merging strategies are currently available for you to choose (see next section).

Once every `yaml` files have been processed, the **stack** dict will contain your whole own pillar data, merged in order by PillarStack. So PillarStack `ext_pillar` returns the **stack** dict, the contents of which Salt takes care to merge in with all of the other pillars and finally return the whole pillar to the minion.

**Merging strategies**

The way the data from a new **yaml_data** dict is merged with the existing **stack** data can be controlled by specifying a merging strategy. Right now this strategy can either be **merge-last** (the default), **merge-first**, **remove**, or **overwrite**.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the **overwrite** strategy (other strategies don't make sense in that case).

The merging strategy can be set by including a dict in the form of:

```
__: <merging_strategy>
```

as the first item of the dict or list. This allows fine grained control over the merging process.

**merge-last** (default) strategy

If the **merge-last** strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the **recurse salt pillar_source_merging_strategy**). This allows for extending previously defined data.
merge-first strategy

If the merge-first strategy is selected, then the content of dict or list variables are swapped between the yaml_data and stack objects before being merged recursively with the merge-last previous strategy.

remove strategy

If the remove strategy is selected, then content of dict or list variables in stack are removed only if the corresponding item is present in the yaml_data dict. This allows for removing items from previously defined data.

overwrite strategy

If the overwrite strategy is selected, then the content of dict or list variables in stack is overwritten by the content of yaml_data dict. So this allows one to overwrite variables from previous definitions.

Merging examples

Let's go through small examples that should clarify what's going on when a yaml_data dict is merged in the stack dict.

When you don't specify any strategy, the default merge-last strategy is selected:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>users:</strong></td>
<td><strong>users:</strong></td>
<td><strong>users:</strong></td>
</tr>
<tr>
<td><strong>tom:</strong></td>
<td><strong>tom:</strong></td>
<td><strong>tom:</strong></td>
</tr>
<tr>
<td></td>
<td><strong>uid:</strong> 500</td>
<td><strong>uid:</strong> 1000</td>
</tr>
<tr>
<td></td>
<td><strong>roles:</strong></td>
<td><strong>roles:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>- sysadmin</strong></td>
</tr>
<tr>
<td></td>
<td><strong>root:</strong></td>
<td><strong>mat:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>uid:</strong> 0</td>
</tr>
<tr>
<td><strong>root:</strong></td>
<td><strong>mat:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>uid:</strong> 0</td>
<td><strong>uid:</strong> 1001</td>
</tr>
</tbody>
</table>

Then you can select a custom merging strategy using the __ key in a dict:
<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
</table>
| **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 |
| **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 1000  
    **roles:**  
      - developer  
    **mat:**  
      **uid:** 1001 | **users:**  
  **tom:**  
    **uid:** 1000  
    **roles:**  
      - developer  
    **mat:**  
      **uid:** 1001 |
| **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 |
| **users:**  
  **tom:**  
    **uid:** 500  
    **roles:**  
      - sysadmin  
  **root:**  
    **uid:** 0 | **users:**  
  **tom:**  
    **uid:** 1000  
    **roles:**  
      - developer  
    **mat:**  
      **uid:** 1001 | **users:**  
  **tom:**  
    **uid:** 1000  
    **roles:**  
      - developer  
    **mat:**  
      **uid:** 1001 |

You can also select a custom merging strategy using a `__` object in a list:
### Stack pillar

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>users:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- tom</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- root</td>
<td></td>
</tr>
<tr>
<td><strong>users:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- **__: merge-last</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- mat</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>users:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- **__: merge-first</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- mat</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>users:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- **__: remove</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- mat</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- tom</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>users:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- **__: overwrite</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- mat</td>
<td></td>
</tr>
</tbody>
</table>

#### salt.pillar.stack

```python
salt.pillar.stack.ext_pillar(minion_id, pillar, *args, **kwargs)
```

Builds stacked pillar from yaml files listed in file(s).

**Parameters**

- `minion_id` (*str*) -- Minion ID
- `pillar` (*dict*) -- Pillar
- `args` (*list*) -- (Optional) file(s) that list yaml files
- `kwargs` (*dict*) -- (Optional) conditional file(s) that list yaml files

### 25.13.42 salt.pillar.git

Clone a remote SVN repository and use the filesystem as a Pillar source.

This external Pillar source can be configured in the master config file like so:

```python
ext_pillar:
  - svn: trunk svn://svnserver/repo root=subdirectory
```

The `root` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (master), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```python
base:
  '*':
    - foo
```
To use other environments from the same SVN repo as svn_pillar sources, just add additional lines, like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo
  - svn: dev svn://svnserver/repo
```

In this case, the dev branch would need its own top.sls with a dev section in it, like this:

```yaml
dev:
  '*':
    - bar
```

```python
class salt.pillar.svn_pillar.SvnPillar(branch, repo_location, root, opts):
    Deal with the remote SVN repository for Pillar
    pillar_dir()
        Returns the directory of the pillars (repo cache + branch + root)
    update()
```

```python
salt.pillar.svn_pillar.ext_pillar(minion_id, pillar, repo_string)
    Execute a command and read the output as YAML
```

25.13.43 salt.pillar.varstack_pillar

Use Varstack data as a Pillar source

Configuring Varstack

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:

```yaml
ext_pillar:
  - varstack: /etc/varstack.yaml
```

Varstack will then use /etc/varstack.yaml to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.

```python
salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)
    Parse varstack data and return the result
```

25.13.44 salt.pillar.vault

Vault Pillar Module

maintainer
    SaltStack

maturity
    New

platform
    all
New in version 2016.11.0.

This module allows pillar data to be stored in Hashicorp Vault.

Base configuration instructions are documented in the *execution module docs*. Below are noted extra configuration required for the pillar module, but the base configuration must also be completed.

After the base Vault configuration is created, add the configuration below to the `ext_pillar` section in the Salt master configuration.

```
ext_pillar:
  - vault: path=secret/salt
```

Each key needs to have all the key-value pairs with the names you require. Avoid naming every key `password` as you they will collide:

If you want to nest results under a nesting_key name use the following format:

```
ext_pillar:
  - vault:
      conf: path=secret/salt
      nesting_key: vault_key_name
```

```
$ vault write secret/salt auth=my_password master=127.0.0.1
```

The above will result in two pillars being available, `auth` and `master`.

You can then use normal pillar requests to get each key pair directly from pillar root. Example:

```
$ salt-ssh '*' pillar.get auth
```

Multiple Vault sources may also be used:

```
ext_pillar:
  - vault: path=secret/salt
  - vault: path=secret/root
  - vault: path=secret/minions/{minion}/pass
  - vault: path=secret/roles/{pillar[roles]}/pass
```

You can also use nesting here as well. Identical nesting keys will get merged.

```
ext_pillar:
  - vault:
      conf: path=secret/salt
      nesting_key: keyname1
  - vault:
      conf: path=secret/root
      nesting_key: keyname1
  - vault:
      conf: path=secret/minions/{minion}/pass
      nesting_key: keyname2
```

The difference between the return with and without the nesting key is shown below. This example takes the key value pairs returned from vault as follows:

```
path=secret/salt
```

(continues on next page)
New in version 3006.0: Pillar values from previously rendered pillars can be used to template vault ext_pillar paths. Using pillar values to template vault pillar paths requires them to be defined before the vault ext_pillar is called. Especially consider the significance of `ext_pillar_first` master config setting.

If a pillar pattern matches multiple paths, the results are merged according to the master configuration values `pillar_source_merging_strategy` and `pillar_merge_lists` by default.

If the optional nesting_key was defined, the merged result will be nested below. There is currently no way to nest multiple results under different keys.

You can override the merging behavior per defined ext_pillar:
25.13.45 salt.pillar.venafi

Venafi Pillar Certificates

This module will only return pillar data if the venafi runner module has already been used to create certificates.

To configure this module, set venafi to True in the ext_pillar section of your master configuration file:

```yaml
ext_pillar:
  - venafi: True

salt.pillar.venafi.ext_pillar(minion_id, pillar, conf)
```

Return an existing set of certificates

25.13.46 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

```python
salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)
```

Accept the key for the VM on the hyper, if authorized.

25.13.47 salt.pillar.vmware_pillar

Pillar data from vCenter or an ESXi host

New in version 2017.7.0.

depends
  • pyVmomi

This external pillar can pull attributes from objects in vCenter or an ESXi host and provide those attributes as pillar data to minions. This can allow for pillar based targeting of minions on ESXi host, Datastore, VM configuration, etc. This setup requires only the salt master have access to the vCenter server/ESXi hosts.

The pillar will return an empty dict if the 'os' or 'virtual' grain are not 'VMWare', 'ESXi', or 'VMWare ESXi'.
Defaults

- The external pillar will search for Virtual Machines with the VM name matching the minion id.
- Data will be returned into the ‘vmware’ pillar key.
- The external pillar has a default set of properties to return for both VirtualMachine and HostSystem types.

Configuring the VMWare pillar

The required minimal configuration in the salt master ext_pillar setup:

```
ext_pillar:
  - vmware:
      host: <vcenter/esx host>
      username: <user to connect with>
      password: <password>
```

Optionally, the following keyword arguments can be passed to the ext_pillar for customized configuration:

- **pillar_key**
  Optionally set the pillar key to return the data into. Default is *vmware*.

- **protocol**
  Optionally set to alternate protocol if the vCenter server or ESX/ESXi host is not using the default protocol. Default protocol is *https*.

- **port**
  Optionally set to alternate port if the vCenter server or ESX/ESXi host is not using the default port. Default port is *443*.

- **property_name**
  Property name to match the minion id against. Defaults to *name*.

- **property_types**
  Optionally specify a list of pyVmomi vim types to search for the minion id in ‘property_name’. Default is *['VirtualMachine']*. For example, to search both *vim.VirtualMachine* and *vim.HostSystem* object types:

```
ext_pillar:
  - vmware:
      host: myesx
      username: root
      password: complex_password
      property_types:
        - VirtualMachine
        - HostSystem
```

Additionally, the list of property types can be dicts, the item of the dict being a list specifying the attribute to return for that vim object type.

The pillar will attempt to recurse the attribute and return all child attributes.

To explicitly specify deeper attributes without attempting to recurse an attribute, convert the list item to a dict with the item of the dict being the child attributes to return. Follow this pattern to return attributes as deep within the object as necessary.
Note: Be careful when specifying custom attributes! Many attributes have objects as attributes which have the parent object as an attribute and which will cause the pillar to fail due to the attempt to convert all sub-objects recursively (i.e. infinite attribute loops). Specifying only the sub-attributes you would like returned will keep the infinite recursion from occurring.

A maximum recursion exception will occur in this case and the pillar will not return as desired.

```
ext_pillar:
  - vmware:
    host: myvcenter
    username: my_user
    password: my_pass
    replace_default_attributes: True
    property_types:
      - VirtualMachine:
        - config:
          - bootOptions:
            bootDelay
            bootRetryDelay
        - HostSystem:
          - datastore:
            name
```

The above ext_pillar example would return a pillar like the following for a VirtualMachine object that's name matched the minion id:

```
vmware:
  config:
    bootOptions:
      bootDelay: 1000
      bootRetryDelay: 1000
```

If you were to retrieve these virtual machine attributes via pyVmomi directly, this would be the same as

```
vmObject.config.bootOptions.bootDelay
vmObject.config.bootOptionis.bootRetryDelay
```

The above ext_pillar example would return a pillar like the following for a HostySystem object that's name matched the minion id:

```
vmware:
  datastore:
    - name: Datastore1
    - name: Datastore2
```

The 'datastore' property of a HostySystem object is a list of datastores, thus a list is returned.

**replace_default_attributes**

If custom attributes are specified by the property_types parameter, replace_default_attributes determines if those will be added to default attributes (False) or replace the default attributes completely (True). The default setting is 'False'.

---

25.13. pillar modules
Note: vCenter "Custom Attributes" (i.e. Annotations) will always be returned if it exists on the object as part of the pillar regardless of this setting.

```
salt.pillar.vmware_pillar.ext_pillar(minion_id, pillar, **kwargs)
```

Check vmware/vcenter for all data
## 25.14 proxy modules

25.14.1 salt.proxy.arista_pyeapi

Arista pyeapi

New in version 2019.2.0.
Proxy module for managing Arista switches via the eAPI using the pyeapi library.

codeauthor
Mircea Ulinic <ping@mirceaulinic.net>
maturity
new
depends
pyeapi
platform
unix

Note: To understand how to correctly enable the eAPI on your switch, please check https://eos.arista.com/arista-eapi-101/.

Dependencies

The pyeapi Proxy module requires pyeapi to be installed: pip install pyeapi.

Pillar

The pyeapi proxy configuration requires the following parameters in order to connect to the network device:

transport: https
    Specifies the type of connection transport to use. Valid values for the connection are socket, http_local, http, and https.

host: localhost
    The IP address or DNS host name of the connection device.

username: admin
    The username to pass to the device to authenticate the eAPI connection.

password
    The password to pass to the device to authenticate the eAPI connection.

port
    The TCP port of the endpoint for the eAPI connection. If this keyword is not specified, the default value is automatically determined by the transport type (80 for http, or 443 for https).

enablepwd
    The enable mode password if required by the destination node.

All the arguments may be optional, depending on your setup.
Proxy Pillar Example

```yaml
proxy:
  proxitype: pyeapi
  host: router1.example.com
  username: example
  password: example
```

```python
salt.proxy.arista_pyeapi.call(method, *args, **kwargs)

Calls an arbitrary pyeapi method.

salt.proxy.arista_pyeapi.conn()

Return the connection object.

salt.proxy.arista_pyeapi.init(opts)

Open the connection to the Arista switch over the eAPI.

salt.proxy.arista_pyeapi.initialized()

Connection finished initializing?

salt.proxy.arista_pyeapi.ping()

Connection open successfully?

salt.proxy.arista_pyeapi.shutdown(opts)

Closes connection with the device.

25.14.2 salt.proxy.chronos

Chronos

Proxy minion for managing a Chronos cluster.

Dependencies

- chronos execution module (salt.modules.chronos)

Pillar

The chronos proxy configuration requires a 'base_url' property that points to the chronos endpoint:

```yaml
proxy:
  proxitype: chronos
  base_url: http://my-chronos-master.mydomain.com:4400
```

New in version 2015.8.2.

```python
salt.proxy.chronos.init(opts)

Perform any needed setup.

salt.proxy.chronos.ping()

Is the chronos api responding?

25.14. proxy modules
salt.proxy.chronos.shutdown\(\texttt{opts}\)
For this proxy shutdown is a no-op

### 25.14.3 \texttt{salt.proxy.cimc}

**Proxy Minion interface module for managing Cisco Integrated Management Controller devices**

New in version 2018.3.0.

- **codeauthor**: Spencer Ervin \(<\texttt{spencer_ervin@hotmail.com}>\)
- **maturity**: new
- **depends**: none
- **platform**: unix

This proxy minion enables Cisco Integrated Management Controller devices (hereafter referred to as simply ‘cimc’ devices to be treated individually like a Salt Minion.

The cimc proxy leverages the XML API functionality on the Cisco Integrated Management Controller. The Salt proxy must have access to the cimc on HTTPS (tcp/443).

More in-depth conceptual reading on Proxy Minions can be found in the *Proxy Minion* section of Salt’s documentation.

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID.

```
**proxy:**
  **proxytype**: cimc
  **host**: <ip or dns name of cimc host>
  **username**: <cimc username>
  **password**: <cimc password>
  **verify_ssl**: True
```
**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this cimc Proxy Module, set this to `cimc`.

**host**

The location, or ip/dns, of the cimc host. Required.

**username**

The username used to login to the cimc host. Required.

**password**

The password used to login to the cimc host. Required.

```python
salt.proxy.cimc.get_config_resolver_class(cid=None, hierarchical=False)
```

The configResolveClass method returns requested managed object in a given class.

```python
salt.proxy.cimc.grains()
```

Get the grains from the proxied device

```python
salt.proxy.cimc.grains_refresh()
```

Refresh the grains from the proxied device

```python
salt.proxy.cimc.init(opts)
```

This function gets called when the proxy starts up.

```python
salt.proxy.cimc.initialized()
```

Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

```python
salt.proxy.cimc.logon()
```

Logs into the cimc device and returns the session cookie.

```python
salt.proxy.cimc.logout(cookie=None)
```

Closes the session with the device.

```python
salt.proxy.cimc.ping()
```

Returns true if the device is reachable, else false.

```python
salt.proxy.cimc.prepare_return(x)
```

Converts the etree to dict

```python
salt.proxy.cimc.set_config_modify(dn=None, inconfig=None, hierarchical=False)
```

The configConfMo method configures the specified managed object in a single subtree (for example, DN).

```python
salt.proxy.cimc.shutdown()
```

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.
25.14.4 salt.proxy.cisconso

Proxy Minion interface module for managing (practically) any network device with Cisco Network Services Orchestrator (Cisco NSO). Cisco NSO uses a series of remote polling agents, APIs and SSH commands to fetch network configuration and represent it in a data model. PyNSO, the Python module used by this proxy minion does the task of converting native Python dictionaries into NETCONF/YANG syntax that the REST API for Cisco NSO can then use to set the configuration of the target network device.

Supported devices:

- A10 AX Series
- Arista 7150 Series
- Ciena 3000, 5000, ESM
- H3c S5800 Series
- Overture 1400, 2200, 5000, 5100, 6000
- Accedian MetroNID
- Avaya ERS 4000, SR8000, VSP 9000
- Cisco: APIC-DC, ASA, IOS, IOS XE, IOS XR, er, ME-4600, NX OS, Prime Network Registrar, Quantum, StarOS, UCS ManagWSA
- Huawei: NE40E, quidway series, Enterprise Network Simulation Framework
- PaloAlto PA-2000, PA-3000, Virtualized Firewalls
- Adtran 900 Series
- Brocade ADX, MLX, Netiron, Vyatta
- Dell Force 10 Networking S-Series
- Infinera DTN-X Multi-Terabit Packet Optical Network Platform
- Pulsecom SuperG
- Adva 150CC Series
- CableLabs Converged Cable Access Platform
- Ericsson EFN324 Series, SE family
- Juniper: Contrail, EX, M, MX, QFX, SRX, Virtual SRX
- Quagga Routing Software
- Affirmed Networks
- Citrix Netscaler
- F5 BIG-IP
- NEC iPasolink
- Riverbed Steelhead Series
- Alcatel-Lucent 7XXX, SAM
- Clavister
- Fortinet
- Nominum DCS
This proxy minion enables a consistent interface to fetch, control and maintain the configuration of network devices via a NETCONF-compliant control plane. Cisco Network Services Orchestrator.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt’s documentation.

Dependencies

- pynso Python module

PyNSO

PyNSO can be installed via pip:

```
pip install pynso
```

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the NSO host, the pillar should look like this:

```
proxy:
    proxitype: cisconso
    host: <ip or dns name of host>
    port: 8080
    use_ssl: false
    username: <username>
    password: password
```
proxypotype

The proxypotype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this Cisco NSO Proxy Module, set this to cisconso.

host

The location, or IP/dns, of the Cisco NSO API host. Required.

username

The username used to login to the Cisco NSO host, such as admin. Required.

passwords

The password for the given user. Required.

use_ssl

Whether to use HTTPS messaging to speak to the API.

port

The port that the Cisco NSO API is running on, 8080 by default

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the Cisco NSO host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the cisconso host>
```

You can confirm that the pillar data is in place for the proxy:
And now you should be able to ping the Cisco NSO host to make sure it is responding:

```
salt <id> test.ping
```

```
salt.proxy.cisconso.apply_rollback(datastore, name)
Apply a system rollback

Parameters
  - datastore (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
  - name (str) -- an ID of the rollback to restore
```

```
salt.proxy.cisconso.get_data(datastore, path)
Get the configuration of the device tree at the given path

Parameters
  - datastore (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
  - path (list of str OR tuple) -- The device path, a list of element names in order, comma separated

Returns
  The network configuration at that tree

Return type
  dict
```

```
salt proxy.cisconso.get_data devices
```

```
salt.proxy.cisconso.get_rollback(name)
Get the backup of stored a configuration rollback

Parameters
  - name (str) -- Typically an ID of the backup

Return type
  str

Returns
  the contents of the rollback snapshot
```

```
salt.proxy.cisconso.get_rollbacks()
Get a list of stored configuration rollbacks
```

```
salt.proxy.cisconso.grains()
Get the grains from the proxy device.
```

```
salt.proxy.cisconso.init(opts)
```

```
salt.proxy.cisconso.ping()
Check to see if the host is responding. Returns False if the host didn't respond, True otherwise.

CLI Example:

```
salt cisco-nso test.ping
```

```
salt.proxy.cisconso.set_data_value(datastore, path, data)
Get a data entry in a datastore

Parameters
```
- **datastore** (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
- **path** (list of str OR tuple) -- The device path to set the value at, a list of element names in order, comma separated
- **data** (dict) -- The new value at the given path

Return type

bool

Returns

True if successful, otherwise error.

salt.proxy.cisconso.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

### 25.14.5 salt.proxy.deltaprox

This is the "master" deltaproxy minion, known better as the control proxy because it controls all the deltaproxies underneath it.

salt.proxy.deltaprox.grains()

Make up some grains

salt.proxy.deltaprox.grains_refresh()

Refresh the grains

salt.proxy.deltaprox.init(opts)

salt.proxy.deltaprox.initialized()

Since grains are loaded in many different places and some of those ws places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.deltaprox.ping()

Degenerate ping

salt.proxy.deltaprox.shutdown(opts)

For this proxy shutdown is a no-op

### 25.14.6 salt.proxy.docker

Docker Proxy Minion

New in version 2019.2.0.

    depends
docker

This proxy minion is just a shim to the docker executor, which will use the docker.call for everything except state runs.

To configure the proxy minion:

```yaml
proxy:
    proxytype: docker
    name: festive_leakey
```

It is also possible to just name the proxy minion the same name as the container, and use grains to configure the proxy minion:
proxy:
    proxytype: docker
    name: {{grains['id']}}

ame
    Name of the docker container

salt.proxy.docker.init(opts)
    Always initialize

salt.proxy.docker.initialized()
    This should always be initialized

salt.proxy.docker.module_executors()
    List of module executors to use for this Proxy Minion

salt.proxy.docker.shutdown(opts)
    Nothing needs to be done to shutdown

25.14.7 salt.proxy.dummy

This is the a dummy proxy-minion designed for testing the proxy minion subsystem.

salt.proxy.dummy.fns()
    Method called by grains module.

salt.proxy.dummy.grains()
    Make up some grains

salt.proxy.dummy.grains_refresh()
    Refresh the grains

salt.proxy.dummy.init(opts)
    Required. Can be used to initialize the server connection.

salt.proxy.dummy.initialized()
    Since grains are loaded in many different places and some of those places occur before the proxy can be
    initialized, return whether our init() function has been called

salt.proxy.dummy.package_install(name, **kwargs)
    Install a "package" on the REST server

salt.proxy.dummy.package_list()
    List "packages" installed on the REST server

salt.proxy.dummy.package_remove(name)
    Remove a "package" on the REST server

salt.proxy.dummy.package_status(name)
    Check the installation status of a package on the REST server

salt.proxy.dummy.ping()
    Degenerate ping

salt.proxy.dummy.service_list()
    List "services" on the REST server
salt.proxy.dummy.service_restart(name)
    Restart a "service" on the REST server
salt.proxy.dummy.service_start(name)
    Start a "service" on the dummy server
salt.proxy.dummy.service_status(name)
    Check if a service is running on the REST server
salt.proxy.dummy.service_stop(name)
    Stop a "service" on the dummy server
salt.proxy.dummy.shutdown(opts)
    For this proxy shutdown is a no-op
salt.proxy.dummy.test_from_state()
    Test function so we have something to call from a state :return:
salt.proxy.dummy.upgrade()
    "Upgrade" packages
salt.proxy.dummy.uptodate()
    Call the REST endpoint to see if the packages on the "server" are up to date.

25.14.8 salt.proxy.esxcluster

Proxy Minion interface module for managing VMWare ESXi clusters.

Dependencies

- pyVmomi
- jsonschema

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. This can now happen from the proxy’s configuration file. Example pillars:

userpass mechanism:

```
proxy:
    proxytype: esxcluster
    cluster: <cluster name>
    datacenter: <datacenter name>
    vcenter: <ip or dns name of parent vcenter>
    mechanism: userpass
    username: <vCenter username>
```

(continues on next page)
passwords: (required if userpass is used)
- first_password
- second_password
- third_password

sspi mechanism:

proxy:
  proxytype: esxcluster
  cluster: <cluster name>
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: sspi
  domain: <user domain>
  principal: <host kerberos principal>

proxytype

To use this Proxy Module, set this to esxdatacenter.

cluster

Name of the managed cluster. Required.

datacenter

Name of the datacenter the managed cluster is in. Required.

vcenter

The location of the VMware vCenter server (host of ip) where the datacenter should be managed. Required.

mechanism

The mechanism used to connect to the vCenter server. Supported values are userpass and sspi. Required.

Note: Connections are attempted using all (username, password) combinations on proxy startup.
username

The username used to login to the host, such as root. Required if mechanism is `userpass`.

passwords

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is `userpass`. When the proxy comes up, it will try the passwords listed in order.

domain

User domain. Required if mechanism is `sspi`.

principal

Kerberos principal. Required if mechanism is `sspi`.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity `<id>`:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is `/etc/salt/proxy`. If in a different location, the `<configuration_folder>` has to be specified when running the proxy: file with at least the following in it:

```
salt-proxy --proxyid <proxy_id> -c <configuration_folder>
```
Commands

Once the proxy is running it will connect back to the specified master and individual commands can be runs against it:

```bash
# Master - minion communication
salt <cluster_name> test.ping

# Test vcenter connection
salt <cluster_name> vsphere.test_vcenter_connection
```

States

Associated states are documented in `salt.states.esxcluster`. Look there to find an example structure for Pillar as well as an example `.sls` file for configuring an ESX cluster from scratch.

```python
salt.proxy.esxcluster.find_credentials()
   Cycle through all the possible credentials and return the first one that works.

salt.proxy.esxcluster.get_details()
   Function that returns the cached details

salt.proxy.esxcluster.init(opts)
   This function gets called when the proxy starts up. For login the protocol and port are cached.

salt.proxy.esxcluster.ping()
   Returns True.

   CLI Example:
   ```
salt esx-cluster test.ping
   ```

salt.proxy.esxcluster.shutdown()
   Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

25.14.9 salt.proxy.esxdatacenter

Proxy Minion interface module for managing VMWare ESXi clusters.

Dependencies

- pyVmomi
- jsonschema
Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt's Pillar. This can now happen from the proxy's configuration file.

Example pillars:

userpass mechanism:

```yaml
proxy:
  proxitype: esxdatacenter
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: userpass
  username: <vCenter username>
  passwords: (required if userpass is used)
    - first_password
    - second_password
    - third_password
```

sspi mechanism:

```yaml
proxy:
  proxitype: esxdatacenter
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: sspi
  domain: <user domain>
  principal: <host kerberos principal>
```

proxitype

To use this Proxy Module, set this to `esxdatacenter`.

datacenter

Name of the managed datacenter. Required.

vcenter

The location of the VMware vCenter server (host of ip) where the datacenter should be managed. Required.
mechanism

The mechanism used to connect to the vCenter server. Supported values are `userpass` and `sspi`. Required.

Note: Connections are attempted using all `(username, password)` combinations on proxy startup.

username

The username used to login to the host, such as `root`. Required if mechanism is `userpass`.

passwords

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is `userpass`. When the proxy comes up, it will try the passwords listed in order.

domain

User domain. Required if mechanism is `sspi`.

principal

Kerberos principal. Required if mechanism is `sspi`.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is `443`.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity `<id>`:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is `/etc/salt/proxy`. If in a different location, the `<configuration_folder>` has to be specified when running the proxy: file with at least the following in it:
salt-proxy --proxyid <proxy_id> -c <configuration_folder>

Commands

Once the proxy is running it will connect back to the specified master and individual commands can be runs against it:

```
# Master - minion communication
salt <datacenter_name> test.ping

# Test vcenter connection
salt <datacenter_name> vsphere.test_vcenter_connection
```

States

Associated states are documented in `salt.states.esxdatacenter`. Look there to find an example structure for Pillar as well as an example .sls file for configuring an ESX datacenter from scratch.

```
salt.proxy.esxdatacenter.find_credentials()
    Cycle through all the possible credentials and return the first one that works.
salt.proxy.esxdatacenter.get_details()
    Function that returns the cached details
salt.proxy.esxdatacenter.init(opts)
    This function gets called when the proxy starts up. All login details are cached.
salt.proxy.esxdatacenter.ping()
    Returns True.
    CLI Example:
    salt dc_id test.ping
salt.proxy.esxdatacenter.shutdown()
    Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.
```

25.14.10 salt.proxy.esxi

Proxy Minion interface module for managing VMware ESXi hosts.

**Warning:** This module will be deprecated in a future release of Salt. VMware strongly recommends using the [VMware Salt extensions](https://github.com/saltstack/salt-extend-esxi) instead of the ESXi module. Because the Salt extensions are newer and actively supported by VMware, they are more compatible with current versions of ESXi and they work well with the latest features in the VMware product line.

**Special Note:** SaltStack thanks [Adobe Corporation](https://www.adobe.com) for their support in creating this Proxy Minion integration.

This proxy minion enables VMware ESXi (hereafter referred to as simply 'ESXi') hosts to be treated individually like a Salt Minion.
Since the ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can't run a Salt Minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the Salt Master. The master does not know nor care that the target is not a "real" Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

Dependencies

- pyVmomi Python Module
- ESXCLI

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.
Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```
proxy:
    proxytype: esxi
    host: <ip or dns name of esxi host>
    username: <ESXi username>
    passwords:
        - first_password
        - second_password
        - third_password
    credstore: <path to credential store>
```

proxytype

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to `esxi`.

host

The location, or ip/dns, of the ESXi host. Required.

username

The username used to login to the ESXi host, such as `root`. Required.

passwords

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

This also allows you to use any number of potential fallback passwords.

Note: When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi's login system. We have to wait for the first attempt to fail before trying the next password on the list.
This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a `True` result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

**protocol**

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`.

**port**

If the ESXi host is not using the default port, set this value to an alternate port. Default is `443`.

**credstore**

If the ESXi host is using an untrusted SSL certificate, set this value to the file path where the credential store is located. This file is passed to `esxcli`. Default is `<HOME>/.vmware/credstore/vicredentials.xml` on Linux and `<APPDATA>/VMware/credstore/vicredentials.xml` on Windows.

**Note:** HOME variable is sometimes not set for processes running as system services. If you want to rely on the default credential store location, make sure HOME is set for the proxy process.

**Salt Proxy**

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the ESXi host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the esxi host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```
And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the host. For example, you can get the ESXi host’s system information:

```
salt <id> esxi.cmd system_info
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. *Salt.modules.vsphere* is a standard Salt execution module. If you pull up the docs for it you'll see that almost every function in the module takes credentials and a target host. When credentials and a host aren't passed, Salt runs commands through *pyVmomi* against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of *pyVmomi* is installed, and that host would reach out over the network and communicate with the ESXi host.

*esxi.cmd* acts as a "shim" between the execution module and the proxy. Its first parameter is always the function from *salt.modules.vsphere*. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for this Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you'll want to look in *salt.modules.vsphere* instead of *salt.modules.esxi*.

**States**

Associated states are thoroughly documented in *salt.states.esxi*. Look there to find an example structure for Pillar as well as an example .sls file for standing up an ESXi host from scratch.

```
salt.proxy.esxi.ch_config(cmd, *args, **kwargs)
```

This function is called by the *salt.modules.esxi.cmd* shim. It then calls whatever is passed in *cmd* inside the *salt.modules.vsphere* module. Passes the return through from the vsphere module.

```
  cmd
    The command to call inside salt.modules.vsphere
  args
    Arguments that need to be passed to that command.
  kwargs
    Keyword arguments that need to be passed to that command.
```

```
salt.proxy.esxi.find_credentials(host)
```

Cycle through all the possible credentials and return the first one that works.

```
salt.proxy.esxi.get_details()
```

Return the proxy details

```
salt.proxy.esxi.grains()
```

Get the grains from the proxy device.

```
salt.proxy.esxi.grains_refresh()
```

Refresh the grains from the proxy device.

```
salt.proxy.esxi.init(opts)
```

This function gets called when the proxy starts up. For ESXi devices, the host, login credentials, and, if configured, the protocol and port are cached.
salt.proxy.esxi.is_connected_via_vcenter()

salt.proxy.esxi.ping()

Returns True if connection is to be done via a vCenter (no connection is attempted). Check to see if the host is responding when connecting directly via an ESXi host.

CLI Example:

```
salt esxi-host test.ping
```

salt.proxy.esxi.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

25.14.11 salt.proxy.esxvm

Proxy Minion interface module for managing VMWare ESXi virtual machines.

Dependencies

- pyVmomi
- jsonschema

Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. This can now happen from the proxy’s configuration file.

Example pillars:

userpass mechanism:

```
proxy:
  proxitype: esxvm
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
  mechanism: userpass
  username: <vCenter username>
  passwords: (required if userpass is used)
  - first_password
  - second_password
  - third_password
```

sspi mechanism:

```
proxy:
  proxitype: esxvm
  datacenter: <datacenter name>
  vcenter: <ip or dns name of parent vcenter>
```

(continues on next page)
**mechanism**: sspi
  **domain**: <user domain>
  **principal**: <host kerberos principal>

**proxytype**

To use this Proxy Module, set this to `esxvm`.

**datacenter**

Name of the datacenter where the virtual machine should be deployed. Required.

**vcenter**

The location of the VMware vCenter server (host of ip) where the virtual machine should be managed. Required.

**mechanism**

The mechanism used to connect to the vCenter server. Supported values are `userpass` and `sspi`. Required.

***Note:*** Connections are attempted using all (username, password) combinations on proxy startup.

**username**

The username used to login to the host, such as `root`. Required if mechanism is `userpass`.

**passwords**

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is `userpass`. When the proxy comes up, it will try the passwords listed in order.

**domain**

User realm domain. Required if mechanism is `sspi`. 

---

Salt Documentation, Release 3006.3
principal

Kerberos principal. Required if mechanism is sspi.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

To start a proxy minion one needs to establish its identity <id>:

```
salt-proxy --proxyid <proxy_id>
```

On the machine that will run the proxy, make sure there is a configuration file present. By default this is /etc/salt/proxy. If in a different location, the <configuration_folder> has to be specified when running the proxy: file with at least the following in it:

```
salt-proxy --proxyid <proxy_id> -c <configuration_folder>
```

Commands

Once the proxy is running it will connect back to the specified master and individual commands can be run against it:

```
# Master - minion communication
salt <proxy_id> test.ping

# Test vcenter connection
salt <proxy_id> vsphere.test_vcenter_connection
```

States

Associated states are documented in salt.states.esxvm. Look there to find an example structure for Pillar as well as an example .sls file for configuring an ESX virtual machine from scratch.

```
salt.proxy.esxvm.find_credentials()
```

Cycle through all the possible credentials and return the first one that works.

```
salt.proxy.esxvm.get_details()
```

Function that returns the cached details
salt.proxy.esxvm.init(opts)

This function gets called when the proxy starts up. For login the protocol and port are cached.

salt.proxy.esxvm.ping()

Returns True.

CLI Example:

```
salt esx-vm test.ping
```

salt.proxy.esxvm.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

25.14.12 salt.proxy.fx2

Dell FX2 chassis

New in version 2015.8.2.

Proxy minion interface module for managing Dell FX2 chassis (Dell Chassis Management Controller version 1.2 and above, iDRAC8 version 2.00 and above)

Dependencies

- iDRAC Remote execution module (salt.modules.dracr)
- Chassis command shim (salt.modules.chassis)
- Dell Chassis States (salt.states.dellchassis)
- Dell's racadm command line interface to CMC and iDRAC devices.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this proxy minion integration.

This proxy minion enables Dell FX2 and FX2s (hereafter referred to as simply "chassis", "CMC", or "FX2") chassis to be treated individually like a salt-minion.

Since the CMC embedded in the chassis does not run an OS capable of hosting a Python stack, the chassis can’t run a minion directly. Salt’s “Proxy Minion” functionality enables you to designate another machine to host a minion process that ”proxies” communication from the salt-master. The master does not know nor care that the target is not a real minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt’s documentation.

To configure this integration, follow these steps:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar, and a reference in the Pillar topfile that matches the ID. At a minimum for communication with the chassis the pillar should look like this:

```
proxy:
    host: <ip or dns name of chassis controller>
    admin_username: <iDRAC username for the CMC, usually 'root'>
```

(continues on next page)
fallback_admin_username: <username to try if the first fails>

passwords:
- first_password
- second_password
- third-password

proxytype: fx2

The proxytype line above is critical, it tells Salt which interface to load from the proxy directory in Salt's install hierarchy, or from /srv/salt/_proxy on the salt-master (if you have created your own proxy module, for example).

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password, a potential fallback password, and the third password can be the one you intend to change the chassis to use. This way, after it is changed, you should not need to restart the proxy minion--it should just pick up the third password in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Beware, many Dell CMC and iDRAC units are configured to lockout IP addresses or users after too many failed password attempts. This can generate user panic in the form of "I no longer know what the password is!!". To mitigate panic try the web interface from a different IP, or setup a emergency administrator user in the CMC before doing a wholesale password rotation.

The automatic lockout can be disabled via Salt with the following:

```
salt <cmc> chassis.cmd set_general cfgRacTuning cfgRacTuneIpBlkEnable 0
```

and then verified with

```
salt <cmc> chassis.cmd get_general cfgRacTuning cfgRacTuneIpBlkEnable
```

salt-proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your salt-master and to the chassis in question. SaltStack recommends that this machine also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can start the proxy with

```
salt-proxy --proxyid <id you want to give the chassis>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you want to give the chassis>
```

You can confirm that the pillar data is in place for the proxy:
And now you should be able to ping the chassis to make sure it is responding:

```bash
salt <id> test.ping
```

At this point you can execute one-off commands against the chassis. For example, you can get the chassis inventory:

```bash
salt <id> chassis.cmd inventory
```

Note that you don’t need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It’s important to understand how this particular proxy works. `Salt.modules.dracr` is a standard Salt execution module. If you pull up the docs for it you’ll see that almost every function in the module takes credentials and a target host. When credentials and a host aren’t passed, Salt runs `racadm` against the local machine. If you wanted you could run functions from this module on any host where an appropriate version of `racadm` is installed, and that host would reach out over the network and communicate with the chassis.

`Chassis.cmd` acts as a "shim" between the execution module and the proxy. Its first parameter is always the function from `salt.modules.dracr` to execute. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the chassis through the proxy, arranging for the credentials and host name to be pulled from the pillar section for this proxy minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the chassis, you’ll want to look in `salt.modules.dracr` instead of `salt.modules.chassis`.

**States**

Associated states are thoroughly documented in `salt.states.dellchassis`. Look there to find an example structure for pillar as well as an example `.sls` file for standing up a Dell Chassis from scratch.

```python
salt.proxy.fx2.admin_password()
    Return the admin_password in the DETAILS dictionary, or 'calvin' (the Dell default) if there is none present

salt.proxy.fx2.admin_username()
    Return the admin_username in the DETAILS dictionary, or root if there is none present

salt.proxy.fx2.chconfig(cmd, *args, **kwargs)
    This function is called by the `salt.modules.chassis.cmd` shim. It then calls whatever is passed in `cmd` inside the `salt.modules.dracr` module.
    **Parameters**
    - `cmd` -- The command to call inside salt.modules.dracr
    - `args` -- Arguments that need to be passed to that command
    - `kwargs` -- Keyword arguments that need to be passed to that command
    **Returns**
    Passthrough the return from the dracr module.

salt.proxy.fx2.find_credentials()
    Cycle through all the possible credentials and return the first one that works

salt.proxy.fx2.grains()
    Get the grains from the proxied device
```
salt.proxy.fx2.grains_refresh()
   Refresh the grains from the proxied device

salt.proxy.fx2.host()

salt.proxy.fx2.init(opts)
   This function gets called when the proxy starts up. We check opts to see if a fallback user and password are supplied. If they are present, and the primary credentials don’t work, then we try the backup before failing.

   Whichever set of credentials works is placed in the persistent DETAILS dictionary and will be used for further communication with the chassis.

salt.proxy.fx2.ping()
   Is the chassis responding?

   Returns
   Returns False if the chassis didn't respond, True otherwise.

salt.proxy.fx2.shutdown(opts)
   Shutdown the connection to the proxied device. For this proxy shutdown is a no-op.

25.14.13 salt.proxy.junos

Interface with a Junos device via proxy-minion. To connect to a junos device via junos proxy, specify the host information in the pillar in `/srv/pillar/details.sls`

```
proxy:
   proxytype: junos
   host: <ip or dns name of host>
   username: <username>
   port: 830
   password: <secret>
```

In `/srv/pillar/top.sls` map the device details with the proxy name.

```
base:
   'vmx':
      - details
```

After storing the device information in the pillar, configure the proxy in `/etc/salt/proxy`

```
master: <ip or hostname of salt-master>
```

Run the salt proxy via the following command:

```
salt-proxy --proxyid=vmx
```

```
class salt.proxy.junos.RebootActive(**kwargs)
   Class to get static variable, to indicate when a reboot/shutdown is being processed and the keep_alive should not probe the connection since it interferes with the shutdown process.

   reboot_shutdown = False
```

```
salt.proxy.junos.alive(opts)
   Validate and return the connection status with the remote device.

   New in version 2018.3.0.
```
Salt Documentation, Release 3006.3

salt.proxy.junos.conn()
salt.proxy.junos.get_reboot_active()
salt.proxy.junos.get_serialized_facts()
salt.proxy.junos.init(opts)
    Open the connection to the Junos device, login, and bind to the Resource class
salt.proxy.junos.initialized()
salt.proxy.junos.ping()
    Ping? Pong!
salt.proxy.junos.proxytype()
    Returns the name of this proxy
salt.proxy.junos.reboot_active()
salt.proxy.junos.reboot_clear()
salt.proxy.junos.shutdown(opts)
    This is called when the proxy-minion is exiting to make sure the connection to the device is closed cleanly.

25.14.14 salt.proxy.marathon

Marathon
Proxy minion for managing a Marathon cluster.

Dependencies
- marathon execution module (salt.modules.marathon)

Pillar
The marathon proxy configuration requires a 'base_url' property that points to the marathon endpoint:

```yaml
proxy:
    proxytype: marathon
    base_url: http://my-marathon-master.mydomain.com:8080
```

New in version 2015.8.2.
salt.proxy.marathon.init(opts)
    Perform any needed setup.
salt.proxy.marathon.ping()
    Is the marathon api responding?
salt.proxy.marathon.shutdown(opts)
    For this proxy shutdown is a no-op
25.14.15  salt.proxy.napalm

NAPALM: Network Automation and Programmability Abstraction Layer with Multivendor support

New in version 2016.11.0.
Proxy minion for managing network devices via NAPALM library.

    codeauthor
        Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>

    maturity
        new

    depends
        napalm

    platform
        unix

Dependencies

The napalm proxy module requires NAPALM library to be installed: pip install napalm Please check Installation for complete details.

---

Note: Beginning with Salt release 2017.7.3, it is recommended to use napalm >= 2.0.0. The library has been unified into a monolithic package, as in opposite to separate packages per driver. For more details you can check this document. While it will still work with the old packages, bear in mind that the NAPALM core team will maintain only the main napalm package.

Moreover, for additional capabilities, the users can always define a library that extends NAPALM's base capabilities and configure the provider option (see below).

---

Pillar

The napalm proxy configuration requires the following parameters in order to connect to the network device:

    driver
        Specifies the network device operating system. For a complete list of the supported operating systems please refer to the NAPALM Read the Docs page.

    host
        The IP Address or FQDN to use when connecting to the device. Alternatively, the following field names can be used instead: hostname, fqdn, ip.

    username
        The username to be used when connecting to the device.

    passwd
        The password needed to establish the connection.

---

Note: This field may not be mandatory when working with SSH-based drivers, and the username has a SSH key properly configured on the device targeted to be managed.
optional_args
  Dictionary with the optional arguments. Check the complete list of supported optional arguments.

always_alive: True
  In certain less dynamic environments, maintaining the remote connection permanently open with the network
device is not always beneficial. In that case, the user can select to initialize the connection only when needed,
by specifying this field to false. Default: true (maintains the connection with the remote network device).

  New in version 2017.7.0.

provider: napalm_base
  The library that provides the get_network_device function. This option is useful when the user has more
specific needs and requires to extend the NAPALM capabilities using a private library implementation. The
only constraint is that the alternative library needs to have the get_network_device function available.

  New in version 2017.7.1.

multiprocessing: False
  Overrides the multiprocessing option, per proxy minion. The multiprocessing option must be
turned off for SSH-based proxies. However, some NAPALM drivers (e.g. Arista, NX-OS) are not SSH-based.
As multiple proxy minions may share the same configuration file, this option permits the configuration of the
multiprocessing option more specifically, for some proxy minions.

  New in version 2017.7.2.

Proxy pillar file example:

```yaml
proxy:
  proxitype: napalm
  driver: junos
  host: core05.nrt02
  username: my_username
  passwd: my_password
  optional_args: 
    port: 12201
```

Example using a user-specific library, extending NAPALM's capabilities, e.g. custom_napalm_base:

```yaml
proxy:
  proxitype: napalm
  driver: ios
  fqdn: cr1.th2.par.as1234.net
  username: salt
  password: ''
  provider: custom_napalm_base
```

• **SNMP configuration module**
• **Users configuration management**

**Note:** Beginning with release codename 2019.2.0, any NAPALM command executed when running under a NAPALM Proxy Minion supports the `force_reconnect` magic argument.

Proxy Minions generally establish a connection with the remote network device at the time of the Minion startup and that connection is going to be used forever.

If one would need execute a command on the device but connecting using different parameters (due to various causes, e.g., unable to authenticate the user specified in the Pillar as the authentication system - say TACACS+ is not available, or the DNS resolver is currently down and would like to temporarily use the IP address instead, etc.), it implies updating the Pillar data and restarting the Proxy Minion process restart. In particular cases like that, you can pass the `force_reconnect=True` keyword argument, together with the alternative connection details, to enforce the command to be executed over a separate connection.

For example, if the usual command is `salt '*' net.arp`, you can use the following to connect using a different username instead: `salt '*' net.arp username=my-alt-usr force_reconnect=True`.

---

**salt.proxy.napalm.alive** *(opts)*

Return the connection status with the remote device.

New in version 2017.7.0.

**salt.proxy.napalm.call** *(method, *args, **kwargs)*

Calls a specific method from the network driver instance. Please check the readthedocs page for the updated list of getters.

**Parameters**

- `method` -- specifies the name of the method to be called
- `params` -- contains the mapping between the name and the values of the parameters needed to call the method

**Returns**

A dictionary with three keys:

- `result` (True/False): if the operation succeeded
- `out` (object): returns the object as-is from the call
- `comment` (string): provides more details in case the call failed
- `traceback` (string): complete traceback in case of exception. Please submit an issue including this traceback on the correct driver repo and make sure to read the FAQ

**Example:**

```python
__proxy__['napalm.call']('cli'
    **{
        'commands': ['show version',
                    'show chassis fan']
    })
```
salt.proxy.napalm.fns()
    Method called by NAPALM grains module.
salt.proxy.napalm.get_device()
    Returns the network device object.
salt.proxy.napalm.get_grains()
    Retrieve facts from the network device.
salt.proxy.napalm.grains_refresh()
    Refresh the grains.
salt.proxy.napalm.init(opts)
    Opens the connection with the network device.
salt.proxy.napalm.initialized()
    Connection finished initializing?
salt.proxy.napalm.ping()
    Connection open successfully?
salt.proxy.napalm.shutdown(opts)
    Closes connection with the device.

25.14.16 salt.proxy.netmiko_px

Netmiko

New in version 2019.2.0.
Proxy module for managing network devices via Netmiko.

codeauthor
    Mircea Ulinic <ping@mirceaulinic.net> & Kirk Byers <ktbyers@twb-tech.com>

maturity
    new
depends
    netmiko
platform
    unix

Dependencies

The netmiko proxy modules requires Netmiko to be installed: pip install netmiko.
Pillar

The netmiko proxy configuration requires the following parameters in order to connect to the network device:

- **device_type** - Class selection based on device type. Supported options:
  - a10: A10 Networks
  - accedian: Accedian Networks
  - alcatel_aos: Alcatel AOS
  - alcatel_sros: Alcatel SROS
  - apresia_aeos: Apresia AEOS
  - arista_eos: Arista EOS
  - aruba_os: Aruba
  - avaya_ers: Avaya ERS
  - avaya_vsp: Avaya VSP
  - brocade_fastiron: Brocade Fastiron
  - brocade_netiron: Brocade Netiron
  - brocade_nos: Brocade NOS
  - brocade_vdx: Brocade NOS
  - brocadeVyos: VyOS
  - checkpointGaia: Check Point GAiA
  - calix_b6: Calix B6
  - ciena_saos: Ciena SAOS
  - cisco_asa: Cisco SA
  - cisco_ios: Cisco IOS
  - cisco_nxos: Cisco NX-os
  - cisco_s300: Cisco S300
  - cisco_tp: Cisco TpTcCe
  - cisco_wlc: Cisco WLC
  - cisco_xe: Cisco IOS
  - cisco_xr: Cisco XR
  - coriant: Coriant

- extreme_telnet: Extreme Networks over Telnet
- ruckus_fastiron_telnet: Ruckus Fastiron over Telnet
- `cisco_ios_serial`: Cisco IOS over serial port

- **ip** - IP address of target device (not required if **host** is provided)
- **host** - Hostname of target device (not required if **ip** is provided)
- **username** - Username to authenticate against target device, if required
- **password** - Password to authenticate against target device, if required
- **secret** - The enable password if target device requires one
- **port** - The destination port used to connect to the target device
- **global_delay_factor** - Multiplication factor affecting Netmiko delays (default: 1)
- **use_keys** - Connect to target device using SSH keys (default: `False`)
- **key_file** - Filename path of the SSH key file to use
- **allow_agent** - Enable use of SSH key-agent
- **ssh_strict** - Automatically reject unknown SSH host keys (default: `False`, which means unknown SSH host keys will be accepted)
- **system_host_keys** - Load host keys from the user's "known_hosts" file (default: `False`)
- **alt_host_keys** - If `True`, host keys will be loaded from the file specified in **alt_key_file** (default: `False`)
- **alt_key_file** - SSH host key file to use (if **alt_host_keys**=`True`)
- **ssh_config_file** - File name of OpenSSH configuration file
- **timeout** - Connection timeout, in seconds (default: 90)
- **session_timeout** - Set a timeout for parallel requests, in seconds (default: 60)
- **keepalive** - Send SSH keepalive packets at a specific interval, in seconds. Currently defaults to 0, for backwards compatibility (it will not attempt to keep the connection alive using the KEEPALIVE packets).
- **default_enter** - Character(s) to send to correspond to enter key (default: `\n`)
- **response_return** - Character(s) to use in normalized return data to represent enter key (default: `\n`)
- **always_alive** - In certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In that case, the user can select to initialize the connection only when needed, by setting this option to `False`. By default this option is set to `True` (maintains the connection with the remote network device)
- **multiprocessing** - Overrides the **multiprocessing** option, per proxy minion, as the Netmiko communication channel is mainly SSH (default: `False`)
- **connection_timeout** - The number of seconds to attempt to connect to the device in seconds. (default: 300)
Proxy Pillar Example

```yaml
proxy:
  proxytype: netmiko
  device_type: juniper_junos
  host: router1.example.com
  username: example
  password: example

proxy:
  proxytype: netmiko
  device_type: cisco_ios
  ip: 1.2.3.4
  username: test
  use_keys: true
  secret: w3@k
```

salt.proxy.netmiko_px.alive(opts)
  Return the connection status with the network device.

salt.proxy.netmiko_px.args()
  Return the Netmiko device args.

salt.proxy.netmiko_px.call(method, *args, **kwargs)
  Calls an arbitrary netmiko method.

salt.proxy.netmiko_px.conn()
  Return the connection object.

salt.proxy.netmiko_px.connection(connection_timeout=300)

salt.proxy.netmiko_px.init(opts)
  Open the connection to the network device managed through netmiko.

salt.proxy.netmiko_px.initialized()
  Connection finished initializing?

salt.proxy.netmiko_px.make_con(connection_timeout=300)

salt.proxy.netmiko_px.ping()
  Connection open successfully?

salt.proxy.netmiko_px.shutdown(opts)
  Closes connection with the device.

### 25.14.17 salt.proxy.nxos

Proxy Minion for Cisco NX-OS Switches

New in version 2016.11.0.

The Cisco NX-OS Proxy Minion is supported on NX-OS devices for the following connection types: 1) Connection Type SSH 2) Connection Type NX-API (If Supported By The Device and Image Version).

maturity
  new
platform
  nxos

SSH uses the built in SSHConnection module in salt.utils.vt_helper

To configure the proxy minion for ssh:

```
proxy:
  proxytype: nxos
  connection: ssh
  host: 192.168.187.100
  username: admin
  password: admin
  prompt_name: nxos-switch
  ssh_args: '-o PubkeyAuthentication=no'
  key_accept: True
```

To configure the proxy minion for nxapi:

```
proxy:
  proxytype: nxos
  connection: nxapi
  host: 192.168.187.100
  username: admin
  password: admin
  transport: http
  port: 80
  verify: False
  save_config: False
```

proxytype:
  (REQUIRED) Use this proxy minion nxos

collection:
  (REQUIRED) connection transport type. Choices: ssh, nxapi Default: ssh

host:
  (REQUIRED) login ip address or dns hostname.

username:
  (REQUIRED) login username.

password:
  (REQUIRED) login password.

save_config:
  If True, 'copy running-config starting-config' is issues for every configuration command. If False, Running config is not saved to startup config Default: True

  The recommended approach is to use the save_running_config function instead of this option to improve performance. The default behavior controlled by this option is preserved for backwards compatibility.

Connection SSH Args:

prompt_name:
  (REQUIRED when connection is ssh) (REQUIRED, this or prompt_regex below, but not both) The name in the prompt on the switch. Recommended to use your device’s hostname.

prompt_regex:
  (REQUIRED when connection is ssh) (REQUIRED, this or prompt_name above, but not both) A
regular expression that matches the prompt on the switch and any other possible prompt at which you need the proxy minion to continue sending input. This feature was specifically developed for situations where the switch may ask for confirmation. prompt_name above would not match these, and so the session would timeout.

Example:

```
xos-switch#.*/\[(y/n)\]?.*
```

This should match

```
xos-switch#
```

or

```
Flash complete. Reboot this switch (y/n)? [n]
```

If neither prompt_name nor prompt_regex is specified the prompt will be defaulted to

```
.*#$
```

which should match any number of characters followed by a # at the end of the line. This may be far too liberal for most installations.

**ssh_args:**
Extra optional arguments used for connecting to switch.

**key_accept:**
Whether or not to accept the host key of the switch on initial login. Default: False

**Connection NXAPI Args:**

**transport:**
(REQUIRED) when connection is nxapi. Choices: http, https Default: https

**port:**
(REQUIRED) when connection is nxapi. Default: 80

**verify:**
(REQUIRED) when connection is nxapi. Either a boolean, in which case it controls whether we verify the NX-API TLS certificate, or a string, in which case it must be a path to a CA bundle to use. Default: True

When there is no certificate configuration on the device and this option is set as True (default), the commands will fail with the following error: SSLError: [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed (_ssl.c:581). In this case, you either need to configure a proper certificate on the device (recommended), or bypass the checks setting this argument as False with all the security risks considered.

The functions from the proxy minion can be run from the salt commandline using the `salt.modules.nxos` execution module.

**salt.proxy.nxos.grains()**

Helper function for nxos execution module functions that need to retrieve nxos grains using the proxy minion.
salt.proxy.nxos.grains_refresh()
   Helper function for nxos execution module functions that need to refresh nxos grains using the proxy minion.

salt.proxy.nxos.init(opts=None)
   Required. Initialize device connection using ssh or nxapi connection type.

salt.proxy.nxos.initialized()
   Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether the init() function has been called.

salt.proxy.nxos.ping()
   Helper function for nxos execution module functions that need to ping the nxos device using the proxy minion.

salt.proxy.nxos.proxy_config(commands, save_config=None)
   Helper function for nxos execution module functions that need to configure an nxos device using the proxy minion.

salt.proxy.nxos.sendline(commands, method='cli_show_ascii', **kwargs)
   Helper function for nxos execution module functions that need to send commands to an nxos device using the proxy minion.

salt.proxy.nxos.shutdown()
   Not supported. Only used as a place holder to satisfy shutdown function requirement.

25.14.18 salt.proxy.nxos_api

Proxy Minion to manage Cisco Nexus Switches (NX-OS) over the NX-API
New in version 2019.2.0.
Proxy module for managing Cisco Nexus switches via the NX-API.

   codeauthor
      Mircea Ulinic <ping@mirceaulinic.net>

   maturity
      new

   platform
      any

Usage

Note: To be able to use this module you need to enable to NX-API on your switch, by executing feature nxapi in configuration mode.

Configuration example:

```bash
switch# conf t
switch(config)# feature nxapi
```

To check that NX-API is properly enabled, execute show nxapi.

Output example:
switch# show nxapi
nxapi enabled
HTTPS Listen on port 443

Note: NX-API requires modern NXOS distributions, typically at least 7.0 depending on the hardware. Due to reliability reasons it is recommended to run the most recent version.

Pillar

The nxos_api proxy configuration requires the following parameters in order to connect to the network switch:

transport: https
   Specifies the type of connection transport to use. Valid values for the connection are http, and https.

host: localhost
   The IP address or DNS host name of the connection device.

username: admin
   The username to pass to the device to authenticate the NX-API connection.

password
   The password to pass to the device to authenticate the NX-API connection.

port
   The TCP port of the endpoint for the NX-API connection. If this keyword is not specified, the default value is automatically determined by the transport type (80 for http, or 443 for https).

timeout: 60
   Time in seconds to wait for the device to respond. Default: 60 seconds.

verify: True
   Either a boolean, in which case it controls whether we verify the NX-API TLS certificate, or a string, in which case it must be a path to a CA bundle to use. Defaults to True.

When there is no certificate configuration on the device and this option is set as True (default), the commands will fail with the following error: SSLError: [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed (_ssl.c:581). In this case, you either need to configure a proper certificate on the device (recommended), or bypass the checks setting this argument as False with all the security risks considered.

All the arguments may be optional, depending on your setup.
Proxy Pillar Example

```yaml
code
proxy:
    proxytype: nxos_api
    host: switch1.example.com
    username: example
    password: example

code

salt.proxy.nxos_api.get_conn_args()
    Returns the connection arguments of the Proxy Minion.

code

salt.proxy.nxos_api.init(opts)
    Open the connection to the Nexus switch over the NX-API.
    As the communication is HTTP based, there is no connection to maintain, however, in order to test the
    connectivity and make sure we are able to bring up this Minion, we are executing a very simple command (show
clock) which doesn't come with much overhead and it's sufficient to confirm we are indeed able to connect
to the NX-API endpoint as configured.

code

salt.proxy.nxos_api.initialized()
    Connection finished initializing?

code

salt.proxy.nxos_api.ping()
    Connection open successfully?

code

salt.proxy.nxos_api.rpc(commands, method='cli', **kwargs)
    Executes an RPC request over the NX-API.

code

salt.proxy.nxos_api.shutdown(opts)
    Closes connection with the device.
```

25.14.19 salt.proxy.panos

Proxy Minion interface module for managing Palo Alto firewall devices

New in version 2018.3.0.

```yaml
code
    codeauthor
    Spencer Ervin <spencer_ervin@hotmail.com>
    maturity
    new
    depends
    none
    platform
    unix
```

This proxy minion enables Palo Alto firewalls (hereafter referred to as simply 'panos') to be treated individually like a Salt Minion.

The panos proxy leverages the XML API functionality on the Palo Alto firewall. The Salt proxy must have access to the Palo Alto firewall on HTTPS (tcp/443).

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.
Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. There are four connection options available for the panos proxy module.

- Direct Device (Password)
- Direct Device (API Key)
- Panorama Pass-Through (Password)
- Panorama Pass-Through (API Key)

Direct Device (Password)

The direct device configuration configures the proxy to connect directly to the device with username and password.

```
proxy:
  proxytype: panos
  host: <ip or dns name of panos host>
  username: <panos username>
  password: <panos password>
  verify_ssl: True
```

proxytype

The proxytype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to panos.

host

The location, or ip/dns, of the panos host. Required.

username

The username used to login to the panos host. Required.
password

The password used to login to the panos host. Required.

Direct Device (API Key)

Palo Alto devices allow for access to the XML API with a generated 'API key' instead of username and password.

```
proxy:
  proxytype: panos
  host: <ip or dns name of panos host>
  apikey: <panos generated api key>
```

proxytype

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.

host

The location, or ip/dns, of the panos host. Required.

apikey

The generated XML API key for the panos host. Required.

Panorama Pass-Through (Password)

The Panorama pass-through method sends all connections through the Panorama management system. It passes the connections to the appropriate device using the serial number of the Palo Alto firewall.

This option will reduce the number of connections that must be present for the proxy server. It will only require a connection to the Panorama server.

The username and password will be for authentication to the Panorama server, not the panos device.

```
proxy:
  proxytype: panos
  serial: <serial number of panos host>
  host: <ip or dns name of the panorama server>
  username: <panorama server username>
  password: <panorama server password>
```
proxotype

The **proxotype** key and value pair is critical, as it tells Salt which interface to load from the **proxy** directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.

serial

The serial number of the panos host. Required.

host

The location, or ip/dns, of the Panorama server. Required.

username

The username used to login to the Panorama server. Required.

password

The password used to login to the Panorama server. Required.

Panorama Pass-Through (API Key)

The Panorama server can also utilize a generated 'API key' for authentication.

```
proxy:
    proxotype: panos
    serial: <serial number of panos host>
    host: <ip or dns name of the panorama server>
    apikey: <panos generated api key>
```

proxotype

The **proxotype** key and value pair is critical, as it tells Salt which interface to load from the **proxy** directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this panos Proxy Module, set this to `panos`.
serial

The serial number of the panos host. Required.

host

The location, or ip/dns, of the Panorama server. Required.

apikey

The generated XML API key for the Panorama server. Required.

salt.proxy.panos.call(payload=None)

This function captures the query string and sends it to the Palo Alto device.

salt.proxy.panos.grains()

Get the grains from the proxied device

salt.proxy.panos.grains_refresh()

Refresh the grains from the proxied device

salt.proxy.panos.init(opts)

This function gets called when the proxy starts up. For panos devices, a determination is made on the connection type and the appropriate connection details that must be cached.

salt.proxy.panos.initialized()

Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.panos.is_required_version(required_version='0.0.0')

Because different versions of Palo Alto support different command sets, this function will return true if the current version of Palo Alto supports the required command.

salt.proxy.panos.ping()

Returns true if the device is reachable, else false.

salt.proxy.panos.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

25.14.20 salt.proxy.philips_hue

Philips HUE lamps module for proxy.

New in version 2015.8.3.

First create a new user on the Hue bridge by following the Meet hue instructions.

To configure the proxy minion:

```
proxy:
  proxytype: philips_hue
  host: [hostname or ip]
  user: [username]
```
class salt.proxy.philips_hue.Const

Constants for the lamp operations.

COLOR_BLUE = {'hue': 46920, 'sat': 254}
COLOR_DAYLIGHT = {'xy': [0.3806, 0.3576]}
COLOR_GREEN = {'hue': 25500, 'sat': 254}
COLOR_ORANGE = {'hue': 12000, 'sat': 254}
COLOR_PINK = {'xy': [0.3688, 0.2095]}
COLOR_PURPLE = {'xy': [0.3787, 0.1724]}
COLOR_RED = {'hue': 0, 'sat': 254}
COLOR_WHITE = {'xy': [0.3227, 0.329]}
COLOR_YELLOW = {'xy': [0.4432, 0.5154]}
LAMP_OFF = {'on': False, 'transitiontime': 0}
LAMP_ON = {'on': True, 'transitiontime': 0}

salt.proxy.philips_hue.call_alert(*args, **kwargs)

Lamp alert

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **on**: Turns on or off an alert. Default is True.

CLI Example:

```
salt '*' hue.alert
salt '*' hue.alert id=1
salt '*' hue.alert id=1,2,3 on=false
```

salt.proxy.philips_hue.call_blink(*args, **kwargs)

Blink a lamp. If lamp is ON, then blink ON-OFF-ON, otherwise OFF-ON-OFF.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **pause**: Time in seconds. Can be less than 1, i.e. 0.7, 0.5 sec.

CLI Example:

```
salt '*' hue.blink id=1
salt '*' hue.blink id=1,2,3
```

salt.proxy.philips_hue.call_brightness(*args, **kwargs)

Set an effect to the lamp.

Arguments:
- **value**: 0–255 brightness of the lamp.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **transition**: Transition 0-200. Default 0.

CLI Example:
salt.proxy.philips_hue.call_color(*args, **kwargs)
    Set a color to the lamp.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    • color: Fixed color. Values are: red, green, blue, orange, pink, white, yellow, daylight, purple. Default white.
    • transition: Transition 0~200.
    Advanced:
    • gamut: XY coordinates. Use gamut according to the Philips HUE devices documentation.
    More: http://www.developers.meethue.com/documentation/hue-xy-values
    CLI Example:
    salt '*' hue.color
    salt '*' hue.color id=1
    salt '*' hue.color id=1,2,3 color=red transition=30
    salt '*' hue.color id=1 gamut=0.3,0.5

salt.proxy.philips_hue.call_effect(*args, **kwargs)
    Set an effect to the lamp.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    • type: Type of the effect. Possible values are "none" or "colorloop". Default "none".
    CLI Example:
    salt '*' hue.effect
    salt '*' hue.effect id=1
    salt '*' hue.effect id=1,2,3 type=colorloop

salt.proxy.philips_hue.call_lights(*args, **kwargs)
    Get info about all available lamps.
    Options:
    • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
    CLI Example:
    salt '*' hue.lights
    salt '*' hue.lights id=1
    salt '*' hue.lights id=1,2,3

salt.proxy.philips_hue.call_ping(*args, **kwargs)
    Ping the lamps by issuing a short inversion blink to all available devices.
    CLI Example:
    salt '*' hue.ping

salt.proxy.philips_hue.call_rename(*args, **kwargs)
    Rename a device.
    Options:
• **id**: Specifies a device ID. Only one device at a time.
  • **title**: Title of the device.

CLI Example:
```
salt '*!' hue.rename id=1 title='WC for cats'
```

```python
salt.proxy.philips_hue.call_status(*args, **kwargs)
```

Return the status of the lamps.

Options:
• **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
```
salt '*!' hue.status
salt '*!' hue.status id=1
salt '*!' hue.status id=1,2,3
```

```python
salt.proxy.philips_hue.call_switch(*args, **kwargs)
```

Switch lamp ON/OFF.

If no particular state is passed, then lamp will be switched to the opposite state.

Options:
• **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
  • **on**: True or False. Inverted current, if omitted

CLI Example:
```
salt '*!' hue.switch
salt '*!' hue.switch id=1
salt '*!' hue.switch id=1,2,3 on=True
```

```python
salt.proxy.philips_hue.call_temperature(*args, **kwargs)
```

Arguments:
• **value**: 150−500.

Options:
• **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
```
salt '*!' hue.temperature value=150
salt '*!' hue.temperature value=150 id=1
salt '*!' hue.temperature value=150 id=1,2,3
```

```python
salt.proxy.philips_hue.init(cnf)
```

Initialize the module.

```python
salt.proxy.philips_hue.ping(*args, **kw)
```

Ping the lamps.

```python
salt.proxy.philips_hue.shutdown(opts, *args, **kw)
```

Shuts down the service.
25.14.21 salt.proxy.rest_sample

This is a simple proxy-minion designed to connect to and communicate with the bottle-based web service contained in https://github.com/saltstack/salt-contrib/tree/master/proxyminion_rest_example

salt.proxy.rest_sample.alive(opts)

salt.proxy.rest_sample.fix_outage()

salt.proxy.rest_sample.fns()

salt.proxy.rest_sample.grains()
    Get the grains from the proxied device

salt.proxy.rest_sample.grains_refresh()
    Refresh the grains from the proxied device

salt.proxy.rest_sample.id(opts)
    Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion

salt.proxy.rest_sample.init(opts)

salt.proxy.rest_sample.initialized()  
    Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.rest_sample.package_install(name, **kwargs)
    Install a "package" on the REST server

salt.proxy.rest_sample.package_list()
    List "packages" installed on the REST server

salt.proxy.rest_sample.package_remove(name)
    Remove a "package" on the REST server

salt.proxy.rest_sample.package_status(name)
    Check the installation status of a package on the REST server

salt.proxy.rest_sample.ping()
    Is the REST server up?

salt.proxy.rest_sample.service_list()
    List "services" on the REST server

salt.proxy.rest_sample.service_restart(name)
    Restart a "service" on the REST server

salt.proxy.rest_sample.service_start(name)
    Start a "service" on the REST server

salt.proxy.rest_sample.service_status(name)
    Check if a service is running on the REST server

salt.proxy.rest_sample.service_stop(name)
    Stop a "service" on the REST server

salt.proxy.rest_sample.shutdown(opts)
    For this proxy shutdown is a no-op
Salt Documentation, Release 3006.3

salt.proxy.rest_sample.test_from_state()
   Test function so we have something to call from a state :return:
salt.proxy.rest_sample.uptodate(name)
   Call the REST endpoint to see if the packages on the "server" are up to date.

25.14.22 salt.proxy.restconf

Proxy Minion to manage RESTCONF Devices

   codeauthor
   Jamie (Bear) Murphy <jamiemurphyit@gmail.com>

   maturity
   new

   platform
   any

Usage

   Note: To be able to use this module you need to enable RESTCONF on your device and have https enabled.
   Cisco Configuration example:

   switch# conf t
   switch(config)# restconf
   switch(config)# ip http secure-server

   Note: RESTCONF requires modern OS distributions. This plugin has been written specifically to use JSON RESTCONF endpoints

Pillar

The restconf proxy configuration requires the following parameters in order to connect to the network switch:

   transport: https (str)
      Specifies the type of connection transport to use. Valid values for the connection are https, and http. The
      RESTCONF standard explicitly requires https, but http is included as an option as some manufacturers have
      ignored this requirement.

   hostname: (str)
      The IP address or DNS host name of the RESTCONF device.

   username: (str)
      The username for the device to authenticate the RESTCONF requests.

   password: (str)
      The password for the device to authenticate the RESTCONF requests.
verify: **True** or **False** *(str, optional, default: true)*  
Verify the RESTCONF SSL certificate?  
When there is no certificate configuration on the device and this option is set as True (default), the commands will fail with the following error: `SSLError: [SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed.`

**Warning:** In this case, you either need to configure a proper certificate on the device *(recommended)*, or bypass the checks setting this argument as **False** with all the security risks considered as you may be MITM'd.

**Proxy Pillar Example**

```yaml
proxy:
  proxytype: restconf
  host: switch1.example.com
  username: example
  password: example
  verify: false
```

- `salt.proxy.restconf.connection_test()`  
  Runs a connection test via http/https. Returns an array.
- `salt.proxy.restconf.init(opts)`  
  Required. Initialize device config and test an initial connection
- `salt.proxy.restconf.initialized()`  
  Connection finished initializing?
- `salt.proxy.restconf.ping()`  
  Triggers connection test. Returns True or False
- `salt.proxy.restconf.request(path, method='GET', dict_payload=None)`  
  Trigger http request to device
- `salt.proxy.restconf.shutdown(opts)`  
  Closes connection with the device.

**25.14.23 salt.proxy.ssh_sample**

This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH. This can be used as an option when the device does not provide an api over HTTP and doesn't have the python stack to run a minion.

- `salt.proxy.ssh_sample.fns()`  
  Method called by grains module.
- `salt.proxy.ssh_sample.grains()`  
  Get the grains from the proxied device
- `salt.proxy.ssh_sample.grains_refresh()`  
  Refresh the grains from the proxied device
salt.proxy.ssh_sample.init(opts)
   Required. Can be used to initialize the server connection.

salt.proxy.ssh_sample.initialized()
   Since grains are loaded in many different places and some of those places occur before the proxy can be
   initialized, return whether our init() function has been called

salt.proxy.ssh_sample.package_install(name, **kwargs)
   Install a "package" on the ssh server

salt.proxy.ssh_sample.package_list()
   List "packages" by executing a command via ssh This function is called in response to the salt command

```
salt target_minion pkg.list_pkgs
```

salt.proxy.ssh_sample.package_remove(name)
   Remove a "package" on the ssh server

salt.proxy.ssh_sample.parse(out)
   Extract json from out.
   Parameter
   out: Type string. The data returned by the ssh command.

salt.proxy.ssh_sample.ping()
   Required. Ping the device on the other end of the connection

salt.proxy.ssh_sample.service_list()
   Start a "service" on the ssh server
   New in version 2015.8.2.

salt.proxy.ssh_sample.service_restart(name)
   Restart a "service" on the ssh server
   New in version 2015.8.2.

salt.proxy.ssh_sample.service_start(name)
   Start a "service" on the ssh server
   New in version 2015.8.2.

salt.proxy.ssh_sample.service_stop(name)
   Stop a "service" on the ssh server
   New in version 2015.8.2.

salt.proxy.ssh_sample.shutdown(opts)
   Disconnect
25.14.24  salt.proxy.vcenter

Proxy Minion interface module for managing VMWare vCenters.

  codeauthor
  Rod McKenzie (roderick.mckenzie@morganstanley.com)
  codeauthor
  Alexandru Bleotu (alexandru.bleotu@morganstanley.com)

Dependencies

- pyVmomi Python Module

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newner must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

Configuration

To use this proxy module, please use on of the following configurations:

```
proxy:
  proxytype: vcenter
  vcenter: <ip or dns name of parent vcenter>
  username: <vCenter username>
  mechanism: userpass
  passwords:
    - first_password
    - second_password
    - third_password

proxy:
  proxytype: vcenter
  vcenter: <ip or dns name of parent vcenter>
  username: <vCenter username>
  domain: <user domain>
```

(continues on next page)
**mechanism**: sspi

**principal**: <host kerberos principal>

### proxytype

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this Proxy Module, set this to `vcenter`.

### vcenter

The location of the VMware vCenter server (host of ip). Required

### username

The username used to login to the vcenter, such as `root`. Required only for `userpass`.

### mechanism

The mechanism used to connect to the vCenter server. Supported values are `userpass` and `sspi`. Required.

### passwords

A list of passwords to be used to try and login to the vCenter server. At least one password in this list is required if mechanism is `userpass`

The proxy integration will try the passwords listed in order.

### domain

User domain. Required if mechanism is `sspi`

### principal

Kerberos principal. Required if mechanism is `sspi`
If the vCenter is not using the default protocol, set this value to an alternate protocol. Default is https.

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the vCenter server in the pillar. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id of the cluster>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the vcenter host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the vcenter. For example, you can get if the proxy can actually connect to the vCenter:

```
salt <id> vsphere.test_vcenter_connection
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. Salt.modules.vsphere is a standard Salt execution module.

If you pull up the docs for it you'll see that almost every function in the module takes credentials and a targets either a vcenter or a host. When credentials and a host aren’t passed, Salt runs commands through pyVmomi against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of pyVmomi is installed, and that host would reach out over the network and communicate with the ESXi host.
salt.proxy.vcenter.find_credentials()

Cycle through all the possible credentials and return the first one that works.

salt.proxy.vcenter.get_details()

Function that returns the cached details

salt.proxy.vcenter.init(opts)

This function gets called when the proxy starts up. For login the protocol and port are cached.

salt.proxy.vcenter.ping()

Returns True.

CLI Example:

```sh
salt vcenter test.ping
```

salt.proxy.vcenter.shutdown()

Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

25.15 queue modules

<table>
<thead>
<tr>
<th>Queue</th>
<th>Added Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgjsonb_queue</td>
<td>2016.3.0</td>
</tr>
<tr>
<td>sqlite_queue</td>
<td>2014.7.0</td>
</tr>
</tbody>
</table>

25.15.1 salt.queues.pgjsonb_queue

New in version 2016.3.0.

This is a queue with postgres as the backend. It uses the jsonb store to store information for queues.

```
depends
  python-psycopg2
```

To enable this queue, the following needs to be configured in your master config. These are the defaults:

```
queue.pgjsonb.host: 'salt'
queue.pgjsonb.user: 'salt'
queue.pgjsonb.password: 'salt'
queue.pgjsonb.dbname: 'salt'
queue.pgjsonb.port: 5432
```

Use the following Pg database schema:

```
CREATE DATABASE salt WITH ENCODING 'utf-8';
```

(continues on next page)
DROP TABLE IF EXISTS salt;
CREATE OR REPLACE TABLE salt(
    id SERIAL PRIMARY KEY,
    data jsonb NOT NULL
);

salt-run queue.insert test '{"name": "redis", "host": "172.16.0.8", "port":6379}' backend=pgjsonb
salt-run queue.process_queue test all backend=pgjsonb

salt.queues.pgjsonb_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.pgjsonb_queue.handle_queue_creation(queue)
salt.queues.pgjsonb_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.pgjsonb_queue.list_items(queue)
    List contents of a queue
salt.queues.pgjsonb_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.pgjsonb_queue.list_queues()
    Return a list of Salt Queues on the Salt Master
salt.queues.pgjsonb_queue.pop(queue, quantity=1, is_runner=False)
    Pop one or more or all items from the queue return them.

25.15.2 salt.queues.sqlite_queue

New in version 2014.7.0.
This is the default local master event queue built on sqlite. By default, an sqlite3 database file is created in the
sqlite_queue_dir which is found at:
/var/cache/salt/master/queues

It's possible to store the sqlite3 database files by setting sqlite_queue_dir to another location:
sqlite_queue_dir: /home/myuser/salt/master/queues

salt.queues.sqlite_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.sqlite_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.sqlite_queue.list_items(queue)
    List contents of a queue
salt.queues.sqlite_queue.list_length(queue)
    Provide the number of items in a queue

25.15. queue modules
salt.queues.sqlite_queue.list_queues()
    Return a list of Salt Queues on the Salt Master

salt.queues.sqlite_queue.pop(queue, quantity=1, is_runner=False)
    Pop one or more or all items from the queue return them.

## 25.16 roster modules

<table>
<thead>

</tr>
<tr>
<td>sshknownhosts</td>
<td>Parses roster entries out of Host directives from SSH known_hosts</td>
</tr>
<tr>
<td>terraform</td>
<td>Dynamic roster from terraform current state</td>
</tr>
</tbody>
</table>

### 25.16.1 salt.roster.ansible

Read in an Ansible inventory file or script.

Flat inventory files should be in the regular ansible inventory format.

```yaml
# /tmp/example_roster
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password' ansible_sudo_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password' ansible_sudo_pass='password'

[computers:children]
desktop
servers

[computers:vars]
http_port=80
```

then salt-ssh can be used to hit any of them
There is also the option of specifying a dynamic inventory, and generating it on the fly

```
#!/bin/bash
# filename: /etc/salt/hosts
echo '{
  "servers": [
    "salt.gtmanfred.com"
  ],
  "desktop": [
    "home"
  ],
  "computers": {
    "hosts": [],
    "children": [
      "desktop",
      "servers"
    ],
    "vars": {
      "http_port": 80
    }
  },
  "_meta": {
    "hostvars": {
      "salt.gtmanfred.com": {
        "ansible_ssh_user": "gtmanfred",
        "ansible_ssh_host": "127.0.0.1",
        "ansible_sudo_pass": "password",
        "ansible_ssh_pass": "password",
        "ansible_ssh_port": 22
      },
      "home": {
        "ansible_ssh_user": "gtmanfred",
      }
    }
  }
}'
```
This is the format that an inventory script needs to output to work with ansible, and thus here.

```bash
[~]# salt-ssh --roster=ansible --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com: True
```

Note: A dynamic inventory script must have the executable bit set. In the above example, `chmod +x /etc/salt/hosts`.

Any of the `[groups]` or direct hostnames will return. The ‘all’ is special, and returns everything.

```python
salt.roster.ansible.targets(tgt, tgt_type='glob', **kwargs)
```

Return the targets from the ansible inventory_file Default: `/etc/salt/roster`

### 25.16.2 salt.roster.cache

The `cache` roster provides a flexible interface to the Salt Masters’ minion cache to access regular minions over `salt-ssh`.

New in version 2017.7.0:

- grains, pillar, mine data matching
- SDB URLs
- IPv6 support
- `roster_order` per config key
- default order changed to industry-wide best practices
- CIDR range selection

**Targeting**

This roster supports all matching and targeting of the Salt Master. The matching will be done using only the Salt Master's cache.
The Roster Order

The roster’s composition can be configured using `roster_order`. In the `roster_order` you can define any roster key and fill it with a parameter overriding the one in `roster_defaults`:

```yaml
roster_order:
  host: id   # use the minion id as hostname
```

You can define lists of parameters as well, the first result from the list will become the value.

Selecting a host

```yaml
# default
roster_order:
  host:
    - ipv6-private   # IPv6 addresses in private ranges
    - ipv6-global    # IPv6 addresses in global ranges
    - ipv4-private   # IPv4 addresses in private ranges
    - ipv4-public    # IPv4 addresses in public ranges
    - ipv4-local     # loopback addresses
```

This is the default `roster_order`. It prefers IPv6 over IPv4 addresses and private addresses over public ones. The relevant data will be fetched from the cache in-order, and the first match will fill the `host` key.

Other address selection parameters are also possible:

```yaml
roster_order:
  host:
    - global|public|private|local   # Both IPv6 and IPv4 addresses in that range
    - 2000::/3   # CIDR networks, both IPv4 and IPv6 are supported
```

Using cached data

Several cached libraries can be selected using the `library:` `prefix, followed by the library key. This can be referenced using the same `:` `syntax as e.g. `pillar.get. Lists of references are also supported during the lookup, as are Salt SDB URLs.

This should be especially useful for the other roster keys:

```yaml
roster_order:
  host:
    - grain: fqdn_ip4   # Lookup this grain
    - mine: network.ip_addrs   # Mine data lookup works the same
  password: sdb://vault/ssh_pass   # Salt SDB URLs are also supported
  user:
    - pillar: ssh:auth:user   # Lookup this pillar key
    - sdb://osenv/USER   # Lookup this env var through sdb
```

(continues on next page)
priv:
  - pillar:
    - salt:ssh:private_key
    - ssh:auth:private_key

salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)

Return the targets from the Salt Masters' minion cache. All targets and matchers are supported.

The resulting roster can be configured using roster_order and roster_default.

25.16.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.

This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

To connect as a user other than root, modify the cloud configuration file usually located at /etc/salt/cloud. For example, add the following:

```yaml
ssh_username: my_user
sudo: True
```

salt.roster.cloud.extract_ipv4(roster_order, ipv4)

Extract the preferred IP address from the ipv4 grain

salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

25.16.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

```bash
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.→ping
```

salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)

Return the targets
25.16.5 salt.roster.dir

Create a salt roster out of a flat directory of files.
Each filename in the directory is a minion id. The contents of each file is rendered using the salt renderer system.
Consider the following configuration for example:

```bash
config/master:
    ... roster: dir roster_dir: config/roster.d ...
```

Where the directory config/roster.d contains two files:

```yaml
config/roster.d/minion-x:
    host: minion-x.example.com port: 22 sudo: true user: ubuntu
```

```yaml
config/roster.d/minion-y:
    host: minion-y.example.com port: 22 sudo: true user: gentoo
```

The roster would find two minions: minion-x and minion-y, with the given host, port, sudo and user settings.

The directory roster also extends the concept of roster defaults by supporting a roster_domain value in config:

```bash
... roster_domain: example.org ...
```

If that option is set, then any roster without a 'host' setting will have an implicit host of its minion id + '.' + the roster_domain. (The default roster_domain is the empty string, so you can also name the files the fully qualified name of each host. However, if you do that, then the fully qualified name of each host is also the minion id.)

This makes it possible to avoid having to specify the hostnames when you always want them to match their minion id plus some domain.

```python
salt.roster.dir.targets(tgt, tgt_type='glob', **kwargs)
```

Return the targets from the directory of flat yaml files, checks opts for location.

25.16.6 salt.roster.flat

Read in the roster from a flat file using the renderer system

```python
salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)
```

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

25.16.7 salt.roster.range

This roster resolves targets from a range server.

```python
depends
    seco.range, https://github.com/ytoolshed/range
```

When you want to use a range query for target matching, use --roster range. For example:

```bash
salt-ssh --roster range '%%%example.range.cluster' test.ping
```

```python
salt.roster.range.target_glob(tgt, hosts)
salt.roster.range.target_range(tgt, hosts)
```
salt.roster.range.targets(tgt, tgt_type='range', **kwargs)
   Return the targets from a range query

25.16.8 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports

**class** salt.roster.scan.RosterMatcher(tgt, tgt_type)
   Matcher for the roster data structure

   **targets()**
   Return ip addrs based on netmask, sitting in the "glob" spot because it is the default

salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)
   Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

25.16.9 salt.roster.sshconfig

Parses roster entries out of Host directives from SSH config

salt-ssh --roster sshconfig '*. -r "echo hi"

**class** salt.roster.sshconfig.RosterMatcher(raw, tgt, tgt_type)
   Matcher for the roster data structure

   **get_data(minion)**
   Return the configured ip

   **ret_glob_minions()**
   Return minions that match via glob

   **targets()**
   Execute the correct tgt_type routine and return

salt.roster.sshconfig.parse_ssh_config(lines)
   Parses lines from the SSH config to create roster targets.

   **Parameters**
   lines -- Individual lines from the ssh config file

   **Returns**
   Dictionary of targets in similar style to the flat roster

salt.roster.sshconfig.targets(tgt, tgt_type='glob', **kwargs)
   Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

25.16.10 salt.roster.sshknownhosts

Parses roster entries out of Host directives from SSH known_hosts

New in version 3006.0.

Sample configuration:

**Note:** The known_hosts file only contains hostname/IP. To pass other parameters, use roster_defaults.
Now you can use the module

```
salt-ssh --roster sshknownhosts '* -r "echo hi"
```

Or with a Saltfile

```
salt-ssh:
  ssh_known_hosts_file: /Users/user1/.ssh/known_hosts
```

```
salt-ssh --roster sshknownhosts '* -r "echo hi"
```

```
salt.roster.sshknownhosts.targets(tgt, tgt_type='glob')
```

Return the targets from a known_hosts file

### 25.16.11 salt.roster.terraform

**Dynamic roster from terraform current state**

This roster module allows you dynamically generate the roster from the terraform resources defined with the Terraform Salt provider.

It exposes all salt_host resources with the same attributes to the salt-ssh roster, making it completely independent of the type of terraform resource, and providing the integration using terraform constructs with interpolation.

**Basic Example**

Given a simple salt-ssh tree with a Saltfile:

```
salt-ssh:
  config_dir: etc/salt
  max_procs: 30
  wipe_ssh: True
```

and etc/salt/master:

```
root_dir: .
  file_roots:
    base:
      - srv/salt
  pillar_roots:
    base:
      - srv/pillar
  roster: terraform
```

In the same folder as your Saltfile, create terraform file with resources like cloud instances, virtual machines, etc. For every single one of those that you want to manage with Salt, create a salt_host resource:
resource "salt_host" "dbminion" {
  salt_id = "dbserver"
  host = "${libvirt_domain.vm-db.network_interface.0.addresses.0}"  
  user = "root"
  passwd = "linux"
}

You can use the count attribute to create multiple roster entries with a single definition. Please refer to the Terraform Salt provider for more detailed examples.

```
salt.roster.terraform.targets(tgt, tgt_type='glob', **kwargs)
```

Returns the roster from the terraform state file, checks opts for location, but defaults to terraform.tfstate

### 25.17 runner modules

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asam</td>

25.17.1 salt.runners.asam

Novell ASAM Runner

New in version 2015.8.0.

Runner to interact with Novell ASAM Fan-Out Driver

**codeauthor**

Nitin Madhok <nmadhok@g.clemson.edu>

To use this runner, set up the Novell Fan-Out Driver URL, username and password in the master configuration at /etc/salt/master or /etc/salt/master.d/asam.conf:

```yaml
asam:
  prov1.domain.com
    username: "testuser"
    password: "verybadpass"
    verify_ssl: true
  prov2.domain.com
    username: "testuser"
    password: "verybadpass"
    verify_ssl: true
```

**Note:** Optionally, protocol and port can be specified if the Fan-Out Driver server is not using the defaults.
Salt Documentation, Release 3006.3

Default is protocol: https and port: 3451.

```python
class salt.runners.asam.ASAMHTMLParser
    handle_starttag(tag, attrs)
```

```python
salt.runners.asam.add_platform(name, platform_set, server_url)
    To add an ASAM platform using the specified ASAM platform set on the Novell Fan-Out Driver
    CLI Example:
    salt-run asam.add_platform my-test-vm test-platform-set prov1.domain.com
```

```python
salt.runners.asam.list_platform_sets(server_url)
    To list all ASAM platform sets present on the Novell Fan-Out Driver
    CLI Example:
    salt-run asam.list_platform_sets prov1.domain.com
```

```python
salt.runners.asam.list_platforms(server_url)
    To list all ASAM platforms present on the Novell Fan-Out Driver
    CLI Example:
    salt-run asam.list_platforms prov1.domain.com
```

```python
salt.runners.asam.remove_platform(name, server_url)
    To remove specified ASAM platform from the Novell Fan-Out Driver
    CLI Example:
    salt-run asam.remove_platform my-test-vm prov1.domain.com
```

---

### 25.17.2 salt.runners.auth

Authentication runner for creating, deleting, and managing eauth tokens.

New in version 2016.11.0.

```python
salt.runners.auth.del_token(token)
    Delete an eauth token by name
    CLI Example:
    salt-run auth.del_token 6556760736e4077daa601baec2b67c24
```

```python
salt.runners.auth.mk_token("load")
    Create an eauth token using provided credentials
    Non-root users may specify an expiration date -- if allowed via the `token_expire_user_override` setting -- by passing an additional `token_expire` param. This overrides the `token_expire` setting of the same name in the Master config and is how long a token should live in seconds.
    CLI Example:
```

3694 Chapter 25. Salt Module Reference
```
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto

# Create a token valid for three years.
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \
    token_expire=94670856

# Calculate the number of seconds using expr.
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \
    token_expire=$(expr \( 365 \* 24 \* 60 \* 60 \) \* 3)
```

### 25.17.3 salt.runners.bgp

BGP Finder

New in version 2017.7.0.

Runner to search BGP neighbors details.

#### Configuration

- Minion (proxy) config

  The `bgp.neighbors` function must be appended in the list of `mine_functions`:

  ```
  mine_functions:
    bgp.neighbors: []
  ```

  Which instructs Salt to cache the data returned by the `neighbors` function from the *NAPALM BGP module*.

  How often the mines are refreshed, can be specified using:

  ```
  mine_interval: <X minutes>
  ```

- Master config

  By default the following options can be configured on the master. They are not mandatory, but available in case the user has different requirements.

  - **tgt:** `*`
    
    From what minions will collect the mine data. Default: `*` (collect mine data from all minions)

  - **tgt_type:** `glob`
    

  - **return_fields**
    
    What fields to return in the output. It can display all the fields from the `neighbors` function from the *NAPALM BGP module*.

    Some fields cannot be removed:

    - `as_number`: the AS number of the neighbor
    - `device`: the minion ID
    - `neighbor_address`: the neighbor remote IP address
By default, the following extra fields are returned (displayed):

- `connection_stats`: connection stats, as described below
- `import_policy`: the name of the import policy
- `export_policy`: the name of the export policy

Special fields:

- `vrf`: return the name of the VRF.
- `connection_stats`: returning an output of the form `<State> <Active>/` `<Received>/` `<Accepted>/` `<Damped>`, e.g. `Established 398/399/` `399/0` similar to the usual output from network devices.
- `interface_description`: matches the neighbor details with the corresponding interface and returns its description. This will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.
- `interface_name`: matches the neighbor details with the corresponding interface and returns the name. Similar to `interface_description`, this will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.

**display:** `True`
Display on the screen or return structured object? Default: `True` (return on the CLI).

**outputter:** `table`
Specify the outputter name when displaying on the CLI. Default: `table`.

Configuration example:

```yaml
runners:
  bgp:
    tgt:  'edge*'
    tgt_type: 'glob'
    return_fields:
      - up
      - connection_state
      - previous_connection_state
      - suppress_4byte_as
      - holdtime
      - flap_count
    outputter: yaml
```

`salt.runners.bgp.neighbors(*asns, **kwargs)`
Search for BGP neighbors details in the mines of the `bgp.neighbors` function.

**Arguments:**

- `asns`  
  A list of AS numbers to search for. The runner will return only the neighbors of these AS numbers.

- `device`  
  Filter by device name (minion ID).

- `ip`  
  Search BGP neighbor using the IP address. In multi-VRF environments, the same IP address could be used by more than one neighbors, in different routing tables.

- `network`  
  Search neighbors within a certain IP network.
title

Custom title.

display: **True**

Display on the screen or return structured object? Default: True (return on the CLI).

outputter: **table**

Specify the outputter name when displaying on the CLI. Default: table.

In addition, any field from the output of the `neighbors` function from the **NAPALM BGP module** can be used as a filter.

CLI Example:

```
salt-run bgp.neighbors 13335 15169
salt-run bgp.neighbors 13335 ip=172.17.19.1
salt-run bgp.neighbors multipath=True
salt-run bgp.neighbors up=False export_policy=my-export-policy
    multihop=False
salt-run bgp.neighbors network=192.168.0.0/16
```

Output example:

```
BGP Neighbors for 13335, 15169

(continues on next page)
25.17.4 salt.runners.cache

Return cached data from minions

salt.runners.cache.clear_all(tgt=None, tgt_type='glob')

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:

cache.clear_all

salt.runners.cache.clear_git_lock(role, remote=None, **kwargs)

New in version 2015.8.2.

Remove the update locks for Salt components (gitfs, git_pillar, winrepo) which use gitfs backend code from salt.utils.gitfs.

Note: Running cache.clear_all will not include this function as it does for pillar, grains, and mine.

Additionally, executing this function with a role of gitfs is equivalent to running salt-run fileserver.clear_lock backend=git.

- **role**: Which type of lock to remove (gitfs, git_pillar, or winrepo)
- **remote**: If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.
- **type**: [update, checkout, mountpoint] The types of lock to clear. Can be one or more of update, checkout, and mountpoint, and can be passed either as a comma-separated or Python list.

Changed in version 2018.3.0: `mountpoint` lock type added

CLI Examples:

```bash
salt-run cache.clear_git_lock gitfs
salt-run cache.clear_git_lock git_pillar
salt-run cache.clear_git_lock git_pillar type=update
salt-run cache.clear_git_lock git_pillar type=update,checkout
salt-run cache.clear_git_lock git_pillar type='["update", "mountpoint"]'
```

```python
salt.runners.cache.clear_grains(tgt=None, tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached grains data of the targeted minions

CLI Example:

```bash
salt-run cache.clear_grains
```

```python
salt.runners.cache.clear_mine(tgt=None, tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine data of the targeted minions

CLI Example:

```bash
salt-run cache.clear_mine
```

```python
salt.runners.cache.clear_mine_func(tgt=None, tgt_type='glob', clear_mine_func_flag=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine function data of the targeted minions

CLI Example:

```bash
salt-run cache.clear_mine_func tgt='*' clear_mine_func_flag='network.interfaces'
```

```python
salt.runners.cache.clear_pillar(tgt=None, tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached pillar data of the targeted minions

CLI Example:

```bash
salt-run cache.clear_pillar
```

```python
salt.runners.cache.cloud(tgt, provider=None)
```

Return cloud cache data for target.

**Note:** Only works with glob matching
tgt
  Glob Target to match minion ids

provider
  Cloud Provider

CLI Example:

```bash
salt-run cache.cloud 'salt*'  
salt-run cache.cloud glance.example.org provider=openstack
```

`salt.runners.cache.fetch` *(bank, key, cachedir=None)*

Fetch data from a salt.cache bank.

CLI Example:

```bash
salt-run cache.fetch cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

`salt.runners.cache.flush` *(bank, key=None, cachedir=None)*

Remove the key from the cache bank with all the key content. If no key is specified remove the entire bank with all keys and sub-banks inside.

CLI Examples:

```bash
salt-run cache.flush cloud/active/ec2/myec2 cachedir=/var/cache/salt/  
salt-run cache.flush cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

`salt.runners.cache.grains` *(tgt, tgt_type='glob'; **kwargs)*

Return cached grains of the targeted minions.

**tgt**

Target to match minion ids.

Changed in version 2017.7.0: The *expr_form* argument has been renamed to *tgt_type*, earlier releases must use *expr_form*.

`tgt_type`

The type of targeting to use for matching, such as *glob*, *list*, etc.

CLI Example:

```bash
salt-run cache.grains '*'
```

`salt.runners.cache.list_` *(bank, cachedir=None)*

Lists entries stored in the specified bank.

CLI Example:

```bash
salt-run cache.list cloud/active/ec2/myec2 cachedir=/var/cache/salt/
```

`salt.runners.cache.mine` *(tgt=None; tgt_type='glob'; **kwargs)*

Return cached mine data of the targeted minions.

Changed in version 2017.7.0: The *expr_form* argument has been renamed to *tgt_type*, earlier releases must use *expr_form*.

3700 Chapter 25. Salt Module Reference
CLI Example:
```
salt-run cache.mine
```

`salt.runners.cache.pillar(tgt=None, tgt_type='glob', **kwargs)`

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Return cached pillars of the targeted minions if `tgt` is set. If `tgt` is not set will return cached pillars for all minions.

CLI Example:
```
salt-run cache.pillar
```

`salt.runners.cache.store(bank, key, data, cachedir=None)`

Lists entries stored in the specified bank.

CLI Example:
```
salt-run cache.store mycache mykey 'The time has come the walrus said'
```

### 25.17.5 `salt.runners.cloud`

**The Salt Cloud Runner**

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

`salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, opts=None, **kwargs)`

Execute a single action on the given map/provider/instance

CLI Example:
```
salt-run cloud.action start my-salt-vm
```

`salt.runners.cloud.create(provider, instances, opts=None, **kwargs)`

Create an instance using Salt Cloud

CLI Example:
```
salt-run cloud.create my-ec2-config myinstance \  
  image=ami-1624987f size='t1.micro' ssh_username=ec2-user \  
  securitygroup=default delvol_on_destroy=True
```

`salt.runners.cloud.destroy(instances, opts=None)`

Destroy the named vm(s)

`salt.runners.cloud.full_query(query_type='list_nodes_full')`

List all available cloud provider data

`salt.runners.cloud.list_images(provider='all')`

List cloud provider images for the given providers
salt.runners.cloud.list_locations(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.list_sizes(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.map_run(path=None, opts=None, **kwargs)
Execute a salt cloud map file

salt.runners.cloud.profile(prof=None, instances=None, opts=None, **kwargs)
Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
```
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3
```

salt.runners.cloud.query(query_type='list_nodes')
List cloud provider data for all providers

salt.runners.cloud.select_query(query_type='list_nodes_select')
List selected nodes

### 25.17.6 salt.runners.config

This runner is designed to mirror the execution module config.py, but for master settings

salt.runners.config.get(key, default='', delimiter=':')
Retrieve master config options, with optional nesting via the delimiter argument.

**Arguments**

- default
  - If the key is not found, the default will be returned instead
- delimiter
  - Override the delimiter used to separate nested levels of a data structure.

CLI Example:
```
salt-run config.get gitfs_remotes
salt-run config.get file_roots:base
salt-run config.get file_roots,base delimiter=','
```

### 25.17.7 salt.runners.ddns

**Dynamic DNS Runner**

New in version 2015.8.0.

Runner to interact with DNS server and create/delete/update DNS records

**codeauthor**
Nitin Madhok <nmadhok@g.clemson.edu>
salt.runners.ddns.add_host(zone, name, ttl, ip, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Create both A and PTR (reverse) records for a host.

CLI Example:

```
salt-run ddns.add_host domain.com my-test-vm 3600 10.20.30.40 my-tsig-key →/etc/salt/tsig.keyring 10.0.0.1 5
```

salt.runners.ddns.create(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Create a DNS record. The nameserver must be an IP address and the master running this runner must have create privileges on that server.

CLI Example:

```
salt-run ddns.create domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key →/etc/salt/tsig.keyring 10.0.0.1 5
```

salt.runners.ddns.delete(zone, name, keyname, keyfile, nameserver, timeout, rdtype=None, data=None, port=53, keyalgorithm='hmac-md5')

Delete a DNS record.

CLI Example:

```
salt-run ddns.delete domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5 A
```

salt.runners.ddns.delete_host(zone, name, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Delete both forward (A) and reverse (PTR) records for a host only if the forward (A) record exists.

CLI Example:

```
salt-run ddns.delete_host domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5
```

salt.runners.ddns.update(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, replace=False, port=53, keyalgorithm='hmac-md5')

Replace, or update a DNS record. The nameserver must be an IP address and the master running this runner must have update privileges on that server.

Note: If replace is set to True, all records for this name and type will first be deleted and then recreated. Default is replace=False.

CLI Example:

```
salt-run ddns.update domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key →/etc/salt/tsig.keyring 10.0.0.1 5
```
25.17.8 salt.runners.digicertapi

Support for Digicert. Heavily based on the Venafi runner by Joseph Hall (jphall@saltstack.com).

Before using this module you need to register an account with Digicert's CertCentral.

Login to CertCentral, ensure you have a payment method configured and/or there are adequate funds attached to your account. Click the Account item in the left sidebar, and select Account Access. The right hand pane should show "Account Access" and a link to create an API key. Create a new API key and assign it to the user that should be attached to requests coming from Salt.

NOTE CertCentral will not show the API key again after revealing it the first time. Make sure you copy it right away or you will have to revoke it and generate a new one.

Now open /etc/salt/master and add the API key as shown below.

```
digicert:
    api_key: ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOP ```

Restart your Salt Master.

You can also include default values of the following variables to help with creating CSRs:

```
digicert:
    api_key: ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZ_ASCII
    shatype: sha256
```

This API currently only supports RSA key types. Support for other key types will be added if interest warrants.

salt.runners.digicertapi.del_cached_domain(domains)

Delete cached domains from the master

CLI Example:

```
salt-run digicert.del_cached_domain domain1.example.com, domain2.example.com
```

salt.runners.digicertapi.gen_csr(minion_id, dns_name=None, organization_id=None, ou_name=None, key_len=2048, shatype='sha256', password=None)

CLI Example:

```
salt-run digicert.gen_csr <minion_id> <dns_name>
```

salt.runners.digicertapi.gen_key(minion_id, dns_name=None, password=None, key_len=2048)

Generate and return a private_key. If a dns_name is passed in, the private_key will be cached under that name.

CLI Example:

```
salt-run digicert.gen_key <minion_id> [dns_name] [password]
```

salt.runners.digicertapi.get_certificate(order_id=None, certificate_id=None, minion_id=None, cert_format='pem_all', filename=None)

Retrieve a certificate by order_id or certificate_id and write it to stdout or a filename.

A list of permissible cert_formats is here:

https://www.digicert.com/services/v2/documentation/appendix-certificate-formats
CLI Example:

```
salt-run digicert.get_certificate order_id=48929454 cert_format=apache
```

Including a 'filename' will write the certificate to the desired file. Note that some cert formats are zipped files, and some are binary.

If the certificate has not been issued, this function will return the order details inside of which will be a status (one of pending, rejected, processing, issued, revoked, canceled, needs_csr, and needs_approval)

If for some reason you want to pipe the output of this command to a file or other command you will want to leave off the filename argument and make sure to include --no-color so there will be no terminal ANSI escape sequences.

```
salt.runners.digicertapi.get_org_details(organization_id)
```

Return the details for an organization

CLI Example:

```
salt-run digicert.get_org_details 34
```

Returns a dictionary with the org details, or with 'error' and 'status' keys.

```
salt.runners.digicertapi.list_domain_cache()
```

List domains that have been cached

CLI Example:

```
salt-run digicert.list_domain_cache
```

```
salt.runners.digicertapi.list_domains(container_id=None)
```

List domains that CertCentral knows about. You can filter by container_id (also known as "Division") by passing a container_id.

CLI Example:

```
salt-run digicert.list_domains
```

```
salt.runners.digicertapi.list_orders(status=None)
```

List certificate orders made to CertCentral.

CLI Example:

```
salt-run digicert.list_orders
```

```
salt.runners.digicertapi.list_organizations(container_id=None, include_validation=True)
```

List organizations that CertCentral knows about. You can filter by container_id (also known as "Division") by passing a container_id. This function returns validation information by default; pass include_validation=False to turn it off.

CLI Example:

```
salt-run digicert.list_organizations
```

```
salt.runners.digicertapi.list_requests(status=None)
```

List certificate requests made to CertCentral. You can filter by status: pending, approved, rejected

CLI Example:
salt-run digicert.list_requests pending

salt.runners.digicertapi.order_certificate(minion_id, common_name, organization_id, validity_years, cert_key_passphrase=None, signature_hash=None, key_len=2048, dns_names=None, organization_units=None, server_platform=None, custom_expiration_date=None, comments=None, disable_renewal_notifications=False, product_type_hint=None, renewal_of_order_id=None)

Order a certificate. Requires that an Organization has been created inside Digicert’s CertCentral.

See here for API documentation: https://www.digicert.com/services/v2/documentation/order/order-ssl-determinator

CLI Example:
salt-run digicert.order_certificate my_minionid my.domain.com 10
← 3 signature_hash=sha256
dns_names=['this.domain.com', 'that.domain.com']
← organization_units='My Domain Org Unit'
← comments='Comment goes here for the approver'

This runner can also be used to renew a certificate by passing renewal_of_order_id. Previous order details can be retrieved with digicertapi.list_orders.

salt.runners.digicertapi.show_csrs()
Show certificate requests for this API key

CLI Example:
salt-run digicert.show_csrs

salt.runners.digicertapi.show_organization(domain)
Show organization information, especially the company id

CLI Example:
salt-run digicert.show_company example.com

salt.runners.digicertapi.show_rsa(minion_id, dns_name)
Show a private RSA key

CLI Example:
salt-run digicert.show_rsa myminion domain.example.com
25.17.9 salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

salt.runners.doc.execute()

Collect all the sys.doc output from each minion and return the aggregate

   CLI Example:

   salt-run doc.execution

salt.runners.doc.runner()

Return all inline documentation for runner modules

   CLI Example:

   salt-run doc.runner

salt.runners.doc.wheel()

Return all inline documentation for wheel modules

   CLI Example:

   salt-run doc.wheel

25.17.10 salt.runners.drac

Manage Dell DRAC from the Master

The login credentials need to be configured in the Salt master configuration file.

   drac:
       username: admin
       password: secret

salt.runners.drac.poweroff(hostname, timeout=20, username=None, password=None)

Power server off

   CLI Example:

   salt-run drac.poweroff example.com

salt.runners.drac.poweron(hostname, timeout=20, username=None, password=None)

Power server on

   CLI Example:

   salt-run drac.poweron example.com

salt.runners.drac.pxe(hostname, timeout=20, username=None, password=None)

Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot

   CLI Example:

   salt-run drac.pxe example.com
salt.runners.drac.reboot( hostname, timeout=20, username=None, password=None)
Reboot a server using the Dell DRAC

CLI Example:
```bash
salt-run drac.reboot example.com
```

salt.runners.drac.version( hostname, timeout=20, username=None, password=None)
Display the version of DRAC

CLI Example:
```bash
salt-run drac.version example.com
```

25.17.11 salt.runners.error

Error generator to enable integration testing of salt runner error handling

salt.runners.error.error(name=None, message='')
If name is None Then return empty dict
Otherwise raise an exception with __name__ from name, message from message

CLI Example:
```bash
salt-run error
salt-run error.error name="Exception" message="This is an error."
```

25.17.12 salt.runners.event

Module for sending events using the runner system.
New in version 2016.11.0.

salt.runners.event.send(tag, data=None)
Send an event with the given tag and data.

This is useful for sending events directly to the master from the shell with salt-run. It is also quite useful for sending events in orchestration states where the fire_event requisite isn't sufficient because it does not support sending custom data with the event.

Note that event tags will not be namespaced like events sent with the fire_event requisite! Whereas events produced from fire_event are prefixed with salt/state_result/<jid>/<minion_id>/<name>, events sent using this runner module will have no such prefix. Make sure your reactors don't expect a prefix!

Parameters
- **tag** -- the tag to send with the event
- **data** -- an optional dictionary of data to send with the event

CLI Example:
```bash
salt-run event.send my/custom/event '{"foo": "bar"}"
```

Orchestration Example:
salt-run state.orchestrate orch.command pillar='"exit_code": 0'
salt-run state.orchestrate orch.command pillar='"exit_code": 1'

25.17.13 salt.runners.f5

Runner to provide F5 Load Balancer functionality

depends

• pycontrol Python module

configuration
In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

load_balancers:
  bigip1.example.com:
    username: admin
    password: secret
  bigip2.example.com:
    username: admin
    password: secret

class salt.runners.f5.\F5Mgmt(lb, username, password)

    add_pool_member(name, port, pool_name)
    Add a node to a pool
**check_member_pool**(*member, pool_name*)
Check a pool member exists in a specific pool

**check_pool**(*name*)
Check to see if a pool exists

**check_virtualserver**(*name*)
Check to see if a virtual server exists

**create_pool**(*name, method='ROUND_ROBIN'* )
Create a pool on the F5 load balancer

**create_vs**(*name, ip, port, protocol, profile, pool_name*)
Create a virtual server

**lbmethods()**
List all the load balancer methods

**salt.runners.f5.add_pool_member**(lb, name, port, pool_name)
Add a node to a pool

CLI Examples:

```
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool
```

**salt.runners.f5.check_member_pool**(lb, member, pool_name)
Check a pool member exists in a specific pool

CLI Examples:

```
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool
```

**salt.runners.f5.check_pool**(lb, name)
Check to see if a pool exists

CLI Examples:

```
salt-run f5.check_pool load_balancer pool_name
```

**salt.runners.f5.check_virtualserver**(lb, name)
Check to see if a virtual server exists

CLI Examples:

```
salt-run f5.check_virtualserver load_balancer virtual_server
```

**salt.runners.f5.create_pool**(lb, name, method='ROUND_ROBIN')
Create a pool on the F5 load balancer

CLI Examples:

```
salt-run f5.create_pool load_balancer pool_name loadbalance_method
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
```

**salt.runners.f5.create_vs**(lb, name, ip, port, protocol, profile, pool_name)
Create a virtual server

CLI Examples:
25.17.14 salt.runners.fileserver

Directly manage the Salt fileserver plugins

salt.runners.fileserver.clear_cache(backend=None)

New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (git, hg, svn). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the `backend` argument.

`backend`

Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

CLI Example:

```
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots
```

salt.runners.fileserver.clear_file_list_cache(saltenv=None, backend=None)

New in version 2016.11.0.

The Salt fileserver caches the files/directories/symlinks for each fileserver backend and environment as they are requested. This is done to help the fileserver scale better. Without this caching, when hundreds/thousands of minions simultaneously ask the master what files are available, this would cause the master's CPU load to spike as it obtains the same information separately for each minion.

`saltenv`

By default, this runner will clear the file list caches for all environments. This argument allows for a list of environments to be passed, to clear more selectively. This list can be passed either as a comma-separated string, or a Python list.

`backend`

Similar to the `saltenv` parameter, this argument will restrict the cache clearing to specific fileserver backends (the default behavior is to clear from all enabled fileserver backends). This list can be passed either as a comma-separated string, or a Python list.

Since the ability to clear these caches is often required by users writing custom runners which add/remove files, this runner can easily be called from within a custom runner using any of the following examples:

```
# Clear all file list caches
__salt__['fileserver.clear_file_list_cache']()
# Clear just the 'base' saltenv file list caches
__salt__['fileserver.clear_file_list_cache'](saltenv='base')
# Clear just the 'base' saltenv file list caches from just the 'roots' fileserver backend
__salt__['fileserver.clear_file_list_cache'](saltenv='base', backend='~roots')
# Clear all file list caches from the 'roots' fileserver backend
__salt__['fileserver.clear_file_list_cache'](backend='roots')
```
Note: In runners, the __salt__ dictionary will likely be renamed to __runner__ in a future Salt release to distinguish runner functions from remote execution functions. See this GitHub issue for discussion/updates on this.

If using Salt's Python API (not a runner), the following examples are equivalent to the ones above:

```python
import salt.config
import salt.runner

opts = salt.config.master_config('/etc/salt/master')
opts['fun'] = 'fileserver.clear_file_list_cache'

# Clear all file list caches
opts['arg'] = []  # No arguments
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches
opts['arg'] = ['base', None]
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches from just the 'roots'
# fileserver backend
opts['arg'] = ['base', 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear all file list caches from the 'roots' fileserver backend
opts['arg'] = [None, 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()
```

This function will return a dictionary showing a list of environments which were cleared for each backend. An empty return dictionary means that no changes were made.

CLI Examples:

```bash
# Clear all file list caches
salt-run fileserver.clear_file_list_cache
# Clear just the 'base' saltenv file list caches
salt-run fileserver.clear_file_list_cache saltenv=base
# Clear just the 'base' saltenv file list caches from just the 'roots'
# fileserver backend
salt-run fileserver.clear_file_list_cache saltenv=base backend=roots
# Clear all file list caches from the 'roots' fileserver backend
salt-run fileserver.clear_file_list_cache backend=roots
```

salt.runners.fileserver.clear_lock(backend=None, remote=None)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (git, hg, svn). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master's
logfile). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

**backend**

Only clear the update lock for the specified backend(s).

**remote**

If specified, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `github` will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
```

**salt.runners.fileserver.dir_list**(saltenv='base', backend=None)

Return a list of directories in the given environment

**saltenv**

[base] The salt fileserver environment to be listed

**backend**

Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
```

**salt.runners.fileserver.empty_dir_list**(saltenv='base', backend=None)

Return a list of empty directories in the given environment

**saltenv**

[base] The salt fileserver environment to be listed

**backend**

Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Note: Some backends (such as `git` and `hg`) do not support empty directories. So, passing `backend=git` or `backend=hg` will result in an empty list being returned.

CLI Example:

```
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```
**salt.runners.fileserver.envs** (backend=None, sources=False)

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

**backend**
Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend=['roots', 'git']`)

CLI Example:
```
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

**salt.runners.fileserver.file_list** (saltenv='base', backend=None)

Return a list of files from the salt fileserver

**saltenv**
[base] The salt fileserver environment to be listed

**backend**
Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:
```
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

**salt.runners.fileserver.lock** (backend=None, remote=None)

New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (`git`, `hg`, `svn`).

**Note:** This will only operate on enabled backends (those configured in `fileserver_backend`).

**backend**
Only set the update lock for the specified backend(s).

**remote**
If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of `*github.com*` will remove the lock from all github.com remotes.

CLI Example:
```
salt-run fileserver.lock
salt-run fileserver.lock backend=git,hg
```
(continues on next page)
salt documentation, release 3006.3

salt-run fileserver.lock backend=git remote='*github.com*'  
salt-run fileserver.lock remote=bitbucket

salt.runners.fileserver.symlink_list(saltenv='base', backend=None)  
Return a list of symlinked files and dirs  
saltenv  
[base] The salt fileserver environment to be listed  
backend  
Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.  

New in version 2015.5.0.  
CLI Example:

```
salt-run fileserver.symlink_list  
salt-run fileserver.symlink_list saltenv=prod  
salt-run fileserver.symlink_list saltenv=dev backend=git  
salt-run fileserver.symlink_list base hg,roots  
salt-run fileserver.symlink_list -git
```

salt.runners.fileserver.update(backend=None, **kwargs)  
Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.  
backend  
Narrow fileserver backends to a subset of the enabled ones.  

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.  

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend="['roots', 'git']")  
kwargs  
Pass additional arguments to backend. See example below  
CLI Example:

```
salt-run fileserver.update  
salt-run fileserver.update backend=roots,git  
salt-run fileserver.update backend=git remotes=myrepo,yourrepo
```

25.17.15 salt.runners.git_pillar  
Runner module to directly manage the git external pillar  
salt.runners.git_pillar.update(branch=None, repo=None)  
New in version 2014.1.0.  

Changed in version 2015.8.4: This runner function now supports the git_pillar configuration schema introduced in 2015.8.0. Additionally, the branch and repo can now be omitted to update all git_pillar remotes. The return data has also changed to a dictionary. The values will be True only if new commits were fetched, and False if there were errors or no new commits were fetched.
Changed in version 2018.3.0: The return for a given git_pillar remote will now be `None` when no changes were fetched. `False` now is reserved only for instances in which there were errors.

Changed in version 3001: The repo parameter also matches against the repo name.

Fetch one or all configured git_pillar remotes.

**Note:** This will not fast-forward the git_pillar cachedir on the master. All it does is perform a `git fetch`. If this runner is executed with `-l debug`, you may see a log message that says that the repo is up-to-date. Keep in mind that Salt automatically fetches git_pillar repos roughly every 60 seconds (or whatever `loop_interval` is set to). So, it is possible that the repo was fetched automatically in the time between when changes were pushed to the repo, and when this runner was executed. When in doubt, simply refresh pillar data using `saltutil.refresh_pillar` and then use `pillar.item` to check if the pillar data has changed as expected.

**CLI Example:**

```bash
# Update specific branch and repo
salt-run git_pillar.update branch='branch' repo='https://foo.com/bar.git'
# Update specific repo, by name
salt-run git_pillar.update repo=myrepo
# Update all repos
salt-run git_pillar.update
# Run with debug logging
salt-run git_pillar.update -l debug
```

### 25.17.16 salt.runners.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

**salt.runners.http.query**(url, output=True, **kwargs)

Query a resource, and decode the return data

Passes through all the parameters described in the `utils.http.query` function:

**CLI Example:**

```bash
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST data='somecontent'
```

**salt.runners.http.update_ca_bundle**(target=None, source=None, merge_files=None)

Update the local CA bundle file from a URL

New in version 2015.5.0.

**CLI Example:**
salt-run http.update_ca_bundle
salt-run http.update_ca_bundle target=/path/to/cacerts.pem
salt-run http.update_ca_bundle source=https://example.com/cacerts.pem

If the target is not specified, it will be pulled from the ca_cert configuration variable available to the master. If it cannot be found there, it will be placed at <<FILE_ROOTS>>/cacerts.pem.

If the source is not specified, it will be pulled from the ca_cert_url configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

merge_files may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```

### 25.17.17 salt.runners.jobs

A convenience system to manage jobs, both active and already run

**salt.runners.jobs.active**(display_progress=False)

Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```
salt-run jobs.active
```

**salt.runners.jobs.exit_success**(jid, ext_source=None)

Check if a job has been executed and exit successfully

jid
The jid to look up.

**ext_source**
The external job cache to use. Default: None.

CLI Example:

```
salt-run jobs.exit_success 20160520145827701627
```

**salt.runners.jobs.last_run**(ext_source=None, outputter=None, metadata=None, function=None, target=None, display_progress=False)

New in version 2015.8.0.

List all detectable jobs and associated functions

CLI Example:

```
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
salt-run jobs.last_run function='cmd.run'
salt-run jobs.last_run metadata="{'foo': 'bar'}"
```

**salt.runners.jobs.list_job**(jid, ext_source=None, display_progress=False)

List a specific job given by its jid
ext_source
If provided, specifies which external job cache to use.

display_progress
[False] If True, fire progress events.

CLI Example:

```
salt-run jobs.list_job 20130916125524463507
salt-run jobs.list_job 20130916125524463507 --out=pprint
```

salt.runners.jobs.list_jobs(ext_source=None, outputter=None, search_metadata=None, search_function=None, search_target=None, start_time=None, end_time=None, display_progress=False)

List all detectable jobs and associated functions

ext_source
If provided, specifies which external job cache to use.

FILTER OPTIONS

Note: If more than one of the below options are used, only jobs which match all of the filters will be returned.

search_metadata
Specify a dictionary to match to the job’s metadata. If any of the key-value pairs in this dictionary match, the job will be returned. Example:

```
salt-run jobs.list_jobs search_metadata='{"foo": "bar", "baz": "qux"} '
```

search_function
Can be passed as a string or a list. Returns jobs which match the specified function. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_function='test.*'
salt-run jobs.list_jobs search_function='["test.*", "pkg.install"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_function='test.*,pkg.install'
```

search_target
Can be passed as a string or a list. Returns jobs which match the specified minion name. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_target='*.mydomain.tld'
salt-run jobs.list_jobs search_target='["db*", "myminion"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_target='db*,myminion'
```

start_time
Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started after this timestamp.
end_time
Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started before this timestamp.

CLI Example:
```
salt-run jobs.list_jobs
salt-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='{"bar": "foo"}'
salt-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'
```

salt.runners.jobs.list_jobs_filter(count, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)
List all detectable jobs and associated functions

ext_source
The external job cache to use. Default: None.

CLI Example:
```
salt-run jobs.list_jobs_filter 50
salt-run jobs.list_jobs_filter 100 filter_find_job=False
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, display_progress=False)
Return the printout from a previously executed job

jid
The jid to look up.

ext_source
The external job cache to use. Default: None.

returned
[True] If True, include the minions that did return from the command.
New in version 2015.8.0.

missing
[False] If True, include the minions that did not return from the command.

display_progress
[False] If True, fire progress events.
New in version 2015.5.0.

CLI Example:
```
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 --out=highstate
```

salt.runners.jobs.master()
Return the actively executing runners for the master

CLI Example:
```
salt-run jobs.master
```

salt.runners.jobs.print_job(jid, ext_source=None)
Print a specific job's detail given by its jid, including the return data.

CLI Example:
25.17.18 salt.runners.launchd

Manage launchd plist files

**salt.runners.launchd.write_launchd_plist**(program)

Write a launchd plist for managing salt-master or salt-minion

CLI Example:

```
salt-run launchd.write_launchd_plist salt-master
```

25.17.19 salt.runners.lxc

Control Linux Containers via Salt

**depends**

lxc execution module

**salt.runners.lxc.cloud_init**(names, host=None, quiet=False, **kwargs)

Wrapper for using lxc.init in saltcloud compatibility mode

names
Name of the containers, supports a single name or a comma delimited list of names.

host
Minion to start the container on. Required.

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**salt.runners.lxc.find_guest**(name, quiet=False, path=None)

Returns the host for a container.

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.find_guest name
```

**salt.runners.lxc.find_guests**(names, path=None)

Return a dict of hosts and named guests

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.find_guests names
```

**salt.runners.lxc.freeze**(name, quiet=False, path=None)

Freeze the named container

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
salt-run lxc.freeze name

salt.runners.lxc.info(name, quiet=False, path=None)

Returns information about a container.

path
path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

salt-run lxc.info name

salt.runners.lxc.init(names, host=None, saltcloud_mode=False, quiet=False, **kwargs)

Initialize a new container

salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset] \ 
 [cpushare=cgroups_cpushare] [memory=cgroups_memory] \ 
 [template=lxc_template_name] [clone=original name] \ 
 [profile=lxc_profile] [network_profile=network_profile] \ 
 [nic=network_profile] [nic_opts=nic_opts] \ 
 [start=(true|false)] [seed=(true|false)] \ 
 [install=(true|false)] [config=minion_config] \ 
 [snapshot=(true|false)]

names
Name of the containers, supports a single name or a comma delimited list of names.

host
Minion on which to initialize the container (required)

path
path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

saltcloud_mode
init the container with the saltcloud opts format instead See lxc.init_interface module documentation

cpuset
cgroups cpuset.

cpushare
cgroups cpu shares.

memory
cgroups memory limit, in MB
Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass memory=0 to set no limit.

template
Name of LXC template on which to base this container

clone
Clone this container from an existing container

profile
A LXC profile (defined in config or pillar).

network_profile
Network profile to use for the container
New in version 2015.5.2.

nic
Deprecated since version 2015.5.0: Use network_profile instead
nic_opts
Extra options for network interfaces. E.g.:
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6": "2001:db8::ff00:42:8329"}}

start
Start the newly created container.

seed
Seed the container with the minion config and autosign its key. Default: true

install
If salt-minion is not already installed, install it. Default: true

cfg
Optional config parameters. By default, the id is set to the name of the container.

salt.runners.lxc.list_(host=None, quiet=False, path=None)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).

path"path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

salt-run lxc.list [host=minion_id]

salt.runners.lxc.purge(name, delete_key=True, quiet=False, path=None)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with
the container.

path"path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

salt-run lxc.purge name

salt.runners.lxc.start(name, quiet=False, path=None)
Start the named container.

path"path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

salt-run lxc.start name

salt.runners.lxc.stop(name, quiet=False, path=None)
Stop the named container.

path"path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.

salt-run lxc.stop name

salt.runners.lxc.unfreeze(name, quiet=False, path=None)
Unfreeze the named container

path"path to the container parent default: /var/lib/lxc (system default)
New in version 2015.8.0.
25.17.20 salt.runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down

salt.runners.manage.alived(subset=None, show_ip=False)

New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
subset
[None] Pass in a list of minion ids.
show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.alived

salt.runners.manage.allowed(subset=None, show_ip=False)

New in version 2015.8.0.
Changed in version 2019.2.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
subset
[None] Pass in a list of minion ids.
show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.allowed

salt.runners.manage.bootstrap(version='develop', script='https://bootstrap.saltproject.io', hosts='', script_args='', roster='flat', ssh_user=None, ssh_password=None, ssh_priv_key=None, tmp_dir='/tmp/.bootstrap', http_backend='tornado')

Bootstrap minions with salt-bootstrap
version
[develop] Git tag of version to install
script
[https://bootstrap.saltproject.io/] URL containing the script to execute
hosts
Comma-separated hosts [example: hosts='host1.local,host2.local']. These hosts need to exist in the specified roster.
script_args
Any additional arguments that you want to pass to the script.
New in version 2016.11.0.
roster
[flat] The roster to use for Salt SSH. More information about roster files can be found in Salt's Roster Documentation.
A full list of roster types, see the `builtin roster modules` documentation.

New in version 2016.11.0.

**ssh_user**

If `user` isn't found in the `roster`, a default SSH user can be set here. Keep in mind that `ssh_user` will not override the roster `user` value if it is already defined.

New in version 2016.11.0.

**ssh_password**

If `passwd` isn't found in the `roster`, a default SSH password can be set here. Keep in mind that `ssh_password` will not override the roster `passwd` value if it is already defined.

New in version 2016.11.0.

**ssh_privkey**

If `priv` isn't found in the `roster`, a default SSH private key can be set here. Keep in mind that `ssh_password` will not override the roster `passwd` value if it is already defined.

New in version 2016.11.0.

**tmp_dir**

`[/tmp/.bootstrap]` The temporary directory to download the bootstrap script in. This directory will have `-<uuid4>` appended to it. For example: `/tmp/.bootstrap-a19a728e-d40a-4801-aba9-d00655c143a7/`

New in version 2016.11.0.

**http_backend**

[tornado] The backend library to use to download the script. If you need to use a file:/// URL, then you should set this to `urllib2`.

New in version 2016.11.0.

CLI Example:

```
salt-run manage.bootstrap hosts='host1,host2'
salt-run manage.bootstrap hosts='host1,host2' version='v3004.2'
salt-run manage.bootstrap hosts='host1,host2' version='v3004.2' script=←'https://bootstrap.saltproject.io/develop'
```

salt.runners.manage.**bootstrap_psexec**

( `hosts``=``", master=None, version=None, arch='win32', installer_url=None, username=None, password=None` )

Bootstrap Windows minions via PsExec.

- **hosts**
  
  Comma separated list of hosts to deploy the Windows Salt minion.

- **master**
  
  Address of the Salt master passed as an argument to the installer.

- **version**
  
  Point release of installer to download. Defaults to the most recent.

- **arch**
  
  Architecture of installer to download. Defaults to win32.

- **installer_url**
  
  URL of minion installer executable. Defaults to the latest version from https://repo.saltproject.io/windows/

- **username**
  
  Optional user name for login on remote computer.

- **password**
  
  Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:
salt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17'
	username='DOMAIN\Administrator'
salt-run manage.bootstrap_psexec hosts='host1,host2' installer_url='http://<exampledomain/salt-installer.exe'

salt.runners.manage.down(removekeys=False, tgt='', tgt_type='glob', timeout=None, gather_job_timeout=None)

Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:
salt-run manage.down
salt-run manage.down removekeys=True
salt-run manage.down tgt="webservers" tgt_type="nodegroup"

salt.runners.manage.joined(subset=None, show_ip=False)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
subset
    [None] Pass in a list of minion ids.
show_ip
    [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.joined

salt.runners.manage.key_regen()

This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED‼

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a salt-key -A command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:
salt-run manage.key_regen

salt.runners.manage.list_not_state(subset=None, show_ip=False)

New in version 2015.8.0.

Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent to minions)

subset
    [None] Pass in a list of minion ids.

show_ip
    [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.list_not_state
```

```
salt.runners.manage.list_state(subset=None, show_ip=False)
```
New in version 2015.8.0.

Changed in version 2019.2.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

subset
    [None] Pass in a list of minion ids.

show_ip
    [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.list_state
```

```
salt.runners.manage.not_alived(subset=None, show_ip=False)
```
New in version 2015.8.0.

Changed in version 2019.2.0.

Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset
    [None] Pass in a list of minion ids.

show_ip
    [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_alived
```

```
salt.runners.manage.not_allowed(subset=None, show_ip=False)
```
New in version 2015.8.0.

Changed in version 2019.2.0.

Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset
    [None] Pass in a list of minion ids.

show_ip
    [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_allowed
```

```
salt.runners.manage.notJoined(subset=None, show_ip=False)
```
New in version 2015.8.0.

Changed in version 2019.2.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset
[None] Pass in a list of minion ids.

show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.notJoined
```

salt.runners.manage.not_present(subset=None, show_ip=False)

New in version 2015.5.0.
Changed in version 2019.2.0.

Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset
[None] Pass in a list of minion ids.

show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_present
```

salt.runners.manage.not_reaped(subset=None, show_ip=False)

New in version 2015.8.0.
Changed in version 2019.2.0.

Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset
[None] Pass in a list of minion ids.

show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_reaped
```

salt.runners.manage.present(subset=None, show_ip=False)

Changed in version 2019.2.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

subset
[None] Pass in a list of minion ids.

show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.present
```

salt.runners.manage.reaped(subset=None, show_ip=False)

New in version 2015.8.0.
Changed in version 2019.2.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset
[None] Pass in a list of minion ids.

show_ip
[False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.reaped
```

```ruby
salt.runners.manage.safe_accept(target, tgt_type='glob')
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Accept a minion’s public key after checking the fingerprint over salt-ssh

CLI Example:

```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2 tgt_type=list
```

```ruby
salt.runners.manage.status(output=True, tgt='', tgt_type='glob', timeout=None, gather_job_timeout=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Print the status of all known salt minions

CLI Example:

```
salt-run manage.status
salt-run manage.status tgt="webservers" tgt_type="nodegroup"
salt-run manage.status timeout=5 gather_job_timeout=10
```

```ruby
salt.runners.manage.up(tgt='', tgt_type='glob', timeout=None, gather_job_timeout=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Print a list of all of the minions that are up

CLI Example:

```
salt-run manage.up
salt-run manage.up tgt="webservers" tgt_type="nodegroup"
salt-run manage.up timeout=5 gather_job_timeout=10
```

```ruby
salt.runners.manage.versions()
```

Check the version of active minions

CLI Example:

```
salt-run manage.versions
```
25.17.21 salt.runners.match

Run matchers from the master context.
New in version 3007.0.

salt.runners.match.compound_matches(expr, minion_id)

Check whether a minion is matched by a given compound match expression. On success, this function will return the minion ID, otherwise False.

**Note:** Pillar values will be matched literally only since this function is intended for remote calling. This also applies to node groups defined on the master. Custom matchers are not respected.

**Note:** If a module calls this runner from a minion, you will need to explicitly allow the remote call. See peer_run.

CLI Example:

```
salt-run match.compound_matches 'I@foo:bar and G@os:Deb* and not db*'
  → myminion
```

- **expr**
  The *Compound Matcher* expression to validate against.
- **minion_id**
  The minion ID of the minion to check the match for.

25.17.22 salt.runners.mattermost

Note for 2017.7 releases!

Due to the salt.runners.config module not being available in this release series, importing the salt.runners.config module from the master branch is required to make this module work.

Ref: Mattermost runner failing to retrieve config values due to unavailable config runner #43479

Module for sending messages to Mattermost
New in version 2017.7.0.

**configuration**

This module can be used by either passing an api_url and hook directly or by specifying both in a configuration profile in the salt master/minion config. For example:

```
mattermost:
  hook: peweBiMOS9HrZG15peWeBiMOS9HrZG15
  api_url: https://example.com
```

salt.runners.mattermost.post_event(event, channel=None, username=None, api_url=None, hook=None)

Send an event to a Mattermost channel. :param channel: The channel name, either will work. :param username: The username of the poster. :param event: The event to send to the Mattermost channel. :param api_url: The Mattermost api url, if not specified in the configuration. :param hook: The Mattermost hook, if not specified in the configuration. :return: Boolean if message was sent successfully.
Salt Documentation, Release 3006.3

salt.runners.mattermost.post_message(message, channel=None, username=None, api_url=None, hook=None)

Send a message to a Mattermost channel. ::param channel: The channel name, either will work. ::param username: The username of the poster. ::param message: The message to send to the Mattermost channel. ::param api_url: The Mattermost api url, if not specified in the configuration. ::param hook: The Mattermost hook, if not specified in the configuration. ::return: Boolean if message was sent successfully.

CLI Example:

```bash
call-run mattermost.post_message message='Build is done'
```

25.17.23 salt.runners.mine

A runner to access data from the salt mine

salt.runners.mine.get(tgt, fun, tgt_type='glob')

Gathers the data from the specified minions' mine, pass in the target, function to look up and the target type

CLI Example:

```bash
call-run mine.get '* network.interfaces'
```

salt.runners.mine.update(tgt, tgt_type='glob', clear=False, mine_functions=None)

New in version 2017.7.0.

Update the mine data on a certain group of minions.

tgt

Which minions to target for the execution.

tgt_type: glob

The type of tgt.

clear: False

Boolean flag specifying whether updating will clear the existing mines, or will update. Default: False

CLI Example:

```bash
call-run mine.update '*'
call-run mine.update 'juniper-edges' tgt_type='nodegroup'
```

25.17.24 salt.runners.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

depends

PyNaCl, https://github.com/pyca/pynacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.

configuration

The following configuration defaults can be define (pillar or config files) Avoid storing private keys in pillars! Ensure master does not have pillar_opts=True:
Salt Documentation, Release 3006.3

```
# cat /etc/salt/master.d/nacl.conf
nacl.config:
    # NOTE: `key` and `key_file` have been renamed to `sk`, `sk_file`
    # also `box_type` default changed from secretbox to sealedbox.
    box_type: sealedbox (default)
    sk_file: /etc/salt/pki/master/nacl (default)
    pk_file: /etc/salt/pki/master/nacl.pub (default)
    sk: None
    pk: None
```

Usage can override the config defaults:

```
salt-run nacl.enc sk_file=/etc/salt/pki/master/nacl pk_file=/etc/salt/pki/master/nacl.pub
```

The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your sk_file and pk_file use:

```
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl
    # or if you want to work without files.
    salt-run nacl.keygen
    local:
    -------
    pk: /kfGX7PbWeu099702PBbKWlPG/9p06IQRswkdWHCDk0=
    sk: SVWut5SSqNpuNzb1b9y6b2eXg2PLIog43GBzp48Sow=
```

Now with your keypair, you can encrypt data:

You have two option, sealedbox or secretbox.
SecretBox is data encrypted using private key pk. Sealedbox is encrypted using public key pk.
Recommend using Sealedbox because the one way encryption permits developers to encrypt data for source control but not decrypt. Sealedbox only has one key that is for both encryption and decryption.

```
salt-run nacl.enc asecretpass pk=/kfGX7PbWeu099702PBbKWlPG/9p06IQRswkdWHCDk0=
tqXzeI3nTAM9Xf0mdLcpEdklMbfBGPj2oTKmlgrm3S1DTVHNh9h8mU1GKllGq/
    cYsk6m5WhGdk58=
```

To decrypt the data:

```
salt-run nacl.dec data=
tqXzeI3nTAM9Xf0mdLcpEdklMbfBGPj2oTKmlgrm3S1DTVHNh9h8mU1GKllGq/
    cYsk6m5WhGdk58=' sk='SVWut5SSqNpuNzb1b9y6b2eXg2PLIog43GBzp48Sow='
```

When the keys are defined in the master config you can use them from the nacl runner without extra parameters:

```
# cat /etc/salt/master.d/nacl.conf
nacl.config:
    sk_file: /etc/salt/pki/master/nacl
    pk: 'cTIqXwnUd1ulg4kXsbeCE7/NoeKEzd4nLeYcCFpd9k=
```

25.17. runner modules

3731
salt-run nacl.enc 'asecretpass'
salt-run nacl.dec data=
    → 'tqXzeI3nTAM9Xf0mdLcpEdklMbfBGpj2oTKmlgrm3S1DTVVHNNh9h8mU1GKllGq/
    → 'cYsk6m5WhGdkS8=

# a salt developers minion could have pillar data that includes a nacl public key
nacl.config:
    pk: '/kFGX7PbWeu099702PBBKWLPg/9p06IQRswkdWHCDk0=

The developer can then use a less-secure system to encrypt data.

class-run nacl.enc apassword

Pillar files can include protected data that the salt master decrypts:

pillarexample:
    user: root
    password1: {{salt.nacl.dec('DRB7Q6/X5gGSRCTpZyxS6hlbWj0llUA+uavYyvou3vJ4=
        → ')|json}}
    cert_key: {{salt.nacl.dec_file('/srv/salt/certs/example.com/key.nacl
        → ')|json}}
    cert_key2: {{salt.nacl.dec_file('salt:///certs/example.com/key.nacl
        → ')|json}}

Larger files like certificates can be encrypted with:

class-run nacl.enc_file /tmp/cert.crt out=/tmp/cert.nacl

salt.runners.nacl.dec(data, **kwargs)
    Alias to [box_type]_decrypt
    box_type: secretbox, sealedbox(default)
salt.runners.nacl.dec_file(name, out=None, **kwargs)
    This is a helper function to decrypt a file and return its contents.
    You can provide an optional output file using out
    name can be a local file or when not using salt-run can be a url like salt://, https:// etc.
    CLI Examples:
        salt-run nacl.dec_file name=/tmp/id_rsa.nacl
        salt-run nacl.dec_file name=/tmp/id_rsa.nacl box_type=secretbox
        sk_file=/etc/salt/pki/master/nacl.pub

salt.runners.nacl.enc(data, **kwargs)
    Alias to [box_type]_encrypt
    box_type: secretbox, sealedbox(default)
salt.runners.nacl.enc_file(name, out=None, **kwargs)
    This is a helper function to encrypt a file and return its contents.
    You can provide an optional output file using out
    name can be a local file or when not using salt-run can be a url like salt://, https:// etc.
CLI Examples:

```bash
salt-run nacl.enc_file name=/tmp/id_rsa
salt-run nacl.enc_file name=/tmp/id_rsa box_type=secretbox sk_file=./etc/salt/pki/master/nacl.pub
```

salt.runners.nacl.keygen*(sk_file=None, pk_file=None, **kwargs)*

Use PyNaCL to generate a keypair.

- If no *sk_file* is defined return a keypair.
- If only the *sk_file* is defined *pk_file* will use the same name with a postfix *.pub*.
- When the *sk_file* is already existing, but *pk_file* is not. The *pk_file* will be generated using the *sk_file*.

CLI Examples:

```bash
salt-run nacl.keygen
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl
salt-run nacl.keygen sk_file=/etc/salt/pki/master/nacl pk_file=/etc/salt/pki/master/nacl.pub
salt-run nacl.keygen
```

salt.runners.nacl.sealedbox_decrypt*(data, **kwargs)*

Decrypt data using a secret key that was encrypted using a public key with *nacl.sealedbox_encrypt*.

CLI Examples:

```bash
salt-run nacl.sealedbox_decrypt data=pEXHQM6cuaF7A=
salt-run nacl.sealedbox_decrypt data='pEXHQM6cuaF7A=' sk_file=/etc/salt/pki/master/nacl
salt-run nacl.sealedbox_decrypt data='pEXHQM6cuaF7A=' sk='YmFkcGFzcwo=
```

salt.runners.nacl.sealedbox_encrypt*(data, **kwargs)*

Encrypt data using a public key generated from *nacl.keygen*. The encryptd data can be decrypted using *nacl.sealedbox_decrypt* only with the secret key.

CLI Examples:

```bash
salt-run nacl.sealedbox_encrypt data=dataoenc
```

salt.runners.nacl.secretbox_decrypt*(data, **kwargs)*

Decrypt data that was encrypted using *nacl.secretbox_encrypt* using the secret key that was generated from *nacl.keygen*.

CLI Examples:

```bash
salt-run nacl.secretbox_decrypt data=pEXHQM6cuaF7A=
salt-run nacl.secretbox_decrypt data='pEXHQM6cuaF7A=' sk_file=/etc/salt/pki/master/nacl
salt-run nacl.secretbox_decrypt data='pEXHQM6cuaF7A=' sk='YmFkcGFzcwo=
```

salt.runners.nacl.secretbox_encrypt*(data, **kwargs)*

Encrypt data using a secret key generated from *nacl.keygen*. The same secret key can be used to decrypt the data using *nacl.secretbox_decrypt*.

CLI Examples:
25.17.25 salt.runners.net

NET Finder

New in version 2017.7.0.
A runner to find network details easily and fast. It’s smart enough to know what you are looking for.

Configuration

• Minion (proxy) config

To have the complete features, one needs to add the following mine configuration in the minion (proxy) config file:

```
mine_functions:
 net.ipaddrs: []
 net.lldp: []
 net.mac: []
 net.arp: []
 net.interfaces: []
```

Which instructs Salt to cache the data returned by the NAPALM-functions. While they are not mandatory, the less functions configured, the less details will be found by the runner.

How often the mines are refreshed, can be specified using:

```
mine_interval: <X minutes>
```

• Master config

By default the following options can be configured on the master. They are not necessary, but available in case the user has different requirements.

**target:** *
From what minions will collect the mine data. Default: * (collect from all minions).

**expr_form:** glob

**ignore_interfaces**
A list of interfaces name to ignore. By default will consider all interfaces.

**display:** True
Display on the screen or return structured object? Default: True (return on the CLI).

**outputter:** table
Specify the outputter name when displaying on the CLI. Default: table.

Configuration example:
**runners:**

```python
net.find:
  target: 'edge*
  expr_form: 'glob'
  ignore_interfaces:
    - lo0
    - em1
    - jsrv
    - fpx0
  outputter: yaml
```

salt.runners.net.find(\emph{addr}, \emph{best=True}, \emph{display=True})

Search in all possible entities (Interfaces, MAC tables, ARP tables, LLDP neighbors), using the following mine functions:

- net.mac
- net.arp
- net.lldp
- net.ipaddrs
- net.interfaces

This function has the advantage that it knows where to look, but the output might become quite long as returns all possible matches.

Optional arguments:

- **best:** \textbf{True}
  Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.

- **display:** \textbf{True}
  Display on the screen or return structured object? Default: \textbf{True} (return on the CLI).

CLI Example:

```
$ sudo salt-run net.find 10.10.10.7
```

Output Example:

```
Details for all interfaces that include network 10.10.10.7/32 - only best match returned
```

```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>UP</th>
<th>Enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.flw01</td>
<td>irb</td>
<td></td>
<td>True</td>
<td>True</td>
</tr>
</tbody>
</table>
```

```
ARP Entries for IP 10.10.10.7
```

```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.flw01</td>
<td>irb</td>
<td>5C:5E:AB:AC:52:B4</td>
<td>10.10.10.1/22</td>
</tr>
</tbody>
</table>
```

(continues on next page)
salt.runners.net.findarp(\texttt{(device=None, interface=None, mac=None, ip=None, display=True)})

Search for entries in the ARP tables using the following mine functions:

- \texttt{net.arp}

Optional arguments:

\begin{itemize}
\item \texttt{device}
\begin{itemize}
\item Return interface data from a certain device only.
\end{itemize}
\item \texttt{interface}
\begin{itemize}
\item Return data selecting by interface name.
\end{itemize}
\item \texttt{mac}
\begin{itemize}
\item Search using a specific MAC Address.
\end{itemize}
\item \texttt{ip}
\begin{itemize}
\item Search using a specific IP Address.
\end{itemize}
\item \texttt{display: True}
\begin{itemize}
\item Display on the screen or return structured object? Default: \texttt{True}, will return on the CLI.
\end{itemize}
\end{itemize}

CLI Example:

\begin{verbatim}
$ sudo salt-run net.findarp mac=8C:60:0F:78:EC:41
\end{verbatim}

Output Example:

\begin{table}
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
Device & Interface & MAC & IP & \\
\hline
edge01.bjm01 & irb.171 [ae0.171] & 8C:60:0F:78:EC:41 & 172.172.17.19 & \\
\hline
\end{tabular}
\caption{ARP Entries for MAC 8C:60:0F:78:EC:41}
\end{table}

salt.runners.net.findmac(\texttt{(device=None, mac=None, interface=None, vlan=None, display=True)})

Search in the MAC Address tables, using the following mine functions:

- \texttt{net.mac}

Optional arguments:

\begin{itemize}
\item \texttt{device}
\begin{itemize}
\item Return interface data from a certain device only.
\end{itemize}
\item \texttt{interface}
\begin{itemize}
\item Return data selecting by interface name.
\end{itemize}
\item \texttt{mac}
\begin{itemize}
\item Search using a specific MAC Address.
\end{itemize}
\item \texttt{vlan}
\begin{itemize}
\item Search using a VLAN ID.
\end{itemize}
\item \texttt{display: True}
\begin{itemize}
\item Display on the screen or return structured object? Default: \texttt{True}, will return on the CLI.
\end{itemize}
\end{itemize}

CLI Example:
$ sudo salt-run net.findmac mac=8C:60:0F:78:EC:41

Output Example:

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>VLAN</th>
<th>Static</th>
<th>Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>ae0.171</td>
<td>8C:60:0F:78:EC:41</td>
<td>171</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>0</td>
<td>0.0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

salt.runners.net.interfaces (device=None, interface=None, title=None, pattern=None, ipnet=None, best=True, display=True)

Search for interfaces details in the following mine functions:
- net.interfaces
- net.ipaddrs

Optional arguments:
- device: Return interface data from a certain device only.
- interface: Return data selecting by interface name.
- pattern: Return interfaces that contain a certain pattern in their description.
- ipnet: Return interfaces whose IP networks associated include this IP network.
- best: True
  When ipnet is specified, this argument says if the runner should return only the best match (the output will contain at most one row). Default: True (return only the best match).
- display: True
  Display on the screen or return structured object? Default: True (return on the CLI).
- title: Display a custom title for the table.

CLI Example:

$ sudo salt-run net.interfaces interface=vt-0/0/10

Output Example:

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>UP</th>
<th>Enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>vt-0/0/10</td>
<td></td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>1000</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
salt.runners.net.lldp

Search in the LLDP neighbors, using the following mine functions:

- net.lldp

Optional arguments:

- **device**
  
  Return interface data from a certain device only.

- **interface**
  
  Return data selecting by interface name.

- **pattern**
  
  Return LLDP neighbors that have contain this pattern in one of the following fields:
  - Remote Port ID
  - Remote Port Description
  - Remote System Name
  - Remote System Description

- **chassis**
  
  Search using a specific Chassis ID.

- **display**:
  
  Display on the screen or return structured object? Default: True (return on the CLI).

- **title**
  
  Display a custom title for the table.

CLI Example:

$ sudo salt-run net.lldp pattern=Ethernet1/48

Output Example:

Pattern "Ethernet1/48" found in one of the following LLDP details

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Parent Interface</th>
<th>Remote Chassis ID</th>
<th>Remote Port ID</th>
<th>Remote Port Description</th>
<th>Remote System Name</th>
<th>Remote System Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>vt-0/0/10</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>vt-0/0/10</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>vt-0/0/10</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
salt.runners.net.multi_find(*patterns, **kwargs)

Execute multiple search tasks. This function is based on the find function. Depending on the search items, some information might overlap.

Optional arguments:
best: True
Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.

display: True

Display on the screen or return structured object? Default: True (return on the CLI).

CLI Example:

```
$ sudo salt-run net.multi_find Ethernet1/49 xe-0/1/2
```

Output Example:

```
Pattern "Ethernet1/49" found in one of the following LLDP details

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Parent Interface</th>
<th>Remote Chassis ID</th>
<th>Description</th>
<th>Remote Port ID</th>
<th>Remote System Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.oua04</td>
<td>xe-0/1/2</td>
<td>ael</td>
<td>DE:AD:BE:EF:DE:AD</td>
<td>Ethernet1/49</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Software (n6000-uk9)</td>
<td>edge07.oua04.dummy.net</td>
<td></td>
</tr>
</tbody>
</table>

Details for interface xe-0/1/2

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>IP Addresses</th>
<th>Enabled</th>
<th>UP</th>
<th>MAC Address</th>
<th>Speed [Mbps]</th>

(continues on next page)
25.17.26 salt.runners.network

Network tools to run from the Master

salt.runners.network.wol(\textit{mac, bcast='255.255.255.255', destport=9})

Send a "Magic Packet" to wake up a Minion

CLI Example:

\begin{verbatim}
salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 080027136977 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
\end{verbatim}

salt.runners.network.wollist(\textit{maclist, bcast='255.255.255.255', destport=9})

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line

CLI Example:

\begin{verbatim}
salt-run network.wollist '/path/to/maclist'
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
\end{verbatim}

salt.runners.network.wolmatch(\textit{tgt, tgt_type='glob', bcast='255.255.255.255', destport=9})

Send a "Magic Packet" to wake up Minions that are matched in the grains cache

CLI Example:

\begin{verbatim}
salt-run network.wolmatch minion_id
salt-run network.wolmatch 192.168.0.0/16 tgt_type='ipcidr' bcast=255.255.255.255 destport=7
\end{verbatim}

25.17.27 salt.runners.pagerduty

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

\textbf{configuration}

This module can be used by specifying the name of a configuration profile in the master config.

For example:

\begin{verbatim}
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbve43rffWf2214
pagerduty.subdomain: mysubdomain
\end{verbatim}
salt.runners.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt-run pagerduty.create_event <service_key> <description> <details> ○
  → profile=my-pagerduty-account
```

The following parameters are required:
- **service_key**
  This key can be found by using pagerduty.list_services.
- **description**
  This is a short description of the event.
- **details**
  This can be a more detailed description of the event.
- **profile**
  This refers to the configuration profile to use to connect to the PagerDuty service.

salt.runners.pagerduty.list_escalation_policies(profile=None, api_key=None)

This function is an alias of list_policies.
List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account
```

salt.runners.pagerduty.list_incidents(profile=None, api_key=None)

List incidents belonging to this account

CLI Example:

```
salt-run pagerduty.list_incidents my-pagerduty-account
```

salt.runners.pagerduty.list_maintenance_windows(profile=None, api_key=None)

This function is an alias of list_windows.
List maintenance windows belonging to this account

CLI Example:

```
salt-run pagerduty.list_windows my-pagerduty-account
```

salt.runners.pagerduty.list_policies(profile=None, api_key=None)

List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account
```

salt.runners.pagerduty.list_schedules(profile=None, api_key=None)

List schedules belonging to this account

CLI Example:

```
salt-run pagerduty.list_schedules my-pagerduty-account
```

salt.runners.pagerduty.list_services(profile=None, api_key=None)

List services belonging to this account

CLI Example:

```
salt-run pagerduty.list_services my-pagerduty-account
```
salt.runners.pagerduty.list_users(profile=None, api_key=None)

List users belonging to this account

CLI Example:
salt-run pagerduty.list_users my-pagerduty-account

salt.runners.pagerduty.list_windows(profile=None, api_key=None)

List maintenance windows belonging to this account

CLI Example:
salt-run pagerduty.list_windows my-pagerduty-account salt-run pager-
duty.list_maintenance_windows my-pagerduty-account

25.17.28 salt.runners.pillar

Functions to interact with the pillar compiler on the master

salt.runners.pillar.clear_pillar_cache(minion='*', **kwargs)

Clears the cached values when using pillar_cache

New in version 3003.

CLI Example:
Clears the pillar cache for a specific minion:
salt-run pillar.clear_pillar_cache 'minion'

salt.runners.pillar.show_pillar(minion='*', **kwargs)

Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes
that no minion has the id * . Function also accepts pillarenv as attribute in order to limit to a specific pillar
branch of git

CLI Example:
shows minion specific pillar:
salt-run pillar.show_pillar 'www.example.com'

shows global pillar:
salt-run pillar.show_pillar

shows global pillar for 'dev' pillar environment: (note that not specifying pillarenv will merge all pillar envi-
ronments using the master config option pillar_source_merging_strategy.)
salt-run pillar.show_pillar 'pillarenv=dev'

shows global pillar for 'dev' pillar environment and specific pillarenv = dev:
salt-run pillar.show_pillar 'saltenv=dev' 'pillarenv=dev'

API Example:

```
import salt.config
import salt.runner
opts = salt.config.master_config('/etc/salt/master')
```
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)

salt.runners.pillar.show_pillar_cache(minion='*', **kwargs)
Shows the cached values in pillar_cache
New in version 3003.
CLI Example:
Shows the pillar cache for a specific minion:
salt-run pillar.show_pillar_cache 'minion'

salt.runners.pillar.show_top(minion=None, saltenv='base')
Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.
CLI Example:
salt-run pillar.show_top

25.17.29 salt.runners.pkg
Package helper functions using salt.modules.pkg
New in version 2015.8.0.
salt.runners.pkg.list_upgrades(jid, style='group', outputter='nested', ext_source=None)
Show list of available pkg upgrades using a specified format style
CLI Example:
salt-run pkg.list_upgrades jid=2014112011414417719 style=group

25.17.30 salt.runners.queue
General management and processing of queues.
This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues
The queue functions such as insert, delete, and pop can be used for typical management of the queue.
The process_queue function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The process_queue function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.
This runner, as well as the Queues system, is not api stable at this time.
There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the process_queue runner function is called events are created on the Salt Event bus that indicate the queue
and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use salt-cloud to destroy the vm, or some other custom action.

**Queued runners**

Using the Salt Queues, references to the commandline arguments of other runners can be saved to be processed later. The queue runners require a queue backend that can store json data (default: pgjsonb).

Once the queue is setup, the `runner_queue` will need to be configured.

```
runner_queue:
  queue: runners
  backend: pgjsonb
```

**Note:** only the queue is required, this defaults to using pgjsonb

Once this is set, then the following can be added to the scheduler on the master and it will run the specified amount of commands per time period.

```
schedule:
  runner_queue:
    schedule:
      function: queue.process_runner
      minutes: 1
      kwargs:
        quantity: 2
```

The above configuration will pop 2 runner jobs off the runner queue, and then run them. And it will do this every minute, unless there are any jobs that are still running from the last time the process_runner task was executed.

**salt.runners.queue.delete**(queue, items, backend='sqlite')

Delete an item or items from a queue

CLI Example:

```
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqlite
salt-run queue.delete myqueue "['item1', 'item2', 'item3']"
```

**salt.runners.queue.insert**(queue, items, backend='sqlite')

Add an item or items to a queue

CLI Example:

```
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue "['item1', 'item2', 'item3']"
salt-run queue.insert myqueue myitem backend=sqlite
salt-run queue.insert myqueue "['item1', 'item2', 'item3']" backend=sqlite
```

**salt.runners.queue.insert_runner**(fun, args=None, kwargs=None, queue=None, backend=None)

Insert a reference to a runner into the queue so that it can be run later.

fun

The runner function that is going to be run
args
list or comma-separated string of args to send to fun
kwargs
dictionary of keyword arguments to send to fun
queue
queue to insert the runner reference into
backend
backend that to use for the queue

CLI Example:

```
salt-run queue.insert_runner test.stdout_print
salt-run queue.insert_runner event.send test_insert_runner kwargs='{"data ↕": {"foo": "bar"}}'
```

_salt.runners.queue.list_items(queue, backend='sqlite')_
List contents of a queue

CLI Example:

```
salt-run queue.list_items myqueue
salt-run queue.list_items myqueue backend=sqlite
```

_salt.runners.queue.list_length(queue, backend='sqlite')_
Provide the number of items in a queue

CLI Example:

```
salt-run queue.list_length myqueue
salt-run queue.list_length myqueue backend=sqlite
```

_salt.runners.queue.list_queues(backend='sqlite')_
Return a list of Salt Queues on the backend

CLI Example:

```
salt-run queue.list_queues
salt-run queue.list_queues backend=sqlite
```

_salt.runners.queue.pop(queue, quantity=1, backend='sqlite', is_runner=False)_
Pop one or more or all items from a queue

CLI Example:

```
salt-run queue.pop myqueue
salt-run queue.pop myqueue 6
salt-run queue.pop myqueue all
salt-run queue.pop myqueue 6 backend=sqlite
salt-run queue.pop myqueue all backend=sqlite
```

_salt.runners.queue.process_queue(queue, quantity=1, backend='sqlite', is_runner=False)_
Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.

CLI Example:
salt-run queue.process_queue myqueue
salt-run queue.process_queue myqueue 6
salt-run queue.process_queue myqueue all backend=sqlite

salt.runners.queue.process_runner(quantity=1, queue=None, backend=None)
Process queued runners
  quantity
    number of runners to process
  queue
    queue to insert the runner reference into
  backend
    backend that to use for the queue

CLI Example:
salt-run queue.process_runner
salt-run queue.process_runner 5

25.17.31 salt.runners.reactor

A convenience system to manage reactors

Beginning in the 2017.7 release, the reactor runner requires that the reactor system is running. This is accomplished one of two ways, either by having reactors configured or by including reactor in the engine configuration for the Salt master.

engines:
- reactor

salt.runners.reactor.add(event, reactors, saltenv='base', test=None)
Add a new reactor

CLI Example:
salt-run reactor.add 'salt/cloud/*/destroyed' reactors='/srv/reactor/*destroy/*.sls'

salt.runners.reactor.delete(event, saltenv='base', test=None)
Delete a reactor

CLI Example:
salt-run reactor.delete 'salt/cloud/*/destroyed'

salt.runners.reactor.is_leader()
Return whether the running reactor is acting as a leader (responding to events).

CLI Example:
salt-run reactor.is_leader
salt.runners.reactor.list_(saltenv='base', test=None)

List currently configured reactors

CLI Example:
salt-run reactor.list

salt.runners.reactor.set_leader(value=True)

Set the current reactor to act as a leader (responding to events). Defaults to True

CLI Example:
salt-run reactor.set_leader True

25.17.32 salt.runners.salt

This runner makes Salt’s execution modules available on the salt master.

New in version 2016.11.0. Salt’s execution modules are normally available on the salt minion. Use this runner to call execution modules on the salt master. Salt execution modules are the functions called by the salt command.

Execution modules can be called with salt-run:
salt-run salt.cmd test.ping
# call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 key=value a=1

Execution modules are also available to salt runners:

__salt__['salt.cmd'](fun=fun, args=args, kwargs=kwargs)
salt.runners.salt.cmd(fun, *args, **kwargs)

Changed in version 2018.3.0: Added with_pillar argument

Execute fun with the given args and kwargs. Parameter fun should be the string name of the execution module to call.

Note: Execution modules will be loaded every time this function is called. Additionally, keep in mind that since runners execute on the master, custom execution modules will need to be synced to the master using salt-run saltutil.sync_modules, otherwise they will not be available.

with_pillar

[False] If True, pillar data will be compiled for the master

Note: To target the master in the pillar top file, keep in mind that the default id for the master is <hostname>_master. This can be overridden by setting an id configuration parameter in the master config file.

CLI Example:
salt-run salt.cmd test.ping
# call functions with arguments and keyword arguments
(continues on next page)
salt-run salt.cmd test.arg 1 2 3 a=1
salt-run salt.cmd mymod.myfunc with_pillar=True

salt.runners.salt.execute(tgt, fun, arg=(), timeout=None, tgt_type='glob', ret='', jid='', kwarg=None, **kwargs)

New in version 2017.7.0.

Execute fun on all minions matched by tgt and tgt_type. Parameter fun is the name of execution module function to call.

This function should mainly be used as a helper for runner modules, in order to avoid redundant code. For example, when inside a runner one needs to execute a certain function on arbitrary groups of minions, only has to:

```
ret1 = __salt__['salt.execute']('*', 'mod.fun')
ret2 = __salt__['salt.execute']('my_nodegroup', 'mod2.fun2', tgt_type=nodegroup)
```

It can also be used to schedule jobs directly on the master, for example:

```
schedule:
    collect_bgp_stats:
        function: salt.execute
        args:
            - edge-routers
            - bgp.neighbors
        kwargs:
            tgt_type: nodegroup
        days: 1
        returner: redis
```

25.17.33 salt.runners.saltutil

The Saltutil runner is used to sync custom types to the Master. See the saltutil module for documentation on managing updates to minions.

New in version 2016.3.0.

salt.runners.saltutil.sync_all(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync all custom types

```
salt-run saltutil.sync_all
salt-run saltutil.sync_all extmod_whitelist={"runners": ["custom_runner"],
  → 'grains': []}
```
salt.runners.saltutil.sync_cache(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync cache modules from salt://_cache to the master

saltenv
- [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
- [None] comma-separated list of modules to sync

extmod_blacklist
- [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_cache
```

salt.runners.saltutil.sync_clouds(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync cloud modules from salt://_clouds to the master

saltenv
- [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
- [None] comma-separated list of modules to sync

extmod_blacklist
- [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_clouds
```

salt.runners.saltutil.sync_eauth_tokens(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2018.3.0.

Sync eauth token modules from salt://_tokens to the master

saltenv
- [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
- [None] comma-separated list of modules to sync

extmod_blacklist
- [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_eauth_tokens
```

salt.runners.saltutil.sync_engines(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync engines from salt://_engines to the master

saltenv
- [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
- [None] comma-separated list of modules to sync

extmod_blacklist
- [None] comma-separated list of modules to blacklist based on type
CLI Example:

```bash
salt-run saltutil.sync_engines
```

**salt.runners.saltutil.sync_executors**

```python
salt.runners.saltutil.sync_executors(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

New in version 3000.

Sync executor modules from `salt://_executors` to the master

- **saltenv**
  - [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

- **extmod_whitelist**
  - [None] comma-separated list of modules to sync

- **extmod_blacklist**
  - [None] comma-separated list of modules to blacklist based on type

CLI Example:

```bash
salt-run saltutil.sync_executors
```

**salt.runners.saltutil.sync_fileserver**

```python
salt.runners.saltutil.sync_fileserver(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

New in version 2018.3.0.

Sync fileserver modules from `salt://_fileserver` to the master

- **saltenv**
  - [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

- **extmod_whitelist**
  - [None] comma-separated list of modules to sync

- **extmod_blacklist**
  - [None] comma-separated list of modules to blacklist based on type

CLI Example:

```bash
salt-run saltutil.sync_fileserver
```

**salt.runners.saltutil.sync_grains**

```python
salt.runners.saltutil.sync_grains(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

Sync grains modules from `salt://_grains` to the master

- **saltenv**
  - [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

- **extmod_whitelist**
  - [None] comma-separated list of modules to sync

- **extmod_blacklist**
  - [None] comma-separated list of modules to blacklist based on type

CLI Example:

```bash
salt-run saltutil.sync_grains
```

**salt.runners.saltutil.sync_modules**

```python
salt.runners.saltutil.sync_modules(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

Sync execution modules from `salt://_modules` to the master

- **saltenv**
  - [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_modules
```

salt.runners.saltutil.sync_output(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync output modules from salt://_output to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_output
```

salt.runners.saltutil.sync_pillar(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync pillar modules from salt://_pillar to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_pillar
```

salt.runners.saltutil.sync_proxymodules(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync proxy modules from salt://_proxy to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_proxymodules
```

salt.runners.saltutil.sync_queues(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync queue modules from salt://_queues to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

3752 Chapter 25. Salt Module Reference
extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_queues
```

```
salt.runners.saltutil.sync_renderers(saltenv='base', extmod_whitelist=None,
                             extmod_blacklist=None)
```

Sync renderer modules from salt://_renderers to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_renderers
```

```
salt.runners.saltutil.sync_returners(saltenv='base', extmod_whitelist=None,
                             extmod_blacklist=None)
```

Sync returner modules from salt://_returners to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_returners
```

```
salt.runners.saltutil.sync_roster(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

New in version 2017.7.0.

Sync roster modules from salt://_roster to the master

saltenv
[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
[None] comma-separated list of modules to sync

extmod_blacklist
[None] comma-separated list of modules to blacklist based on type

CLI Example:
```
salt-run saltutil.sync_roster
```

```
salt.runners.saltutil.sync_runners(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

Sync runners from salt://_runners to the master
saltenv
  [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist
  [None] comma-separated list of modules to sync

extmod_blacklist
  [None] comma-separated list of modules to blacklist based on type

CLI Example:

```bash
salt-run saltutil.sync_runners
```

**salt.runners.saltutil.sync_sdb** *(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)*

New in version 2017.7.0.

Sync sdb modules from `salt://_sdb` to the master

```bash
salt-run saltutil.sync_sdb
```

**salt.runners.saltutil.sync_serializers** *(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)*

New in version 2019.2.0.

Sync serializer modules from `salt://_serializers` to the master

```bash
salt-run saltutil.sync_serializers
```

**salt.runners.saltutil.sync_states** *(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)*

Sync state modules from `salt://_states` to the master

```bash
salt-run saltutil.sync_states
```
salt.runner.saltutil.sync_thorium

New in version 2018.3.0.

Sync Thorium from salt://_thorium to the master

saltenv: `base`

The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist

comma-separated list of modules to sync

extmod_blacklist

comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_thorium
```

salt.runner.saltutil.sync_tops

New in version 2016.3.7, 2016.11.4, 2017.7.0.

Sync master_tops modules from salt://_tops to the master

saltenv

[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

CLI Example:

```
salt-run saltutil.sync_tops
```

salt.runner.saltutil.sync_utils

New in version 2016.11.0.

Sync utils modules from salt://_utils to the master

saltenv

[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist

[None] comma-separated list of modules to sync

extmod_blacklist

[None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_utils
```

salt.runner.saltutil.sync_wheel

Sync wheel modules from salt://_wheel to the master

saltenv

[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist

[None] comma-separated list of modules to sync

extmod_blacklist

[None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_wheel
```
salt.runners.saltutil.sync_wrapper(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 3007.0.

Sync salt-ssh wrapper modules from salt://_wrapper to the master.

`saltenv`

[base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

`extmod_whitelist`

[None] comma-separated list of modules to sync

`extmod_blacklist`

[None] comma-separated list of modules to blacklist based on type

CLI Example:

```bash
salt-run saltutil.sync_wrapper
```

### 25.17.34 salt.runners.sdb

Runner for setting and querying data via the sdb API on the master

salt.runners.sdb.delete(uri)

Delete a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully deleted, return False.

CLI Example:

```bash
salt-run sdb.delete sdb://mymemcached/foo
```

salt.runners.sdb.get(uri)

Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:

```bash
salt-run sdb.get sdb://mymemcached/foo
```

salt.runners.sdb.get_or_set_hash(uri, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#$%^&*(-_=+)

Perform a one-time generation of a hash and write it to sdb. If that value has already been set return the value instead.

This is useful for generating passwords or keys that are specific to multiple minions that need to be stored somewhere centrally.

CLI Example:

```bash
salt-run sdb.get_or_set_hash 'SECRET_KEY' 50
```

**Warning:** This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with %. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.
salt.runners.sdb.set_(uri, value)

Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:

```
salt-run sdb.set sdb://mymemcached/foo bar
```

25.17.35 salt.runners.smartos_vmadm

Runner for SmartOS minions control vmadm

salt.runners.smartos_vmadm.get(search, one=True)

Return information for vms

- search [string] filter vms, see the execution module.
- one [boolean] return only one vm

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.get 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.get search='alias=saskia'
```

salt.runners.smartos_vmadm.is_running(search)

Return true if vm is running

- search [string] filter vms, see the execution module.

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

**Note:** If multiple vms are matched, the result will be true of ALL vms are running

CLI Example:

```
salt-run vmadm.is_running 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.is_running search='alias=julia'
```

salt.runners.smartos_vmadm.list_vms(search=None, verbose=False)

List all vms

- search [string] filter vms, see the execution module
- verbose [boolean] print additional information about the vm

CLI Example:
salt-run vmadm.list
salt-run vmadm.list search='type=KVM'
salt-run vmadm.list verbose=True

salt.runners.smartos_vmadm.nodes(verbos=False)
List all compute nodes

verbose
[boolean] print additional information about the node e.g. platform version, hvm capable, ...

CLI Example:
salt-run vmadm.nodes
salt-run vmadm.nodes verbose=True

salt.runners.smartos_vmadm.reboot(search, one=True, force=False)
Reboot one or more vms

search
[string] filter vms, see the execution module.

one
[boolean] reboot only one vm

force
[boolean] force reboot, faster but no graceful shutdown

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:
salt-run vmadm.reboot 91244bba-1146-4ec-c07e-e825e0223aa9
salt-run vmadm.reboot search='alias=marije'
salt-run vmadm.reboot search='type=KVM' one=False

salt.runners.smartos_vmadm.start(search, one=True)
Start one or more vms

search
[string] filter vms, see the execution module.

one
[boolean] start only one vm

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:
salt-run vmadm.start 91244bba-1146-4ec-c07e-e825e0223aa9
salt-run vmadm.start search='alias=jiska'
salt-run vmadm.start search='type=KVM' one=False

salt.runners.smartos_vmadm.stop(search, one=True)
Stop one or more vms

search
[string] filter vms, see the execution module.
one

[boolean] stop only one vm

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.stop 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.stop search='alias=jody'
salt-run vmadm.stop search='type=KVM' one=False
```

25.17.36 salt.runners.spacewalk

Spacewalk Runner

New in version 2016.3.0.

Runner to interact with Spacewalk using Spacewalk API

codeauthor

Nitin Madhok <nmadhok@g.clemson.edu>, Joachim Werner <joe@suse.com>, Benedikt Werner <1benediktwerner@gmail.com>

maintainer

Benedikt Werner <1benediktwerner@gmail.com>

To use this runner, set up the Spacewalk URL, username and password in the master configuration at /etc/salt/master or /etc/salt/master.d/spacewalk.conf:

```
spacewalk:
    spacewalk01.domain.com:
        username: 'testuser'
        password: 'verybadpass'
    spacewalk02.domain.com:
        username: 'testuser'
        password: 'verybadpass'
```

Note: Optionally, protocol can be specified if the spacewalk server is not using the defaults. Default is protocol: https.

salt.runners.spacewalk.addGroupsToKey(server, activation_key, groups)

Add server groups to a activation key

CLI Example:

```
salt-run spacewalk.addGroupsToKey spacewalk01.domain.com 1-my-key → '[group1, group2]'```

salt.runners.spacewalk.api(server, command, *args, **kwargs)

Call the Spacewalk xmlrpc api.

CLI Example:
**salt-run spacewalk.api spacewalk01.domain.com systemgroup.create MyGroup**

→ Description

**salt-run spacewalk.api spacewalk01.domain.com systemgroup.create**

→ arguments=['"MyGroup", "Description"']

State Example:

```python
create_group:
salt.runner:
  - name: spacewalk.api
  - server: spacewalk01.domain.com
  - command: systemgroup.create
  - arguments:
    - MyGroup
    - Description
```

salt.runners.spacewalk.deleteAllActivationKeys(server)

Delete all activation keys from Spacewalk

CLI Example:

```bash
salt-run spacewalk.deleteAllActivationKeys spacewalk01.domain.com
```

salt.runners.spacewalk.deleteAllGroups(server)

Delete all server groups from Spacewalk

salt.runners.spacewalk.deleteAllSystems(server)

Delete all systems from Spacewalk

CLI Example:

```bash
salt-run spacewalk.deleteAllSystems spacewalk01.domain.com
```

salt.runners.spacewalk.unregister(name, server_url)

Unregister specified server from Spacewalk

CLI Example:

```bash
salt-run spacewalk.unregister my-test-vm spacewalk01.domain.com
```

### 25.17.37 salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.

This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.

salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, tgt_type='glob', kwarg=None)

New in version 2015.5.0.

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Execute a single command via the salt-ssh subsystem and return all routines at once

A wrapper around the SSHClient.cmd method.
25.17.38  salt.runners.state

Execute orchestration functions

salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False, node='master')

Watch Salt's event bus and block until the given tag is matched

New in version 2014.7.0.

Changed in version 2019.2.0: tagmatch can now be either a glob or regular expression.

This is useful for utilizing Salt's event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

Parameters

- **tagmatch** -- the event is written to stdout for each tag that matches this glob or regular expression.
- **count** -- this number is decremented for each event that matches the tagmatch parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.
- **node** -- Watch the minion-side or master-side event bus. .. versionadded:: 2016.3.0

CLI Examples:

```bash
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot && \
  salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True && \
  →  \
  salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot && \
  salt-run state.event 'salt/minion/*/start' count=3 quiet=True && \
  salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do \
  echo $tag \
  echo $data | jq --color-output .
do
```

See also:

See tests/eventlisten.sh for an example of usage within a shell script.

salt.runners.state.orch(mods, saltenv='base', test=None, exclude=None, pillar=None, pillarenv=None, pillar_enc=None, orchestration_jid=None)

This function is an alias of orchestrate.

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation
- Full Orchestrate Tutorial
- Docs for the master-side state module

CLI Examples:

```
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
salt-run state.orchestrate webserver saltenv=dev pillarenv=aws
```

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestrate

Changed in version 2014.7.0: Runner uses the pillar variable

Changed in version 2017.5.0: Runner uses the pillar_enc variable that allows renderers to render the pillar. This is usable when supplying the contents of a file as pillar, and the file contains gpg-encrypted entries.

See also:

GPG renderer documentation

CLI Examples:

```
salt-run state.orchestrate webserver pillar_enc=gpg pillar="\n-$(cat somefile.json)"
```

```
salt.runners.state.orchshow_sls(mods, saltenv='base', test=\nNone, queue=False, pillar=None, pillarenv=None, pillar_enc=\nNone)
```

This function is an alias of orchestrate_show_sls.

Display the state data from a specific sls, or list of sls files, after being render using the master minion.

Note, the master minion adds a "_master" suffix to its minion id.

See also:

The state.show_sls module function

CLI Example:

```
salt-run state.orch_show_sls my-orch-formula.my-orch-state
-\'pillar={ nodegroup: ng1 }\'
```

```
salt.runners.state.orchestrate(mods, saltenv='base', test=\nNone, exclude=None, pillar=None, pillarenv=None, pillar_enc=\nNone, orchestration_jid=None)
```

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation
- Full Orchestrate Tutorial
- Docs for the master-side state module

CLI Examples:

```
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
salt-run state.orchestrate webserver saltenv=dev pillarenv=aws
```
Changed in version 2014.1.1: Runner renamed from `state.sls` to `state.orchestrate`

Changed in version 2014.7.0: Runner uses the pillar variable

Changed in version 2017.5.0: Runner uses the pillar_enc variable that allows renderers to render the pillar. This is usable when supplying the contents of a file as pillar, and the file contains gpg-encrypted entries.

See also:

GPG renderer documentation

CLI Examples:

```
salt-run state.orchestrate webserver pillar_enc=gpg pillar="$(cat ~/somefile.json)"
```

```
salt.runners.state.orchestrate_high(data, test=None, queue=False, pillar=None, **kwargs)
```

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_high '{
  stage_one:
    {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
  stage_two:
    {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
      require: [{salt: stage_one}],
    }]],
}
'
```

```
salt.runners.state.orchestrate_show_sls(mods, saltenv='base', test=None, queue=False, pillar=None, pillarenv=None, pillar_enc=None)
```

Display the state data from a specific sls, or list of sls files, after being render using the master minion.

Note, the master minion adds a "_master" suffix to its minion id.

See also:

The state.show_sls module function

CLI Example:

```
salt-run state.orch_showsls my-orch-formula.my-orch-state 'pillar={nodegroup: ngl }'
```

```
salt.runners.state.orchestrate_single(fun, name, test=None, queue=False, pillar=None, **kwargs)
```

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

```
salt.runners.state.pause(jid, state_id=None, duration=None)
```

Set up a state id pause, this instructs a running state to pause at a given state id. This needs to pass in the jid of the running state and can optionally pass in a duration in seconds.
**salt.runners.state.resume** *(jid, state_id=None)*

Remove a pause from a jid, allowing it to continue

**salt.runners.state.rm_pause** *(jid, state_id=None)*

This function is an alias of resume.

Remove a pause from a jid, allowing it to continue

**salt.runners.state.set_pause** *(jid, state_id=None, duration=None)*

This function is an alias of pause.

Set up a state id pause, this instructs a running state to pause at a given state id. This needs to pass in the jid of the running state and can optionally pass in a duration in seconds.

**salt.runners.state.sls** *(mods, saltenv='base', test=None, exclude=None, pillar=None, pillarenv=None, pillar_enc=None, orchestration_jid=None)*

This function is an alias of orchestrate.

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation
- Full Orchestrate Tutorial
- Docs for the master-side state module

CLI Examples:

```
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
salt-run state.orchestrate webserver saltenv=dev pillarenv=aws
```

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestrate

Changed in version 2014.7.0: Runner uses the pillar variable

Changed in version 2017.5.0: Runner uses the pillar_enc variable that allows renderers to render the pillar. This is usable when supplying the contents of a file as pillar, and the file contains gpg-encrypted entries.

See also:

GPG renderer documentation

CLI Examples:

```
salt-run state.orchestrate webserver pillar_enc=gpg pillar="$_$(cat somefile.json)"
```

**salt.runners.state.soft_kill** *(jid, state_id=None)*

Set up a state run to die before executing the given state id, this instructs a running state to safely exit at a given state id. This needs to pass in the jid of the running state. If a state_id is not passed then the jid referenced will be safely exited at the beginning of the next state run.
### 25.17.39 salt.runners.survey

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.

```python
salt.runners.survey.diff(*args, **kwargs)
```

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.

These pools are determined from the aggregated and sorted results of a salt command.

This command displays the "diffs" as a series of 2-way differences -- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set.

Differences are displayed according to the Python difflib.unified_diff() as in the case of the salt execution module file.get_diff.

This command is submitted via a salt runner using the general form:

```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (Example to display the "differences of files")

```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

```python
salt.runners.survey.hash(*args, **kwargs)
```

Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (functionally equivalent to `salt-run manage.up`)

```
salt-run survey.hash "*" test.ping
```

CLI Example #2: (find an "outlier" minion config file)

```
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```
25.17.40  salt.runners.test

This runner is used only for test purposes and serves no production purpose

```python
salt.runners.test.arg(*args, **kwargs)
```

Output the given args and kwargs

Kwargs will be filtered for 'private' keynames.

CLI Example:

```
salt-run test.arg foo bar=baz
```

```python
salt.runners.test.get_opts()
```

New in version 2018.3.0.

Return the configuration options of the master.

CLI Example:

```
salt-run test.get_opts
```

```python
salt.runners.test.metasyntactic(locality='us')
```

Return common metasyntactic variables for the given locality

CLI Example:

```
salt-run test.metasyntactic locality=uk
```

```python
salt.runners.test.raw_arg(*args, **kwargs)
```

Output the given args and kwargs

CLI Example:

```
salt-run test.arg foo __bar=baz
```

```python
salt.runners.test.sleep(s_time=10)
```

Sleep t seconds, then return True

CLI Example:

```
salt-run test.sleep s_time=5
```

```python
salt.runners.test.stdout_print()
```

Print 'foo' and return 'bar'

CLI Example:

```
salt-run test.stdout_print
```

```python
salt.runners.test.stream()
```

Fire a stream of 100 test events, then return True

CLI Example:

```
salt-run test.stream
```
25.17.41 salt.runners.thin

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

salt.runners.thin.generate(extra_mods='', overwrite=False, so_mods='', absonly=True, compress='gzip')

Generate the salt-thin tarball and print the location of the tarball. Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate
tsalt-run thin.generate mako
salts-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

salt.runners.thin.generate_min(extra_mods='', overwrite=False, so_mods='')

Generate the salt-thin tarball and print the location of the tarball. Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate_min
```

25.17.42 salt.runners.vault

Runner functions supporting the Vault modules. Configuration instructions are documented in the execution module docs.

maintainer
SaltStack

maturity
new

platform
all

class salt.runners.vault.LazyPillar(opts, grains, minion_id, extra_minion_data=None)

Simulates a pillar dictionary. Only compiles the pillar once an item is requested.

salt.runners.vault.generate_token(minion_id, signature, impersonated_by_master=False, ttl=None, uses=None)

Generate a Vault token for minion minion_id

minion_id
The id of the minion that requests a token

signature
Cryptographic signature which validates that the request is indeed sent by the minion (or the master, see impersonated_by_master).

impersonated_by_master
If the master needs to create a token on behalf of the minion, this is True. This happens when the master generates minion pillars.

ttl
Ticket time to live in seconds, 1m minutes, or 2h hrs
uses
Number of times a token can be used

salt.runners.vault.show_policies(minion_id, refresh_pillar=Constant.NOT_SET, expire=None)
Show the Vault policies that are applied to tokens for the given minion.

minion_id
The minion's id.

refresh_pillar
Whether to refresh the pillar data when rendering templated policies. None will only refresh when the cached data is unavailable, boolean values force one behavior always. Defaults to config value policies_refresh_pillar or None.

expire
Policy computation can be heavy in case pillar data is used in templated policies and it has not been cached. Therefore, a short-lived cache specifically for rendered policies is used. This specifies the expiration timeout in seconds. Defaults to config value policies_cache_time or 60.

CLI Example:
salt-run vault.show_policies myminion

salt.runners.vault.unseal()
Unseal Vault server

This function uses the 'keys' from the 'vault' configuration to unseal vault server

vault:
    keys:
        • n63/TbrQuL3xaIw7ZZpuXj/tfKnKl/MBvXo4vT3wYD2A
        • S9OwCvMRhE44rEA4NVVELY86w/Me6+urgUr24xGkK44Uy3
        • F1ja4b7Jkq850N66Kboiy5ja0xY8dWvB3fwA+SraYl
        • 1cYtvjKJNDVam9c7HvNfjUfNk4PYYxPjDkPqN/sluzPv
        • 3pFK3x6gTwLhNOFv1U2elaheC3HpRFlNXYJFYLy6lid

CLI Examples:
salt-run vault.unseal

25.17.43 salt.runners.venafiapi
Support for Venafi

depends
    • vcert Python module

configuration
In order to connect to Venafi services you need to specify it in Salt master configuration. Example for Venafi Cloud (using env variables):

venafi:
    api_key: "sdb://osenv/CLOUDAPIKEY"

Example for Venafi Platform (using env variables):
venafi:
    base_url: "https://tpp.example.com/"
tpp_user: admin
tpp_password: "sdb://osenv/TPP_PASSWORD"
trust_bundle: "/opt/venafi/bundle.pem"
salt.runners.venafiapi.del_cached_domain(domains)
    Delete cached domains from the master
    CLI Example:
    ```
salt-run venafi.del_cached_domain domain1.example.com,domain2.example.com
    ```
salt.runners.venafiapi.list_domain_cache()
    List domains that have been cached
    CLI Example:
    ```
salt-run venafi.list_domain_cache
    ```
salt.runners.venafiapi.renew(minion_id, dns_name=None, zone=None, country=None, state=None,
    loc=None, org=None, org_unit=None, key_password=None, csr_path=None, pkey_path=None)
    Request a new certificate
    CLI Example:
    ```
salt-run venafi.request <minion_id> <dns_name>
    ```
salt.runners.venafiapi.request(minion_id, dns_name=None, zone=None, country=None, state=None,
    loc=None, org=None, org_unit=None, key_password=None, csr_path=None, pkey_path=None)
    Request a new certificate
    CLI Example:
    ```
salt-run venafi.request <minion_id> <dns_name>
    ```
salt.runners.venafiapi.show_cert(dns_name)
    Show issued certificate for domain
    CLI Example:
    ```
salt-run venafi.show_cert example.com
    ```

25.17.44 salt.runners.virt

Control virtual machines via Salt
salt.runners.virt.force_off(name)
    Force power down the named virtual machine
salt.runners.virt.host_info(host=host=None)
    Return information about the host connected to this master
salt.runners.virt.init(name, cpu, mem, image, hypervisor='kvm', host=None, seed=True, nic='default',
    install=True, start=True, disk='default', saltenv='base', enable_vnc=False, seed_cmd='seed.apply', enable_qcow=False, serial_type='None')
This routine is used to create a new virtual machine. This routine takes a number of options to determine what the newly created virtual machine will look like.

**name**
The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.

**cpu**
The number of cpus to allocate to this new virtual machine.

**mem**
The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.

**image**
The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.

**hypervisor**
The hypervisor to use for the new virtual machine. Default is `kvm`.

**host**
The host to use for the new virtual machine, if this is omitted Salt will automatically detect what host to use.

**seed**
Set to `False` to prevent Salt from seeding the new virtual machine.

**nic**
The nic profile to use, defaults to the "default" nic profile which assumes a single network interface per VM associated with the "br0" bridge on the master.

**install**
Set to False to prevent Salt from installing a minion on the new VM before it spins up.

**disk**
The disk profile to use

**saltenv**
The Salt environment to use

**enable_vnc**
Whether a VNC screen is attached to resulting VM. Default is `False`.

**seed_cmd**
If seed is `True`, use this execution module function to seed new VM. Default is `seed.apply`.

**enable_qcow**
Clone disk image as a copy-on-write qcow2 image, using downloaded `image` as backing file.

**serial_type**
Enable serial console. Set to 'pty' for serial console or 'tcp' for telnet. Default is 'None'

---

**salt.runners.virt.list**

List the virtual machines on each host, this is a simplified query, showing only the virtual machine names belonging to each host. A single host can be passed in to specify an individual host to list.

**salt.runners.virt.migrate**

Migrate a VM from one host to another. This routine will just start the migration and display information on how to look up the progress.

**salt.runners.virt.next_host**

Return the host to use for the next autodeployed VM. This queries the available host and executes some math the determine the most "available" next host.

**salt.runners.virt.pause**

Pause the named VM

**salt.runners.virt.purge**

Destroy the named VM
salt.runners.virt.**query***(host=None, quiet=False)*

Query the virtual machines. When called without options all hosts are detected and a full query is returned. A single host can be passed in to specify an individual host to query.

salt.runners.virt.**reset***(name)***

Force power down and restart an existing VM

salt.runners.virt.**resume***(name)***

Resume a paused VM

salt.runners.virt.**start***(name)***

Start a named virtual machine

salt.runners.virt.**vm_info***(name, quiet=False)***

Return the information on the named VM

---

**25.17.45  salt.runners.vistara**

Vistara Runner

Runner to interact with the Vistara ([http://www.vistarait.com/](http://www.vistarait.com/)) REST API

**codeauthor**

Brad Thurber <brad.thurber@gmail.com>

To use this runner, the Vistara client_id and Vistara oauth2 client_key and client_secret must be set in the master config.

For example /etc/salt/master.d/_vistara.conf:

```
[<Vistara>]
client_id:   client_012345
client_key:  NotReallyaR3alKeyButShouldB12345
client_secret:  ThisISAreallyLongsecretKeyIwonderwhyTheyMakeThemSoBigTheseDays00
```

salt.runners.vistara.**delete_device***(name, safety_on=True)***

Deletes a device from Vistara based on DNS name or partial name. By default, delete_device will only perform the delete if a single host is returned. Set safety_on=False to delete all matches (up to default API search page size)

CLI Example:

```
salt-run vistara.delete_device 'hostname-101.mycompany.com'
salt-run vistara.delete_device 'hostname-101'
salt-run vistara.delete_device 'hostname-1' safety_on=False
```
25.17.46  salt.runners.winrepo

Runner to manage Windows software repo

salt.runners.winrepo.genrepo(\texttt{opts=None, fire\_event=True})

Generate winrepo\_cache\_file based on sls files in the winrepo\_dir

\texttt{opts}

Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.

\texttt{fire\_event}

\texttt{[True]} Fire an event on failure. Only supported on the master.

CLI Example:

\begin{verbatim}
salt-run winrepo.genrepo
\end{verbatim}

salt.runners.winrepo.update\_git\_repos(\texttt{opts=None, clean=False, masterless=False})

Checkout git repos containing Windows Software Package Definitions

\texttt{opts}

Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.

\texttt{clean}

\texttt{[False]} Clean repo cachedirs which are not configured under \texttt{winrepo\_remotes}.

\begin{center}
\textbf{Warning:} This argument should not be set to \texttt{True} if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.
\end{center}

New in version 2015.8.0.

CLI Examples:

\begin{verbatim}
salt-run winrepo.update\_git\_repos
salt-run winrepo.update\_git\_repos clean=True
\end{verbatim}

25.18.1 salt.sdb.cache

cache Module

maintainer
SaltStack

maturity
New

platform
all

New in version 2017.7.0.

This module provides access to Salt's cache subsystem.

Like all sdb modules, the cache module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mastercloudcache:
  driver: cache
  bank: cloud/active/ec2/my-ec2-conf/saltmaster
  cachedir: /var/cache/salt
```

The `driver` refers to the cache module, `bank` refers to the cache bank that contains the data and `cachedir` (optional), if used, points to an alternate directory for cache data storage.

```yaml
master_ip: sdb://mastercloudcache/public_ips
```

It is also possible to override both the `bank` and `cachedir` options inside the SDB URI:

```yaml
```

For this reason, both the `bank` and the `cachedir` options can be omitted from the SDB profile. However, if the `bank` option is omitted, it must be specified in the URI:

```yaml
```

salt.sdb.cache.delete(key, service=None, profile=None)

Get a value from the cache service

salt.sdb.cache.get(key, service=None, profile=None)

Get a value from the cache service

salt.sdb.cache.set_(key, value, service=None, profile=None)

Set a key/value pair in the cache service
25.18.2 salt.sdb.confidant

An SDB module for getting credentials from confidant.

Configuring the Confidant module

The module can be configured via sdb in the minion config:

```yaml
confidant:
    driver: confidant
    # The URL of the confidant web service
    url: 'https://confidant-production.example.com'
    # The context to use for KMS authentication
    auth_context:
        from: example-production-iad
        to: confidant-production-iad
        user_type: service
    # The KMS master key to use for authentication
    auth_key: "alias/authnz"
    # Cache file for KMS auth token
    token_cache_file: /run/confidant/confidant_token
    # The duration of the validity of a token, in minutes
    token_duration: 60
    # key, keyid and region can be defined in the profile, but it's generally
    # best to use IAM roles or environment variables for AWS auth.
    keyid: 98nh9h9h908h09kjjk
    key: jhf908gyeghehe0he0g8h9u0j0n0n09hj09h0
    region: us-east-1
```

depends

confidant-common, confidant-client

Module Documentation

salt.sdb.confidant.get(*key*, *profile=None*)

Read pillar data from Confidant via its API.

CLI Example:

```bash
salt myminion sdb.get 'sdb://confidant/credentials'
```

Valid keys are: credentials, credentials_metadata, result. credentials returns a dict of joined credential_pairs, credentials_metadata returns a dict of metadata relevant to the credentials mapped to the confidant service, and result returns a bool that can be used to determine if the sdb call succeeded or failed to fetch credentials from confidant (or from local cache). If result is false, the data in credentials or credentials_metadata can't be trusted.
25.18.3 salt.sdb.consul

Consul sdb Module

maintainer
SaltStack

maturity
New

platform
all

This module allows access to Consul using an sdb:// URI

Like all sdb modules, the Consul module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
myconsul:
  driver: consul
  host: 127.0.0.1
  port: 8500
  token: b6376760-a8bb-edd5-fcda-33bc13bfc556
  scheme: http
  consistency: default
  dc: dev
  verify: True
```

The driver refers to the Consul module, all other options are optional. For option details see: https://python-consul.readthedocs.io/en/latest/#consul

salt.sdb.consul.get(key, profile=None)

salt.sdb.consul.get_conn(profile)

Return a client object for accessing consul

salt.sdb.consul.set_(key, value, profile=None)

25.18.4 salt.sdb.couchdb

CouchDB sdb Module

maintainer
SaltStack

maturity
New

depends
python2-couchdb

platform
all

This allow interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in salt configuration files.

To use the couchbase sdb module, it must first be configured in the salt master or minion config. The following arguments are required:
One could then query the CouchDB instance via an sdb:// URI such as the following:

```
password: sdb://couchdb_sdb/mykey
```

To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

```
salt.sdb.couchdb.get(key, profile=None)
    Get a value from couchdb by id

salt.sdb.couchdb.set_(key, value, profile=None)
    Set a key/value pair in couchdb
```

### 25.18.5 `salt.sdb.env`

Environment sdb Module

```
maintainer
SaltStack

maturity
New

depends
None

platform
all
```

This module allows access to environment variables using an sdb:// URI.

Example configuration for this module:

```
osenv:
    driver: env
```

**WARNING:**

OS environment variables will be available to read via SDB. Please make sure you don't have any sensitive data in your environment variables‼

Example usage of sdb env module:

```
set some env var:
    cmd.run:
        - name: echo {{ salt['sdb.set']('sdb://osenv/foo', 'bar') }}
        - order: 1
```
{% if salt['sdb.get']('sdb://osenv/foo') == 'bar' %}
always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo
{% else %}
always-changes-and-fails:
  test.fail_with_changes:
    - name: foo
{% endif %}

The above example will return success.

The env sdb module can also be used with salt cloud. Assuming you have exported the environment variable named compute (and have osenv defined). The example below will look for the salt cloud config key compute_name in the environment:

```yaml
my-openstack-config:
  compute_name: sdb://osenv/compute
.. snip
```

```
salt.sdb.env.get(key, profile=None)

Get a value
```

```
salt.sdb.env.set_(key, value, profile=None)

Set a key/value pair
```

### 25.18.6 salt.sdb.etcd_db

etcd Database Module

- maintainer: SaltStack
- maturity: New
- depends: python-etcd or etcd3-py
- platform: all

New in version 2015.5.0.

This module allows access to the etcd database using an sdb:// URL. This package is located at https://pypi.python.org/pypi/python-etcd.

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
myetcd:
  driver: etcd
  etcd.host: 127.0.0.1
  etcd.port: 2379
```
The **driver** refers to the etcd module, **etcd.host** refers to the host that is hosting the etcd database and **etcd.port** refers to the port on that host.

In order to choose whether to use etcd API v2 or v3, you can put the following configuration option in the same place as your etcd configuration. This option defaults to true, meaning you will use v2 unless you specify otherwise.

```
etcd.require_v2: True
```

**password**: sdb://myetcd/mypassword

```
salt.sdb.etcd_db.delete(key, service=None, profile=None)
  Get a value from the etcd service

salt.sdb.etcd_db.get(key, service=None, profile=None)
  Get a value from the etcd service

salt.sdb.etcd_db.set_(key, value, service=None, profile=None)
  Set a key/value pair in the etcd service
```

### 25.18.7 salt.sdb.keyring_db

Keyring Database Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: keyring
- **platform**: all

This module allows access to the keyring package using an sdb:// URI. This package is located at https://pypi.python.org/pypi/keyring.

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mykeyring:
  driver: keyring
  service: system
```

The **driver** refers to the keyring module, **service** refers to the service that will be used inside of keyring (which may be likened unto a database table) and **mykeyring** refers to the name that will appear in the URI:

**password**: sdb://mykeyring/mypassword
The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

```
salt.sdb.keyring_db.get(key, service=None, profile=None)
    Get a value from a keyring service

tsalt.sdb.keyring_db.set_(key, value, service=None, profile=None)
    Set a key/value pair in a keyring service
```

### 25.18.8 salt.sdb.memcached

Memcached sdb Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: python-memcached
- **platform**: all

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.

Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
my_memcache:
    driver: memcached
    memcached.host: localhost
    memcached.port: 11211
```

The `driver` refers to the memcached module, `host` and `port` the memcached server to connect to (defaults to localhost and 11211, and `mymemcached` refers to the name that will appear in the URI:

```
password: sdb://mymemcached/mykey
```

```
salt.sdb.memcached.get(key, profile=None)
    Get a value from memcached

tsalt.sdb.memcached.set_(key, value, profile=None)
    Set a key/value pair in memcached
```
25.18.9 salt.sdb.redis_sdb

Redis SDB module

New in version 2019.2.0.

This module allows access to Redis using an sdb:// URI.

Like all SDB modules, the Redis module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```yaml
sdb_redis:
  driver: redis
  host: 127.0.0.1
  port: 6379
  password: pass
  db: 1
```

The `driver` refers to the Redis module, all other options are optional. For option details see: https://redis-py.readthedocs.io/en/latest/

salt.sdb.redis_sdb.delete(key, profile=None)
Delete a key from the Redis SDB.

salt.sdb.redis_sdb.get(key, profile=None)
Get a value from the Redis SDB.

salt.sdb.redis_sdb.set_(key, value, profile=None)
Set a value into the Redis SDB.

25.18.10 salt.sdb.rest

Generic REST API SDB Module

maintainer
SaltStack

maturity
New

platform
all

New in version 2015.8.0.

This module allows access to a REST interface using an sdb:// URL.

Like all REST modules, the REST module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
my-rest-api:
  driver: rest
  urls:
    url: https://api.github.com/
  keys:
    url: https://api.github.com/users/{{user}}/keys
  backend: requests
```
The **driver** refers to the REST module, and must be set to **rest** in order to use this driver. Each of the other items inside this block refers to a separate set of HTTP items, including a URL and any options associated with it. The options used here should match the options available in `salt.utils.http.query()`.

In order to call the `urls` item in the example, the following reference can be made inside a configuration file:

```yaml
github_urls: sdb://my-rest-api/urls
```

Key/Value pairs may also be used with this driver, and merged into the URL using the configured renderer (`jinja`, by default). For instance, in order to use the `keys` item in the example, the following reference can be made:

```yaml
github_urls: sdb://my-rest-api/keys?user=myuser
```

This will cause the following URL to actually be called:

```
https://api.github.com/users/myuser/keys
```

Key/Value pairs will **NOT** be passed through as GET data. If GET data needs to be sent to the URL, then it should be configured in the SDB configuration block. For instance:

```yaml
another-rest-api:
  driver: rest
  user_data:
    url: https://api.example.com/users/
    params:
      user: myuser
```

```python
salt.sdb.rest.get(key, service=None, profile=None)
```
Get a value from the REST interface

```python
salt.sdb.rest.query(key, value=None, service=None, profile=None)
```
Get a value from the REST interface

```python
salt.sdb.rest.set_(key, value, service=None, profile=None)
```
Set a key/value pair in the REST interface

### 25.18.11 salt.sdb.sqlite3

SQLite sdb Module

- **maintainer**
  SaltStack
- **maturity**
  New
- **platform**
  all

This module allows access to sqlite3 using an **sdb://** URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```yaml
mysqlite:
  driver: sqlite3
  database: /tmp/sdb.sqlite
```

(continues on next page)
**table**: `sdb`  
**create_table**: `True`  

The **driver** refers to the `sqlite3` module, **database** refers to the `sqlite3` database file. **table** is the table within the db that will hold keys and values (defaults to `sdb`). The database and table will be created if they do not exist.

**Advanced Usage:**

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

```python
def myadvanced:
    driver: sqlite3
database: /tmp/sdb-advanced.sqlite
create_statements:
    - "CREATE TABLE advanced (a text, b text, c blob, d blob)"
    - "CREATE INDEX myidx ON advanced (a)"
get_query: "SELECT d FROM advanced WHERE a=:key"
set_query: "INSERT OR REPLACE INTO advanced (a, d) VALUES (:key, :value)"
```

```python
salt.sdb.sqlite3.get(key, profile=None)
Get a value from sqlite3
```

```python
salt.sdb.sqlite3.set_(key, value, profile=None)
Set a key/value pair in sqlite3
```

### 25.18.12 salt.sdb.tism

**tISM - the Immutable Secrets Manager SDB Module**

- **maintainer**
  - tISM
- **maturity**
  - New
- **platform**
  - all

New in version 2017.7.0.

This module will decrypt PGP encrypted secrets against a tISM server.

```python
sdb://<profile>/<encrypted secret>
sdb://tism/
- hQEMAzJ+GfdAB3KqAQf9E3cyvrPEWR1sf1tMVh0nrJ0bZa9kDFLPxvtwAOqlRiNp0F7ipiiVRF+h*sW5Mb4fFBI7FlE/
- G5ptd6CjmgBFb5uGeajWmvLEi41C6/
- 9vIrGjjLeOCeCn4D15AhI4Uuxv8akTDvSAAnPvGhtRTZqDlltl5UEHsyYXM8RaeCrBw50ryvC9Ct2saVp3xM=
- H30L/r50+CBkuI/u4M2pXdcMYsvt4ajCbJn91qaQ7BDI=
```

A profile must be setup in the minion configuration or pillar. If you want to use sdb in a runner or pillar you must also place a profile in the master configuration.
salt.sdb.tism.get(key, service=None, profile=None)

Get a decrypted secret from the tISMd API

25.18.13 salt.sdb.vault

Vault SDB Module

maintainer
SaltStack

maturity
New

platform
all

New in version 2016.11.0.

This module allows access to Hashicorp Vault using an sdb:// URL.

Base configuration instructions are documented in the execution module docs. Below are noted extra configuration required for the sdb module, but the base configuration must also be completed.

Like all sdb modules, the vault module requires a configuration profile to be configured in either the minion configuration file or a pillar. This profile requires only setting the driver parameter to vault:

myvault:
  driver: vault

Once configured you can access data using a URL such as:

password: sdb://myvault/secret/passwords/mypassword

In this URL, myvault refers to the configuration profile, secret/passwords is the path where the data resides, and mypassword is the key of the data to return.

The above URI is analogous to running the following vault command:

$ vault read -field=mypassword secret/passwords

salt.sdb.vault.get(key, profile=None)

Get a value from the vault service

salt.sdb.vault.set_(key, value, profile=None)

Set a key/value pair in the vault service
25.18.14 salt.sdb.yaml

Pull sdb values from a YAML file

maintainer
SaltStack

maturity
New

platform
all

New in version 2017.7.0.

Configuration:

```yaml
my-yaml-file:
  driver: yaml
  files:
    - /path/to/foo.yaml
    - /path/to/bar.yaml
```

The files are merged together and the result is searched using the same mechanism Salt uses for searching Grains and Pillar data structures.

Optional configuration:

```yaml
my-yaml-file:
  driver: yaml
  files:
    - /path/to/foo.yaml
    - /path/to/bar.yaml
  merge:
    strategy: smart
  merge_list: false
  gpg: true
```

New in version 2018.3.0.

Setting the `gpg` option to `true` (default is `false`) will decrypt embedded GPG-encrypted data using the GPG renderer.

`salt.sdb.yaml.get(key, profile=None)`

Get a value from the dictionary

`salt.sdb.yaml.set_("args", **kwargs)`

Setting a value is not supported; edit the YAML files directly
25.19 serializer modules

25.19.1 salt.serializers

This module implements all the serializers needed by salt. Each serializer offers the same functions and attributes:

- `deserialize`
  function for deserializing string or stream
- `serialize`
  function for serializing a Python object
- `available`
  flag that tells if the serializer is available (all dependencies are met etc.)

**exception** `salt.serializers.DeserializationError`

```
(message, line_num=None, buf='', marker='<======================', trace=None)
```

Raised when stream of string failed to be deserialized

**exception** `salt.serializers.SerializationError`

```
(message='')
```

Raised when stream of string failed to be serialized

<table>
<thead>
<tr>
<th>Serializer</th>
<th>Module</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configparser</code></td>
<td><code>salt.serializers.configparser</code></td>
</tr>
<tr>
<td><code>json</code></td>
<td><code>salt.serializers.json</code></td>
</tr>
<tr>
<td><code>keyvalue</code></td>
<td><code>salt.serializers.keyvalue</code></td>
</tr>
<tr>
<td><code>msgpack</code></td>
<td><code>salt.serializers.msgpack</code></td>
</tr>
<tr>
<td><code>plist</code></td>
<td><code>salt.serializers.plist</code></td>

<td><code>salt.serializers.tomlmod</code></td>
</tr>
<tr>
<td><code>yaml</code></td>
<td><code>salt.serializers.yaml</code></td>
</tr>
<tr>
<td><code>yamlex</code></td>
<td><code>salt.serializers.yamlex</code></td>
</tr>
</tbody>
</table>

New in version 3006.0.

New in version 2016.3.0.

Implements a configparser serializer.

**exception** `salt.serializers.configparser.DeserializationError`

```
(message, line_num=None, buf='', marker='<======================', trace=None)
```

Raised when stream of string failed to be deserialized

**exception** `salt.serializers.configparser.SerializationError`

```
(message='')
```

Raised when stream of string failed to be serialized

`salt.serializers.configparser.deserialize(stream_or_string, **options)`

Deserialize any string or stream like object into a Python data structure.

Parameters
stream_or_string -- stream or string to deserialize.

options -- options given to lower configparser module.

salt.serializers.configparser.serialize(obj, **options)

Serialize Python data to a configparser formatted string or file.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower configparser module.

25.19.3 salt.serializers.json

salt.serializers.json

Implements JSON serializer.

It’s just a wrapper around json (or simplejson if available).

exception salt.serializers.json.DeserializationError(message, line_num=None, buf='', marker='<======================', trace=None)

Raised when stream of string failed to be deserialized

exception salt.serializers.json.SerializationError(message='')

Raised when stream of string failed to be serialized

salt.serializers.json.deserialize(stream_or_string, **options)

Deserialize any string or stream like object into a Python data structure.

Parameters

- stream_or_string -- stream or string to deserialize.
- options -- options given to lower json/simplejson module.

salt.serializers.json.serialize(obj, **options)

Serialize Python data to JSON.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower json/simplejson module.

25.19.4 salt.serializers.keyvalue

salt.serializers.keyvalue

New in version 3006.0.

Implements keyvalue serializer which can be used for serializing or deserializing any file which defines keys and values separated by a common set of characters, such environment files, which are in "KEY=value" format.

Options:

param line_ending
   String representation of LF or CRLF to be used for serialization to a file. Defaults to \r\n on Windows and \n on other operating systems.

param quoting
   Boolean flag to determine if values should be quoted (True) during serialization or dequoted (False) during deserialization. Defaults to None (no action).
param separator

String representing the character(s) used when concatenating or reading key/value pairs. Defaults to `.=`.

A dataset such as:

```
foo: bar
wang: chung
```

or

```
- [foo, bar]
- [wang, chung]
```

can be represented as:

```
foo=bar
wang=chung
```

**exception** `salt.serializers.keyvalue.DeserializationError`

Raised when stream of string failed to be deserialized

**exception** `salt.serializers.keyvalue.SerializationError`

Raised when stream of string failed to be serialized

`salt.serializers.keyvalue.dequote(value)`

Remove extra quotes around a string.

`salt.serializers.keyvalue.deserialize(stream_or_string, **options)`

Deserialize any string or stream like object into a Python data structure.

Parameters

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to the function

`salt.serializers.keyvalue.quote(txt)`

Wraps a text around quotes.

```
{% set my_text = 'my_text' %}
{{ my_text | quote }}
```

will be rendered as:

```
'my_text'
```

`salt.serializers.keyvalue.serialize(obj, **options)`

Serialize Python data to environment file.

Parameters

- `obj` -- the data structure to serialize
- `options` -- options given to the function
25.19.5 salt.serializers.msgpack

salt.serializers.msgpack

Implements MsgPack serializer.

salt.serializers.msgpack.deserialize(stream_or_string, **options)

Deserialize any string of stream like object into a Python data structure.

Parameters

- stream_or_string -- stream or string to deserialize.
- options -- options given to lower msgpack module.

salt.serializers.msgpack.serialize(obj, **options)

Serialize Python data to MsgPack.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower msgpack module.

25.19.6 salt.serializers.plist

salt.serializers.plist

New in version 3001.

Implements plist serializer.

Wrapper around plistlib.

exception salt.serializers.plist.DeserializationError(message, line_num=None, buf='', marker='<======================', trace=None)

Raised when stream of string failed to be deserialized

exception salt.serializers.plist.SerializationError(message='')

Raised when stream of string failed to be serialized

salt.serializers.plist.deserialize(stream_or_string, **options)

Deserialize any string or stream like object into a Python data structure.

Parameters

- stream_or_string -- stream or string to deserialize.
- options -- options given to lower plist module.

Returns

Deserialized data structure.

salt.serializers.plist.serialize(value, **options)

Serialize Python data to plist. To create a binary plist pass fmt: FMT_BINARY as an option.

Parameters

- obj -- the data structure to serialize
- options -- options given to lower plist module.

Returns

bytes of serialized plist.
25.19.7 salt.serializers.python

salt.serializers.python

New in version 2016.3.0.
Implements a Python serializer (via pprint.format)
salt.serializers.python.serialize(obj, **options)
Serialize Python data to a Python string representation (via pprint.format)
Parameters
• obj -- the data structure to serialize
• options -- options given to pprint.format

25.19.8 salt.serializers.toml

salt.serializers.tomlmod

Implements TOML serializer.
It's just a wrapper around the python toml module.
exception salt.serializers.tomlmod.DeserializationError(message, line_num=None, buf='', marker='<=------------------------', trace=None)
Raised when stream of string failed to be deserialized
exception salt.serializers.tomlmod.SerializationError(message='')
Raised when stream of string failed to be serialized
salt.serializers.tomlmod.deserialize(stream_or_string, **options)
Deserialize from TOML into Python data structure.
Parameters
• stream_or_string -- toml stream or string to deserialize.
• options -- options given to the python toml module.
salt.serializers.tomlmod.serialize(obj, **options)
Serialize Python data to TOML.
Parameters
• obj -- the data structure to serialize.
• options -- options given to the python toml module.

25.19.9 salt.serializers.yaml

salt.serializers.yaml

Implements YAML serializer.
Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.
salt.serializers.yaml.BaseDumper
alias of CSafeDumper
salt.serializers.yaml.BaseLoader
   alias of CSafeLoader

**exception** salt.serializers.yaml.ConstructorError(
   context=None, context_mark=None,
   problem=None, problem_mark=None,
   note=None)

**exception** salt.serializers.yaml.DeserializationError(
   message, line_num=None, buf='',
   marker='----------------------------------',
   trace=None)

Raised when stream of string failed to be deserialized

class salt.serializers.yaml.Dumper(
   stream, default_style=None, default_flow_style=False,
   canonical=None, indent=None, width=None,
   allow_unicode=None, line_break=None, encoding=None,
   explicit_start=None, explicit_end=None, version=None,
   tags=None, sort_keys=True)

Overwrites Dumper as not for pollute legacy Dumper

yaml_multi_representers = {
   'salt.serializers.yaml.EncryptedString':
      <function EncryptedString.yaml_dumper>,
   'NoneType':
      <function SafeRepresenter.represent_none>,
   'str':
      <function SafeRepresenter.represent_str>,
   'bool':
      <function SafeRepresenter.represent_bool>,
   'int':
      <function SafeRepresenter.represent_int>,
   'float':
      <function SafeRepresenter.represent_float>,
   'list':
      <function SafeRepresenter.represent_list>,
   'tuple':
      <function SafeRepresenter.represent_tuple>,
   'dict':
      <function SafeRepresenter.represent_dict>,
   'set':
      <function SafeRepresenter.represent_set>,
   'datetime.date':
      <function SafeRepresenter.represent_date>,
   'datetime.datetime':
      <function SafeRepresenter.represent_datetime>,
   'Undefined':
      <function SafeRepresenter.represent_undefined>,
   'salt.utils.odict.OrderedDict':
      <function SafeRepresenter.represent_dict>
}

class salt.serializers.yaml.EncryptedString

   static yaml_constructor(loader, tag, node)

   static yaml_dumper(dumper, data)

yaml_tag = '!encrypted'

class salt.serializers.yaml.Loader(stream)

   Overwrites Loader as not for pollute legacy Loader

class salt.serializers.yaml.OrderedDict

exception salt.serializers.yaml.ScannerError(context=None, context_mark=None, problem=None, problem_mark=None, note=None)

exception salt.serializers.yaml.SerializationError(message='')

Raised when stream of string failed to be serialized

salt.serializers.yaml.deserialize(stream_or_string, **options)

Deserialize any string of stream like object into a Python data structure.

Parameters

• stream_or_string -- stream or string to deserialize.

• options -- options given to lower yaml module.

salt.serializers.yaml.serialize(obj, **options)

Serialize Python data to YAML.

Parameters

• obj -- the data structure to serialize

• options -- options given to lower yaml module.

25.19.10 salt.serializers.yamlex

salt.serializers.yamlex

YAMLEX is a format that allows for things like sls files to be more intuitive.

It’s an extension of YAML that implements all the salt magic: - it implies omap for any dict like. - it implies that string like data are str, not unicode - ...

For example, the file states.sls has this contents:

```yaml
foo:
  bar: 42
  baz: [1, 2, 3]
```

The file can be parsed into Python like this
from salt.serializers import yamlex

with open('state.sls', 'r') as stream:
    obj = yamlex.deserialize(stream)

Check that obj is an OrderedDict

from salt.utils.odict import OrderedDict

assert isinstance(obj, dict)
assert isinstance(obj, OrderedDict)

yamlex __repr__ and __str__ objects' methods render YAML understandable string. It means that they are template friendly.

print '{{0}}'.format(obj)

returns:

{foo: {bar: 42, baz: [1, 2, 3]}}

and they are still valid YAML:

from salt.serializers import yaml

yml_obj = yaml.deserialize(str(obj))
assert yml_obj == obj

yamlex implements also custom tags:

!aggregate

this tag allows structures aggregation.

For example:

placeholder: !aggregate foo
placeholder: !aggregate bar
placeholder: !aggregate baz

is rendered as

placeholder: [foo, bar, baz]

!reset

this tag flushes the computing value.

placeholder: {!aggregate foo: {foo: 42}}
placeholder: {!aggregate foo: {bar: null}}

!reset placeholder: {!aggregate foo: {baz: inga}}

is roughly equivalent to

placeholder: {!aggregate foo: {baz: inga}}

Document is defacto an aggregate mapping.
**class** salt.serializers.yamlex.AggregatedMap

**class** salt.serializers.yamlex.AggregatedSequence(iterable=(),)

salt.serializers.yamlex.BaseDumper
    alias of SafeDumper
salt.serializers.yamlex.BaseLoader
    alias of CSafeLoader

**exception** salt.serializers.yamlex.ConstructorError(context=None, context_mark=None, problem=None, problem_mark=None, note=None)

**exception** salt.serializers.yamlex.DeserializationError(message, line_num=None, buf='", marker='
              '<--------------------------', trace=None)

Raised when stream of string failed to be deserialized

**class** salt.serializers.yamlex.Dumper(stream, default_style=None, default_flow_style=False, canonical=None, indent=None, width=None, allow_unicode=None, line_break=None, encoding=None, explicit_start=None, explicit_end=None, version=None, tags=None, sort_keys=True)

sls dumper.

**represent_odict**(data)

yaml_multi_representers = {'NoneType': <function SafeRepresenter.represent_none>, 'bytes': <function SafeRepresenter.represent_binary>, 'str': <function SafeRepresenter.represent_str>, 'bool': <function SafeRepresenter.represent_bool>, 'int': <function SafeRepresenter.represent_int>, 'float': <function SafeRepresenter.represent_float>, 'list': <function SafeRepresenter.represent_list>, 'tuple': <function SafeRepresenter.represent_list>, 'dict': <function Dumper.represent_odict>, 'set': <function SafeRepresenter.represent_set>, 'datetime.date': <function SafeRepresenter.represent_datetime>, None: <function SafeRepresenter.represent_undefined>}

**class** salt.serializers.yamlex.Loader(stream)

Create a custom YAML loader that uses the custom constructor. This allows for the YAML loading defaults to be manipulated based on needs within salt to make things like sls file more intuitive.

**DEFAULT_MAPPING_TAG** = 'tag:yaml.org,2002:omap'

**DEFAULT_SCALAR_TAG** = 'tag:yaml.org,2002:str'

**DEFAULT_SEQUENCE_TAG** = 'tag:yaml.org,2002:seq'

compose_document()
construct_sls_aggregate(node)

construct_sls_int(node)
    Verify integers and pass them in correctly if they are declared as octal

construct_sls_reset(node)

construct_sls_str(node)
    Build the SLSString.

construct_yaml_omap(node)
    Build the SLSMap

resolve_sls_tag(node)

yaml_constructors = {'tag:yaml.org,2002:null': <function
    SafeConstructor.construct_yaml_null>, 'tag:yaml.org,2002:bool': <function

        <function SafeConstructor.construct_yaml_pairs>, 'tag:yaml.org,2002:seq':
        <function SafeConstructor.construct_yaml_seq}, 'tag:yaml.org,2002:map': <function
    SafeConstructor.construct_yaml_map}, None: <function
    SafeConstructor.construct_undefined>, '!aggregate': <function
    Loader.construct_sls_aggregate>, '!reset': <function
    Loader.construct_sls_reset}

yaml_multi_constructors = {'tag:yaml.org,2002:binary': <function
    SafeConstructor.construct_yaml_binary>, 'tag:yaml.org,2002:bool': <function
    SafeConstructor.construct_yaml_bool}, 'tag:yaml.org,2002:int': <function
    SafeConstructor.construct_yaml_int}, 'tag:yaml.org,2002:float': <function
    SafeConstructor.construct_yaml_float}, 'tag:yaml.org,2002:omap':
        <function SafeConstructor.construct_yaml_omap}, 'tag:yaml.org,2002:pairs':
        <function SafeConstructor.construct_yaml_pairs}, 'tag:yaml.org,2002:seq':
        <function SafeConstructor.construct_yaml_seq}, 'tag:yaml.org,2002:map': <function
    SafeConstructor.construct_yaml_map}, None: <function
    SafeConstructor.construct_undefined}, '!aggregate': <function
    Loader.construct_sls_aggregate}, '!reset': <function
    Loader.construct_sls_reset}

class salt.serializers.yamllex.Map
    Map aggregation.

class salt.serializers.yamllex.MappingNode(tag, value, start_mark=None, end_mark=None, flow_style=None)

    id = 'mapping'

class salt.serializers.yamllex.OrderedDict
class salt.serializers.yamlex.SLSMap

Ensures that dict str() and repr() are YAML friendly.

```python
>>> mapping = OrderedDict([('a', 'b'), ('c', None)])
>>> print(mapping
OrderedDict([('a', 'b'), ('c', None)])

>>> sls_map = SLSMap(mapping)
>>> print(sls_map.__str__())
{'a': 'b', 'c': None}
```

class salt.serializers.yamlex.SLSString

Ensures that str str() and repr() are YAML friendly.

```python
>>> scalar = str('foo')
>>> print('foo'
foo

>>> sls_scalar = SLSString(scalar)
>>> print(sls_scalar
"foo"
```

exception salt.serializers.yamlex.ScannerError(context=None, context_mark=None, problem=None, problem_mark=None, note=None)

class salt.serializers.yamlex.Sequence(iterable=(), /
Sequence aggregation.

exception salt.serializers.yamlex.SerializationError(message='')

Raised when stream of string failed to be serialized

salt.serializers.yamlex.aggregate(obj_a, obj_b, level=False, map_class=<class
'salt.utils.aggregation.Map'>, sequence_class=<class
'salt.utils.aggregation.Sequence'>)

Merge obj_b into obj_a.

```python
>>> aggregate('first', 'second', True) == ['first', 'second']
True
```

class salt.serializers.yamlex.deserialize(stream_or_string, **options)

Deserialize any string of stream like object into a Python data structure.

Parameters
- stream_or_string -- stream or string to deserialize.
- options -- options given to lower yaml module.

class salt.serializers.yamlex.merge_recursive(obj_a, obj_b, level=False)

Merge obj_b into obj_a.

class salt.serializers.yamlex.serialize(obj, **options)

Serialize Python data to YAML.

Parameters
- obj -- the data structure to serialize
- options -- options given to lower yaml module.
## 25.20 state modules

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acme</td>
<td>ACME / Let's Encrypt certificate management state</td>
</tr>
<tr>
<td>alias</td>
<td>Configuration of email aliases</td>

### 25.20.1 salt.states.acme

**ACME / Let’s Encrypt certificate management state**

New in version 2016.3.0.

See also the module documentation

```python
reload-gitlab:
    cmd.run:
        - name: gitlab-ctl hup

dev.example.com:
    acme.cert:
        - aliases:
            - gitlab.example.com
        - email: acmemaster@example.com
        - webroot: /opt/gitlab/embedded/service/gitlab-rails/public
        - renew: 14
        - fire_event: acme/dev.example.com
        - onchanges_in:
            - cmd: reload-gitlab
```

25.20. state modules 3803
salt.states.acme.cert(name, aliases=None, email=None, webroot=None, test_cert=False, renew=None, keysize=None, server=None, owner='root', group='root', mode='0640', certname=None, preferred_challenges=None, tls_sni_01_port=None, tls_sni_01_address=None, http_01_port=None, http_01_address=None, dns_plugin=None, dns_plugin_credentials=None)

Obtain/renew a certificate from an ACME CA, probably Let's Encrypt.

Parameters
- name -- Common Name of the certificate (DNS name of certificate)
- aliases -- subjectAltNames (Additional DNS names on certificate)
- email -- e-mail address for interaction with ACME provider
- webroot -- True or a full path to webroot. Otherwise use standalone mode
- test_cert -- Request a certificate from the Happy Hacker Fake CA (mutually exclusive with 'server')
- renew -- True/'force' to force a renewal, or a window of renewal before expiry in days
- keysize -- RSA key bits
- server -- API endpoint to talk to
- owner -- owner of the private key file
- group -- group of the private key file
- mode -- mode of the private key file
- certname -- Name of the certificate to save
- preferred_challenges -- A sorted, comma delimited list of the preferred challenge to use during authorization with the most preferred challenge listed first.
- tls_sni_01_port -- Port used during tls-sni-01 challenge. This only affects the port Certbot listens on. A conforming ACME server will still attempt to connect on port 443.
- tls_sni_01_address -- The address the server listens to during tls-sni-01 challenge.
- http_01_port -- Port used in the http-01 challenge. This only affects the port Certbot listens on. A conforming ACME server will still attempt to connect on port 80.
- https_01_address -- The address the server listens to during http-01 challenge.
- dns_plugin -- Name of a DNS plugin to use (currently only 'cloudflare')
- dns_plugin_credentials -- Path to the credentials file if required by the specified DNS plugin

25.20.2 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```
username:
  alias.present:
    - target: user@example.com

thomas:
  alias.present:
    - target: thomas@example.com
```

The default alias file is set to /etc/aliases, as defined in Salt's `config execution module`. To change the alias file from the default location, set the following in your minion config:
**aliases.file**: `/my/alias/file`

**salt.states.alias.absent**(name)

Ensure that the named alias is absent

name

The alias to remove

**salt.states.alias.present**(name, target)

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

name

The local user/address to assign an alias to

target

The forwarding address

---

### 25.20.3 **salt.states.alternatives**

Configuration of the alternatives system

Control the alternatives system

```
{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
  file.directory

hadoop-0.20-conf:
  alternatives.install:
    - name: hadoop-0.20-conf
    - link: /etc/hadoop-0.20/conf
    - path: {{ my_hadoop_conf }}
    - priority: 30
    - require:
    - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
  alternatives.remove:
    - name: hadoop-0.20-conf
    - path: {{ my_hadoop_conf }}

salt.states.alternatives.auto**(name)**

New in version 0.17.0.

Instruct alternatives to use the highest priority path for `<name>`

name

is the master name for this link group (e.g. pager)

**salt.states.alternatives.install**(name, link, path, priority)

Install new alternative for defined `<name>`

name

is the master name for this link group (e.g. pager)

link

is the symlink pointing to `/etc/alternatives/<name>`. (e.g. /usr/bin/pager)
path is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)

priority is an integer; options with higher numbers have higher priority in automatic mode.

**salt.states.alternatives.remove(name, path)**
Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.

name is the master name for this link group (e.g. pager)

path is the location of one of the alternative target files. (e.g. /usr/bin/less)

**salt.states.alternatives.set_(name, path)**
New in version 0.17.0.
Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.

name is the master name for this link group (e.g. pager)

path is the location of one of the alternative target files. (e.g. /usr/bin/less)

```yaml
foo:
  alternatives.set:
    - path: /usr/bin/foo-2.0
```

### 25.20.4 salt.states.ansiblegate

**Execution of Ansible modules from within states**

With `ansible.call` these states allow individual Ansible module calls to be made via states. To call an Ansible module function use a `module.run` state:

```yaml
some_set_of_tasks:
  ansible:
    - system.ping
    - packaging.os.zypper
      - name: emacs
        - state: installed
```

**class salt.states.ansiblegate.AnsibleState**

An Ansible state caller.

**get_args(argset)**

Get args and kwargs from the argset.

Parameters

argset --

Returns

salt.states.ansiblegate.playbooks(name, rundir=None, git_repo=None, git_kwargs=None, ansible_kwargs=None)

Run Ansible Playbooks

Parameters
- **name** -- path to playbook. This can be relative to rundir or the git repo
- **rundir** -- location to run ansible-playbook from.
- **git_repo** -- git repository to clone for ansible playbooks. This is cloned using the `git.latest` state, and is cloned to the **rundir** if specified, otherwise it is cloned to the **cache_dir**
- **git_kwargs** -- extra kwargs to pass to `git.latest` state module besides the **name** and **target**
- **ansible_kwargs** -- extra kwargs to pass to `ansible.playbooks` execution module besides the **name** and **target**

**Returns**

Ansible playbook output.

**run nginx install:**

```yaml
ansible.playbooks:
  - name: install.yml
  - git_repo: git://github.com/gituser/playbook.git
  - git_kwargs:
    rev: master
```

## 25.20.5 salt.states.apache

Apache state

New in version 2014.7.0.

Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable `this` is special and signifies what should be included with the above word between angle brackets (`<>`).

```yaml
/etc/httpd/conf.d/website.com.conf:
  apache.configfile:
    - config:
      - VirtualHost:
        this: '*:80'
        ServerName:
          - website.com
        ServerAlias:
          - www.website.com
          - dev.website.com
        ErrorLog: logs/website.com-error_log
        CustomLog: logs/website.com-access_log combined
        DocumentRoot: /var/www/vhosts/website.com
        Directory:
          this: /var/www/vhosts/website.com
          Order: Deny,Allow
          Deny from: all
          Allow from:
            - 127.0.0.1
            - 192.168.100.0/24
        Options:
          - Indexes
          - FollowSymlinks
        AllowOverride: All
```

Changed in version 2018.3.0.
Allows having the same section container multiple times (e.g. <Directory /path/to/dir>).

YAML structure stays the same only replace dictionary with a list.

When a section container does not have mandatory attribute, such as <Else>, it still needs keyword this with empty string (or "" if nicer output is required - without space).

```
/etc/httpd/conf.d/website.com.conf:
    apache.configfile:
        - config:
            - VirtualHost:
                - this: '*:80'
            - ServerName:
                - website.com
            - DocumentRoot: /var/www/vhosts/website.com
            - Directory:
                - this: /var/www/vhosts/website.com/
                  Order: Deny,Allow
                  Deny from: all
                  Allow from:
                    - 127.0.0.1
                    - 192.168.100.0/24
                  Options:
                    - Indexes
                    - FollowSymlinks
                  AllowOverride: All
            - Directory:
                - this: /var/www/vhosts/website.com/private
                  Order: Deny,Allow
                  Deny from: all
                  Allow from:
                    - 127.0.0.1
                    - 192.168.100.0/24
                  If:
                    - this: some condition
                      do: something
                  Else:
                    - this:
                      do: something else
                  Else:
                    - this: ""
                      do: another thing
```

`salt.states.apache.configfile(name, config)`
25.20.6 salt.states.apache_conf

Manage Apache Confs
New in version 2016.3.0.
Enable and disable apache confs.

Enable security conf:
   apache_conf.enabled:
   - name: security

Disable security conf:
   apache_conf.disabled:
   - name: security

salt.states.apache_conf.disabled(name)
   Ensure an Apache conf is disabled.
   name
   Name of the Apache conf

salt.states.apache_conf.enabled(name)
   Ensure an Apache conf is enabled.
   name
   Name of the Apache conf

25.20.7 salt.states.apache_module

Manage Apache Modules
New in version 2014.7.0.
Enable and disable apache modules.

Enable cgi module:
   apache_module.enabled:
   - name: cgi

Disable cgi module:
   apache_module.disabled:
   - name: cgi

salt.states.apache_module.disabled(name)
   Ensure an Apache module is disabled.
   New in version 2016.3.0.
   name
   Name of the Apache module

salt.states.apache_module.enabled(name)
   Ensure an Apache module is enabled.
   New in version 2016.3.0.
   name
   Name of the Apache module
25.20.8 salt.states.apache_site

Manage Apache Sites

New in version 2016.3.0.

Enable and disable apache sites.

**Enable default site:**

```python
apache_site.enabled:
    - name: default
```

**Disable default site:**

```python
apache_site.disabled:
    - name: default
```

salt.states.apache_site.disabled(name)

Ensure an Apache site is disabled.

```python
name
      Name of the Apache site
```

salt.states.apache_site.enabled(name)

Ensure an Apache site is enabled.

```python
name
      Name of the Apache site
```

25.20.9 salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

salt.states.aptpkg.held(name)

Set package in 'hold' state, meaning it will not be upgraded.

```python
name
      The name of the package, e.g., 'tmux'
```

25.20.10 salt.states.archive

Extract an archive

New in version 2014.1.0.

salt.states.archive.extracted(name, source, source_hash=None, source_hash_name=None, source_hash_update=False, skip_files_list_verify=False, skip_verify=False, password=None, options=None, list_options=None, force=False, overwrite=False, clean=False, clean_parent=False, user=None, group=None, if_missing=None, trim_output=False, use_cmd_unzip=None, extract_perms=True, enforce_toplevel=True, enforce_ownership_on=None, archive_format=None, use_etag=False, **kwargs)

New in version 2014.1.0.

Changed in version 2016.11.0,3005: This state has been rewritten. Some arguments are new to this release and will not be available in the 2016.3 release cycle (and earlier). Additionally, the **ZIP Archive Handling** section below applies specifically to the 2016.11.0 release (and newer).
Ensure that an archive is extracted to a specific directory.

**Important: Changes for 2016.11.0**

In earlier releases, this state would rely on the `if_missing` argument to determine whether or not the archive needed to be extracted. When this argument was not passed, then the state would just assume `if_missing` is the same as the `name` argument (i.e. the parent directory into which the archive would be extracted).

This caused a number of annoyances. One such annoyance was the need to know beforehand a path that would result from the extraction of the archive, and setting `if_missing` to that directory, like so:

```
extract_myapp:
  archive.extracted:
    - name: /var/www
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
    - if_missing: /var/www/myapp-16.2.4
```

If `/var/www` already existed, this would effectively make `if_missing` a required argument, just to get Salt to extract the archive.

Some users worked around this by adding the top-level directory of the archive to the end of the `name` argument, and then used `--strip` or `--strip-components` to remove that top-level dir when extracting:

```
extract_myapp:
  archive.extracted:
    - name: /var/www/myapp-16.2.4
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
```

With the rewrite for 2016.11.0, these workarounds are no longer necessary. `if_missing` is still a supported argument, but it is no longer required. The equivalent SLS in 2016.11.0 would be:

```
extract_myapp:
  archive.extracted:
    - name: /var/www
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
```

Salt now uses a function called `archive.list` to get a list of files/directories in the archive. Using this information, the state can now check the minion to see if any paths are missing, and know whether or not the archive needs to be extracted. This makes the `if_missing` argument unnecessary in most use cases.

**Important: ZIP Archive Handling**

*Note: this information applies to 2016.11.0 and later.*

Salt has two different functions for extracting ZIP archives:

1. `archive.unzip`, which uses Python's `zipfile` module to extract ZIP files.
2. `archive.cmd_unzip`, which uses the `unzip` CLI command to extract ZIP files.
Salt will prefer the use of `archive.cmd_unzip` when CLI options are specified (via the `options` argument), and will otherwise prefer the `archive.unzip` function. Use of `archive.cmd_unzip` can be forced however by setting the `use_cmd_unzip` argument to `True`. By contrast, setting this argument to `False` will force usage of `archive.unzip`. For example:

```
/var/www:
    archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - use_cmd_unzip: True
```

When `use_cmd_unzip` is omitted, Salt will choose which extraction function to use based on the source archive and the arguments passed to the state. When in doubt, simply do not set this argument; it is provided as a means of overriding the logic Salt uses to decide which function to use.

There are differences in the features available in both extraction functions. These are detailed below.

- **Command-line options** (only supported by `archive.cmd_unzip`) - When the `options` argument is used, `archive.cmd_unzip` is the only function that can be used to extract the archive. Therefore, if `use_cmd_unzip` is specified and set to `False`, and `options` is also set, the state will not proceed.

- **Permissions** - Due to an upstream bug in Python, permissions are not preserved when the `zipfile` module is used to extract an archive. As of the 2016.11.0 release, `archive.unzip` (as well as this state) has an `extract_perms` argument which, when set to `True` (the default), will attempt to match the permissions of the extracted files/directories to those defined within the archive. To disable this functionality and have the state not attempt to preserve the permissions from the ZIP archive, set `extract_perms` to `False`:

```
/var/www:
    archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - extract_perms: False
```

**name**
Directory into which the archive should be extracted

**source**
Archive to be extracted

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

**source_hash**
Hash of source file, or file with list of hash-to-file mappings

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

Changed in version 2016.11.0: If this argument specifies the hash itself, instead of a URI to a file containing hashes, the hash type can now be omitted and Salt will determine the hash type based on the length of the hash. For example, both of the below states are now valid, while before only the second one would be:

```
foo_app:
    archive.extracted:
    - name: /var/www
    - source: https://mydomain.tld/foo.tar.gz
    - source_hash: 3360db35e682f1c5f9c58aa307de16d41361618c
```
(continues on next page)
source_hash_name

When source_hash refers to a hash file, Salt will try to find the correct hash by matching the filename part of the source URI. When managing a file with a source of salt://files/foo.tar.gz, then the following line in a hash file would match:

acbd18db4cc2f85cedef654fccc4a4d8 foo.tar.gz

This line would also match:

acbd18db4cc2f85cedef654fccc4a4d8 ./dir1/foo.tar.gz

However, sometimes a hash file will include multiple similar paths:

37b51d194a7513e45b56f6524f2d51f2 ./dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8 ./dir2/foo.txt
73fefffa4b7f6bb6e44cf984c85f6e88 ./dir3/foo.txt

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

/var/www:
  archive.extracted:
    - source: https://mydomain.tld/dir2/foo.tar.gz
    - source_hash: https://mydomain.tld/_hashes
    - source_hash_name: ./dir2/foo.tar.gz

Note: This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using foo.txt would not match.

New in version 2016.11.0.

source_hash_update

[False] Set this to True if archive should be extracted if source_hash has changed and there is a difference between the archive and the local files. This would extract regardless of the if_missing parameter.

Note that this is only checked if the source value has not changed. If it has (e.g. to increment a version number in the path) then the archive will not be extracted even if the hash has changed.

Note: Setting this to True along with keep_source set to False will result the source re-download to do a archive file list check. If it's not desirable please consider the skip_files_list_verify argument.

New in version 2016.3.0.
**skip_files_list_verify**

[False] Set this to True if archive should be extracted if source_hash has changed but only checksums of the archive will be checked to determine if the extraction is required.

It will try to find a local cache of the source and check its hash against the source_hash. If there is no local cache available, for example if you set the keep_source to False, it will try to find a cached source hash file in the Minion archives cache directory.

**Note:** The current limitation of this logic is that you have to set minions hash_type config option to the same one that you’re going to pass via source_hash argument.

**Warning:** With this argument set to True Salt will only check for the source_hash against the local hash of the source. So if you, for example, remove extracted files without clearing the Salt Minion cache next time you execute the state Salt will not notice that extraction is required if the hashes are still match.

New in version 3000.

**skip_verify**

[False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.4.

**keep_source**

[True] For source archives not local to the minion (i.e. from the Salt fileserver or a remote source such as http(s) or ftp), Salt will need to download the archive to the minion cache before they can be extracted. To remove the downloaded archive after extraction, set this argument to False.

New in version 2017.7.3.

**keep**

[True] Same as keep_source, kept for backward-compatibility.

**Note:** If both keep_source and keep are used, keep will be ignored.

**password**

For ZIP archives only. Password used for extraction.

New in version 2016.3.0.

Changed in version 2016.11.0: The newly-added archive.is_encrypted function will be used to determine if the archive is password-protected. If it is, then the password argument will be required for the state to proceed.

**options**

For tar and zip archives only. This option can be used to specify a string of additional arguments to pass to the tar/zip command.

If this argument is not used, then the minion will attempt to use Python’s native tarfile/zipfile support to extract it. For zip archives, this argument is mostly used to overwrite existing files with o.

Using this argument means that the tar or unzip command will be used, which is less platform-independent, so keep this in mind when using this option; the CLI options must be valid options for the tar/unzip implementation on the minion’s OS.

New in version 2016.11.0.
Changed in version 2015.8.11,2016.3.2: XZ-compressed tar archives no longer require `J` to manually be set in the options, they are now detected automatically and decompressed using the `xz` CLI command and extracted using `tar xvf`. This is a more platform-independent solution, as not all tar implementations support the `J` argument for extracting archives.

**Note:** For tar archives, main operators like `-x`, `--extract`, `--get`, `-c` and `-f|--file` should **not** be used here.

### list_options

**For tar archives only.** This state uses `archive.list` to discover the contents of the source archive so that it knows which file paths should exist on the minion if the archive has already been extracted. For the vast majority of tar archives, `archive.list` "just works". Archives compressed using gzip, bzip2, and xz/lzma (with the help of the `xz` CLI command) are supported automatically. However, for archives compressed using other compression types, CLI options must be passed to `archive.list`.

This argument will be passed through to `archive.list` as its `options` argument, to allow it to successfully list the archive's contents. For the vast majority of archives, this argument should not need to be used, it should only be needed in cases where the state fails with an error stating that the archive's contents could not be listed.

**New in version 2016.11.0.**

### force

[False] If a path that should be occupied by a file in the extracted result is instead a directory (or vice-versa), the state will fail. Set this argument to `True` to force these paths to be removed in order to allow the archive to be extracted.

**Warning:** Use this option very carefully.

**New in version 2016.11.0.**

### overwrite

[False] Set this to `True` to force the archive to be extracted. This is useful for cases where the filenames/directories have not changed, but the content of the files have.

**New in version 2016.11.1.**

### clean

[False] Set this to `True` to remove any top-level files and recursively remove any top-level directory paths before extracting.

**Note:** Files will only be cleaned first if extracting the archive is deemed necessary, either by paths missing on the minion, or if `overwrite` is set to `True`.

**New in version 2016.11.1.**

### clean_parent

[False] If `True`, and the archive is extracted, delete the parent directory (i.e. the directory into which the archive is extracted), and then re-create that directory before extracting. Note that `clean` and `clean_parent` are mutually exclusive.

**New in version 3000.**

### user

The user to own each extracted file. Not available on Windows.

**New in version 2015.8.0.**
Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the `enforce_ownership_on` argument.

**group**

The group to own each extracted file. Not available on Windows.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the `enforce_ownership_on` argument.

**if_missing**

If specified, this path will be checked, and if it exists then the archive will not be extracted. This path can be either a directory or a file, so this option can also be used to check for a semaphore file and conditionally skip extraction.

Changed in version 2016.3.0: When used in combination with either user or group, ownership will only be enforced when if_missing is a directory.

Changed in version 2016.11.0: Ownership enforcement is no longer tied to this argument, it is simply checked for existence and extraction will be skipped if if is present.

**trim_output**

[False] Useful for archives with many files in them. This can either be set to True (in which case only the first 100 files extracted will be in the state results), or it can be set to an integer for more exact control over the max number of files to include in the state results.

New in version 2016.3.0.

**use_cmd_unzip**

[False] Set to True for zip files to force usage of the `archive.cmd_unzip` function to extract.

New in version 2016.11.0.

**extract_perms**

[True] For ZIP archives only. When using `archive.unzip` to extract ZIP archives, Salt works around an upstream bug in Python to set the permissions on extracted files/directories to match those encoded into the ZIP archive. Set this argument to False to skip this workaround.

New in version 2016.11.0.

**enforce_toplevel**

[True] This option will enforce a single directory at the top level of the source archive, to prevent extracting a `tar-bomb`. Set this argument to False to allow archives with files (or multiple directories) at the top level to be extracted.

New in version 2016.11.0.

**enforce_ownership_on**

When user or group is specified, Salt will default to enforcing permissions on the file/directory paths detected by running `archive.list` on the source archive. Use this argument to specify an alternate directory on which ownership should be enforced.

---

**Note:** This path must be within the path specified by the name argument.

New in version 2016.11.0.
archive_format

One of tar, zip, or rar.

Changed in version 2016.11.0: If omitted, the archive format will be guessed based on the value of the source argument. If the minion is running a release older than 2016.11.0, this option is required.

use_etag

If True, remote http/https file sources will attempt to use the ETag header to determine if the remote file needs to be downloaded. This provides a lightweight mechanism for promptly refreshing files changed on a web server without requiring a full hash comparison via the source_hash parameter.

New in version 3005.

Examples

1. tar with lmza (i.e. xz) compression:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   ```

2. tar archive with flag for verbose output, and enforcement of user/group ownership:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   - options: v
   - user: foo
   - group: foo
   ```

3. tar archive, with source_hash_update set to True to prevent state from attempting extraction unless the source_hash differs from the previous time the archive was extracted:

   ```
   graylog2-server:
   archive.extracted:
   - name: /opt/
   - source: https://github.com/downloads/Graylog2/graylog2-server/
   - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
   - source_hash_update: True
   ```

25.20.11 salt.states.artifactory

This state downloads artifacts from artifactory.

salt.states.artifactory.downloaded(name, artifact, target_dir='/tmp', target_file=None, use_literal_group_id=False)

Ensures that the artifact from artifactory exists at given location. If it doesn’t exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

artifact

Details of the artifact to be downloaded from artifactory. Various options are:
• artifact_url: URL of the artifactory instance
• repository: Repository in artifactory
• artifact_id: Artifact ID
• group_id: Group ID
• packaging: Packaging
• classifier: Classifier .. versionadded:: 2015.8.0
• version: Version
  One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
• username: Artifactory username .. versionadded:: 2015.8.0
• password: Artifactory password .. versionadded:: 2015.8.0

target_dir
  Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.

target_file
  Target file to download artifact to. By default file name is resolved by artifactory.

An example to download an artifact to a specific file:

```
jboss_module_downloaded:
  artifact_downloaded:
    - artifact:
        artifact_url: http://artifactory.intranet.example.com/
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```
jboss_module_downloaded:
  artifact_downloaded:
    - artifact:
        artifact_url: http://artifactory.intranet.example.com/
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_dir: /opt/jboss7/modules/com/company/lib
```
25.20.12 salt.states.at

Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.
salt.states.at.absent(name, jobid=None, **kwargs)
    Changed in version 2017.7.0.
    Remove a job from queue
    jobid: string|int
        Specific jobid to remove
    tag
        [string] Job's tag
    runas
        [string] Runs user-specified jobs
    kwargs
        Addition kwargs can be provided to filter jobs. See output of at.jobcheck for more.

```
example1:
    at.absent:
        Warning: this will remove all jobs!

example2:
    at.absent:
        - year: 13

example3:
    at.absent:
        - tag: rose

example4:
    at.absent:
        - tag: rose
        - day: 13
        - hour: 16

example5:
    at.absent:
        - jobid: 4
```

salt.states.at.mod_watch(name, **kwargs)
    The at watcher, called to invoke the watch command.

    Note: This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

    name
        The name of the atjob
salt.states.at.present(name, timespec, tag=None, user=None, job=None, unique_tag=False)

Changed in version 2017.7.0.
Add a job to queue.
job
[string] Command to run.
timespec
[string] The 'timespec' follows the format documented in the at(1) manpage.
tag
[string] Make a tag for the job.
user
[string] The user to run the at job .. versionadded:: 2014.1.4
unique_tag
[boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

```yaml
rose:
  at.present:
    - job: 'echo "I love saltstack" > love'
    - timespec: '9:09 11/09/13'
    - tag: love
    - user: jam
```

salt.states.at.watch(name, timespec, tag=None, user=None, job=None, unique_tag=False)

New in version 2017.7.0.
Add an at job if trigger by watch
job
[string] Command to run.
timespec
[string] The 'timespec' follows the format documented in the at(1) manpage.
tag
[string] Make a tag for the job.
user
[string] The user to run the at job .. versionadded:: 2014.1.4
unique_tag
[boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

```yaml
minion_restart:
  at.watch:
    - job: 'salt-call --local service.restart salt-minion'
    - timespec: 'now +1 min'
    - tag: minion_restart
    - unique_tag: trye
    - watch:
        - file: /etc/salt/minion
```
25.20.13 salt.states.augeas

Configuration management using Augeas

New in version 0.17.0.

This state requires the augeas Python module.

Augeas can be used to manage configuration files.

Warning: Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

salt.states.augeas.change(name, context=None, changes=None, lens=None, load_path=None, **kwargs)

New in version 2014.7.0.

This state replaces setvalue().

Issue changes to Augeas, optionally for a specific context, with a specific lens.

name
State name

countext
A file path, prefixed by /files. Should resolve to an actual file (not an arbitrary augeas path). This is used to avoid duplicating the file name for each item in the changes list (for example, set bind 0.0.0.0 in the example below operates on the file specified by context). If context is not specified, a file path prefixed by /files should be included with the set command.

The file path is examined to determine if the specified changes are already present.

| redis-conf: | augeas.change:
| --- | --- |
| context: /files/etc/redis/redis.conf | changes:
| set bind 0.0.0.0 | - set bind 0.0.0.0
| set maxmemory 1G | - set maxmemory 1G

changes
List of changes that are issued to Augeas. Available commands are set, setm, mv/move, ins/insert, and rm/remove.

dlens
The lens to use, needs to be suffixed with .Ins, e.g.: Nginx.lns. See the list of stock lenses shipped with Augeas.

New in version 2016.3.0.

cload_path
A list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUDEAS_LENS_LIB.

Usage examples:

Set the bind parameter in /etc/redis/redis.conf:
redis-conf:
  augeas.change:
    - changes:
      - set /files/etc/redis/redis.conf/bind 0.0.0.0

Note: Use the context parameter to specify the file you want to manipulate. This way you don’t have to include this in the changes every time:

redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
      - set databases 4
      - set maxmemory 1G

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with lenses, which provide mappings between the Augeas tree and the file.

There are many preconfigured lenses that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn’t know about, you can specify the lens to use like this:

redis-conf:
  augeas.change:
    - lens: redis.lns
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0

Note: Even though Augeas knows that /etc/redis/redis.conf is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

zabbix-service:
  augeas.change:
    - lens: services.lns
    - context: /files/etc/services
    - changes:
      - ins service-name after service-name[last()]
      - set service-name[last()] "zabbix-agent"
      - set "service-name[. = 'zabbix-agent']/port" 10050
      - set "service-name[. = 'zabbix-agent']/protocol" tcp
      - set "service-name[. = 'zabbix-agent']/#comment" "Zabbix Agent"
      - rm "service-name[. = 'im-obsolete']"
      - unless: grep "zabbix-agent" /etc/services
Warning: Don't forget the `unless` here, otherwise it will fail on next runs because the service is already defined. Additionally you have to quote lines containing `service-name[. = 'zabbix-agent']` otherwise `augeas_cfg` execute will fail because it will receive more parameters than expected.

Note: Order is important when defining a service with Augeas, in this case it's `port`, `protocol` and `#comment`. For more info about the lens check services lens documentation.

http://augeas.net/docs/references/lenses/files/services-aug.html#Services.record

### 25.20.14 salt.states.aws_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses the awscli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awscli for configuration information.

```yaml
myqueue:
  aws_sqs.exists:
    - region: eu-west-1
```

**salt.states.aws_sqs.absent**(name, region, user=None, opts=False)

Remove the named SQS queue if it exists.

- **name**: Name of the SQS queue.
- **region**: Region to remove the queue from
- **user**: Name of the user performing the SQS operations
- **opts**: Include additional arguments and options to the aws command line

**salt.states.aws_sqs.exists**(name, region, user=None, opts=False)

Ensure the SQS queue exists.

- **name**: Name of the SQS queue.
- **region**: Region to create the queue
- **user**: Name of the user performing the SQS operations
- **opts**: Include additional arguments and options to the aws command line
25.20.15  salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

```yaml
ps:
  beacon.present:
    - save: True
    - enable: False
    - services:
      salt-master: running
      apache2: stopped

sh:
  beacon.present: []

load:
  beacon.present:
    - averages:
      1m:
        - 0.0
        - 2.0
      5m:
        - 0.0
        - 1.5
      15m:
        - 0.1
        - 1.0

.. versionadded:: 3000

Beginning in the 3000 release, multiple copies of a beacon can be configured using the `beacon_module` parameter.

inotify_infs:
  beacon.present:
    - save: True
    - enable: True
    - files:
      /etc/infs.conf:
        mask:
          - create
          - delete
          - modify
        recurse: True
        auto_add: True
        interval: 10
        beacon_module: inotify
        disable_during_state_run: True

inotify_ntp:
  beacon.present:
```

(continues on next page)
- **save**: True
- **enable**: True
- **files**: 
  - `/etc/ntp.conf`:
    - **mask**: 
      - create
      - delete
      - modify
    - **recurse**: True
    - **auto_add**: True
- **interval**: 10
- **beacon_module**: inotify
- **disable_during_state_run**: True

```python
salt.states.beacon.absent(name, save=False, **kwargs)
```
Ensure beacon is absent.

- **name**: The name of the beacon that is ensured absent.
- **save**: True/False, if True the beacons.conf file be updated too. Default is False.

Example:
```python
remove_beacon:
  beacon.absent:
    - name: ps
    - save: True
```

```python
salt.states.beacon.disabled(name, **kwargs)
```
Disable a beacon.

- **name**: The name of the beacon to disable.

Example:
```python
disable_beacon:
  beacon.disabled:
    - name: psp
```

```python
salt.states.beacon.enabled(name, **kwargs)
```
Enable a beacon.

- **name**: The name of the beacon to enable.

Example:
```python
enable_beacon:
  beacon.enabled:
    - name: ps
```

```python
salt.states.beacon.present(name, save=False, **kwargs)
```
Ensure beacon is configured with the included beacon data.

- **name**: The name of the beacon to ensure is configured.
- **save**: True/False, if True the beacons.conf file be updated too. Default is False.
Example:

```yaml
ps_beacon:
  beacon.present:
    - name: ps
    - save: True
    - enable: False
    - services:
      salt-master: running
      apache2: stopped
```

25.20.16 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.

```python
salt.states.bigip.add_pool_member(hostname, username, password, name, member)
```

A function to connect to a bigip device and add a new member to an existing pool.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the pool to modify
- **member**: The member to add to the pool

```python
salt.states.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
```

A function to connect to a bigip device and create a monitor.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **monitor_type**: The type of monitor to create
- **name**: The name of the monitor to create
- **kwargs**: `[ arg=val ] ...`

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

```python
salt.states.bigip.create_node(hostname, username, password, name, address)
```

Create a new node if it does not already exist.
hostname
The host/address of the bigip device

username
The iControl REST username

password
The iControl REST password

name
The name of the node to create

address
The address of the node

salt.states.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Create a new node if it does not already exist.

hostname
The host/address of the bigip device

username
The iControl REST username

password
The iControl REST password

name
The name of the pool to create

members
List of members to be added to the pool

allow_nat
[yes | no]

allow_snat
[yes | no]

salt.states.bigip.create_profile(hostname, username, password, profile_type, name, **kwargs)
A function to connect to a bigip device and create a profile.

hostname
The host/address of the bigip device

username
The iControl REST username

password
The iControl REST password

profile_type
The type of profile to create

name
The name of the profile to create

kwargs
[ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

Special Characters |, , and : must be escaped using \ when used within strings.
salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

A function to connect to a bigip device and create a virtual server if it does not already exist.

**hostname**
- The host/address of the bigip device

**username**
- The iControl REST username

**password**

salt.states.bigip.delete_monitor( hostname, username, password, monitor_type, name )
Modify an existing monitor. If it does exist, only the parameters specified will be enforced.

- **hostname**
  - The host/address of the bigip device
- **username**
  - The iControl REST username
- **password**
  - The iControl REST password
- **monitor_type**
  - The type of monitor to create
- **name**
  - The name of the monitor to create
- **kwargs**
  - [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

```python
salt.states.bigip.delete_node(hostname, username, password, name)
```
Delete an existing node.

- **hostname**
  - The host/address of the bigip device
- **username**
  - The iControl REST username
- **password**
  - The iControl REST password
- **name**
  - The name of the node which will be deleted.

```python
salt.states.bigip.delete_pool(hostname, username, password, name)
```
Delete an existing pool.

- **hostname**
  - The host/address of the bigip device
- **username**
  - The iControl REST username
- **password**
  - The iControl REST password
- **name**
  - The name of the pool which will be deleted

```python
salt.states.bigip.delete_pool_member(hostname, username, password, name, member)
```
Delete an existing pool member.

- **hostname**
  - The host/address of the bigip device
- **username**
  - The iControl REST username
- **password**
  - The iControl REST password
- **name**
  - The name of the pool to be modified
- **member**
  - The name of the member to delete from the pool

```python
salt.states.bigip.delete_profile(hostname, username, password, profile_type, name)
```
Modify an existing profile. If it does exist, only the parameters specified will be enforced.
hostname
  The host/address of the bigip device
username
  The iControl REST username
password
  The iControl REST password
profile_type
  The type of profile to create
name
  The name of the profile to create
kwargs
  [ arg=val ] …
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.
salt.states.bigip.delete_virtual(hostname, username, password, name)
  Delete an existing virtual.
hostname
  The host/address of the bigip device
username
  The iControl REST username
password
  The iControl REST password
name
  The name of the virtual which will be deleted
salt.states.bigip.list_monitor(hostname, username, password, monitor_type, name)
  A function to list an existing monitor.
hostname
  The host/address of the bigip device
username
  The iControl REST username
password
  The iControl REST password
monitor_type
  The type of monitor to list
name
  The name of the monitor to list
salt.states.bigip.list_node(hostname, username, password, name)
  A function to connect to a bigip device and list a specific node.
hostname
  The host/address of the bigip device
username
  The iControl REST username
password
  The iControl REST password
name
  The name of the node to list.
salt.states.bigip.list_pool(hostname, username, password, name)
  A function to connect to a bigip device and list a specific pool.
hostname
  The host/address of the bigip device
username
    The iControl REST username
password
    The iControl REST password
name
    The name of the pool to list.
salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
    A function to list an existing profile.
    hostname
        The host/address of the bigip device
username
    The iControl REST username
password
    The iControl REST password
profile_type
    The type of profile to list
name
    The name of the profile to list
salt.states.bigip.list_virtual(hostname, username, password, name)
    A function to list a specific virtual.
    hostname
        The host/address of the bigip device
username
    The iControl REST username
password
    The iControl REST password
name
    The name of the virtual to list
salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
    Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the
    parameters specified will be enforced.
    hostname
        The host/address of the bigip device
username
    The iControl REST username
password
    The iControl REST password
monitor_type
    The type of monitor to create
name
    The name of the monitor to create
    [ arg=val ] ...
        Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are
        used.
salt.states.bigip.manage_node(hostname, username, password, name, address, connection_limit=None,
    description=None, dynamic_ratio=None, logging=None, monitor=None,
    rate_limit=None, ratio=None, session=None, node_state=None)
    Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the
    properties which are different than the existing will be updated.
hostname
    The host/address of the bigip device
username
    The iControl REST username
password
    The iControl REST password
name
    The name of the node to manage.

25.20.17 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
  blockdev.tuned:
    - read-only: True

master-data:
  blockdev.tuned:
    - name: /dev/vg/master-data
      - read-only: True
```

(continues on next page)
New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', force=False, **kwargs)

Manage filesystems of partitions.

- **name**: The name of the block device
- **fs_type**: The filesystem it should be formatted as
- **force**: Force mke2fs to create a filesystem, even if the specified device is not a partition on a block special device. This option is only enabled for ext and xfs filesystems

This option is dangerous, use it with caution.

New in version 2016.11.0.

salt.states.blockdev.tuned(name, **kwargs)

Manage options of block device

- **name**: The name of the block device

opts:

- **read-ahead**: Read-ahead buffer size
- **filesystem-read-ahead**: Filesystem Read-ahead buffer size
- **read-only**: Set Read-Only
- **read-write**: Set Read-Write

25.20.18 salt.states.boto3_elasticache

Manage Elasticache with boto3

New in version 2017.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3 behind the scenes - as a result it inherits any limitations it boto3’s implementation of the AWS API. It is also designed to as directly as possible leverage boto3’s parameter naming and semantics. This allows one to use http://boto3.readthedocs.io/en/latest/reference/services/elasticache.html as an excellent source for details too involved to reiterate here.

Note: This module is designed to be transparent (“intentionally ignorant” is the phrase I used to describe it to my boss) to new AWS / boto options - since all AWS API params are passed directly through both the state and executions modules, any new args to existing functions which become available after this documentation is written should work immediately.

Brand new API calls, of course, would still require new functions to be added ;)

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information is available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs
  region: us-east-1
```

Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs
```

# Using a profile from pillars
Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile
Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs
```

salt.states.boto3_elasticache.cache_cluster_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster is deleted.

name

Name of the cache cluster.
wait
Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the
desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the
cluster to become available is generally the better course, as failure to do so will often lead to subsequent
failures when managing dependent resources.

CacheClusterId
The node group (shard) identifier. Note: In general this parameter is not needed, as 'name' is used if it's
not provided.

FinalSnapshotIdentifier
The user-supplied name of a final cache cluster snapshot. This is the unique name that identifies the
snapshot. ElastiCache creates the snapshot, and then deletes the cache cluster immediately afterward.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto3_elasticache.cache_cluster_present(name, wait=900, security_groups=None, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster exists.

name
Name of the cache cluster (cache cluster id).

wait
Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the
desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the
cluster to become available is generally the better course, as failure to do so will often lead to subsequent
failures when managing dependent resources.

security_groups
One or more VPC security groups (names and/or IDs) associated with the cache cluster.

Note: This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use
this parameter ONLY when you are creating a cluster in a VPC.

CacheClusterId
The node group (shard) identifier. This parameter is stored as a lowercase string.

Constraints:
• A name must contain from 1 to 20 alphanumeric characters or hyphens.
• The first character must be a letter.
• A name cannot end with a hyphen or contain two consecutive hyphens.

Note: In general this parameter is not needed, as 'name' is used if it's not provided.

ReplicationGroupId
The ID of the replication group to which this cache cluster should belong. If this parameter is specified,
the cache cluster is added to the specified replication group as a read replica; otherwise, the cache cluster
is a standalone primary that is not part of any replication group. If the specified replication group is
Multi-AZ enabled and the Availability Zone is not specified, the cache cluster is created in Availability
Zones that provide the best spread of read replicas across Availability Zones.

AZMode
Specifies whether the nodes in this Memcached cluster are created in a single Availability Zone or created across multiple Availability Zones in the cluster’s region. If the AZMode and PreferredAvailabilityZones are not specified, ElastiCache assumes single-az mode.

**Note:** This parameter is ONLY supported for Memcached cache clusters.

### PreferredAvailabilityZone
The EC2 Availability Zone in which the cache cluster is created. All nodes belonging to this Memcached cache cluster are placed in the preferred Availability Zone. If you want to create your nodes across multiple Availability Zones, use PreferredAvailabilityZones.

Default: System chosen Availability Zone.

### PreferredAvailabilityZones
A list of the Availability Zones in which cache nodes are created. The order of the zones in the list is not important. The number of Availability Zones listed must equal the value of NumCacheNodes. If you want all the nodes in the same Availability Zone, use PreferredAvailabilityZone instead, or repeat the Availability Zone multiple times in the list.

Default: System chosen Availability Zones.

**Note:** This option is ONLY supported on Memcached.

If you are creating your cache cluster in an Amazon VPC (recommended) you can only locate nodes in Availability Zones that are associated with the subnets in the selected subnet group.

### NumCacheNodes
The initial (integer) number of cache nodes that the cache cluster has.

**Note:** For clusters running Redis, this value must be 1.

For clusters running Memcached, this value must be between 1 and 20.

### CacheNodeType
The compute and memory capacity of the nodes in the node group (shard). Valid node types (and pricing for them) are exhaustively described at https://aws.amazon.com/elasticache/pricing/

**Note:**

All T2 instances must be created in a VPC

Redis backup/restore is not supported for Redis (cluster mode disabled) T1 and T2 instances.

Backup/restore is supported on Redis (cluster mode enabled) T2 instances.

Redis Append-only files (AOF) functionality is not supported for T1 or T2 instances.

### Engine
The name of the cache engine to be used for this cache cluster. Valid values for this parameter are: memcached | redis

### EngineVersion
The version number of the cache engine to be used for this cache cluster. To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.

**Note:** You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.
CacheParameterGroupName
The name of the parameter group to associate with this cache cluster. If this argument is omitted, the default parameter group for the specified engine is used. You cannot use any parameter group which has cluster-enabled='yes' when creating a cluster.

CacheSubnetGroupName
The name of the Cache Subnet Group to be used for the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.

**Note:** If you're going to launch your cluster in an Amazon VPC, you need to create a subnet group before you start creating a cluster.

CacheSecurityGroupNames
A list of Cache Security Group names to associate with this cache cluster. Use this parameter ONLY when you are creating a cache cluster outside of a VPC.

SecurityGroupIds
One or more VPC security groups associated with the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.

Tags
A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for Elasticache, these can only be set during resource creation - later modification is not (currently) supported.

SnapshotArns
A single-element string list containing an Amazon Resource Name (ARN) that uniquely identifies a Redis RDB snapshot file stored in Amazon S3. The snapshot file is used to populate the node group (shard). The Amazon S3 object name in the ARN cannot contain any commas.

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

SnapshotName
The name of a Redis snapshot from which to restore data into the new node group (shard). The snapshot status changes to restoring while the new node group (shard) is being created.

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

PreferredMaintenanceWindow
Specifies the weekly time range during which maintenance on the cache cluster is permitted. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed, thu, fri, sat

Example: sun:23:00-mon:01:30

Port
The port number on which each of the cache nodes accepts connections.

Default: 6379

NotificationTopicArn
The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications are sent.

**Note:** The Amazon SNS topic owner must be the same as the cache cluster owner.

AutoMinorVersionUpgrade
This (boolean) parameter is currently disabled.

SnapshotRetentionLimit
The number of days for which ElastiCache retains automatic snapshots before deleting them.
Default: 0 (i.e., automatic backups are disabled for this cache cluster).

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

---

**SnapshotWindow**

The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an appropriate time range.

Example: 05:00-09:00

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

---

**AuthToken**

The password used to access a password protected server.

Password constraints:
- Must be only printable ASCII characters.
- Must be at least 16 characters and no more than 128 characters in length.
- Cannot contain any of the following characters: '/', '"', or '@'.

**CacheNodeIdsToRemove**

A list of cache node IDs to be removed. A node ID is a numeric identifier (0001, 0002, etc.). This parameter is only valid when NumCacheNodes is less than the existing number of cache nodes. The number of cache node IDs supplied in this parameter must match the difference between the existing number of cache nodes in the cluster or pending cache nodes, whichever is greater, and the value of NumCacheNodes in the request.

**NewAvailabilityZones**

The list of Availability Zones where the new Memcached cache nodes are created. This parameter is only valid when NumCacheNodes in the request is greater than the sum of the number of active cache nodes and the number of cache nodes pending creation (which may be zero). The number of Availability Zones supplied in this list must match the cache nodes being added in this request. Note: This option is only supported on Memcached clusters.

**NotificationTopicStatus**

The status of the SNS notification topic. Notifications are sent only if the status is active.

Valid values: active | inactive

**region**

Region to connect to.

**key**

Secret key to be used.

**keyid**

Access key to be used.

**profile**

A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto3_elasticache.cache_subnet_group_absent(name, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache subnet group is deleted.

**name**

Name of the cache subnet group.

**CacheSubnetGroupName**

A name for the cache subnet group. Note: In general this parameter is not needed, as ‘name’ is used if it’s not provided.
region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto3_elasticache.cache_subnet_group_present(name, subnets=None, region=None, key=None, keyid=None, profile=None, **args)`

Ensure cache subnet group exists.

name
A name for the cache subnet group. This value is stored as a lowercase string. Constraints: Must contain no more than 255 alphanumeric characters or hyphens.

subnets
A list of VPC subnets (IDs, Names, or a mix) for the cache subnet group.

`CacheSubnetGroupName`
A name for the cache subnet group. This value is stored as a lowercase string. Constraints: Must contain no more than 255 alphanumeric characters or hyphens. Note: In general this parameter is not needed, as 'name' is used if it's not provided.

`CacheSubnetGroupDescription`
A description for the cache subnet group.

`SubnetIds`
A list of VPC subnet IDs for the cache subnet group. This is ADDITIVE with 'subnets' above.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto3_elasticache.replication_group_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)`

Ensure a given replication group is deleted.

name
Name of the replication group.

wait
Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

`ReplicationGroupId`
The replication group identifier. Note: In general this parameter is not needed, as 'name' is used if it's not provided.

`RetainPrimaryCluster`
If set to true, all of the read replicas are deleted, but the primary node is retained.

`FinalSnapshotIdentifier`
The name of a final node group (shard) snapshot. ElastiCache creates the snapshot from the primary
node in the cluster, rather than one of the replicas; this is to ensure that it captures the freshest data. After the final snapshot is taken, the replication group is immediately deleted.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto3_elasticache.replication_group_present(name, wait=900,
security_groups=None,
region=None, key=None,
keyid=None, profile=None,
**args)
```

Ensure a replication group exists and is in the given state.

**name**
Name of replication group

**wait**
Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

**security_groups**
One or more VPC security groups (names and/or IDs) associated with the cache cluster.

*Note:* This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use this parameter ONLY when you are creating a cluster in a VPC.

**ReplicationGroupId**
The replication group identifier. This parameter is stored as a lowercase string.

**Constraints:**
- A name must contain from 1 to 20 alphanumeric characters or hyphens.
- The first character must be a letter.
- A name cannot end with a hyphen or contain two consecutive hyphens.

*Note:* In general this parameter is not needed, as 'name' is used if it's not provided.

**ReplicationGroupDescription**
A user-created description for the replication group.

**PrimaryClusterId**
The identifier of the cache cluster that serves as the primary for this replication group. This cache cluster must already exist and have a status of available. This parameter is not required if NumCacheClusters, NumNodeGroups, or ReplicasPerNodeGroup is specified.

**AutomaticFailoverEnabled**
Specifies whether a read-only replica is automatically promoted to read/write primary if the existing primary fails. If true, Multi-AZ is enabled for this replication group. If false, Multi-AZ is disabled for this replication group.

Default: False

*Note:* AutomaticFailoverEnabled must be enabled for Redis (cluster mode enabled) replication groups.
ElastiCache Multi-AZ replication groups is not supported on:
- Redis versions earlier than 2.8.6.
- Redis (cluster mode disabled): T1 and T2 node types.
- Redis (cluster mode enabled): T2 node types.

**NumCacheClusters**
The number of clusters this replication group initially has. This parameter is not used if there is more than one node group (shard). You should use ReplicasPerNodeGroup instead. If Multi-AZ is enabled, the value of this parameter must be at least 2. The maximum permitted value for NumCacheClusters is 6 (primary plus 5 replicas).

**PreferredCacheClusterAZs**
A list of EC2 Availability Zones in which the replication group’s cache clusters are created. The order of the Availability Zones in the list is the order in which clusters are allocated. The primary cluster is created in the first AZ in the list. This parameter is not used if there is more than one node group (shard). You should use NodeGroupConfiguration instead. The number of Availability Zones listed must equal the value of NumCacheClusters.

Default: System chosen Availability Zones.

**Note:** If you are creating your replication group in an Amazon VPC (recommended), you can only locate cache clusters in Availability Zones associated with the subnets in the selected subnet group.

**NumNodeGroups**
An optional parameter that specifies the number of node groups (shards) for this Redis (cluster mode enabled) replication group. For Redis (cluster mode disabled) either omit this parameter or set it to 1.

Default: 1

**ReplicasPerNodeGroup**
An optional parameter that specifies the number of replica nodes in each node group (shard). Valid values are: 0 to 5

**NodeGroupConfiguration**
A list of node group (shard) configuration options. Each node group (shard) configuration has the following: Slots, PrimaryAvailabilityZone, ReplicaAvailabilityZones, ReplicaCount. If you’re creating a Redis (cluster mode disabled) or a Redis (cluster mode enabled) replication group, you can use this parameter to configure one node group (shard) or you can omit this parameter. For fiddly details of the expected data layout of this param, see http://boto3.readthedocs.io/en/latest/reference/services/elasticafe.html?#ElastiCache.Client.create_replication_group

**CacheNodeType**
The compute and memory capacity of the nodes in the node group (shard). See https://aws.amazon.com/elasticache/pricing/ for current sizing, prices, and constraints.

**Engine**
The name of the cache engine to be used for the cache clusters in this replication group.

**EngineVersion**
The version number of the cache engine to be used for the cache clusters in this replication group. To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.

**Note:** You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.

**CacheParameterGroupName**
The name of the parameter group to associate with this replication group. If this argument is omitted, the default cache parameter group for the specified engine is used.
Note: If you are running Redis version 3.2.4 or later, only one node group (shard), and want to use a default parameter group, we recommend that you specify the parameter group by name.

To create a Redis (cluster mode disabled) replication group, use CacheParameterGroupName=default.redis3.2

To create a Redis (cluster mode enabled) replication group, use CacheParameterGroupName=default.redis3.2.cluster.on

CacheSubnetGroupName
The name of the cache subnet group to be used for the replication group.

Note: If you're going to launch your cluster in an Amazon VPC, you need to create a subnet group before you start creating a cluster. For more information, see Subnets and Subnet Groups.

CacheSecurityGroupNames
A list of cache security group names to associate with this replication group.

SecurityGroupIds
One or more Amazon VPC security groups associated with this replication group. Use this parameter only when you are creating a replication group in an VPC.

Tags
A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for ElastiCache, these can only be set during resource creation - later modification is not (currently) supported.

SnapshotArns
A list of ARNs that uniquely identify the Redis RDB snapshot files stored in Amazon S3. These snapshot files are used to populate the replication group. The Amazon S3 object name in the ARN cannot contain any commas. The list must match the number of node groups (shards) in the replication group, which means you cannot repartition.

Note: This parameter is only valid if the Engine parameter is redis.

SnapshotName
The name of a snapshot from which to restore data into the new replication group. The snapshot status changes to restoring while the new replication group is being created. Note: This parameter is only valid if the Engine parameter is redis.

PreferredMaintenanceWindow
Specifies the weekly time range during which maintenance on the cluster is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed, thu, fri, sat

Example: sun:23:00-mon:01:30

Port
The port number on which each member of the replication group accepts connections.

NotificationTopicArn
The ARN of an SNS topic to which notifications are sent.

Note: The SNS topic owner must be the same as the cache cluster owner.

AutoMinorVersionUpgrade
This parameter is currently disabled.

SnapshotRetentionLimit
The number of days for which ElastiCache will retain automatic snapshots before deleting them.
Default: 0 (that is, automatic backups are disabled for this cache cluster).

Note: This parameter is only valid if the Engine parameter is redis.

**SnapshotWindow**
The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an appropriate time range.

Example: 05:00-09:00

Note: This parameter is only valid if the Engine parameter is redis.

**AuthToken**
The password used to access a password protected server. Password constraints:
- Must be only printable ASCII characters.
- Must be at least 16 characters and no more than 128 characters in length.
- Cannot contain any of the following characters: ‘/’, ‘\’, or ‘@’.

**SnapshottingClusterId**
The cache cluster ID that is used as the daily snapshot source for the replication group.

**NotificationTopicStatus**
The status of the SNS notification topic. Notifications are sent only if the status is active. Valid values: active | inactive

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 25.20.19 salt.states.boto3_elasticsearch

Manage Elasticsearch Service

New in version 3001.

*configuration*
This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
es.keyid: GKTADJGHEIQSXMKKRBJ08H
es.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:
es.region: us-east-1

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

depends
  boto3

salt.states.boto3_elasticsearch.absent(name, blocking=True, region=None, keyid=None, key=None, profile=None)

Ensure the Elasticsearch Domain specified does not exist.

Parameters
  • name (str) -- The name of the Elasticsearch domain to be made absent.
  • blocking (bool) -- Whether or not the state should wait for the deletion to be completed. Default: True

New in version 3001.

Example:

Remove Elasticsearch Domain:
  boto3_elasticsearch.absent:
  - name: my_domain
  - region: eu-west-1

salt.states.boto3_elasticsearch.latest(name, minor_only=True, region=None, keyid=None, key=None, profile=None)

Ensures the Elasticsearch domain specifies runs on the latest compatible version of elasticsearch, upgrading it if it is not.

Note that this operation is blocking until the upgrade is complete.

Parameters
  • name (str) -- The name of the Elasticsearch domain to upgrade.
  • minor_only (bool) -- Only upgrade to the latest minor version.

New in version 3001.

Example:

The following example will ensure the elasticsearch domain my_domain is upgraded to the latest minor version. So if it is currently 5.1 it will be upgraded to 5.6.

Upgrade Elasticsearch Domain:
  boto3_elasticsearch.latest:
  - name: my_domain
  - minor_only: True
  - region: eu-west-1
salt.states.boto3_elasticsearch.present(name, elasticsearch_version=None, elasticsearch_cluster_config=None, ebs_options=None, access_policies=None, snapshot_options=None, vpc_options=None, cognito_options=None, encryption_at_rest_options=None, node_to_node_encryption_options=None, advanced_options=None, log_publishing_options=None, blocking=True, tags=None, region=None, keyid=None, key=None, profile=None)

Ensure an Elasticsearch Domain exists.

Parameters

- **name (str)** -- The name of the Elasticsearch domain that you are creating. Domain names are unique across the domains owned by an account within an AWS region. Domain names must start with a letter or number and can contain the following characters: a-z (lowercase), 0-9, and - (hyphen).
- **elasticsearch_version (str)** -- String of format X.Y to specify version for the Elasticsearch domain eg. "1.5" or "2.3".
- **elasticsearch_cluster_config (dict)** -- Dict specifying the configuration options for an Elasticsearch domain. Keys (case sensitive) in here are:
  - **InstanceType (str)**: The instance type for an Elasticsearch cluster.
  - **InstanceCount (int)**: The instance type for an Elasticsearch cluster.
  - **DedicatedMasterEnabled (bool)**: Indicate whether a dedicated master node is enabled.
  - **ZoneAwarenessEnabled (bool)**: Indicate whether zone awareness is enabled.
  - **ZoneAwarenessConfig (dict)**: Specifies the zone awareness configuration for a domain when zone awareness is enabled. Keys (case sensitive) in here are:
    - **AvailabilityZoneCount (int)**: An integer value to indicate the number of availability zones for a domain when zone awareness is enabled. This should be equal to number of subnets if VPC endpoints is enabled.
    - **DedicatedMasterType (str)**: The instance type for a dedicated master node.
    - **DedicatedMasterCount (int)**: Total number of dedicated master nodes, active and on standby, for the cluster.
- **ebs_options (dict)** -- Dict specifying the options to enable or disable and specifying the type and size of EBS storage volumes. Keys (case sensitive) in here are:
  - **EBSEnabled (bool)**: Specifies whether EBS-based storage is enabled.
  - **VolumeType (str)**: Specifies the volume type for EBS-based storage.
  - **VolumeSize (int)**: Integer to specify the size of an EBS volume.
  - **Iops (int)**: Specifies the IOPD for a Provisioned IOPS EBS volume (SSD).
- **access_policies (str or dict)** -- Dict or JSON string with the IAM access policy.
- **snapshot_options (dict)** -- Dict specifying the snapshot options. Keys (case sensitive) in here are:
  - **AutomatedSnapshotStartHour (int)**: Specifies the time, in UTC format, when the service takes a daily automated snapshot of the specified Elasticsearch domain. Default value is 0 hours.
- **vpc_options (dict)** -- Dict with the options to specify the subnets and security groups for the VPC endpoint. Keys (case sensitive) in here are:
  - **SubnetIds (list)**: The list of subnets for the VPC endpoint.
  - **SecurityGroupIds (list)**: The list of security groups for the VPC endpoint.
- **cognito_options (dict)** -- Dict with options to specify the cognito user and identity pools for Kibana authentication. Keys (case sensitive) in here are:
  - **Enabled (bool)**: Specifies the option to enable Cognito for Kibana authentication.
  - **UserPoolId (str)**: Specifies the Cognito user pool ID for Kibana authentication.
- IdentityPoolId (str): Specifies the Cognito identity pool ID for Kibana authentication.
- RoleArn (str): Specifies the role ARN that provides Elasticsearch permissions for accessing Cognito resources.

- **encryption_at_rest_options (dict)** -- Dict specifying the encryption at rest options. This option can only be used for the creation of a new Elasticsearch domain. Keys (case sensitive) in here are:
  - Enabled (bool): Specifies the option to enable Encryption At Rest.
  - KmsKeyId (str): Specifies the KMS Key ID for Encryption At Rest options.

- **node_to_node_encryption_options (dict)** -- Dict specifying the node to node encryption options. This option can only be used for the creation of a new Elasticsearch domain. Keys (case sensitive) in here are:
  - Enabled (bool): Specify True to enable node-to-node encryption.

- **advanced_options (dict)** -- Dict with option to allow references to indices in an HTTP request body. Must be False when configuring access to individual sub-resources. By default, the value is True. See http://docs.aws.amazon.com/elasticsearch-service/latest/developerguide/es-createupdatedomains.html#es-createdomain-configure-advanced-options for more information.

- **log_publishing_options (dict)** -- Dict with options for various type of logs. The keys denote the type of log file and can be one of the following:
  - INDEX_SLOW_LOGS
  - SEARCH_SLOW_LOGS
  - ES_APPLICATION_LOGS

  The value assigned to each key is a dict with the following case sensitive keys:
  - CloudWatchLogsLogGroupArn (str): The ARN of the Cloudwatch log group to which the log needs to be published.
  - Enabled (bool): Specifies whether given log publishing option is enabled or not.

- **blocking (bool)** -- Whether or not the state should wait for all operations (create/update/upgrade) to be completed. Default: True

- **tags (dict)** -- Dict of tags to ensure are present on the Elasticsearch domain.

New in version 3001.

Example:

This will create an elasticsearch domain consisting of a single t2.small instance in the eu-west-1 region (Ireland) and will wait until the instance is available before returning from the state.

Create new domain:
```python
boto3_elasticsearch.present:
  - name: my_domain
  - elasticsearch_version: '5.1'
  - elasticsearch_cluster_config:
    - InstanceType: t2.small.elasticsearch
    - InstanceCount: 1
    - DedicatedMasterEnabled: False
    - ZoneAwarenessEnabled: False
  - ebs_options:
    - EBSEnabled: True
    - VolumeType: gp2
    - VolumeSize: 10
  - snapshot_options:
    - AutomatedSnapshotStartHour: 3
  - vpc_options:
```

(continues on next page)
SubnetIds:
- subnet-12345678

SecurityGroupIds:
- sg-12345678

node_to_node_encryption_options:
  Enabled: False

region: eu-west-1

tags:
  foo: bar
  baz: qux

salt.states.boto3_elasticsearch.tagged(name, tags=None, replace=False, region=None, keyid=None, key=None, profile=None)

Ensures the Elasticsearch domain has the tags provided. Adds tags to the domain unless replace is set to True, in which case all existing tags will be replaced with the tags provided in tags. (This will remove all tags if replace is True and tags is empty).

Parameters
- name (str) -- The Elasticsearch domain to work with.
- tags (dict) -- The tags to add to/replace on the Elasticsearch domain.
- replace (bool) -- Whether or not to replace (True) all existing tags on the Elasticsearch domain, or add (False) tags to the ES domain.

New in version 3001.

salt.states.boto3_elasticsearch.upgraded(name, elasticsearch_version, blocking=True, region=None, keyid=None, key=None, profile=None)

Ensures the Elasticsearch domain specified runs on the specified version of elasticsearch. Only upgrades are possible as downgrades require a manual snapshot and an S3 bucket to store them in.

Note that this operation is blocking until the upgrade is complete.

Parameters
- name (str) -- The name of the Elasticsearch domain to upgrade.
- elasticsearch_version (str) -- String of format X.Y to specify version for the Elasticsearch domain eg. "1.5" or "2.3".

New in version 3001.

Example:

Upgrade Elasticsearch Domain:
  boto3_elasticsearch.upgraded:
  - name: my_domain
  - elasticsearch_version: '7.2'
  - region: eu-west-1
25.20.20  salt.states.boto3_route53

Manage Route53 records with Boto 3

New in version 2017.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto3, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

An exciting new AWS Route 53 Hosted Zone:

```
boto_route53.hosted_zone_present:
  - Name: example.com.
  - PrivateZone: true
  - VPCs:
    - VPCName: MyLittleVPC
      VPCRegion: us-east-1
    - VPCID: vpc-12345678
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
boto_route53.rr_present:
  - Name: test.example.com.
  - ResourceRecords:
    - my-elb.us-east-1.elb.amazonaws.com.
    - DomainName: example.com.
    - region: us-east-1
    - Type: CNAME
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
salt.states.boto3_route53.hosted_zone_absent(name=None, Name=None, PrivateZone=False, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 Hostes Zone described is absent
```

25.20.  state modules

3859
name
    The name of the state definition.

Name
    The name of the domain. This should be a fully-specified domain, and should terminate with a period.
    If not provided, the value of name will be used.

PrivateZone
    Set True if deleting a private hosted zone.

salt.states.boto3_route53.hosted_zone_present(name, Name=None, PrivateZone=False,
    CallerReference=None, Comment=None,
    VPCs=None, region=None, key=None,
    keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes.

name
    The name of the state definition.

Name
    The name of the domain. This should be a fully-specified domain, and should terminate with a period.
    This is the name you have registered with your DNS registrar. It is also the name you will delegate from
    your registrar to the Amazon Route 53 delegation servers returned in response to this request. If not
    provided, the value of name will be used.

PrivateZone
    Set True if creating a private hosted zone. If true, then 'VPCs' is also required.

Comment
    Any comments you want to include about the hosted zone.

CallerReference
    A unique string that identifies the request and that allows create_hosted_zone() calls to be retried with-
    out the risk of executing the operation twice. This helps ensure idempotency across state calls, but can
    cause issues if a zone is deleted and then an attempt is made to recreate it with the same CallerReference.
    If not provided, a unique UUID will be generated at each state run, which can potentially lead to dupli-
    cate zones being created if the state is run again while the previous zone creation is still in PENDING
    status (which can occasionally take several minutes to clear). Maximum length of 128.

VPCs
    A list of dicts, each dict composed of a VPCRegion, and either a VPCId or a VPCName. Note that this
    param is ONLY used if PrivateZone == True

VPCId
    When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required.
    Exclusive with VPCName.

VPCName
    When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required.
    Exclusive with VPCId.

VPCRegion
    When creating a private hosted zone, the region of the associated VPC is required. If not provided,
    an effort will be made to determine it from VPCId or VPCName, if possible. This will fail if a given
    VPCName exists in multiple regions visible to the bound account, in which case you'll need to
    provide an explicit value for VPCRegion.

salt.states.boto3_route53.rr_absent(name, HostedZoneId=None, DomainName=None,
    PrivateZone=False, Name=None, Type=None,
    SetIdentifier=None, region=None, key=None,
    keyid=None, profile=None)

Ensure the Route53 record is deleted.

name
    The name of the state definition. This will be used for Name if the latter is not provided.

HostedZoneId
The ID of the zone to delete the record from. Exclusive with DomainName.

**DomainName**
The domain name of the zone to delete the record from. Exclusive with HostedZoneId.

**PrivateZone**
Set to True if the RR to be removed is in a private zone, False if public.

**Name**
Name of the resource record.

**Type**
The record type (A, NS, MX, TXT, etc.)

**SetIdentifier**
Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.

**region**
The region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.

```python
salt.states.boto3_route53.rr_present(name, HostedZoneId=None, DomainName=None, PrivateZone=False, Name=None, Type=None, SetIdentifier=None, Weight=None, Region=None, GeoLocation=None, Failover=None, TTL=None, ResourceRecords=None, AliasTarget=None, HealthCheckId=None, TrafficPolicyInstanceId=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the Route53 record is present.

**name**
The name of the state definition. This will be used for Name if the latter is not provided.

**HostedZoneId**
The ID of a zone to create the record in. Exclusive with DomainName.

**DomainName**
The domain name of a zone to create the record in. Exclusive with HostedZoneId.

**PrivateZone**
Set to True if the resource record should be in a private zone, False if public.

**Name**
Name of the Route 53 resource record being managed.

**Type**
The record type (A, NS, MX, TXT, etc.)

**SetIdentifier**
Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.

**Weight**
Valid for Weighted resource record sets only. Among resource record sets that have the same combination of DNS name and type, a value that determines the proportion of DNS queries that Amazon Route 53 responds to using the current resource record set. Amazon Route 53 calculates the sum of the weights for the resource record sets that have the same combination of DNS name and type. Amazon Route 53 then responds to queries based on the ratio of a resource's weight to the total.
Note the following:

- You must specify a value for the Weight element for every weighted resource record set.
- You can only specify one ResourceRecord per weighted resource record set.
- You can’t create latency, failover, or geolocation resource record sets that have the same values for the Name and Type elements as weighted resource record sets.
- You can create a maximum of 100 weighted resource record sets that have the same values for the Name and Type elements.
- For weighted (but not weighted alias) resource record sets, if you set Weight to 0 for a resource record set, Amazon Route 53 never responds to queries with the applicable value for that resource record set. However, if you set Weight to 0 for all resource record sets that have the same combination of DNS name and type, traffic is routed to all resources with equal probability. The effect of setting Weight to 0 is different when you associate health checks with weighted resource record sets. For more information, see Options for Configuring Amazon Route 53 Active-Active and Active-Passive Failover in the Amazon Route 53 Developer Guide.

Region

Valid for Latency-based resource record sets only. The Amazon EC2 Region where the resource that is specified in this resource record set resides. The resource typically is an AWS resource, such as an EC2 instance or an ELB load balancer, and is referred to by an IP address or a DNS domain name, depending on the record type.

GeoLocation

Geo location resource record sets only. A dict that lets you control how Route 53 responds to DNS queries based on the geographic origin of the query. For example, if you want all queries from Africa to be routed to a web server with an IP address of 192.0.2.111, create a resource record set with a Type of A and a ContinentCode of AF.

<table>
<thead>
<tr>
<th>ContinentCode</th>
<th>The two-letter code for the continent.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid values:</td>
<td>AF</td>
</tr>
</tbody>
</table>

| CountryCode | The two-letter code for the country. |
| SubdivisionCode | The code for the subdivision, for example, a state in the United States or a province in Canada. |

Notes

- Creating geolocation and geolocation alias resource record sets in private hosted zones is not supported.
- If you create separate resource record sets for overlapping geographic regions (for example, one resource record set for a continent and one for a country on the same continent), priority goes to the smallest geographic region. This allows you to route most queries for a continent to one resource and to route queries for a country on that continent to a different resource.
- You can’t create two geolocation resource record sets that specify the same geographic location.
- The value * in the CountryCode element matches all geographic locations that aren’t specified in other geolocation resource record sets that have the same values for the Name and Type elements.
- Geolocation works by mapping IP addresses to locations. However, some IP addresses aren’t mapped to geographic locations, so even if you create geolocation resource record sets that cover all seven continents, Amazon Route 53 will receive some DNS queries from locations that it can’t identify. We recommend that you create a resource record set for which the value of CountryCode is *, which handles both queries that come from locations for which you haven’t created geolocation resource record sets and queries from IP addresses that aren’t mapped to a location. If you
don't create a * resource record set, Amazon Route 53 returns a "no answer" response for queries from those locations.
- You can't create non-geolocation resource record sets that have the same values for the Name and Type elements as geolocation resource record sets.

**TTL**

The resource record cache time to live (TTL), in seconds. Note the following:
- If you're creating an alias resource record set, omit TTL. Amazon Route 53 uses the value of TTL for the alias target.
- If you're associating this resource record set with a health check (if you're adding a HealthCheckId element), we recommend that you specify a TTL of 60 seconds or less so clients respond quickly to changes in health status.
- All of the resource record sets in a group of weighted, latency, geolocation, or failover resource record sets must have the same value for TTL.
- If a group of weighted resource record sets includes one or more weighted alias resource record sets for which the alias target is an ELB load balancer, we recommend that you specify a TTL of 60 seconds for all of the non-alias weighted resource record sets that have the same name and type. Values other than 60 seconds (the TTL for load balancers) will change the effect of the values that you specify for Weight.

**ResourceRecords**

A list, containing one or more values for the resource record. No single value can exceed 4,000 characters. For details on how to format values for different record types, see Supported DNS Resource Record Types in the Amazon Route 53 Developer Guide.

Note: You can specify more than one value for all record types except CNAME and SOA.

It is also possible to pass "magic" strings as resource record values. This functionality can easily be extended, but for the moment supports the following:

-magic:ec2_instance_tag:some_tag_name:some_string:some_instance_attr

This tells salt to lookup an EC2 instance with a tag 'some_tag_name' which has the value 'some_string' and substitute the 'some_instance_attr' attribute of that instance as the resource record value being evaluated.

This should work generally for any EC2 instance tags, as long as the instance attribute being fetched is available to getattr(instance, 'attribute') as seen in the code below. Anything else will most likely require this function to be extended to handle it.

The canonical use-case for this (at least at our site) is to query the Name tag (which we always populate with the host's FQDN) to lookup the public or private IPs bound to the instance, so we can then automatically create Route 53 records for them.

**AliasTarget**

The rules governing how to define an AliasTarget for the various supported use-cases are obtuse beyond reason and attempting to paraphrase them (or even worse, cut-and-paste them in their entirety) would be silly and counterproductive. If you need this feature, then Read The Fine Materials at the Boto 3 Route 53 page and/or the AWS Route 53 docs and suss them for yourself - I sure won't claim to understand them particularly well.

**region**

The region to connect to.

**key**

Secret key to be used.

**keyid**

Access key to be used.

**profile**

Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.
25.20.21  salt.states.boto3_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

```
mytopic:
    boto3_sns.topic_present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

Using a profile from pillars

```
mytopic:
    boto3_sns.topic_present:
        - region: us-east-1
        - profile: mysnsprofile
```

Passing in a profile

```
mytopic:
    boto3_sns.topic_present:
        - region: us-east-1
        - profile:
            keyid: GKTADJGHEIQSXMKKRBJ08H
            key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto3_sns.topic_absent(name, unsubscribe=False, region=None, key=None, keyid=None, profile=None)

Ensure the named sns topic is deleted.

name
    Name of the SNS topic.
unsubscribe
   If True, unsubscribe all subscriptions to the SNS topic before deleting the SNS topic
region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto3_sns.topic_present(name, subscriptions=None, attributes=None, region=None, key=None, keyid=None, profile=None)
Ensure the SNS topic exists.
name
   Name of the SNS topic.
subscriptions
   List of SNS subscriptions.
   Each subscription is a dictionary with a protocol and endpoint key:
   
   subscriptions:
   - Protocol: https
     Endpoint: https://www.example.com/sns-endpoint
   - Protocol: sqs
attributes
   Dictionary of attributes to set on the SNS topic Valid attribute keys are:
   • Policy: the JSON serialization of the topic's access control policy
   • DisplayName: the human-readable name used in the "From" field for notifications
to email and email-json endpoints
   • DeliveryPolicy: the JSON serialization of the topic’s delivery policy
region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.22 salt.states.boto_apigateway

Manage Apigateway Rest APIs
New in version 2016.11.0.
depends
   • boto >= 2.8.0
   • boto3 >= 1.2.1
   • botocore >= 1.4.49
Create and destroy rest apis depending on a swagger version 2 definition file. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
| vpc.keyid: GKTADJGHEIQSXMKKRBJ08H |
| vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
| myprofile: |
|keyid: GKTADJGHEIQSXMKKRBJ08H |
|key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |
|region: us-east-1 |
```

**Ensure Apigateway API exists:**

```
boto_apigateway.present:
  - name: myfunction
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
salt.states.boto_apigateway.absent(name, api_name, stage_name, nuke_api=False, region=None, key=None, keyid=None, profile=None)
```

Ensure the stage_name associated with the given api_name deployed by boto_apigateway's present state is removed. If the currently associated deployment to the given stage_name has no other stages associated with it, the deployment will also be removed.

- **name**: Name of the swagger file in YAML format
- **api_name**: Name of the rest api on AWS ApiGateway to ensure is absent.
- **stage_name**: Name of the stage to be removed irrespective of the swagger file content. If the current deployment associated with the stage_name has no other stages associated with it, the deployment will also be removed.
- **nuke_api**: If True, removes the API itself only if there are no other stages associated with any other deployments once the given stage_name is removed.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_apigateway.present(name, api_name, swagger_file, stage_name, api_key_required, lambda_integration_role, lambda_region=None, stage_variables=None, region=None, key=None, keyid=None, profile=None, lambda_funcname_format='{stage}_{api}_{resource}_{method}', authorization_type='NONE', error_response_template=None, response_template=None)

Ensure the specified api_name with the corresponding swagger file is deployed to the given stage_name in AWS ApiGateway.

This state currently only supports ApiGateway integration with AWS Lambda, and CORS support is handled through a Mock integration.

There may be multiple deployments for the API object, each deployment is tagged with a description (i.e. unique label) in pretty printed json format consisting of the following key/values.

```
{
    "api_name": api_name,
    "swagger_file": basename_of_swagger_file
    "swagger_file_md5sum": md5sum_of_swagger_file,
    "swagger_info_object": info_object_content_in_swagger_file
}
```

Please note that the name of the lambda function to be integrated will be derived via the provided lambda_funcname_format parameters:

- the default lambda_funcname_format is a string with the following substitutable keys: "[stage]_[api]_[resource]_[method]". The user can choose to reorder the known keys.
- the stage key corresponds to the stage_name passed in.
- the api key corresponds to the api_name passed in.
- the resource corresponds to the resource path defined in the passed swagger file.
- the method corresponds to the method for a resource path defined in the passed swagger file.

For the default lambda_funcname_format, given the following input:

```
api_name = 'Test Service'
stage_name = 'alpha'
basePath = '/api'
path = '/a/{b}/c'
method = 'POST'
```

We will end up with the following Lambda Function Name that will be looked up: 'test_service_alpha_a_b_c_post'

The canonicalization of these input parameters is done in the following order:

1. lambda_funcname_format is formatted with the input parameters as passed,
2. resulting string is stripped for leading/trailing spaces,
3. path parameter’s curly braces are removed from the resource path,
4. consecutive spaces and forward slashes in the paths are replaced with '_'
5. consecutive '_' are replaced with '_'

Please note that for error response handling, the swagger file must have an error response model with the following schema. The lambda functions should throw exceptions for any non successful responses. An optional pattern field can be specified in errorMessage field to aid the response mapping from Lambda to the proper error return status codes.

```
Error:
    type: object
```

(continues on next page)
properties:
  stackTrace:
    type: array
    items:
      type: array
      items:
        type: string
        description: call stack
  errorType:
    type: string
    description: error type
  errorMessage:
    type: string
    description: |  
      Error message, will be matched based on pattern.  
      If no pattern is specified, the default pattern used for response mapping will be `*`.

name
  The name of the state definition

api_name
  The name of the rest api that we want to ensure exists in AWS API Gateway

swagger_file
  Name of the location of the swagger rest api definition file in YAML format.

stage_name
  Name of the stage we want to be associated with the given api_name and swagger_file definition

api_key_required
  True or False - whether the API Key is required to call API methods

lambda_integration_role
  The name or ARN of the IAM role that the AWS ApiGateway assumes when it executes your lambda function to handle incoming requests

lambda_region
  The region where we expect to find the lambda functions. This is used to determine the region where we should look for the Lambda Function for integration purposes. The region determination is based on the following priority:
  1. lambda_region as passed in (is not None)
  2. if lambda_region is None, use the region as if a boto_lambda function were executed without explicitly specifying lambda region.
  3. if region determined in (2) is different than the region used by boto_apigateway functions, a final lookup will be attempted using the boto_apigateway region.

stage_variables
  A dict with variables and their values, or a pillar key (string) that contains a dict with variables and their values. key and values in the dict must be strings. {'string': 'string'}

region
  Region to connect to.

key
  Secret key to be used.

keyid
  Access key to be used.

profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

lambda_funcname_format
  Please review the earlier example for the usage. The only substitutable keys in the funcname format are
{stage}, {api}, {resource}, {method}. Any other keys or positional substitution parameters will be flagged as an invalid input.

authorization_type
This field can be either 'NONE', or 'AWS_IAM'. This will be applied to all methods in the given swagger spec file. Default is set to 'NONE'

error_response_template
String value that defines the response template mapping that should be applied in cases error occurs. Refer to AWS documentation for details: http://docs.aws.amazon.com/apigateway/latest/developerguide/api-gateway-mapping-template-reference.html

If set to None, the following default value is used:

```source
"#set($inputRoot = $input.path('$$'))\n
'\n
' "errorMessage" : "$inputRoot.errorMessage",\n' "errorType" : "$inputRoot.errorType",\n' "stackTrace" : [\n'
' #foreach($stackTrace in $inputRoot.stackTrace)\n' ]\n'
' #foreach($elem in $stackTrace)\n' "$elem\\n'
' #if($foreach.hasNext),#end\n' ]\n'
' #if($foreach.hasNext),#end\n' ]\n'
```

New in version 2017.7.0.

response_template
String value that defines the response template mapping applied in case of success (including OPTIONS method) If set to None, empty ({}) template is assumed, which will transfer response from the lambda function as is.

New in version 2017.7.0.

```python
salt.states.boto_apigateway.usage_plan_absent(name, plan_name, region=None, key=None, keyid=None, profile=None)
```

Ensures usage plan identified by name is no longer present

New in version 2017.7.0.

- name: name of the state
- plan_name: name of the plan to remove

```yaml
usage_plan_absent:  
boto_apigateway.usage_plan_absent:  
- plan_name: my_usage_plan  
- profile: my_profile
```

```python
salt.states.boto_apigateway.usage_plan_association_absent(name, plan_name, api_stages, region=None, key=None, keyid=None, profile=None)
```

Ensures usage plan identified by name is removed from provided api_stages If a plan is associated to stages not listed in api_stages parameter, those associations remain intact.
New in version 2017.7.0.

name  
name of the state

plan_name  
name of the plan to use

api_stages  
list of dictionaries, where each dictionary consists of the following keys:
  
apId   
apId of the api to attach usage plan to
  
  stage   
  stage name of the api to attach usage plan to

UsagePlanAssociationAbsent:

boto_apigateway.usage_plan_association_absent:
  
    - plan_name: my_plan
    - api_stages:
      
        - apiId: 9kb0404ec0
          stage: my_stage
        - apiId: l9v7o2aj90
          stage: my_stage
    - profile: my_profile

salt.states.boto_apigateway.usage_plan_association_present(name, plan_name, api_stages, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is added to provided api_stages

New in version 2017.7.0.

name  
name of the state

plan_name  
name of the plan to use

api_stages  
list of dictionaries, where each dictionary consists of the following keys:
  
apId   
apId of the api to detach usage plan from
  
  stage   
  stage name of the api to detach usage plan from

UsagePlanAssociationPresent:

boto_apigateway.usage_plan_association_present:
  
    - plan_name: my_plan
    - api_stages:
      
        - apiId: 9kb0404ec0
          stage: my_stage
        - apiId: l9v7o2aj90
          stage: my_stage
    - profile: my_profile

salt.states.boto_apigateway.usage_plan_present(name, plan_name, description=None, throttle=None, quota=None, region=None, key=None, keyid=None, profile=None)

Ensure the specified usage plan with the corresponding metrics is deployed
New in version 2017.7.0.

**name**

name of the state

**plan_name**

[Required] name of the usage plan

**throttle**

[Optional] throttling parameters expressed as a dictionary. If provided, at least one of the throttling parameters must be present

- **rateLimit**
  
  rate per second at which capacity bucket is populated

- **burstLimit**
  
  maximum rate allowed

**quota**

[Optional] quota on the number of api calls permitted by the plan. If provided, limit and period must be present

- **limit**
  
  [Required] number of calls permitted per quota period

- **offset**
  
  [Optional] number of calls to be subtracted from the limit at the beginning of the period

- **period**
  
  [Required] period to which quota applies. Must be DAY, WEEK or MONTH

```yaml
UsagePlanPresent:
  boto_apigateway.usage_plan_present:
    - plan_name: my_usage_plan
      throttle:
        rateLimit: 70
        burstLimit: 100
      quota:
        limit: 1000
        offset: 0
        period: DAY
    - profile: my_profile
```

## 25.20.23 salt.states.boto_asg

**Manage Autoscale Groups**

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
It’s also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - suspended_processes:
      - AddToLoadBalancer
      - AlarmNotification
    - scaling_policies
      - adjustment_type: ChangeInCapacity
      - as_name: api-production-iad
      - cooldown: 1800
      - min_adjustment_step: None
      - name: ScaleDown
      - scaling_adjustment: -1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
# Using a profile from pillars.
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
      - profile: myprofile
```

```
# Passing in a profile.
(continues on next page)
Ensure myasg exists:

```yaml
boto_asg.present:
  - name: myasg
  - launch_config_name: mylc
  - availability_zones:
    - us-east-1a
    - us-east-1b
  - min_size: 1
  - max_size: 1
  - desired_capacity: 1
  - load_balancers:
    - myelb
  - profile:
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwupUjasdfldfkjgjsdflajkgjs
    - region: us-east-1
```

# Deleting an autoscale group with running instances.

Ensure myasg is deleted:

```yaml
boto_asg.absent:
  - name: myasg
# If instances exist, we must force the deletion of the asg.
  - force: True
```

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the name attribute defined, plus the ASG resource name.

Ensure myasg exists:

```yaml
boto_asg.present:
  - name: myasg
  - launch_config_name: mylc
  - availability_zones:
    - us-east-1a
    - us-east-1b
  - min_size: 1
  - max_size: 1
  - desired_capacity: 1
  - load_balancers:
    - myelb
  - profile: myprofile
  - alarms:
    - CPU:
      - name: 'ASG CPU **MANAGED BY SALT**'
      - attributes:
        - metric: CPUUtilization
        - namespace: AWS/EC2
        - statistic: Average
        - comparison: '>= '
        - threshold: 65.0
        - period: 60
        - evaluation_periods: 30
        - unit: null
```

(continues on next page)
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_asg_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```yaml
my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>= '
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
    alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
```

Overriding the alarm values on the resource:

```yaml
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile
    - alarms_from_pillar: my_asg_alarm
      # override CPU:attributes:threshold
    - alarms:
      CPU:
        attributes:
          threshold: 50.0
```

```python
salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None, remove_lc=False)
```

Ensure the named autoscale group is deleted.
name
Name of the autoscale group.

force
Force deletion of autoscale group.

remove_lc
Delete the launch config as well.

region
The region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_asg.present(name, launch_config_name, availability_zones, min_size, max_size, launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, subnet_names=None, tags=None, termination_policies=None, termination_policies_from_pillar='boto_asg_termination_policies', suspended_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies', scheduled_actions=None, scheduled_actions_from_pillar='boto_asg_scheduled_actions', alarms=None, alarms_from_pillar='boto_asg_alarms', region=None, key=None, keyid=None, profile=None, notification_arn=None, notification_arn_from_pillar='boto_asg_notification_arn', notification_types=None, notification_types_from_pillar='boto_asg_notification_types')
```

Ensure the autoscale group exists.

name
Name of the autoscale group.

launch_config_name
Name of the launch config to use for the group. Or, if launch_config is specified, this will be the launch config name's prefix. (see below)

launch_config
A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the launch_config_name followed by a hyphen followed by a hash of the launch_config dict contents. Example:

```
my_asg:
- boto_asg.present:
  - launch_config:
    - ebs_optimized: false
    - instance_profile_name: my_iam_profile
    - kernel_id: '
    - ramdisk_id: '
    - key_name: my_ssh_key
    - image_name: aws2015091-hvm
    - instance_type: c3.xlarge
    - instance_monitoring: false
```

(continues on next page)
- **security_groups:**
  - my_sec_group_01
  - my_sec_group_02

**availability_zones**
List of availability zones for the group.

**min_size**
Minimum size of the group.

**max_size**
Maximum size of the group.

**desired_capacity**
The desired capacity of the group.

**load_balancers**
List of load balancers for the group. Once set this can not be updated (Amazon restriction).

**default_cooldown**
Number of seconds after a Scaling Activity completes before any further scaling activities can start.

**health_check_type**
The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).

**health_check_period**
Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.

**placement_group**
Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).

**vpc_zone_identifier**
A list of the subnet identifiers of the Virtual Private Cloud.

**subnet_names**
For VPC, a list of subnet names (NOT subnet IDs) to deploy into. Exclusive with vpc_zone_identifier.

**tags**
A list of tags. Example:

```yaml
- key: 'key'
  value: 'value'
  propagate_at_launch: true
```

**termination_policies**
A list of termination policies. Valid values are:
- OldestInstance
- NewestInstance
- OldestLaunchConfiguration
- ClosestToNextInstanceHour
- Default

If no value is specified, the Default value is used.

**termination_policies_from_pillar:**
name of pillar dict that contains termination policy settings. Termination policies defined for this specific state will override those from pillar.

**suspended_processes**

**scaling_policies**

**scaling_policies_from_pillar:**
name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state
will override those from pillar.

**scheduled_actions:**

A dictionary of scheduled actions. Each key is the name of scheduled action and each value is dictionary of options. For example:

```
- scheduled_actions:
  scale_up_at_10:
    desired_capacity: 4
    min_size: 3
    max_size: 5
    recurrence: "0 9 * * 1-5"
  scale_down_at_7:
    desired_capacity: 1
    min_size: 1
    max_size: 1
    recurrence: "0 19 * * 1-5"
```

**scheduled_actions_from_pillar:**

Name of pillar dict that contains scheduled_actions settings. Scheduled actions for this specific state will override those from pillar.

**alarms:**

A dictionary of name->boto_cloudwatch_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG.

See the `salt.states.boto_cloudwatch_alarm` state for information about these attributes.

If any alarm actions include "self:" this will be replaced with the asg name. For example, alarm_actions reading "["scaling_policy:self:ScaleUp"]" will map to the arn for this asg's scaling policy named "ScaleUp". In addition, any alarms that have only scaling_policy as actions will be ignored if min_size is equal to max_size for this ASG.

**alarms_from_pillar:**

Name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region**

The region to connect to.

**key**

Secret key to be used.

**keyid**

Access key to be used.

**profile**

A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**notification_arn**

The AWS arn that notifications will be sent to.

**notification_arn_from_pillar**

Name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.

**notification_types**

A list of event names that will trigger a notification. The list of valid notification types is:

- autoscaling:EC2_INSTANCE_LAUNCH
- autoscaling:EC2_INSTANCE_LAUNCH_ERROR
- autoscaling:EC2_INSTANCE_TERMINATE
- autoscaling:EC2_INSTANCE_TERMINATE_ERROR
- autoscaling:TEST_NOTIFICATION

**notification_types_from_pillar**

Name of the pillar dict that contains notification_types settings. notification_types defined for this specific state will override those from the pillar.
25.20.24 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

depends
  boto

configuration
  This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
stack-present:
boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json
  - disable_rollback: true
  - region: eu-west-1
  - keyid: 'AKIAJHMIQ2ASDFLASDF'
  - key: 'fdkjhsafkljsASSADFalkfjasdf'
```

```
stack-absent:
boto_cfn.absent:
  - name: mystack
```

salt.states.boto_cfn.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure cloud formation stack is absent.

- name (string) - The name of the stack to delete.
- region (string) - Region to connect to.
- key (string) - Secret key to be used.
- keyid (string) - Access key to be used.
- profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cfn.present(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, region=None, key=None, keyid=None, profile=None)

Ensure cloud formation stack is present.

- name (string) - Name of the stack.
- template_body (string) – Structure containing the template body. Can also be loaded from a file by using salt://.
template_url (string) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.

parameters (list) – A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.

notification_arns (list) – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the SNS console or your Command Line Interface (CLI).

disable_rollback (bool) – Indicates whether or not to rollback on failure.

timeout_in_minutes (integer) – The amount of time that can pass before the stack status becomes CREATE FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.

capabilities (list) – The list of capabilities you want to allow in the stack. Currently, the only valid capability is 'CAPABILITY_IAM'.

tags (dict) – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

on_failure (string) – Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.

stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using salt://.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyBody and StackPolicyURL, only StackPolicyBody is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via TemplateBody or TemplateURL.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used. Can also be loaded from a file by using salt://.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyDuringUpdateBody and StackPolicy-DuringUpdateURL, only StackPolicyDuringUpdateBody is used.

region (string) - Region to connect to.

key (string) - Secret key to be used.

keyid (string) - Access key to be used.

profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
25.20.25 salt.states.boto_cloudfront

Manage CloudFront distributions
New in version 2018.3.0.
Create, update and destroy CloudFront distributions.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them, either in a pillar file or in the minion's config file:

```yaml
cloudfront.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudfront.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid, and region via a profile, either passed in as a dict, or a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

aws:
  region: us-east-1:
    profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
      region: us-east-1
```

depends
boto3

salt.states.boto_cloudfront.present(name, config, tags, region=None, key=None, keyid=None, profile=None)

Ensure the CloudFront distribution is present.

name (string)
   Name of the CloudFront distribution
config (dict)
   Configuration for the distribution
tags (dict)
   Tags to associate with the distribution
region (string)
   Region to connect to
key (string)
   Secret key to use
keyid (string)
   Access key to use
profile (dict or string)
   A dict with region, key, and keyid, or a pillar key (string) that contains such a dict.
Example:
Manage CloudTrail Objects

New in version 2016.3.0.

Create and destroy CloudTrail objects. Be aware that this interacts with Amazon's services, and so may incur charges.

```
depends
  - boto
  - boto3
```

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure trail exists:

```
Ensure trail exists:
  boto_cloudtrail.present:
    - Name: mytrail
    - S3BucketName: mybucket
    - S3KeyPrefix: prefix
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_cloudtrail.absent(name, Name=None, region=None, key=None, keyid=None, profile=None)

Ensure trail with passed properties is absent.
name
  The name of the state definition.
Name
  Name of the trail.
region
  Region to connect to.
key
  Secret key to be used.
keyid
  Access key to be used.
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_cloudtrail.present(name, Name, S3BucketName, S3KeyPrefix=None,
  SnsTopicName=None, IncludeGlobalServiceEvents=True,
  IsMultiRegionTrail=None, EnableLogFileValidation=False,
  CloudWatchLogsLogGroupArn=None,
  CloudWatchLogsRoleArn=None, KmsKeyId=None,
  LoggingEnabled=True, Tags=None, region=None, key=None,
  keyid=None, profile=None)

Ensure trail exists.
name
  The name of the state definition
Name
  Name of the trail.
S3BucketName
  Specifies the name of the Amazon S3 bucket designated for publishing log files.
S3KeyPrefix
  Specifies the Amazon S3 key prefix that comes after the name of the bucket you have designated for log file delivery.
SnsTopicName
  Specifies the name of the Amazon SNS topic defined for notification of log file delivery. The maximum length is 256 characters.
IncludeGlobalServiceEvents
  Specifies whether the trail is publishing events from global services such as IAM to the log files.
EnableLogFileValidation
  Specifies whether log file integrity validation is enabled. The default is false.
CloudWatchLogsLogGroupArn
  Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.
CloudWatchLogsRoleArn
  Specifies the role for the CloudWatch Logs endpoint to assume to write to a user's log group.
KmsKeyId
  Specifies the KMS key ID to use to encrypt the logs delivered by CloudTrail. The value can be a an alias name prefixed by "alias/", a fully specified ARN to an alias, a fully specified ARN to a key, or a globally unique identifier.
LoggingEnabled
  Whether logging should be enabled for the trail
Tags
  A dictionary of tags that should be set on the trail
region
  Region to connect to.
key
  Region to connect to.
Secret key to be used.
keyid

Access key to be used.
profile

A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.27 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
cloudwatch:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

```yaml
my test alarm:
    boto_cloudwatch_alarm.present:
        - name: my test alarm
        - attributes:
            metric: ApproximateNumberOfMessagesVisible
            namespace: AWS/SQS
            statistic: Average
            comparison: ">="
            threshold: 20000.0
            period: 60
            evaluation_periods: 1
            description: test alarm via salt
            dimensions:
                QueueName:
                    - the-sqs-queue-name
            alarm_actions:
                - arn:aws:sns:us-east-1:1111111:myalerting-action
```

```python
salt.states.boto_cloudwatch_alarm.absent(name, region=None, key=None, keyid=None, profile=None)
```
Ensure the named cloudwatch alarm is deleted.

```python
name
   Name of the alarm.
region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None, keyid=None, profile=None)
```

Ensure the cloudwatch alarm exists.

```python
name
   Name of the alarm
attributes
   A dict of key/value cloudwatch alarm attributes.
region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```

25.20.28 **salt.states.boto_cloudwatch_event**

Manage CloudTrail Objects

New in version 2016.11.0.

Create and destroy CloudWatch event rules. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses `boto3`, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
cloudwatch_event.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch_event.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:  
   keyid: GKTADJGHEIQSXMKKRBJ08H
```

(continues on next page)
Ensure event rule exists:

```python
boto_cloudwatch_event.present:
- Name: mytrail
- ScheduleExpression: 'rate(120 minutes)'
- State: 'DISABLED'
- Targets:
  - Id: "target1"
    Input: '{"arbitrary": "json"}'
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkgwupUjasdflkdfklgjsdfjajkghs
```

Ensure CloudWatch event rule with passed properties is absent.

```python
salt.states.boto_cloudwatch_event.absent(name, Name=None, region=None, key=None, keyid=None, profile=None)
```

Ensure trail exists.

```python
salt.states.boto_cloudwatch_event.present(name, Name=None, ScheduleExpression=None, EventPattern=None, Description=None, RoleArn=None, State=None, Targets=None, region=None, key=None, keyid=None, profile=None)
```
A list of resources to be invoked when the rule is triggered.

- **region**
  Region to connect to.
- **key**
  Secret key to be used.
- **keyid**
  Access key to be used.
- **profile**
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 25.20.29 salt.states.boto_cognitoidentity

**Manage CognitoIdentity Functions**

New in version 2016.11.0.

Create and destroy CognitoIdentity identity pools. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**Ensure function exists:**

```python
cognito.identity.pool_present:
  - PoolName: my_identity_pool
  - region: us-east-1
  - keyid: GKTADJGHEIQXSXMKRRB3J08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_cognitoidentity.pool_absent(name, IdentityPoolName, RemoveAllMatched=False, region=None, key=None, keyid=None, profile=None)

Ensure cognito identity pool with passed properties is absent.

- **name**
  The name of the state definition.
- **IdentityPoolName**
  Name of the Cognito Identity Pool. Please note that this may match multiple pools with the same given name, in which case, all will be removed.
RemoveAllMatched
If True, all identity pools with the matching IdentityPoolName will be removed. If False and there are
more than one identity pool with the matching IdentityPoolName, no action will be taken. If False and
there is only one identity pool with the matching IdentityPoolName, the identity pool will be removed.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cognitoidentity.pool_present(name, IdentityPoolName, AuthenticatedRole,
AllowUnauthenticatedIdentities=False,
UnauthenticatedRole=None,
SupportedLoginProviders=None,
DeveloperProviderName=None,
OpenIdConnectProviderARNs=None,
region=None, key=None, keyid=None,
profile=None)

Ensure Cognito Identity Pool exists.

name
The name of the state definition

IdentityPoolName
Name of the Cognito Identity Pool

AuthenticatedRole
An IAM role name or ARN that will be associated with temporary AWS credentials for an authenticated
cognito identity.

AllowUnauthenticatedIdentities
Whether to allow anonymous user identities

UnauthenticatedRole
An IAM role name or ARN that will be associated with anonymous user identities

SupportedLoginProviders
A dictionary or pillar that contains key:value pairs mapping provider names to provider app IDs.

DeveloperProviderName
A string which is the domain by which Cognito will refer to your users. This name acts as a placeholder
that allows your backend and the Cognito service to communicate about the developer provider. Once
you have set a developer provider name, you cannot change it. Please take care in setting this parameter.

OpenIdConnectProviderARNs
A list or pillar name that contains a list of OpenID Connect provider ARNs.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
25.20.30 salt.states.boto_datapipeline

Manage Data Pipelines

New in version 2016.3.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
datapipeline.keyid: GKTADJGHEIQSXMKKRBJ08H
datapipeline.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Ensure daily data pipeline exists:
```
boto_datapipeline.present:
    - name: my-datapipeline
    - pipeline_objects:
        DefaultSchedule:
            name: Every 1 day
            fields:
                period: 1 Day
                type: Schedule
                startAt: FIRST_ACTIVATION_DATE_TIME
        - parameter_values:
            myDDBTableName: my-dynamo-table
```

salt.states.boto_datapipeline.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure a pipeline with the service_name does not exist

name
Name of the service to ensure a data pipeline does not exist for.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_datapipeline.present(name, pipeline_objects=None, pipeline_objects_from_pillars='boto_datapipeline_pipeline_objects', parameter_objects=None, parameter_objects_from_pillars='boto_datapipeline_parameter_objects', parameter_values=None, parameter_values_from_pillars='boto_datapipeline_parameter_values', region=None, key=None, keyid=None, profile=None)

Ensure the data pipeline exists with matching definition.

name
Name of the service to ensure a data pipeline exists for.

pipeline_objects
Pipeline objects to use. Will override objects read from pillars.

pipeline_objects_from_pillars
The pillar key to use for lookup.

parameter_objects
Parameter objects to use. Will override objects read from pillars.

parameter_objects_from_pillars
The pillar key to use for lookup.

parameter_values
Parameter values to use. Will override values read from pillars.

parameter_values_from_pillars
The pillar key to use for lookup.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.31 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.

Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

| keyid: | GKTADJGHEIQSXMKKRBJ08H |
| key: | askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |
| region: | us-east-1 |

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgqhWupUjasdfklgfdkglgsdfjajkghs
  region: us-east-1

Ensure DynamoDB table does not exist:
  boto_dynamodb.absent:
    - table_name: new_table
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgqhWupUjasdfklgfdkglgsdfjajkghs
    - region: us-east-1

Ensure DynamoDB table exists:
  boto_dynamodb.present:
    - table_name: new_table
    - read_capacity_units: 1
    - write_capacity_units: 2
    - hash_key: primary_id
    - hash_key_data_type: N
    - range_key: start_timestamp
    - range_key_data_type: N
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgqhWupUjasdfklgfdkglgsdfjajkghs
    - region: us-east-1
    - local_indexes:
      - index:
        - name: "primary_id_end_timestamp_index"
        - hash_key: primary_id
        - hash_key_data_type: N
        - range_key: end_timestamp
        - range_key_data_type: N
    - global_indexes:
      - index:
        - name: "name_end_timestamp_index"
        - hash_key: name
        - hash_key_data_type: S
        - range_key: end_timestamp
        - range_key_data_type: N
        - read_capacity_units: 3
        - write_capacity_units: 4

It's possible to specify cloudwatch alarms that will be setup along with the DynamoDB table. Note the alarm name will be defined by the name attribute provided, plus the DynamoDB resource name.

Ensure DynamoDB table exists:
  boto_dynamodb.present:
    - name: new_table
    - read_capacity_units: 1
    - write_capacity_units: 2
    - hash_key: primary_id
    - hash_key_data_type: N
    - range_key: start_timestamp
    - range_key_data_type: N
(continues on next page)
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_dynamodb_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```yaml
boto_dynamodb_alarms:
  ConsumedWriteCapacityUnits:
    name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
    attributes:
      metric: ConsumedWriteCapacityUnits
      namespace: AWS/DynamoDB
      statistic: Sum
      comparison: '>='
      # threshold_percent is used to calculate the actual threshold 
      # based on the provisioned capacity for the table.
      threshold_percent: 0.75
      period: 300
      evaluation_periods: 2
      unit: Count
      description: 'DynamoDB ConsumedWriteCapacityUnits'
    alarm_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]

  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkJgsdfjajkggh
  - region: us-east-1
```

Ensure DynamoDB table exists:

```yaml
boto_dynamodb.present:
  - name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
```

(continues on next page)
- **hash_key_data_type**: N
- **range_key**: start_timestamp
- **range_key_data_type**: N
- **alarms**: 
  - **ConsumedWriteCapacityUnits**: 
    - **attributes**: 
      - **threshold_percent**: 0.90
      - **period**: 900

**exception** `salt.states.boto_dynamodb.GsiNotUpdatableError`

Raised when a global secondary index cannot be updated.

**salt.states.boto_dynamodb.absent**(`name`, `region=None`, `key=None`, `keyid=None`, `profile=None`)  
Ensure the DynamoDB table does not exist.

**salt.states.boto_dynamodb.present**(`name=None`, `table_name=None`, `region=None`, `key=None`, `keyid=None`, `profile=None`, `read_capacity_units=None`, `write_capacity_units=None`, `alarms=None`, `alarms_from_pillar='boto_dynamodb_alarms'`, `hash_key=None`, `hash_key_data_type=None`, `range_key=None`, `range_key_data_type=None`, `local_indexes=None`, `global_indexes=None`, `backup_configs_from_pillars='boto_dynamodb_backup_configs'`)  
Ensure the DynamoDB table exists. Table throughput can be updated after table creation.

Global secondary indexes (GSIs) are managed with some exceptions:

- If a GSI deletion is detected, a failure will occur (deletes should be done manually in the AWS console).
- If multiple GSIs are added in a single Salt call, a failure will occur (boto supports one creation at a time). Note that this only applies after table creation; multiple GSIs can be created during table creation.
- Updates to existing GSIs are limited to read/write capacity only (DynamoDB limitation).

**name**  
Name of the DynamoDB table

**table_name**  
Name of the DynamoDB table (deprecated)

**region**  
Region to connect to.

**key**  
Secret key to be used.

**keyid**  
Access key to be used.

**profile**  
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
read_capacity_units
The read throughput for this table
write_capacity_units
The write throughput for this table
hash_key
The name of the attribute that will be used as the hash key for this table
hash_key_data_type
The DynamoDB datatype of the hash key
range_key
The name of the attribute that will be used as the range key for this table
range_key_data_type
The DynamoDB datatype of the range key
local_indexes
The local indexes you would like to create
global_indexes
The global indexes you would like to create
backup_configs_from_pillars
Pillars to use to configure DataPipeline backups

25.20.32 salt.states.boto_ec2

Manage EC2

New in version 2015.8.0.

This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.

The below code creates a key pair:

```
create-key-pair:
    boto_ec2.key_present:
      - name: mykeypair
      - save_private: /root/
      - region: eu-west-1
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
import-key-pair:
    boto_ec2.key_present:
      - name: mykeypair
      - upload_public: 'ssh-rsa AAAA'
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

You can also use salt:// in order to define the public key.

```
import-key-pair:
    boto_ec2.key_present:
      - name: mykeypair
      - upload_public: salt://mybase/public_key.pub
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

The below code deletes a key pair:

```
delete-key-pair:
    boto_ec2.key_present:
      - name: mykeypair
```

25.20. state modules
delete-key-pair:
    boto_ec2.key_absent:
    - name: mykeypair
    - region: eu-west-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfdkflgjsdfjajkghs

salt.states.boto_ec2.eni_absent(name, release_eip=False, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI is absent.

New in version 2016.3.0.

name
    Name tag associated with the ENI.
release_eip
    True/False - release any EIP associated with the ENI
region
    Region to connect to.
key
    Secret key to be used.
keyid
    Access key to be used.
profile
    A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_ec2.eni_present(name, subnet_id=None, subnet_name=None, private_ip_address=None, description=None, groups=None, source_dest_check=True, allocate_eip=None, arecords=None, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI exists.

New in version 2016.3.0.

name
    Name tag associated with the ENI.
subnet_id
    The VPC subnet ID the ENI will exist within.
subnet_name
    The VPC subnet name the ENI will exist within.
private_ip_address
    The private ip address to use for this ENI. If this is not specified AWS will automatically assign a private IP address to the ENI. Must be specified at creation time; will be ignored afterward.
description
    Description of the key.
groups
    A list of security groups to apply to the ENI.
source_dest_check
    Boolean specifying whether source/destination checking is enabled on the ENI.
allocate_eip
    allocate and associate an EIP to the ENI. Could be ‘standard’ to allocate Elastic IP to EC2 region or ‘vpc’ to get it for a particular VPC.

Changed in version 2016.11.0.

arecords
    A list of arecord dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the
boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. By default, the private ENI IP address will be used, set 'public: True' in the arecord dict to use the ENI's public IP address

New in version 2016.3.0.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_ec2.**instance_absent**(name, instance_name=None, instance_id=None, release_eip=False, region=None, key=None, keyid=None, profile=None, filters=None)

Ensure an EC2 instance does not exist (is stopped and removed).

Changed in version 2016.11.0.

**name**
(string) - The name of the state definition.

**instance_name**
(string) - The name of the instance.

**instance_id**
(string) - The ID of the instance.

**release_eip**
(bool) - Release any associated EIPs during termination.

**region**
(string) - Region to connect to.

**key**
(string) - Secret key to be used.

**keyid**
(string) - Access key to be used.

**profile**
(variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**filters**
(dict) - A dict of additional filters to use in matching the instance to delete.

YAML example fragment:

```yaml
- filters:
  vpc-id: vpc-abcdef12
```
salt.states.boto_ec2.instance_present(name, instance_name=None, instance_id=None,
image_id=None, image_name=None, tags=None,
key_name=None, security_groups=None, user_data=None,
instance_type=None, placement=None, kernel_id=None,
ramdisk_id=None, vpc_id=None, vpc_name=None,
monitoring_enabled=None, subnet_id=None,
subnet_name=None, private_ip_address=None,
block_device_map=None, disable_api_termination=None,
instance_initiated_shutdown_behavior=None,
placement_group=None, client_token=None,
security_group_ids=None, security_group_names=None,
additional_info=None, tenancy=None,
instance_profile_arn=None, instance_profile_name=None,
ebs_optimized=None, network_interfaces=None,
network_interface_name=None, network_interface_id=None,
attributes=None, target_state=None, public_ip=None,
allocation_id=None, allocate_eip=False, region=None,
key=None, keyid=None, profile=None)

Ensure an EC2 instance is running with the given attributes and state.

name: (string) - The name of the state definition. Recommended that this match the instance_name attribute (generally the FQDN of the instance).

instance_name: (string) - The name of the instance, generally its FQDN. Exclusive with 'instance_id'.

instance_id: (string) - The ID of the instance (if known). Exclusive with 'instance_name'.

image_id: (string) - The ID of the AMI image to run.

image_name: (string) - The name of the AMI image to run.

tags: (dict) - Tags to apply to the instance.

key_name: (string) - The name of the key pair with which to launch instances.

security_groups: (list of strings) - The names of the EC2 classic security groups with which to associate instances.

user_data: (string) - The Base64-encoded MIME user data to be made available to the instance(s) in this reservation.

instance_type: (string) - The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.

placement: (string) - The Availability Zone to launch the instance into.

kernel_id: (string) - The ID of the kernel with which to launch the instance.

ramdisk_id: (string) - The ID of the RAM disk with which to launch the instance.

vpc_id: (string) - The ID of a VPC disk with which to launch the instance.

vpc_name: (string) - The name of a VPC to attach the instance to.

monitoring_enabled: (bool) - Enable detailed CloudWatch monitoring on the instance.

subnet_id: (string) - Enable detailed CloudWatch monitoring on the instance.
(string) – The ID of the subnet within which to launch the instances for VPC.

subnet_name
(string) – The name of the subnet within which to launch the instances for VPC.

private_ip_address
(string) – If you’re using VPC, you can optionally use this parameter to assign the instance a specific available IP address from the subnet (e.g., 10.0.0.25).

block_device_map
(boto.ec2.blockdevicemapping.BlockDeviceMapping) – A BlockDeviceMapping data structure describing the EBS volumes associated with the Image.

disable_api_termination
(bool) – If True, the instances will be locked and will not be able to be terminated via the API.

instance_initiated_shutdown_behavior
(string) – Specifies whether the instance stops or terminates on instance-initiated shutdown. Valid values are:

- 'stop'
- 'terminate'

placement_group
(string) – If specified, this is the name of the placement group in which the instance(s) will be launched.

client_token
(string) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. Maximum 64 ASCII characters.

security_group_ids
(list of strings) – The IDs of the VPC security groups with which to associate instances.

security_group_names
(list of strings) – The names of the VPC security groups with which to associate instances.

additional_info
(string) – Specifies additional information to make available to the instance(s).

tenancy
(string) – The tenancy of the instance you want to launch. An instance with a tenancy of ’dedicated’ runs on single-tenant hardware and can only be launched into a VPC. Valid values are: ”default” or ”dedicated”. NOTE: To use dedicated tenancy you MUST specify a VPC subnet-ID as well.

instance_profile_arn
(string) – The Amazon resource name (ARN) of the IAM Instance Profile (IIP) to associate with the instances.

instance_profile_name
(string) – The name of the IAM Instance Profile (IIP) to associate with the instances.

ebs_optimized
(bool) – Whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and a tuned configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types.

network_interfaces
(boto.ec2.networkinterface.NetworkInterfaceCollection) – A NetworkInterfaceCollection data structure containing the ENI specifications for the instance.

network_interface_name
(string) - The name of Elastic Network Interface to attach

New in version 2016.11.0.

network_interface_id
(string) - The id of Elastic Network Interface to attach

New in version 2016.11.0.

attributes
(dict) - Instance attributes and value to be applied to the instance. Available options are:

- instanceType - A valid instance type (m1.small)
- kernel - Kernel ID (None)
- ramdisk - Ramdisk ID (None)
target_state
  (string) - The desired target state of the instance. Available options are:
  • running
  • stopped
  Note that this option is currently UNIMPLEMENTED.

public_ip:
  (string) - The IP of a previously allocated EIP address, which will be attached to the instance. EC2 Classic instances ONLY - for VCP pass in an allocation_id instead.

allocation_id:
  (string) - The ID of a previously allocated EIP address, which will be attached to the instance. VPC instances ONLY - for Classic pass in a public_ip instead.

allocate_eip:
  (bool) - Allocate and attach an EIP on-the-fly for this instance. Note you'll want to release this address when terminating the instance, either manually or via the 'release_eip' flag to 'instance_absent'.
keyid
   (string) - Access key to be used.
profile
   (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_ec2.private_ips_present(name, network_interface_name=None,
   network_interface_id=None,
   private_ip_addresses=None, allow_reassignment=False,
   region=None, key=None, keyid=None, profile=None)

Ensure an ENI has secondary private ip addresses associated with it
name
   (String) - State definition name
network_interface_id
   (String) - The EC2 network interface id, example eni-123456789
private_ip_addresses
   (List or String) - The secondary private ip address(es) that should be present on the ENI.
allow_reassignment
   (Boolean) - If true, will reassign a secondary private ip address associated with another ENI. If false, state will fail if the secondary private ip address is associated with another ENI.
region
   (string) - Region to connect to.
key
   (string) - Secret key to be used.
keyid
   (string) - Access key to be used.
profile
   (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_ec2.snapshot_created(name, ami_name, instance_name,
   wait_until_available=True, wait_timeout_seconds=300, **kwargs)

Create a snapshot from the given instance
New in version 2016.3.0.
salt.states.boto_ec2.volume_absent(name, volume_name=None, volume_id=None,
   instance_name=None, instance_id=None, device=None,
   region=None, key=None, keyid=None, profile=None)

Ensure the EC2 volume is detached and absent.
New in version 2016.11.0.
name
   State definition name.
volume_name
   Name tag associated with the volume. For safety, if this matches more than one volume, the state will refuse to apply.
volume_id
   Resource ID of the volume.
instance_name
   Only remove volume if it is attached to instance with this Name tag. Exclusive with 'instance_id'. Requires 'device'.
instance_id
   Only remove volume if it is attached to this instance. Exclusive with 'instance_name'. Requires 'device'.
device
  Match by device rather than ID. Requires one of 'instance_name' or 'instance_id'.
region
  Region to connect to.
key
  Secret key to be used.
keyid
  Access key to be used.
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_ec2.volume_present(
    name, volume_name=None, volume_id=None,
    instance_name=None, instance_id=None, device=None,
    size=None, snapshot_id=None, volume_type=None, iops=None,
    encrypted=False, kms_key_id=None, region=None, key=None,
    keyid=None, profile=None)
```

Ensure the EC2 volume is present and attached.

**name**
  State definition name.

**volume_name**
  The Name tag value for the volume. If no volume with that matching name tag is found, a new volume
  will be created. If multiple volumes are matched, the state will fail.

**volume_id**
  Resource ID of the volume. Exclusive with 'volume_name'.

**instance_name**
  Attach volume to instance with this Name tag. Exclusive with 'instance_id'.

**instance_id**
  Attach volume to instance with this ID. Exclusive with 'instance_name'.

**device**
  The device on the instance through which the volume is exposed (e.g. /dev/sdh)

**size**
  The size of the new volume, in GiB. If you're creating the volume from a snapshot and don't specify
  a volume size, the default is the snapshot size. Optionally specified at volume creation time; will be
  ignored afterward. Requires 'volume_name'.

**snapshot_id**
  The snapshot ID from which the new Volume will be created. Optionally specified at volume creation
  time; will be ignored afterward. Requires 'volume_name'.

**volume_type**
  The type of the volume. Optionally specified at volume creation time; will be ignored afterward. Requires
  'volume_name'. Valid volume types for AWS can be found here: http://docs.aws.amazon.com/AWSEC2/
  latest/UserGuide/EBSVolumeTypes.html

**iops**
  The provisioned IOPS you want to associate with this volume. Optionally specified at volume creation
  time; will be ignored afterward. Requires 'volume_name'.

**encrypted**
  Specifies whether the volume should be encrypted. Optionally specified at volume creation time; will
  be ignored afterward. Requires 'volume_name'.

**kms_key_id**
  If encrypted is True, this KMS Key ID may be specified to encrypt volume with this key. Optionally specified
  at volume creation time; will be ignored afterward. Requires 'volume_name'. e.g.: arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef

**region**
  Region to connect to.

**key**
Secret key to be used.

Keyid
Access key to be used.

Profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_ec2.volumes_tagged(name, tag_maps, authoritative=False, region=None, key=None, keyid=None, profile=None)
```

Ensure EC2 volume(s) matching the given filters have the defined tags.

New in version 2016.11.0.

**name**
State definition name.

**tag_maps**
List of dicts of filters and tags, where ‘filters’ is a dict suitable for passing to the ‘filters’ argument of `boto_ec2.get_all_volumes()`, and ‘tags’ is a dict of tags to be set on volumes as matched by the given filters. The filter syntax is extended to permit passing either a list of volume_ids or an instance_name (with instance_name being the Name tag of the instance to which the desired volumes are mapped). Each mapping in the list is applied separately, so multiple sets of volumes can be all tagged differently with one call to this function.

YAML example fragment:

```
- filters:
  attachment.instance_id: i-abcdef12
  tags:
    Name: dev-int-abcdef12.aws-foo.com
- filters:
  attachment.device: /dev/sdf
  tags:
    ManagedSnapshots: true
    BillingGroup: bubba.hotep@aws-foo.com
- filters:
  instance_name: prd-foo-01.aws-foo.com
  tags:
    Name: prd-foo-01.aws-foo.com
    BillingGroup: infra-team@aws-foo.com
- filters:
  volume_ids: [ vol-12345689, vol-abcdef12 ]
  tags:
    BillingGroup: infra-team@aws-foo.com
```

**authoritative**
Should un-declared tags currently set on matched volumes be deleted? Boolean.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
25.20.33  salt.states.boto_elasticache

Manage Elasticache

New in version 2014.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon’s services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

| elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H |
| elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

| myprofile: |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |
| region: us-east-1 |

Ensure myelasticache exists:

| boto_elasticache.present: |
| name: myelasticache |
| engine: redis |
| cache_node_type: cache.t1.micro |
| num_cache_nodes: 1 |
| region: us-east-1 |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |

# Using a profile from pillars
Ensure myelasticache exists:

| boto_elasticache.present: |
| name: myelasticache |
| engine: redis |
| cache_node_type: cache.t1.micro |
| num_cache_nodes: 1 |
| region: us-east-1 |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |

# Passing in a profile
Ensure myelasticache exists:

| boto_elasticache.present: |
| name: myelasticache |
| engine: redis |
| cache_node_type: cache.t1.micro |
| num_cache_nodes: 1 |
| region: us-east-1 |
| profile: myprofile |
- **name**: myelasticache
- **engine**: redis
- **cache_node_type**: cache.t1.micro
- **num_cache_nodes**: 1
- **notification_topic_arn**: arn:aws:sns:us-east-1:879879:my-sns-topic
- **region**: us-east-1
- **profile**:
  - **keyid**: GKTADJGHEIQSXMKKRBJ08H
  - **key**: askdjghsdfjkgWupUjasdfklkdgjsdfjajkgghs

salt.states.boto_elasticache.absent(name, wait=True, region=None, key=None, keyid=None, profile=None)

Ensure the named elasticache cluster is deleted.

- **name**: Name of the cache cluster.
- **wait**: Boolean. Wait for confirmation from boto that the cluster is in the deleting state.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.cache_cluster_absent(*args, **kwargs)

cache_cluster_absent

salt.states.boto_elasticache.cache_cluster_present(*args, **kwargs)

salt.states.boto_elasticache.creategroup(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the a replication group is create.

- **name**: Name of replication group
- **wait**: Waits for the group to be available
- **primary_cluster_id**: Name of the master cache node
- **replication_group_description**: Description for the group
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_elasticache.present(name=None, cache_node_type=None, num_cache_nodes=None, preferred_availability_zone=None, port=None, cache_parameter_group_name=None, cache_security_group_names=None, replication_group_id=None, auto_minor_version_upgrade=True, security_group_ids=None, cache_subnet_group_name=None, engine=None, engine_version=None, notification_topic_arn=None, preferred_maintenance_window=None, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the cache cluster exists.

name
  Name of the cache cluster (cache cluster id).

group
  The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.

cache_node_type
  The compute and memory capacity of the nodes in the cache cluster. cache.t1.micro, cache.m1.small, etc. See: https://boto.readthedocs.io/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cluster

num_cache_nodes
  The number of cache nodes that the cache cluster will have.

preferred_availability_zone
  The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.

port
  The port number on which each of the cache nodes will accept connections.

cache_parameter_group_name
  The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.

cache_security_group_names
  A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.

replication_group_id
  The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.

auto_minor_version_upgrade
  Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.

security_group_ids
  One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

cache_subnet_group_name
  The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

group
  The version number of the cache engine to be used for this cluster.

notification_topic_arn
  The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.

preferred_maintenance_window
  The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00
wait
  Boolean. Wait for confirmation from boto that the cluster is in the available state.
region
  Region to connect to.
key
  Secret key to be used.
keyid
  Access key to be used.
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_elasticache.replication_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
salt.states.boto_elasticache.replication_group_present(*args, **kwargs)
salt.states.boto_elasticache.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
salt.states.boto_elasticache.subnet_group_present(name, subnet_ids=None, subnet_names=None, description=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure ElastiCache subnet group exists.
New in version 2015.8.0.
name
  The name for the ElastiCache subnet group. This value is stored as a lowercase string.
subnet_ids
  A list of VPC subnet IDs for the cache subnet group. Exclusive with subnet_names.
subnet_names
  A list of VPC subnet names for the cache subnet group. Exclusive with subnet_ids.
description
  Subnet group description.
tags
  A list of tags.
region
  Region to connect to.
key
  Secret key to be used.
keyid
  Access key to be used.
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
25.20.34 salt.states.boto_elasticsearch_domain

Manage Elasticsearch Domains

New in version 2016.11.0.

Create and destroy Elasticsearch domains. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure domain exists:

```yaml
boto_elasticsearch_domain.present:
  - DomainName: mydomain
  - profile='user-credentials'
  - ElasticsearchVersion: "2.3"
  - ElasticsearchClusterConfig:
    InstanceType: "t2.micro.elasticsearch"
    InstanceCount: 1
    DedicatedMasterEnabled: False
    ZoneAwarenessEnabled: False
  - EBSOptions:
    EBSEnabled: True
    VolumeType: "gp2"
    VolumeSize: 10
    Iops: 0
  - AccessPolicies:
    Version: "2012-10-17"
    Statement:
    - Effect: "Allow"
    - Principal:
      AWS: "*
    - Action:
      - "es:*"
    - Condition:
      IpAddress:
      "aws:SourceIp":
```

(continues on next page)
- "127.0.0.1"
- "127.0.0.2"

- **SnapshotOptions**:
  - **AutomatedSnapshotStartHour**: 0
- **AdvancedOptions**:
  - `rest.action.multi.allow_explicit_index`: "true"
- **Tags**:
  - `a`: "b"
- **region**: us-east-1
- **keyid**: GKTADJGHEIQSXMKKRBJ08H
- **key**: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

```python
salt.states.boto_elasticsearch_domain.absent(name, DomainName, region=None, key=None, keyid=None, profile=None)
```

Ensure domain with passed properties is absent.

- **name**: The name of the state definition.
- **DomainName**: Name of the domain.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_elasticsearch_domain.present(name, DomainName, ElasticsearchClusterConfig=None, EBSOptions=None, AccessPolicies=None, SnapshotOptions=None, AdvancedOptions=None, Tags=None, region=None, key=None, keyid=None, profile=None, ElasticsearchVersion='1.5')
```

Ensure domain exists.

- **name**: The name of the state definition.
- **DomainName**: Name of the domain.
- **ElasticsearchClusterConfig**: Configuration options for an Elasticsearch domain. Specifies the instance type and number of instances in the domain cluster.
  - **InstanceType** (string) -- The instance type for an Elasticsearch cluster.
  - **InstanceCount** (integer) -- The number of instances in the specified domain cluster.
  - **DedicatedMasterEnabled** (boolean) -- A boolean value to indicate whether a dedicated master node is enabled. See About Dedicated Master Nodes for more information.
  - **ZoneAwarenessEnabled** (boolean) -- A boolean value to indicate whether zone awareness is enabled. See About Zone Awareness for more information.
  - **DedicatedMasterType** (string) -- The instance type for a dedicated master node.
DedicatedMasterCount (integer) -- Total number of dedicated master nodes, active and on standby, for the cluster.

**EBSOptions**
Options to enable, disable and specify the type and size of EBS storage volumes.
- EBSEnabled (boolean) -- Specifies whether EBS-based storage is enabled.
- VolumeType (string) -- Specifies the volume type for EBS-based storage.
- VolumeSize (integer) -- Integer to specify the size of an EBS volume.
- Iops (integer) -- Specifies the IOPD for a Provisioned IOPS EBS volume (SSD).

**AccessPolicies**
IAM access policy

**SnapshotOptions**
Option to set time, in UTC format, of the daily automated snapshot. Default value is 0 hours.
- AutomatedSnapshotStartHour (integer) -- Specifies the time, in UTC format, when the service takes a daily automated snapshot of the specified Elasticsearch domain. Default value is 0 hours.

**AdvancedOptions**
Option to allow references to indices in an HTTP request body. Must be false when configuring access to individual sub-resources. By default, the value is true.
- region
  Region to connect to.
- key
  Secret key to be used.
- keyid
  Access key to be used.
- profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**ElasticsearchVersion**
String of format X.Y to specify version for the Elasticsearch domain eg. "1.5" or "2.3".

---

**25.20.35 salt.states.boto_elb**

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
**elb.keyid:** GKTADJGHEIQSXMKKRBJ08H
**elb.key:** askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
**myprofile:**
  **keyid:** GKTADJGHEIQSXMKKRBJ08H
```

(continues on next page)
### Ensure myelb ELB exists:

```python
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - availability_zones:
    - us-east-1a
    - us-east-1c
    - us-east-1d
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfrgkWupUjasdfklfklgjsdfajkghs
  - listeners:
    - elb_port: 443
      instance_port: 80
      elb_protocol: HTTPS
      instance_protocol: HTTP
      certificate: 'arn:aws:iam::111111111111111111:server-certificate/mycert'
      policies:
        - my-ssl-policy
        - cookie-policy
    - elb_port: 8210
      instance_port: 8210
      elb_protocol: TCP
  - backends:
    - instance_port: 80
      policies:
        - enable-proxy-protocol
  - health_check:
    - target: 'HTTP:80/'
  - attributes:
    - cross_zone_load_balancing: enabled: true
    - access_log:
      enabled: true
    - s3_bucket_name: 'mybucket'
    - s3_bucket_prefix: 'my-logs'
    - emit_interval: 5
    - connecting_settings:
      idle_timeout: 60
  - cnames:
    - name: mycname.example.com.
      zone: example.com.
      ttl: 60
    - name: myothercname.example.com.
      zone: example.com.
  - security_groups:
    - my-security-group
  - policies:
    - policy_name: my-ssl-policy
      policy_type: SSLNegotiationPolicyType
```

(continues on next page)
Salt Documentation, Release 3006.3

(continued from previous page)

- **policy**: Protocol-TLSv1.2: true
- **Server-Defined-Cipher-Order**: true
- **ECDHE-ECDSA-AES128-GCM-SHA256**: true
  - **policy_name**: cookie-policy
  - **policy_type**: LBCookieStickinessPolicyType
  - **policy**: {} # no policy means this is a session cookie
- **policy_name**: enable-proxy-protocol
- **policy_type**: ProxyProtocolPolicyType
- **policy**: ProxyProtocol: true

# Using a profile from pillars
Ensure myelb ELB exists:
  boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile

# Passing in a profile
Ensure myelb ELB exists:
  boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs

It’s possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillard by setting the attributes on the resource. The module will use the default pillar key `boto_elb_attributes`, which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:

<table>
<thead>
<tr>
<th>my_elb_attributes:</th>
</tr>
</thead>
<tbody>
<tr>
<td>cross_zone_load_balancing:</td>
</tr>
<tr>
<td>enabled: true</td>
</tr>
<tr>
<td>connection_draining:</td>
</tr>
<tr>
<td>enabled: true</td>
</tr>
<tr>
<td>timeout: 20</td>
</tr>
<tr>
<td>access_log:</td>
</tr>
<tr>
<td>enabled: true</td>
</tr>
<tr>
<td>s3_bucket_name: 'mybucket'</td>
</tr>
<tr>
<td>s3_bucket_prefix: 'my-logs'</td>
</tr>
<tr>
<td>emit_interval: 5</td>
</tr>
</tbody>
</table>

Overriding the attribute values on the resource:

Ensure myelb ELB exists:
  boto_elb.present:
  - name: myelb
  - region: us-east-1

(continues on next page)
- **attributes_from_pillar**: my_elb_attributes
  # override cross_zone_load_balancing:enabled
- **attributes**:
  - **cross_zone_load_balancing**:
    - **enabled**: false
  - **profile**: myelbprofile

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

**Ensure myelb ELB exists:**
```
boto_elb.present:
  - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms:
      UnHealthyHostCount:
        name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
        attributes:
          metric: UnHealthyHostCount
          namespace: AWS/ELB
          statistic: Average
          comparison: '>='
          threshold: 1.0
          period: 600
          evaluation_periods: 6
          unit: null
          description: ELB UnHealthyHostCount
        insufficient_data_actions: []
        ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_elb_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:
```
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
      description: ELB UnHealthyHostCount
    insufficient_data_actions: []
    ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

(continues on next page)
ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']

Overriding the alarm values on the resource:

```yaml
Ensure myelb ELB exists:
boto_elb.present:
- name: myelb
- region: us-east-1
- profile: myelbprofile
- alarms_from_pillar: my_elb_alarm
  # override UnHealthyHostCount:attributes:threshold
- alarms:
  UnHealthyHostCount:
    attributes:
      threshold: 2.0
```

Tags can also be set:

New in version 2016.3.0.

```yaml
Ensure myelb ELB exists:
boto_elb.present:
- name: myelb
- region: us-east-1
- profile: myelbprofile
- tags:
  MyTag: 'My Tag Value'
  OtherTag: 'My Other Value'
```

```
salt.states.boto_elb.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure an ELB does not exist
name
```

```
salt.states.boto_elb.present(name, listeners, availability_zones=None, subnets=None, subnet_names=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', policies=None, policies_from_pillar='boto_elb_policies', backends=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, tags=None, instance_ids=None, instance_names=None)
Ensure the ELB exists.
name
```

name

Name of the ELB.

availability_zones
A list of availability zones for this ELB.

listeners
A list of listener lists; example:

```yaml
[
  ['443', 'HTTPS', 'arn:aws:iam::111111:server-certificate/mycert'],
  ...
]
```
A list of subnet IDs in your VPC to attach to your LoadBalancer.

**subnet_names**
A list of subnet names in your VPC to attach to your LoadBalancer.

**security_groups**
The security groups assigned to your LoadBalancer within your VPC. Must be passed either as a list or a comma-separated string.

For example, a list:

```
- security_groups:
  - secgroup-one
  - secgroup-two
```

Or as a comma-separated string:

```
- security_groups: secgroup-one,secgroup-two
```

**scheme**
The type of a LoadBalancer, internet-facing or internal. Once set, can not be modified.

**health_check**
A dict defining the health check for this ELB.

**attributes**
A dict defining the attributes to set on this ELB. Unknown keys will be silently ignored.

See the `salt.modules.boto_elb.set_attributes` function for recognized attributes.

**attributes_from_pillar**
name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

**cnames**
A list of cname dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. The cnames dict will be passed to the state as kwargs.

See the `salt.states.boto_route53` state for information about these attributes.

**alarms**:
a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB.

See the `salt.states.boto_cloudwatch_alarm` state for information about these attributes.

**alarms_from_pillar**
name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync
   Wait for an INSYNC change status from Route53.

tags
   dict of tags

instance_ids
   list of instance ids. The state will ensure that these, and ONLY these, instances are registered with the
   ELB. This is additive with instance_names.

instance_names
   list of instance names. The state will ensure that these, and ONLY these, instances are registered with
   the ELB. This is additive with instance_ids.

salt.states.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)

   Add EC2 instance(s) to an Elastic Load Balancer. Removing an instance from the instances list does not
   remove it from the ELB.

   name
      The name of the Elastic Load Balancer to add EC2 instances to.

   instances
      A list of EC2 instance IDs that this Elastic Load Balancer should distribute traffic to. This state will
      only ever append new instances to the ELB. EC2 instances already associated with this ELB will not be
      removed if they are not in the instances list.

New in version 2015.8.0.

25.20.36 salt.states.boto_elbv2

Manage AWS Application Load Balancer

New in version 2017.7.0.

   Add and remove targets from an ALB target group.

   This module uses boto3, which can be installed via package, or pip.

   This module accepts explicit alb credentials but can also utilize IAM roles assigned to the instance through Instance
   Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is neces-
   sary. More information available here.

   If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

elbv2.keyid: GKTADJGHEIQXSXMKKRBJ08H
elbv2.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
elbv2.region: us-west-2

   It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
   from pillars or minion config:

myprofile:
   keyid: GKTADJGHEIQXSXMKKRBJ08H

(continues on next page)
salt.states.boto_elbv2.create_target_group(name, protocol, port, vpc_id, region=None, key=None, keyid=None, profile=None, health_check_protocol='HTTP', health_check_port='traffic-port', health_check_path='/', health_check_interval_seconds=30, health_check_timeout_seconds=5, healthy_threshold_count=5, unhealthy_threshold_count=2, **kwargs)

New in version 2017.11.0.

Create target group if not present.

name
  (string) - The name of the target group.
protocol
  (string) - The protocol to use for routing traffic to the targets
port
  (int) - The port on which the targets receive traffic. This port is used unless you specify a port override when registering the traffic.
vpc_id
  (string) - The identifier of the virtual private cloud (VPC).
health_check_protocol
  (string) - The protocol the load balancer uses when performing health check on targets. The default is the HTTP protocol.
health_check_port
  (string) - The port the load balancer uses when performing health checks on targets. The default is 'traffic-port', which indicates the port on which each target receives traffic from the load balancer.
health_check_path
  (string) - The ping path that is the destination on the targets for health checks. The default is '/.
health_check_interval_seconds
  (integer) - The approximate amount of time, in seconds, between health checks of an individual target. The default is 30 seconds.
health_check_timeout_seconds
  (integer) - The amount of time, in seconds, during which no response from a target means a failed health check. The default is 5 seconds.
healthy_threshold_count
  (integer) - The number of consecutive health checks successes required before considering an unhealthy target healthy. The default is 5.
unhealthy_threshold_count
  (integer) - The number of consecutive health check failures required before considering a target unhealthy. The default is 2.

returns
  (bool) - True on success, False on failure.

CLI Example:

```python
create-target:
  boto_elb2.create_target_group:
    - name: myALB
    - protocol: https
```

salt.states.boto_elbv2.delete_target_group

Delete target group.

name (string) - The Amazon Resource Name (ARN) of the resource.

returns (bool) - True on success, False on failure.

CLI Example:

```yaml
check-target:
boto_elb2.delete_target_group:
  - name: myALB
    - protocol: https
    - port: 443
    - vpc_id: myVPC
```

salt.states.boto_elbv2.targets_deregistered

Remove targets to an Application Load Balancer target group.

name

The ARN of the Application Load Balancer Target Group to remove targets from.

targets

A list of target IDs or a string of a single target registered to the target group to be removed

New in version 2017.7.0.

```yaml
remove-targets:
boto_elb.target_deregistered:
  - name: arn:myloadbalancer
    targets:
      - instance-id1
      - instance-id2
```

salt.states.boto_elbv2.targets_registered

Add targets to an Application Load Balancer target group. This state will not remove targets.

name

The ARN of the Application Load Balancer Target Group to add targets to.

targets

A list of target IDs or a string of a single target that this target group should distribute traffic to.

```yaml
add-targets:
boto_elb.targets_registered:
  - name: arn:myloadbalancer
    targets:
      - instance-id1
      - instance-id2
```
25.20.37 salt.states.boto_iam

Manage IAM objects

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
delete-user:
    boto_iam.user_absent:
        - name: myuser
        - delete_keys: true
```

```
delete-keys:
    boto_iam.keys_absent:
        - access_keys:
            - 'AKIAJHTMIQ2ASDFLASDF'
            - 'PQIAJHTMIQ2ASRTLASFR'
        - user_name: myuser
```

```
create-user:
    boto_iam.user_present:
        - name: myuser
        - policies:
            mypolicy: |
            
                "Version": "2012-10-17",
                "Statement": [{
                    "Effect": "Allow",
                    "Action": "*",
                    "Resource": "*"}
                ]
            
        - password: NewPassword$$1
        - region: eu-west-1
        - keyid: 'AKIAJHTMIQ2ASDFLASDF'
        - key: 'fdkjsafkljsASSADFalkfjasdf'
```

```
create-group:
    boto_iam.group_present:
        - name: mygroup
        - users:
            - myuser
            - myuser1
        - policies:
            mypolicy: |
            
                "Version": "2012-10-17",
```

(continues on next page)
<table>

- key: 'safsdfsalsdfkjsafkljsASSADFalkfjasdf'
```

**create policy:**

```
boto_iam.policy_present:
```

```yaml
- name: myname
- region: eu-west-1
- keyid: 'AKIAJHTMIQ2ASDFLASDF'
- key: 'safsdfsalsdfkjsafkljsASSADFalkfjasdf'
```

**add-saml-provider:**

(continues on next page)
**boto_iam.saml_provider_present:**
- **name:** my_saml_provider
- **saml_metadata_document:** salt://base/files/provider.xml
- **keyid:** 'AKIAJHTMIQ2ASDFLASDF'
- **key:** 'safsdfsaldfjkjksASSADFalkfj'

**salt.states.boto_iam.account_policy**
(name=None, allow_users_to_change_password=None, hard_expiry=None, max_password_age=None, minimum_password_length=None, password_reuse_prevention=None, require_lowercase_characters=None, require_numbers=None, require_symbols=None, require_uppercase_characters=None, region=None, key=None, keyid=None, profile=None)

Change account policy.

New in version 2015.8.0.

**name** (string)
The name of the account policy

**allow_users_to_change_password** (bool)
Allows all IAM users in your account to use the AWS Management Console to change their own passwords.

**hard_expiry** (bool)
Prevents IAM users from setting a new password after their password has expired.

**max_password_age** (int)
The number of days that an IAM user password is valid.

**minimum_password_length** (int)
The minimum number of characters allowed in an IAM user password.

**password_reuse_prevention** (int)
Specifies the number of previous passwords that IAM users are prevented from reusing.

**require_lowercase_characters** (bool)
Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).

**require_numbers** (bool)
Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).

**require_symbols** (bool)
Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: ! @ # $ % ^ & * ( ) _ + - = [ ] { } | ' .

**require_uppercase_characters** (bool)
Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).

**region** (string)
Region to connect to.

**key** (string)
Secret key to be used.

**keyid** (string)
Access key to be used.

**profile** (dict)
A dict with region, key and keyid, or a pillar key (string)

**salt.states.boto_iam.group_absent**
(name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM group is absent.
name (string)
    The name of the group.
region (string)
    Region to connect to.
key (string)
    Secret key to be used.
keyid (string)
    Access key to be used.
profile (dict)
    A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None,
    managed_policies=None, users=None, path='/', region=None,
    key=None, keyid=None, profile=None, delete_policies=True)

    New in version 2015.8.0.
    Ensure the IAM group is present
    name (string)
        The name of the new group.
    path (string)
        The path for the group, defaults to '/'
    policies (dict)
        A dict of IAM group policy documents.
    policies_from_pillars (list)
        A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined
        in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The
        policies defined here will be merged with the policies defined in the policies argument. If keys conflict,
        the keys in the policies argument will override the keys defined in policies_from_pillars.
    managed_policies (list)
        A list of policy names or ARNs that should be attached to this group.
    users (list)
        A list of users to be added to the group.
    region (string)
        Region to connect to.
    key (string)
        Secret key to be used.
    keyid (string)
        Access key to be used.
    profile (dict)
        A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
    delete_policies (boolean)
        Delete or detach existing policies that are not in the given list of policies. Default value is True. If
        False is specified, existing policies will not be deleted or detached allowing manual modifications on
        the IAM group to be persistent.
salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None,
    profile=None)

    New in version 2015.8.0.
    Ensure the IAM user access_key_id is absent.
    access_key_id (list)
        A list of access key ids
    user_name (string)
        The username of the user
    region (string)
Region to connect to.

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None, save_format='{2}n{0}n{3}n{1}n')`

New in version 2015.8.0.

Ensure the IAM access keys are present.

name (string)
The name of the new user.

number (int)
Number of keys that user should have.

save_dir (string)
The directory that the key/keys will be saved. Keys are saved to a file named according to the username provided.

region (string)
Region to connect to.

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

save_format (dict)
Save format is repeated for each key. Default format is "\[2]\n[0]\n[3]\n[1]\n\" where [0] and [1] are placeholders for new key_id and key respectively, whereas [2] and [3] are 'key_id-{number}' and 'key-{number}' strings kept for compatibility.

`salt.states.boto_iam.policy_absent(name, region=None, key=None, keyid=None, profile=None)`

New in version 2015.8.0.

Ensure the IAM managed policy with the specified name is absent.

name (string)
The name of the new policy.

region (string)
Region to connect to.

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_iam.policy_present(name, policy_document, path=None, description=None, region=None, key=None, keyid=None, profile=None)`

New in version 2015.8.0.

Ensure the IAM managed policy is present.

name (string)
The name of the new policy.
policy_document (dict)
The document of the new policy

path (string)
The path in which the policy will be created. Default is '/'.

description (string)
Description

region (string)
Region to connect to.

dict)

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.saml_providerAbsent(name, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.

Ensure the SAML provider with the specified name is absent.

name (string)
The name of the SAML provider.

saml_metadata_document (string)
The xml document of the SAML provider.

region (string)
Region to connect to.

dict)

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.saml_providerPresent(name, saml_metadata_document, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.

Ensure the SAML provider with the specified name is present.

name (string)
The name of the SAML provider.

saml_metadata_document (string)
The xml document of the SAML provider.

region (string)
Region to connect to.

dict)

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.server_certAbsent(name, region=None, key=None, keyid=None, profile=None)

Deletes a server certificate.

New in version 2015.8.0.
name (string)
The name for the server certificate. Do not include the path in this value.
region (string)
The name of the region to connect to.
key (string)
The key to be used in order to connect
keyid (string)
The keyid to be used in order to connect
profile (string)
The profile that contains a dict of region, key, keyid

**salt.states.boto_iam.server_cert_present**(
  name, public_key, private_key, cert_chain=None,
  path=None, region=None, key=None, keyid=None,
  profile=None)

Create server certificate.
New in version 2015.8.0.

name (string)
The name for the server certificate. Do not include the path in this value.

public_key (string)
The contents of the public key certificate in PEM-encoded format.

private_key (string)
The contents of the private key in PEM-encoded format.

cert_chain (string)
The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.

path (string)
The path for the server certificate.

region (string)
The name of the region to connect to.

key (string)
The key to be used in order to connect

keyid (string)
The keyid to be used in order to connect

profile (string)
The profile that contains a dict of region, key, keyid

**salt.states.boto_iam.user_absent**(
  name, delete_keys=True, delete_mfa_devices=True, 
  delete_profile=True, region=None, key=None, keyid=None, 
  profile=None)

New in version 2015.8.0.

Ensure the IAM user is absent. User cannot be deleted if it has keys.

name (string)
The name of the new user.

delete_keys (bool)
Delete all keys from user.

delete_mfa_devices (bool)
Delete all mfa devices from user.

New in version 2016.3.0.

delete_profile (bool)
Delete profile from user.

New in version 2016.3.0.
region (string)
Region to connect to.

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, managed_policies=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM user is present

name (string)
The name of the new user.

policies (dict)
A dict of IAM group policy documents.

policies_from_pillars (list)
A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

managed_policies (list)
A list of managed policy names or ARNs that should be attached to this user.

password (string)
The password for the new user. Must comply with account policy.

path (string)
The path of the user. Default is '/'.

New in version 2015.8.2.

region (string)
Region to connect to.

key (string)
Secret key to be used.

keyid (string)
Access key to be used.

profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.38 salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:
It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdkldfklgjdfajkghs
  region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkgWupUjasdkldfklgjdfajkghs
    - policies_from_pillars:
      - shared_iam_bootstrap_policy
    - policies:
      - MySQSPolicy:
        Statement:
          - Action:
            - sqs:*
        Effect: Allow
        Resource:
          - arn:aws:sqs:*
        Sid: MyPolicySQS1
      - MyS3Policy:
        Statement:
          - Action:
            - s3:GetObject
        Effect: Allow
        Resource:
          - arn:aws:s3:mybucket/*
```

# Using a credentials profile from pillars

```
myrole:
  boto_iam_role.present:
    - profile: myiamprofile
```

# Passing in a credentials profile

```
myrole:
  boto_iam_role.present:
    - profile:
      key: GKTADJGHEIQSXMKKRBJ08H
      keyid: askdjghsdfjkgWupUjasdkldfklgjdfajkghs
      region: us-east-1
```

If delete_policies: False is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.
Note: When using the `profile` parameter and `region` is set outside of the profile group, region is ignored and a default region will be used.

If `region` is missing from the `profile` data set, `us-east-1` will be used as the default region.

```python
salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure the IAM role is deleted.

- **name**
  - Name of the IAM role.
- **region**
  - Region to connect to.
- **key**
  - Secret key to be used.
- **keyid**
  - Access key to be used.
- **profile**
  - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_iam_role.present(name, policy_document=None, policy_document_from_pillars=None, path=None, policies=None, policies_from_pillars=None, managed_policies=None, create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)
```

Ensure the IAM role exists.

- **name**
  - Name of the IAM role.
- **policy_document**
  - The policy that grants an entity permission to assume the role. (See [https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role](https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role))
- **policy_document_from_pillars**
  - A pillar key that contains a role policy document. The statements defined here will be appended with the policy document statements defined in the policy_document argument.
    - New in version 2017.7.0.
- **path**
  - The path to the role/instance profile. (See [https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role](https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role))
- **policies**
  - A dict of IAM role policies.
- **policies_from_pillars**
  - A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
- **managed_policies**
  - A list of (AWS or Customer) managed policies to be attached to the role.
- **create_instance_profile**
  - A boolean of whether or not to create an instance profile and associate it with this role.
- **region**
  - Region to connect to.
- **key**
  - Secret key to be used.
- **keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**delete_policies**
Deletes existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted allowing manual modifications on the IAM role to be persistent.

New in version 2015.8.0.

### 25.20.39 salt.states.boto_iot

**Manage IoT Objects**

New in version 2016.3.0.

Create and destroy IoT objects. Be aware that this interacts with Amazon’s services, and so may incur charges.

**depends**

- boto
- boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQXSXMKRRBJ08H
vpc.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQXSXMKRRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**Ensure policy exists:**

```
boto_iot.policy_present:
  - policyName: mypolicy
  - policyDocument:
    Version: "2012-10-17"
    Statement:
      Action:
        - iot:Publish
      Resource:
        - "*"
      Effect: "Allow"
  - region: us-east-1
  - keyid: GKTADJGHEIQXSXMKRRBJ08H
```

(continues on next page)
### Ensure topic rule exists:

```python
data = {
    'key': askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs,
}

Ensure topic rule exists:

```python
data = {
    'key': askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs,
}

salt.states.boto_iot.topic_rule_present(
    name=data['key'],
    sql='SELECT * FROM "iot/test"',
    description='test rule',
    ruleDisabled=False,
    actions=[
        {
            'lambda':
                functionArn: 'arn:aws:us-east-1:1234:function/functionname',
            'region': 'us-east-1',
            'keyid': GKTADJGHEIQSXMKKRBJ08H,
            'key': askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs,
        },
    ],
}
```

salt.states.boto_iot.policyAbsent(
    name=data['key'],
    policyName=data['key'],
    region=None,
    key=None,
    keyid=None,
    profile=None)
```

Ensure policy with passed properties is absent.

name
The name of the state definition.

policyName
Name of the policy.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policyAttached(
    name=data['key'],
    policyName=data['key'],
    principal=data['key'],
    region=None,
    key=None,
    keyid=None,
    profile=None)
```

Ensure policy is attached to the given principal.

name
The name of the state definition.

policyName
Name of the policy.

principal
The principal which can be a certificate ARN or a Cognito ID.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policyDetached(
    name=data['key'],
    policyName=data['key'],
    principal=data['key'],
    region=None,
    key=None,
    keyid=None,
    profile=None)
```

Ensure policy is attached to the given principal.
name
   The name of the state definition.

policyName
   Name of the policy.

principal
   The principal which can be a certificate ARN or a Cognito ID.

region
   Region to connect to.

key
   Secret key to be used.

keyid
   Access key to be used.

profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_present(name, policyName, policyDocument, region=None, key=None, keyid=None, profile=None)

Ensure policy exists.

name
   The name of the state definition

policyName
   Name of the policy.

policyDocument
   The JSON document that describes the policy. The length of the policyDocument must be a minimum length of 1, with a maximum length of 2048, excluding whitespace.

region
   Region to connect to.

key
   Secret key to be used.

keyid
   Access key to be used.

profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.thing_type_absent(name, thingTypeName, region=None, key=None, keyid=None, profile=None)

Ensure thing type with passed properties is absent.

New in version 2016.11.0.

name
   The name of the state definition.

thingTypeName
   Name of the thing type.

region
   Region to connect to.

key
   Secret key to be used.

keyid
   Access key to be used.

profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.thing_type_present(name, thingTypeName, thingTypeDescription, searchableAttributesList, region=None, key=None, keyid=None, profile=None)
Ensure thing type exists.
New in version 2016.11.0.

name
  The name of the state definition

thingTypeName
  Name of the thing type

thingTypeDescription
  Description of the thing type

searchableAttributesList
  List of string attributes that are searchable for the thing type

region
  Region to connect to.

key
  Secret key to be used.

keyid
  Access key to be used

profile
  A dict with region, key, keyid, or a pillar key (string) that contains a dict with region, key, and keyid

salt.states.boto_iot.topic_rule_absent(name, ruleName, region=None, key=None, keyid=None, profile=None)

Ensure topic rule with passed properties is absent.

name
  The name of the state definition.

ruleName
  Name of the policy.

region
  Region to connect to.

key
  Secret key to be used.

keyid
  Access key to be used.

profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.topic_rule_present(name, ruleName, sql, actions, description='', ruleDisabled=False, region=None, key=None, keyid=None, profile=None)

Ensure topic rule exists.

name
  The name of the state definition

ruleName
  Name of the rule.

sql
  The SQL statement used to query the topic.

actions
  The actions associated with the rule.

description
  The description of the rule.

ruleDisabled
  Specifies whether the rule is disabled.

region
  Region to connect to.

key
Secret key to be used.
keyid
Access key to be used.
profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.40 salt.states.boto_kinesis

Manage Kinesis Streams

New in version 2017.7.0.

Create and destroy Kinesis streams. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit Kinesis credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure Kinesis stream does not exist:
```yaml
boto_kinesis.absent:
  - name: new_stream
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Ensure Kinesis stream exists:
```yaml
boto_kinesis.present:
  - name: new_stream
    retention_hours: 168
    enhanced_monitoring: ['ALL']
    num_shards: 2
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

salt.states.boto_kinesis.absent(name, region=None, key=None, keyid=None, profile=None)
Delete the kinesis stream, if it exists.
```yaml
name (string)
Stream name
```
region (string)
Region to connect to.
key (string)
Secret key to be used.
keyid (string)
Access key to be used.
profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_kinesis.present(name, retention_hours=None, enhanced_monitoring=None, num_shards=None, do_reshard=True, region=None, key=None, keyid=None, profile=None)

Ensure the kinesis stream is properly configured and scaled.
name (string)
Stream name
retention_hours (int)
Retain data for this many hours. AWS allows minimum 24 hours, maximum 168 hours.
enhanced_monitoring (list of string)
Turn on enhanced monitoring for the specified shard-level metrics. Pass in ['ALL'] or True for all metrics, [] or False for no metrics. Turn on individual metrics by passing in a list: ['IncomingBytes', 'Outgoing-Bytes'] Note that if only some metrics are supplied, the remaining metrics will be turned off.
num_shards (int)
Reshard stream (if necessary) to this number of shards !!! Resharding is expensive! Each split or merge can take up to 30 seconds, and the reshard method balances the partition space evenly. Resharding from N to N+1 can require 2N operations. Resharding is much faster with powers of 2 (e.g. 2^N to 2^N+1) !!!
do_reshard (boolean)
If set to False, this script will NEVER reshard the stream, regardless of other input. Useful for testing.
region (string)
Region to connect to.
key (string)
Secret key to be used.
keyid (string)
Access key to be used.
profile (dict)
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.41 salt.states.boto_kms

Manage KMS keys, key policies and grants.
New in version 2015.8.0.
Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
[elb]
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMCKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfkflgjsdfjajkghs
  region: us-east-1
```

Ensure mykey key exists:

```yaml
boto_kms.key_present:
  - name: mykey
  - region: us-east-1
```

# Using a profile from pillars

Ensure mykey key exists:

```yaml
boto_kms.key_present:
  - name: mykey
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile

Ensure mykey key exists:

```yaml
boto_key.key_present:
  - name: mykey
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQXSXMCKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfkflgjsdfjajkghs
```

```python
salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None, grants=None, manage_grants=False, key_rotation=False, enabled=True, region=None, key=None, keyid=None, profile=None)
```

Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is enabled or disabled.

- **name**
  Name of the key.

- **policy**
  Key usage policy.

- **description**
  Description of the key.

- **key_usage**
  Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT, which is also the only supported option.

- **grants**
  A list of grants to apply to the key. Not currently implemented.

- **manage_grants**
  Whether or not to manage grants. False by default, which will not manage any grants.

- **key_rotation**
  Whether or not key rotation is enabled for the key. False by default.

- **enabled**
  Whether or not the key is enabled. True by default.

- **region**
  Region to connect to.

- **key**

---

25.20. state modules 3933
Secret key to be used.

```
keyid
```

Access key to be used.

```
profile
```

A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 25.20.42 salt.states.boto_lambda

**Manage Lambda Functions**

New in version 2016.3.0.

Create and destroy Lambda Functions. Be aware that this interacts with Amazon’s services, and so may incur charges.

```
depends
```

- boto
- boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**Ensure function exists:**

```
boto_lambda.function_present:
  - FunctionName: myfunction
  - Runtime: python2.7
  - Role: iam_role_name
  - Handler: entry_function
  - ZipFile: code.zip
  - S3Bucket: bucketname
  - S3Key: keyname
  - S3ObjectVersion: version
  - Description: "My Lambda Function"
  - Timeout: 3
  - MemorySize: 128
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```
salt.states.boto_lambda.\texttt{alias\_absent}(name, FunctionName, Name, region=None, key=None, keyid=None, profile=None)

Ensure alias with passed properties is absent.

- \texttt{name} The name of the state definition.
- \texttt{FunctionName} Name of the function.
- \texttt{Name} Name of the alias.
- \texttt{region} Region to connect to.
- \texttt{key} Secret key to be used.
- \texttt{keyid} Access key to be used.
- \texttt{profile} A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.\texttt{alias\_present}(name, FunctionName, Name, FunctionVersion, Description='', region=None, key=None, keyid=None, profile=None)

Ensure alias exists.

- \texttt{name} The name of the state definition.
- \texttt{FunctionName} Name of the function for which you want to create an alias.
- \texttt{Name} The name of the alias to be created.
- \texttt{FunctionVersion} Function version for which you are creating the alias.
- \texttt{Description} A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.
- \texttt{region} Region to connect to.
- \texttt{key} Secret key to be used.
- \texttt{keyid} Access key to be used.
- \texttt{profile} A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.\texttt{event\_source\_mapping\_absent}(name, EventSourceArn, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping with passed properties is absent.

- \texttt{name} The name of the state definition.
- \texttt{EventSourceArn} ARN of the event source.
- \texttt{FunctionName} Name of the lambda function.
- \texttt{region} Region to connect to.
- \texttt{key}

\section*{25.20. state modules}
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.event_source_mapping_present(name, EventSourceArn, FunctionName, StartingPosition, Enabled=True, BatchSize=100, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping exists.

name
The name of the state definition.

EventSourceArn
The Amazon Resource Name (ARN) of the Amazon Kinesis or the Amazon DynamoDB stream that is the event source.

FunctionName
The Lambda function to invoke when AWS Lambda detects an event on the stream.

You can specify an unqualified function name (for example, "Thumbnail") or you can specify Amazon Resource Name (ARN) of the function (for example, "arn:aws:lambda:us-west-2:account-id:function:ThumbNail"). AWS Lambda also allows you to specify only the account ID qualifier (for example, "account-id:Thumbnail"). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

StartingPosition
The position in the stream where AWS Lambda should start reading. (TRIM_HORIZON | LATEST)

Enabled
Indicates whether AWS Lambda should begin polling the event source. By default, Enabled is true.

BatchSize
The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records. The default is 100 records.

region
Region to connect to.

deloquent in.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.function_absent(name, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure function with passed properties is absent.

name
The name of the state definition.

FunctionName
Name of the function.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.
profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_lambda.function_present(
    name, FunctionName, Runtime, Role, Handler,
    ZipFile=None, S3Bucket=None, S3Key=None,
    S3ObjectVersion=None, Description='', Timeout=3,
    MemorySize=128, Permissions=None, RoleRetries=5,
    region=None, key=None, keyid=None, profile=None,
    VpcConfig=None, Environment=None)
```

Ensure function exists.

**name**
The name of the state definition

**FunctionName**
Name of the Function.

**Runtime**
The Runtime environment for the function. One of 'nodejs', 'java8', or 'python2.7'

**Role**
The name or ARN of the IAM role that the function assumes when it executes your function to access any other AWS resources.

**Handler**
The function within your code that Lambda calls to begin execution. For Node.js it is the module-name."export" value in your function. For Java, it can be package.classname::handler or package.class-name.

**ZipFile**
A path to a .zip file containing your deployment package. If this is specified, S3Bucket and S3Key must not be specified.

**S3Bucket**
Amazon S3 bucket name where the .zip file containing your package is stored. If this is specified, S3Key must be specified and ZipFile must NOT be specified.

**S3Key**
The Amazon S3 object (the deployment package) key name you want to upload. If this is specified, S3Key must be specified and ZipFile must NOT be specified.

**S3ObjectVersion**
The version of S3 object to use. Optional, should only be specified if S3Bucket and S3Key are specified.

**Description**
A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.

**Timeout**
The function execution time at which Lambda should terminate this function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

**MemorySize**
The amount of memory, in MB, your function is given. Lambda uses this memory size to infer the amount of CPU and memory allocated to your function. Your function use-case determines your CPU and memory requirements. For example, a database operation might need less memory compared to an image processing function. The default value is 128 MB. The value must be a multiple of 64 MB.

**VpcConfig**
If your Lambda function accesses resources in a VPC, you must provide this parameter identifying the list of security group IDs/Names and subnet IDs/Name. These must all belong to the same VPC. This is a dict of the form:

```python
VpcConfig:
    SecurityGroupNames:
    - mysecgroup1
```

(continues on next page)
If VpcConfig is provided at all, you MUST pass at least one security group and one subnet.

**Permissions**
A list of permission definitions to be added to the function's policy

**RoleRetries**
IAM Roles may take some time to propagate to all regions once created. During that time function creation may fail; this state will automatically retry this number of times. The default is 5.

**Environment**
The parent object that contains your environment's configuration settings. This is a dictionary of the form:

```python
{
    'Variables': {
        'VariableName': 'VariableValue'
    }
}
```

New in version 2017.7.0.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 25.20.43 salt.states.boto_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon's services, and so may incur charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn't match. This is due to a limitation in Amazon's launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that's in use by an autoscale group can not be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.
This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
| asg.keyid: GKTADJGHEIQSXMKKRBJ08H  
| asg.key: askdjghsdfjkgWupUjasdfklgjgsdfjajkghs |
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
| myprofile:                     
|   keyid: GKTADJGHEIQSXMKKRBJ08H  
|   key: askdjghsdfjkgWupUjasdfklgjgsdfjajkghs  
|   region: us-east-1 |
```

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

```
Ensure mylc exists:
    boto_lc.present: 
      - name: mylc 
      - image_id: ami-0b9c9f62  
      - key_name: mykey  
      - security_groups:  
        - mygroup  
      - instance_type: m1.small  
      - instance_monitoring: true  
      - block_device_mappings:  
        - '/dev/sda1':  
          - size: 20  
          - volume_type: 'io1'  
          - iops: 220  
          - delete_on_termination: true  
      - cloud_init:  
        boothooks:  
          'disable-master.sh': |  
          #!/bin/bash  
          echo "manual" > /etc/init/salt-master.override  
        scripts:  
          'run_salt.sh': |  
          #!/bin/bash  
          add-apt-repository -y ppa:saltstack/salt  
          apt-get update  
          apt-get install -y salt-minion  
          salt-call state.highstate  
      - region: us-east-1  
      - keyid: GKTADJGHEIQSXMKKRBJ08H  
      - key: askdjghsdfjkgWupUjasdfklgjgsdfjajkghs  
```

# Using a profile from pillars.
Ensure mylc exists:

(continues on next page)
**boto_lc.present:**
- **name:** mylc
- **image_id:** ami-0b9c9f62
- **profile:** myprofile

# Passing in a profile.
**Ensure mylc exists:**

```yaml
boto_lc.present:
- name: mylc
- image_id: ami-0b9c9f62
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwUpUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**salt.states.boto_lc.absent** *(name, region=None, key=None, keyid=None, profile=None)*

Ensure the named launch configuration is deleted.

- **name**
  Name of the launch configuration.
- **region**
  The region to connect to.
- **key**
  Secret key to be used.
- **keyid**
  Access key to be used.
- **profile**
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_lc.present** *(name, image_id=None, key_name=None, vpc_id=None, vpc_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, delete_on_termination=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, region=None, key=None, keyid=None, profile=None)*

Ensure the launch configuration exists.

- **name**
  Name of the launch configuration.
- **image_id**
  AMI to use for instances. AMI must exist or creation of the launch configuration will fail.
- **key_name**
  Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.
- **vpc_id**
  The VPC id where the security groups are defined. Only necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_name.
- **vpc_name**
  Name of the VPC where the security groups are defined. Only Necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_id.
- **security_groups**
  List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.
user_data
    The user data available to launched EC2 instances.

cloud_init
    A dict of cloud_init configuration. Currently supported keys: boothooks, scripts and cloud-config. Mutually exclusive with user_data.

instance_type
    The instance type. ex: m1.small.

kernel_id
    The kernel id for the instance.

ramdisk_id
    The RAM disk ID for the instance.

block_device_mappings
    A dict of block device mappings that contains a dict with volume_type, delete_on_termination, iops, size, encrypted, snapshot_id.

volume_type
    Indicates what volume type to use. Valid values are standard, io1, gp2. Default is standard.

delete_on_termination
    Whether the volume should be explicitly marked for deletion when its instance is terminated (True), or left around (False). If not provided, or None is explicitly passed, the default AWS behaviour is used, which is True for ROOT volumes of instances, and False for all others.

iops
    For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.

size
    Desired volume size (in GiB).

encrypted
    Indicates whether the volume should be encrypted. Encrypted EBS volumes must be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or an unencrypted volume from an encrypted snapshot.

instance_monitoring
    Whether instances in group are launched with detailed monitoring.

spot_price
    The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.

instance_profile_name
    The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.

ebs_optimized
    Specifies whether the instance is optimized for EBS I/O (true) or not (false).

associate_public_ip_address
    Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in a Amazon VPC.

region
    The region to connect to.

key
    Secret key to be used.

keyid
    Access key to be used.

profile
    A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
25.20.44 salt.states.boto_rds

Manage RDSs

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
[rds.keyid]  GKTADJGHEIQSXMKKRBJ08H
[rds.key]  askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid:  GKTADJGHEIQSXMKKRBJ08H
  key:  askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region:  us-east-1
```

Ensure myrds RDS exists:

```
boto_rds.present:
  - name: myrds
  - allocated_storage: 5
  - storage_type: standard
  - db_instance_class: db.t2.micro
  - engine: MySQL
  - master_username: myuser
  - master_user_password: mypass
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  - tags:
    - key: value
```

Ensure parameter group exists:

```
create-parameter-group:
  boto_rds.parameter_present:
    - name: myparametergroup
    - db_parameter_group_family: mysql5.6
    - description: "parameter group family"
    - parameters:
      - binlog_cache_size: 32768
      - binlog_checksum: CRC32
    - region: eu-west-1
```

depends

```
boto3
```
salt.states.boto_rds.absent(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tags=None, wait_for_deletion=True, timeout=180, region=None, key=None, keyid=None, profile=None)

Ensure RDS instance is absent.

**name**
Name of the RDS instance.

**skip_final_snapshot**
Whether a final db snapshot is created before the instance is deleted. If True, no snapshot is created. If False, a snapshot is created before deleting the instance.

**final_db_snapshot_identifier**
If a final snapshot is requested, this is the identifier used for that snapshot.

**tags**
A dict of tags.

**wait_for_deletion** (bool)
Wait for the RDS instance to be deleted completely before finishing the state.

**timeout** (in seconds)
The amount of time that can pass before raising an Exception.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_rds.parameter_present(name, db_parameter_group_family, description, parameters=None, apply_method='pending-reboot', tags=None, region=None, key=None, keyid=None, profile=None)

Ensure DB parameter group exists and update parameters.

**name**
The name for the parameter group.

**db_parameter_group_family**
The DB parameter group family name. A DB parameter group can be associated with one and only one DB parameter group family, and can be applied only to a DB instance running a database engine and engine version compatible with that DB parameter group family.

**description**
Parameter group description.

**parameters**
The DB parameters that need to be changed of type dictionary.

**apply_method**
The apply-immediate method can be used only for dynamic parameters; the pending-reboot method can be used with MySQL and Oracle DB instances for either dynamic or static parameters. For Microsoft SQL Server DB instances, the pending-reboot method can be used only for static parameters.

**tags**
A dict of tags.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**

---

25.20. state modules

3943
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_rds.present(name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None, storage_type=None, db_security_groups=None, vpc_security_group_ids=None, vpc_security_groups=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, db_cluster_identifier=None, tde_credential_arn=None, tde_credential_password=None, storage_encrypted=None, kms_keyid=None, backup_retention_period=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None, iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None, copy_tags_to_snapshot=None, region=None, domain=None, key=None, keyid=None, monitoring_interval=None, monitoring_role_arn=None, domain_iam_role_name=None, promotionTier=None, profile=None)
```

Ensure RDS instance exists.

**name**
Name of the RDS state definition.

**allocated_storage**
The amount of storage (in gigabytes) to be initially allocated for the database instance.

**db_instance_class**
The compute and memory capacity of the Amazon RDS DB instance.

**engine**
The name of the database engine to be used for this instance. Supported engine types are: MySQL, mariadb, oracle-se1, oracle-se, oracle-ee, sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web, postgres and aurora. For more information, please see the `engine` argument in the Boto3 RDS `create_db_instance` documentation.

**master_username**
The name of master user for the client DB instance.

**master_user_password**
The password for the master database user. Can be any printable ASCII character except "/", """, or "@".

**db_name**
The meaning of this parameter differs according to the database engine you use. See the Boto3 RDS documentation to determine the appropriate value for your configuration. [https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance](https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance)

**storage_type**
Specifies the storage type to be associated with the DB instance. Options are standard, gp2 and io1. If you specify io1, you must also include a value for the iops parameter.

**db_security_groups**
A list of DB security groups to associate with this DB instance.

**vpc_security_group_ids**
A list of EC2 VPC security group IDs to associate with this DB instance.

**vpc_security_groups**
A list of EC2 VPC security groups (IDs or Name tags) to associate with this DB instance.

**availability_zone**
The EC2 Availability Zone that the database instance will be created in.

**db_subnet_group_name**
A DB subnet group to associate with this DB instance.

**preferred_maintenance_window**
The weekly time range (in UTC) during which system maintenance can occur.

**db_parameter_group_name**
A DB parameter group to associate with this DB instance.

**db_cluster_identifier**
- If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.

**tde_credential_arn**
- The ARN from the Key Store with which the instance is associated for TDE encryption.

**tde_credential_password**
- The password to use for TDE encryption if an encryption key is not used.

**storage_encrypted**
- Specifies whether the DB instance is encrypted.

**kms_keyid**
- If storage_encrypted is true, the KMS key identifier for the encrypted DB instance.

**backup_retention_period**
- The number of days for which automated backups are retained.

**preferred_backup_window**
- The daily time range during which automated backups are created if automated backups are enabled.

**port**
- The port number on which the database accepts connections.

**multi_az**
- Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.

**engine_version**
- The version number of the database engine to use.

**auto_minor_version_upgrade**
- Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.

**license_model**
- License model information for this DB instance.

**iops**
- The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

**option_group_name**
- Indicates that the DB instance should be associated with the specified option group.

**character_set_name**
- For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.

**publicly_accessible**
- Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

**wait_status**
- Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up

**tags**
- A dict of tags.

**copy_tags_to_snapshot**
- Specifies whether tags are copied from the DB instance to snapshots of the DB instance.

**region**
- Region to connect to.

**domain**
- The identifier of the Active Directory Domain.

**key**
- AWS secret key to be used.

**keyid**
- AWS secret key ID to be used.
AWS access key to be used.

**monitoring_interval**
The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB instance.

**monitoring_role_arn**
The ARN for the IAM role that permits RDS to send Enhanced Monitoring metrics to CloudWatch Logs.

**domain_iam_role_name**
Specify the name of the IAM role to be used when making API calls to the Directory Service.

**promotion_tier**
A value that specifies the order in which an Aurora Replica is promoted to the primary instance after a failure of the existing primary instance. For more information, see Fault Tolerance for an Aurora DB Cluster.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None, db_parameter_group_name=None)
```

Ensure RDS replica exists.

```yaml
Ensure myrds replica RDS exists:
  boto_rds.create_replica:
    - name: myreplica
    - source: mydb
```

```python
class boto_rds
  subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure DB subnet group exists.

```python
class boto_rds
  subnet_group_present(name, description, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure DB subnet group exists.

**name**
The name for the DB subnet group. This value is stored as a lowercase string.

**subnet_ids**
A list of the EC2 Subnet IDs for the DB subnet group. Either subnet_ids or subnet_names must be provided.

**subnet_names**
A list of The EC2 Subnet names for the DB subnet group. Either subnet_ids or subnet_names must be provided.

**description**
Subnet group description.

**tags**
A dict of tags.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 25.20.45 `salt.states.boto_route53`

Manage Route53 records

New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or `pip`.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

mycnamerecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
    - ttl: 60
    - record_type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile: myprofile

# Passing in a profile
myarecord:
  boto_route53.present:
    - name: test.example.com.
```

(continues on next page)
- **value**: 1.1.1.1
- **zone**: example.com.
- **ttl**: 60
- **record_type**: A
- **region**: us-east-1
- **profile**:
  - **keyid**: GKTADJGHEIQSXMKKRBJ08H
  - **key**: askdjghsdfjkgWupUjasdfklkglgjsdfjajkghs

salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is deleted.

- **name**
  - Name of the record.
- **zone**
  - The zone to delete the record from.
- **record_type**
  - The record type (A, NS, MX, TXT, etc.).
- **identifier**
  - An identifier to match for deletion.
- **region**
  - The region to connect to.
- **key**
  - Secret key to be used.
- **keyid**
  - Access key to be used.
- **profile**
  - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- **wait_for_sync**
  - Wait for an INSYNC change status from Route53.
- **split_dns**
  - Route53 supports a public and private DNS zone with the same names.
- **private_zone**
  - If using split_dns, specify if this is the private zone.

salt.states.boto_route53.hosted_zone_absent(name, domain_name=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 Hostes Zone described is absent

- **name**
  - The name of the state definition.
- **domain_name**
  - The FQDN (including final period) of the zone you wish absent. If not provided, the value of name will be used.

salt.states.boto_route53.hosted_zone_present(name, domain_name=None, private_zone=False, caller_ref=None, comment='', vpc_id=None, vpc_name=None, vpc_region=None, region=None, key=None, keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes. Note that most things cannot be modified once a zone is created - it must be deleted and re-spun to update these attributes:

- **private_zone** (AWS API limitation).
• comment (the appropriate call exists in the AWS API and in boto3, but has not, as of this writing, been added to boto2).
• vpc_id (same story - we really need to rewrite this module with boto3)
• vpc_name (really just a pointer to vpc_id anyway).
• vpc_region (again, supported in boto3 but not boto2).

If you need the ability to update these attributes, please use the newer boto3_route53 module instead.

name
The name of the state definition.

domain_name
The name of the domain. This must be fully-qualified, terminating with a period. This is the name you have registered with your domain registrar. It is also the name you will delegate from your registrar to the Amazon Route 53 delegation servers returned in response to this request. Defaults to the value of name if not provided.

private_zone
Set True if creating a private hosted zone.

caller_ref
A unique string that identifies the request and that allows create_hosted_zone() calls to be retried without the risk of executing the operation twice. This helps ensure idempotency across state calls, but can cause issues if a zone is deleted and then an attempt is made to recreate it with the same caller_ref. If not provided, a unique UUID will be generated at each state run, which avoids the risk of the above (transient) error. This option is generally not needed. Maximum length of 128.

comment
Any comments you want to include about the hosted zone.

vpc_id
When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with vpc_name. Ignored when creating a non-private zone.

vpc_name
When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with vpc_id. Ignored when creating a non-private zone.

vpc_region
When creating a private hosted zone, the region of the associated VPC is required. If not provided, an effort will be made to determine it from vpc_id or vpc_name, where possible. If this fails, you'll need to provide an explicit value for this option. Ignored when creating a non-private zone.

salt.states.boto_route53.present(name, value, zone, record_type, ttl=None, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is present.

name
Name of the record.

value
Value of the record. As a special case, you can pass in:

  private:<Name tag> to have the function autodetermine the private IP
  public:<Name tag> to have the function autodetermine the public IP

zone
The zone to create the record in.

record_type
The record type (A, NS, MX, TXT, etc.)

ttl
The time to live for the record.

identifier
The unique identifier to use for this record.

region
The region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync
   Wait for an INSYNC change status from Route53 before returning success.
splitdns
   Route53 supports parallel public and private DNS zones with the same name.
private_zone
   If using split_dns, specify if this is the private zone.
salt.states.boto_route53.rr_absent(*args, **kwargs)
salt.states.boto_route53.rr_present(*args, **kwargs)

25.20.46 salt.states.boto_s3

Manage S3 Resources

New in version 2018.3.0.

Manage S3 resources. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
   keyid: GKTADJGHEIQSXMKKRBJ08H
   key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
   region: us-east-1
```

Ensure s3 object exists:

```
boto_s3.object_present:
   - name: s3-bucket/s3-key
   - source: /path/to/local/file
   - region: us-east-1
   - keyid: GKTADJGHEIQSXMKKRBJ08H
   - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
   - profile: my-profile
```

depends
   boto3
salt.states.boto_s3.object_present(name, source=None, hash_type=None, extra_args=None, extra_args_from_pillar='boto_s3_object_extra_args', region=None, key=None, keyid=None, profile=None)

Ensure object exists in S3.

name
The name of the state definition. This will be used to determine the location of the object in S3, by splitting on the first slash and using the first part as the bucket name and the remainder as the S3 key.

source
The source file to upload to S3, currently this only supports files hosted on the minion’s local file system (starting with /).

hash_type
Hash algorithm to use to check that the object contents are correct. Defaults to the value of the hash_type config option.

extra_args
A dictionary of extra arguments to use when uploading the file. Note that these are only enforced if new objects are uploaded, and not modified on existing objects. The supported args are those in the ALLOWED_UPLOAD_ARGS list at http://boto3.readthedocs.io/en/latest/reference/customizations/s3.html. However, Note that the ‘ACL’, ‘GrantFullControl’, ‘GrantRead’, ‘GrantReadACP’, and ‘GrantWriteACL’ keys are currently not supported.

extra_args_from_pillar
Name of pillar dict that contains extra arguments. Extra arguments defined for this specific state will be merged over those from the pillar.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.47 salt.states.boto_s3_bucket

Manage S3 Buckets

New in version 2016.3.0.

Create and destroy S3 buckets. Be aware that this interacts with Amazon’s services, and so may incur charges.

depends

- boto
- boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgghWupUjasdfklkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure bucket exists:
```yaml
boto_s3_bucket.present:
  - Bucket: mybucket
  - LocationConstraint: EU
  - ACL:
    - GrantRead: "uri=http://acs.amazonaws.com/groups/global/AllUsers"
  - CORSRules:
    - AllowedHeaders: []
      AllowedMethods: ["GET"]
      AllowedOrigins: ["*"]
      ExposeHeaders: []

          keyid: GKTADJGHEIQSXMKKRBJ08H
          key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

salt.states.boto_s3_bucket.absent(name, Bucket, Force=False, region=None, key=None, keyid=None, profile=None)
Ensure bucket with passed properties is absent.

name
The name of the state definition.

Bucket
Name of the bucket.

Force
Empty the bucket first if necessary - Boolean.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_s3_bucket.present(name, Bucket, LocationConstraint=None, ACL=None,
CORSRules=None, LifecycleConfiguration=None, Logging=None,
NotificationConfiguration=None, Policy=None, Replication=None,
RequestPayment=None, Tagging=None, Versioning=None,
Website=None, region=None, key=None, keyid=None,
profile=None)
```

Ensure bucket exists.

name
The name of the state definition

Bucket
Name of the bucket.

LocationConstraint
'EU'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1' |

ACL
The permissions on a bucket using access control lists (ACL).

CORSRules
The cors configuration for a bucket.

LifecycleConfiguration
Lifecycle configuration for your bucket

Logging
The logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters.

NotificationConfiguration
notifications of specified events for a bucket

Policy
Policy on the bucket

Replication
Replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB

RequestPayment
The request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download

Tagging
A dictionary of tags that should be set on the bucket

Versioning
The versioning state of the bucket
Website
The website configuration of the bucket

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.48 salt.states.boto_secgroup

Manage Security Groups

New in version 2014.7.0.

Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQXSXMKRRBJ08H
secgroup.key: askdjghsdfjkghWupUjasdflkdkflgjsdfajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQXSXMKRRBJ08H
    key: askdjghsdfjkghWupUjasdflkdkflgjsdfajkghs
    region: us-east-1
```

Ensure mysecgroup exists:

```
boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - vpc_name: myvpc
    - rules:
        - ip_protocol: tcp
          from_port: 80
          to_port: 80
          cidr_ip:
            - 10.0.0.0/8
            - 192.168.0.0/16
        - ip_protocol: tcp
          from_port: 8080
          to_port: 8090
          cidr_ip:
```

(continues on next page)
- 10.0.0.0/8
- 192.168.0.0/16

- **ip_protocol**: icmp
  - **from_port**: -1
  - **to_port**: -1
  - **source_group_name**: mysecgroup
- **ip_protocol**: tcp
  - **from_port**: 8080
  - **to_port**: 8080
  - **source_group_name**: MyOtherSecGroup
  - **source_group_name_vpc**: MyPeeredVPC

- **rules_egress**:
  - **ip_protocol**: all
    - **from_port**: -1
    - **to_port**: -1
    - **cidr_ip**:
      - 10.0.0.0/8
      - 192.168.0.0/16

- **tags**:
  - **SomeTag**: 'My Tag Value'
  - **SomeOtherTag**: 'Other Tag Value'
- **region**: us-east-1
- **keyid**: GKTADJGHEIQSXMKKRBJ08H
- **key**: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
**Ensure mysecgroup exists**:

```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile: myprofile
```

# Passing in a profile
**Ensure mysecgroup exists**:

```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile:
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    - region: us-east-1
```

**Note**: When using the **profile** parameter and **region** is set outside of the profile group, region is ignored and a default region will be used.

*If* **region** *is missing from the profile data set,* **us-east-1** *will be used as the default region.*

```
salt.states.boto_secgroup.absent(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Ensure a security group with the specified name does not exist.

**name**
Name of the security group.

**vpc_id**
The ID of the VPC to remove the security group from, if any. Exclusive with vpc_name.

**vpc_name**
The name of the VPC to remove the security group from, if any. Exclusive with vpc_name.

New in version 2016.3.0.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.

```python
salt.states.boto_secgroup.present(name, description, vpc_id=None, vpc_name=None, rules=None, rules_egress=None, delete_ingress_rules=True, delete_egress_rules=True, region=None, key=None, keyid=None, profile=None, tags=None)
```

Ensure the security group exists with the specified rules.

**name**
Name of the security group.

**description**
A description of this security group.

**vpc_id**
The ID of the VPC to create the security group in, if any. Exclusive with vpc_name.

**vpc_name**
The name of the VPC to create the security group in, if any. Exclusive with vpc_id.

New in version 2016.3.0.

New in version 2015.8.2.

**rules**
A list of ingress rule dicts. If not specified, `rules=None`, the ingress rules will be unmanaged. If set to an empty list, `[]`, then all ingress rules will be removed.

**rules_egress**
A list of egress rule dicts. If not specified, `rules_egress=None`, the egress rules will be unmanaged. If set to an empty list, `[]`, then all egress rules will be removed.

**delete_ingress_rules**
Some tools (EMR comes to mind) insist on adding rules on-the-fly, which salt will happily remove on the next run. Set this param to False to avoid deleting rules which were added outside of salt.

**delete_egress_rules**
Some tools (EMR comes to mind) insist on adding rules on-the-fly, which salt will happily remove on the next run. Set this param to False to avoid deleting rules which were added outside of salt.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.

**tags**
List of key:value pairs of tags to set on the security group
New in version 2016.3.0.

25.20.49 salt.states.boto_sns

Manage SNS Topics
Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```bash
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkgWupUjasdfdkfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```bash
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfdkfklgjsdfjajkghs
  region: us-east-1
```

```bash
mytopic:
  boto_sns.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWupUjasdfdkfklgjsdfjajkghs
```

```bash
# Using a profile from pillars
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile: mysnsprofile
```

```bash
# Passing in a profile
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgWupUjasdfdkfklgjsdfjajkghs
```

```bash
salt.states.boto_sns.absent(name, region=None, key=None, keyid=None, profile=None, unsubscribe=False)
```

Ensure the named sns topic is deleted.
name
Name of the SNS topic.
region
Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
unsubscribe
   If True, unsubscribe all subscriptions to the SNS topic before deleting the SNS topic
New in version 2016.11.0.
salt.states.boto_sns.present(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)

Ensure the SNS topic exists.
name
   Name of the SNS topic.
subscriptions
   List of SNS subscriptions.
   Each subscription is a dictionary with a protocol and endpoint key:

   

```
[
  {'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
  {'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'}
]
```

region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.50 salt.states.boto_sqs

Manage SQS Queues
New in version 2014.7.0.
Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

25.20. state modules
Salt Documentation, Release 3006.3

myprofile:
  - keyid: GKTADJGHEIQXSXMKRRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkdfkQjsdFjajkghs
  - region: us-east-1

myqueue:
  - boto_sqs.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQXSXMKRRBJ08H
    - key: askdjghsdfjkgWupUjasdfklkdfkQjsdFjajkghs
    - attributes:
      - ReceiveMessageWaitTimeSeconds: 20

# Using a profile from pillars
myqueue:
  - boto_sqs.present:
    - region: us-east-1
    - profile: mysqsprofile

# Passing in a profile
myqueue:
  - boto_sqs.present:
    - region: us-east-1
    - profile:
      - keyid: GKTADJGHEIQXSXMKRRBJ08H
      - key: askdjghsdfjkgWupUjasdfklkdfkQjsdFjajkghs

salt.states.boto_sqs.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named sqs queue is deleted.
  - name
    - Name of the SQS queue.
  - region
    - Region to connect to.
  - key
    - Secret key to be used.
  - keyid
    - Access key to be used.
  - profile
    - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_sqs.present(name, attributes=None, region=None, key=None, keyid=None, profile=None)

Ensure the SQS queue exists.
  - name
    - Name of the SQS queue.
  - attributes
    - A dict of key/value SQS attributes.
  - region
    - Region to connect to.
  - key
    - Secret key to be used.
  - keyid
    - Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

25.20.51 salt.states.boto_vpc

Manage VPCs

New in version 2015.8.0.

  depends
    • boto >= 2.8.0
    • boto3 >= 1.2.6

Create and destroy VPCs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
[vpc.keyid]: GKTADJGHEIQSXMKKRBJ08H
[vpc.key]: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```
aws:
  region:
    us-east-1:
      profile:
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
        region: us-east-1
```

Ensure VPC exists:
```
boto_vpc.present:
  - name: myvpc
  - cidr_block: 10.10.11.0/24
  - dns_hostnames: True
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

Ensure subnet exists:
```
boto_vpc.subnet_present:
  - name: mysubnet
  - vpc_id: vpc-123456
```
(continues on next page)
- cidr_block: 10.0.0.0/16
- region: us-east-1
- profile: myprofile

{% set profile = salt['pillar.get']('aws:region:us-east-1:profile') %}

Ensure internet gateway exists:
```yaml
- name: myigw
- vpc_name: myvpc
- profile: {{ profile }}
```

Ensure route table exists:
```yaml
- name: my_route_table
- vpc_id: vpc-123456
- routes:
  - destination_cidr_block: 0.0.0.0/0
    instance_id: i-123456
  - subnet_names:
    - subnet1
    - subnet2
- region: us-east-1
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

New in version 2016.11.0.

Request, accept and delete VPC peering connections. VPC peering connections can be named allowing the name to
be used throughout the state file. Following example shows how to request and accept a VPC peering connection.

```yaml
accept the vpc peering connection:
  boto_vpc.accept_vpc_peering_connection:
    - conn_name: salt_vpc_peering
    - region: us-west-2
    - require:
      - boto_vpc: request a vpc peering connection

request a vpc peering connection:
  boto_vpc.request_vpc_peering_connection:
    - requester_vpc_id: vpc-4a3d522e
    - peer_vpc_id: vpc-ae81e9ca
    - region: us-west-2
    - conn_name: salt_vpc_peering
```

VPC peering connections need not be named. In this case the VPC peering connection ID should be used in the state
file.

```yaml
accept the vpc peering connection:
  boto_vpc.accept_vpc_peering_connection:
    - conn_id: pcx-1873c371
    - region: us-west-2
```

VPC peering connections can be deleted, as shown below.
**delete a named vpc peering connection:**
```
boto_vpc.delete_vpc_peering_connection:
- conn_name: salt_vpc_peering
```
Delete also accepts a VPC peering connection id.

**delete a vpc peering connection by id:**
```
boto_vpc.delete_vpc_peering_connection:
- conn_id: pcx-1873c371
```

salt.states.boto_vpc.absent
```
(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Ensure VPC with passed properties is absent.
```
name
  Name of the VPC.
```
```
tags
  A list of tags. All tags must match.
```
```
region
  Region to connect to.
```
```
key
  Secret key to be used.
```
```
keyid
  Access key to be used.
```
```
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```

salt.states.boto_vpc.accept_vpc_peering_connection
```
(name=None, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)
```
Accept a VPC pending requested peering connection between two VPCs.
```
name
  Name of this state
```
```
conn_id
  The connection ID to accept. Exclusive with conn_name. String type.
```
```
conn_name
  The name of the VPC peering connection to accept. Exclusive with conn_id. String type.
```
```
region
  Region to connect to.
```
```
key
  Secret key to be used.
```
```
keyid
  Access key to be used.
```
```
profile
  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```
New in version 2016.11.0.

Example:
```
boto_vpc.accept_vpc_peering_connection:
- conn_name: salt_peering_connection
```
```
# usage with vpc peering connection id and region
boto_vpc.accept_vpc_peering_connection:
- conn_id: pbx-1873d472
- region: us-west-2
```

25.20. state modules 3963
salt.states.boto_vpc.delete_vpc_peering_connection(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)

name
   Name of the state
conn_id
   ID of the peering connection to delete. Exclusive with conn_name.
conn_name
   The name of the peering connection to delete. Exclusive with conn_id.
region
   Region to connect to.
key
   Secret key to be used.
keyid
   Access key to be used.
profile
   A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

Example:

```
delete a vpc peering connection:
  boto_vpc.delete_vpc_peering_connection:
    - region: us-west-2
    - conn_id: pcx-4613b12e
```

Connection name can be specified (instead of ID). Specifying both conn_name and conn_id will result in an error.

```
delete a vpc peering connection:
  boto_vpc.delete_vpc_peering_connection:
    - conn_name: salt_vpc_peering
```

salt.states.boto_vpc.dhcp_options_absent(name=None, dhcp_options_id=None, region=None, key=None, keyid=None, profile=None)

Ensure a set of DHCP options with the given settings exist.

name
   (string) Name of the DHCP options set.
dhcp_options_id
   (string) Id of the DHCP options set.
region
   (string) Region to connect to.
key
   (string) Secret key to be used.
keyid
   (string) Access key to be used.
profile
   (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.
salt.states.boto_vpc.dhcp_options_present(name, dhcp_options_id=None, vpc_name=None, vpc_id=None, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a set of DHCP options with the given settings exist. Note that the current implementation only SETS values during option set creation. It is unable to update option sets in place, and thus merely verifies the set exists via the given name and/or dhcp_options_id param.

name

(string) Name of the DHCP options.

vpc_name

(string) Name of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.

vpc_id

(string) Id of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.

domain_name

(string) Domain name to be associated with this option set.

domain_name_servers

(list of strings) The IP address(es) of up to four domain name servers.

ntp_servers

(list of strings) The IP address(es) of up to four desired NTP servers.

netbios_name_servers

(list of strings) The IP address(es) of up to four NetBIOS name servers.

netbios_node_type

(string) The NetBIOS node type (1, 2, 4, or 8). For more information about the allowed values, see RFC 2132. The recommended is 2 at this time (broadcast and multicast are currently not supported).

tags

(dict of key:value pairs) A set of tags to be added.

region

(string) Region to connect to.

key

(string) Secret key to be used.

keyid

(string) Access key to be used.

profile

(various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.

salt.states.boto_vpc.internet_gateway_absent(name, detach=False, region=None, key=None, keyid=None, profile=None)

Ensure the named internet gateway is absent.

name

Name of the internet gateway.

detach

First detach the internet gateway from a VPC, if attached.

region

Region to connect to.

key

Secret key to be used.

keyid

Access key to be used.
Ensure an internet gateway exists.

**name**
Name of the internet gateway.

**vpc_name**
Name of the VPC to which the internet gateway should be attached.

**vpc_id**
Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id may be provided.

**tags**
A list of tags.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure the nat gateway in the named subnet is absent.

This function requires boto3.

New in version 2016.11.0.

**name**
Name of the state.

**subnet_name**
Name of the subnet within which the nat gateway should exist

**subnet_id**
Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**wait_for_delete_retries**
NAT gateway may take some time to be go into deleted or failed state. During the deletion process, subsequent release of elastic IPs may fail; this state will automatically retry this number of times to ensure the NAT gateway is in deleted or failed state before proceeding. Default is set to 0 for backward compatibility.

Ensure the nat gateway in the named subnet is present.

This function requires boto3.

New in version 2016.11.0.

**name**
Name of the state.

**subnet_name**
Name of the subnet within which the nat gateway should exist

**subnet_id**
Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**allocation_id**
Id of the Elastic IP to be associated with the NAT gateway.

Ensure the nat gateway in the named subnet is present.

This function requires boto3.

New in version 2016.11.0.

**name**
Name of the state.

**subnet_name**
Name of the subnet within which the nat gateway should exist

**subnet_id**
Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**allocation_id**
Id of the Elastic IP to be associated with the NAT gateway.
Ensure a nat gateway exists within the specified subnet

This function requires boto3.

New in version 2016.11.0.

Example:

```yaml
boto_vpc.nat_gateway_present:
  - subnet_name: my-subnet
```

**name**
Name of the state

**subnet_name**
Name of the subnet within which the nat gateway should exist

**subnet_id**
Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.

**allocation_id**
If specified, the elastic IP address referenced by the ID is associated with the gateway. Otherwise, a new allocation_id is created and used.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.present(
    name, cidr_block, instance_tenancy=None, dns_support=None,
    dns_hostnames=None, tags=None, region=None, key=None, keyid=None,
    profile=None)
```

Ensure VPC exists.

**name**
Name of the VPC.

**cidr_block**
The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.

**instance_tenancy**
Instances launched in this VPC will be single-tenant or dedicated hardware.

**dns_support**
Indicates whether the DNS resolution is supported for the VPC.

**dns_hostnames**
Indicates whether the instances launched in the VPC get DNS hostnames.

**tags**
A list of tags.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.request_vpc_peering_connection(name, requester_vpc_id=None, requester_vpc_name=None, peer_vpc_id=None, peer_vpc_name=None, conn_name=None, peer_owner_id=None, peer_region=None, region=None, key=None, keyid=None, profile=None)

name
Name of the state

requester_vpc_id
ID of the requesting VPC. Exclusive with requester_vpc_name. String type.

requester_vpc_name
Name tag of the requesting VPC. Exclusive with requester_vpc_id. String type.

peer_vpc_id
ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name. String type.

peer_vpc_name
Name tag of the VPC to create VPC peering connection with. This can only be a VPC the same account and region. Exclusive with peer_vpc_id. String type.

conn_name
The (optional) name to use for this VPC peering connection. String type.

peer_owner_id
ID of the owner of the peer VPC. String type. If this isn’t supplied AWS uses your account ID. Required if peering to a different account.

peer_region
Region of peer VPC. For inter-region vpc peering connections. Not required for intra-region peering connections.

New in version 3005.

region
Region to connect to.

key
Secret key to be used.

keyid
Access key to be used.

profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid. New in version 2016.11.0.

Example:

```yaml
request a vpc peering connection:
  boto_vpc.request_vpc_peering_connection:
    - requester_vpc_id: vpc-4b3522e
    - peer_vpc_id: vpc-ae83f9ca
    - conn_name: salt_peering_connection
```

salt.states.boto_vpc.route_table_absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named route table is absent.

name
Name of the route table.

region
Region to connect to.
key
Secret key to be used.
keyid
Access key to be used.
profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.route_table_present(name, vpc_name=None, vpc_id=None, routes=None, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure route table with routes exists and is associated to a VPC.
This function requires boto3 to be installed if nat gateways are specified.
Example:

```yaml
destination_cidr_block: 0.0.0.0/0
internet_gateway_name: InternetGateway
destination_cidr_block: 10.10.11.0/24
instance_id: i-123456
destination_cidr_block: 10.10.12.0/24
interface_id:eni-123456
destination_cidr_block: 10.10.13.0/24
instance_name: mygatewayserver
```

name
Name of the route table.
vpc_name
Name of the VPC with which the route table should be associated.
vpc_id
Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.
routes
A list of routes. Each route has a cidr and a target.
subnet_ids
A list of subnet ids to associate
subnet_names
A list of subnet names to associate
tags
A list of tags.
region
Region to connect to.
key
Secret key to be used.
keyid
Access key to be used.
profile
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.subnet_absent(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)

Ensure subnet with passed properties is absent.

- name: Name of the subnet.
- region: Region to connect to.
- key: Secret key to be used.
- keyid: Access key to be used.
- profile: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_present(name, cidr_block, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None, route_table_id=None, route_table_name=None, auto_assign_public_ipv4=False)

Ensure a subnet exists.

- name: Name of the subnet.
- cidr_block: The range if IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
- vpc_name: Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
- vpc_id: Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
- availability_zone: AZ in which the subnet should be placed.
- tags: A list of tags.
- route_table_id: A route table ID to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.
- route_table_name: A route table name to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.
- New in version 2016.11.0.
- auto_assign_public_ipv4: New in version 2016.11.0.
- profile: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.vpc_peering_connection_absent(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)

A route table name to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.
salt.states.boto_vpc.vpc_peering_connection_present(name, requester_vpc_id=None,
requester_vpc_name=None,
peer_vpc_id=None,
peer_vpc_name=None,
conn_name=None,
peer_owner_id=None,
peer_region=None,
region=None,
key=None, keyid=None, profile=None)

**name**
Name of the state

**requester_vpc_id**
ID of the requesting VPC. Exclusive with requester_vpc_name.

**requester_vpc_name**
Name tag of the requesting VPC. Exclusive with requester_vpc_id.

**peer_vpc_id**
ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name.

**peer_vpc_name**
Name tag of the VPC to create VPC peering connection with. This can only be a VPC in the same account, else resolving it into a vpc ID will fail. Exclusive with peer_vpc_id.

**conn_name**
The name to use for this VPC peering connection.

**peer_owner_id**
ID of the owner of the peer VPC. Defaults to your account ID, so a value is required if peering with a VPC in a different account.

**peer_region**
Region of peer VPC. For inter-region vpc peering connections. Not required for intra-region peering connections.

New in version 3005.

**region**
Region to connect to.

**key**
Secret key to be used.

**keyid**
Access key to be used.

**profile**
A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid. New in version 2016.11.0.

Example:

```bash
twixt local vpc and the other guys:
boto_vpc.vpc_peering_connection_present:
  - requester_vpc_name: my_local_vpc
  - peer_vpc_name: some_other_guys_vpc
  - conn_name: peering_from_here_to_there
  - peer_owner_id: 012345654321
```
25.20.52 salt.states.bower

Installation of Bower Packages

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:
```
npm:
  pkg.installed

git:
  pkg.installed

bower:
  npm.installed
  require:
    - pkg: npm
    - pkg: git

underscore:
  bower.installed:
    - dir: /path/to/project
    - require:
      - npm: bower
```

salt.states.bower.bootstrap(name, user=None)

Bootstrap a frontend distribution.

Will execute 'bower install' on the specified directory.

user
  The user to run Bower with

salt.states.bower.installed(name, dir, pkgs=None, user=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

```
underscore:
  bower.installed:
    - dir: /path/to/project
    - user: someuser

jquery#2.0:
  bower.installed:
    - dir: /path/to/project
```

name
  The package to install

dir
  The target directory in which to install the package

pkgs
  A list of packages to install with a single Bower invocation; specifying this argument will ignore the name argument

user
  The user to run Bower with
env
A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

`salt.states.bower.pruned(name, user=None, env=None)`
New in version 2017.7.0.
Cleans up local bower_components directory.
Will execute 'bower prune' on the specified directory (param: name)
user
The user to run Bower with

`salt.states.bower.removed(name, dir, user=None)`
Verify that the given package is not installed.
dir
The target directory in which to install the package
user
The user to run Bower with

25.20.53 `salt.states.btrfs`
Manage BTRFS file systems.

maintainer
Alberto Planas <aplanas@suse.com>
maturity
new
depends
None
platform
Linux

`salt.states.btrfs.properties(name, device, use_default=False, __dest=None, **properties)`
Makes sure that a list of properties are set in a subvolume, file or device.
name
Name of the object to change
device
Device where the object lives, if None, the device will be in name
use_default
If True, this subvolume will be resolved to the default subvolume assigned during the create operation
properties
Dictionary of properties
Valid properties are ‘ro’, ‘label’ or ‘compression’. Check the documentation to see where those properties are valid for each object.

`salt.states.btrfs.subvolume_created(name, device, qgroupids=None, set_default=False, copy_on_write=True, force_set_default=True, __dest=None)`
Makes sure that a btrfs subvolume is present.
name
Name of the subvolume to add
device
Device where to create the subvolume
### qgroupids
Add the newly created subvolume to a qgroup. This parameter is a list

**set_default**
If True, this new subvolume will be set as default when mounted, unless subvol option in mount is used

**copy_on_write**
If false, set the subvolume with chattr +C

**force_set_default**
If false and the subvolume is already present, it will not force it as default if set_default is True

### salt.states.btrfs.subvolume_deleted
Makes sure that a btrfs subvolume is removed.

- **name**
  Name of the subvolume to remove
- **device**
  Device where to remove the subvolume
- **commit**
  Wait until the transaction is over

#### 25.20.54 salt.states.cabal

**Installation of Cabal Packages**

New in version 2015.8.0.

These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides cabal (cabal-install in case of Debian based distributions). Example:

```yaml
cabal-install:
pkg.installed
```

**ShellCheck**

- **cabal.installed**
  
  * require: - pkg: cabal-install

### salt.states.cabal.installed
Verify that the given package is installed and is at the correct version (if specified).

```yaml
ShellCheck-0.3.5:
cabal:
  - installed:
```

- **name**
  The package to install
- **user**
  The user to run cabal install with
- **install_global**
  Install package globally instead of locally
- **env**
  A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.
salt.states.cabal.removed(name, user=None, env=None)

Verify that given package is not installed.

25.20.55 salt.states.ceph

Manage ceph with salt.

New in version 2016.11.0.

salt.states.ceph.quorum(name, **kwargs)

Quorum state

This state checks the mon daemons are in quorum. It does not alter the cluster but can be used in formula as a dependency for many cluster operations.

Example usage in sls file:

```yaml
quorum:
  sesceph.quorum:
    - require:
      - sesceph: mon_running
```

25.20.56 salt.states.chef

Execute Chef client runs

Run chef-client or chef-solo

```
my-chef-run:
  chef.client:
    - override-runlist: 'demo1,demo2'
    - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev
```

salt.states.chef.client(name, **kwargs)

name

Unique identifier for the state. Does not affect the Chef run.

server

The chef server URL

client_key

Set the client key file location

config

The configuration file to use

config-file-jail

Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).
### salt.states.chef

- **name**: Unique identifier for the state. Does not affect the Chef run.
- **config**: The configuration file to use
- **environment**: Set the Chef Environment on the node
- **group**: Group to set privilege to
- **json-attributes**: Load attributes from a JSON file or URL
- **log_level**: Set the log level (debug, info, warn, error, fatal)
- **logfile**: Set the log file location
- **node-name**: The node name for this client
- **override-runlist**: Replace current run list with specified items for a single run
- **pid**: Set the PID file location, defaults to /tmp/chef-client.pid
- **run-lock-timeout**: Set maximum duration to wait for another client run to finish, default is indefinitely.
- **runlist**: Permanently replace current run list with specified items
- **user**: User to set privilege to
- **validation_key**: Set the validation key file location, used for registering new clients

#### salt.states.chef.solo(name, **kwargs)

- **name**: Unique identifier for the state. Does not affect the Chef run.
- **config**: The configuration file to use
- **environment**: Set the Chef Environment on the node
- **group**: Group to set privilege to
- **json-attributes**: Load attributes from a JSON file or URL
- **log_level**: Set the log level (debug, info, warn, error, fatal)
- **logfile**: Set the log file location
- **node-name**: The node name for this client
- **override-runlist**: Replace current run list with specified items for a single run
- **recipe-url**: Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
- **run-lock-timeout**: Set maximum duration to wait for another client run to finish, default is indefinitely.
- **user**: User to set privilege to
25.20.57 salt.states.chocolatey

Manage Windows Packages using Chocolatey . versionadded:: 2016.3.0

Note: Chocolatey pulls data from the Chocolatey internet database to determine current versions, find available versions, etc. This is normally a slow operation and may be optimized by specifying a local, smaller chocolatey repo.

salt.states.chocolatey.installed(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None, allow_multiple=False, execution_timeout=None)

Installs a package if not already installed

Parameters

- name (str) -- The name of the package to be installed. Required.
- version (str) -- Install a specific version of the package. Defaults to the latest version. If the version is different to the one installed, then the specified version will be installed. Default is None.
- source (str) -- Chocolatey repository (directory, share or remote URL, feed). None defaults to the official Chocolatey feed. Default is None.
- force (bool) -- Reinstall the current version of an existing package. Do not use with allow_multiple. Default is False.
- pre_versions (bool) -- Include pre-release packages. Default is False.
- install_args (str) -- Install arguments you want to pass to the installation process, i.e. product key or feature list. Default is None.
- override_args (bool) -- Set to True to override the original install arguments (for the native installer) in the package and use your own. When this is set to False, install_args will be appended to the end of the default arguments. Default is False.
- force_x86 (bool) -- Force x86 (32bit) installation on 64bit systems. Default is False.
- package_args (str) -- Arguments you want to pass to the package. Default is None.
- allow_multiple (bool) -- Allow multiple versions of the package to be installed. Do not use with force. Does not work with all packages. Default is False.

New in version 2017.7.0.

- execution_timeout (str) -- Chocolatey execution timeout value you want to pass to the installation process. Default is None.

Example:

```
install_some_package:
    chocolatey.installed:
        - name: packagename
        - version: '12.04'
        - source: 'mychocolatey/source'
        - force: True
```

salt.states.chocolatey.source_present(name, source_location, username=None, password=None, force=False, priority=None)

Adds a Chocolatey source if not already present.

Parameters

- name (str) -- The name of the source to be added as a chocolatey repository.
- source (str) -- Location of the source you want to work with.
- **username** *(str)* -- The username for a chocolatey source that needs authentication credentials.
- **password** *(str)* -- The password for a chocolatey source that needs authentication credentials.
- **force** *(bool)* -- Salt will not modify an existing repository with the same name. Set this option to `True` to update an existing repository.
- **priority** *(int)* -- The priority order of this source as compared to other sources. Lower is better. Defaults to 0 (no priority). All priorities above 0 will be evaluated first, then zero-based values will be evaluated in config file order.

**Example:**

```yaml
add_some_source:
  chocolatey.source_present:
    - name: reponame
    - source: https://repo.exemple.com
    - username: myuser
    - password: mypassword
    - priority: 100
```

**salt.states.chocolatey.uninstalled** *(name, version=None, uninstall_args=None, override_args=False)*

Uninstalls a chocolatey package

**Parameters**

- **name** *(str)* -- The name of the package to be uninstalled. Required.
- **version** *(str)* -- Uninstalls a specific version of the package. Defaults to the latest version installed.
- **uninstall_args** *(str)* -- A list of uninstall arguments you want to pass to the uninstallation process. i.e. product key or feature list.
- **override_args** *(str)* -- Set to `True` if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to `False`, uninstall_args will be appended to the end of the default arguments.

**Example:**

```yaml
remove_my_package:
  chocolatey.uninstalled:
    - name: mypackage
    - version: '21.5'
```

**salt.states.chocolatey.upgraded** *(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None)*

Upgrades a chocolatey package. Will install the package if not installed.

New in version 2018.3.0.

**Parameters**

- **name** *(str)* -- The name of the package to be installed. Required.
- **version** *(str)* -- Install a specific version of the package. Defaults to latest version. If the version is greater than the one installed then the specified version will be installed. Default is `None`.
- **source** *(str)* -- Chocolatey repository (directory, share or remote URL, feed). Defaults to the official Chocolatey feed. Default is `None`.
- **force** *(bool)* -- True will reinstall an existing package with the same version. Default is `False`.
- **pre_versions** *(bool)* -- True will include pre-release packages. Default is `False`. 

• **install_args** *(str)* -- Install arguments you want to pass to the installation process, i.e product key or feature list. Default is *None*.

• **override_args** *(bool)* -- *True* will override the original install arguments (for the native installer) in the package and use those specified in **install_args**. *False* will append **install_args** to the end of the default arguments. Default is *False*.

• **force_x86** *(bool)* -- *True* forces 32bit installation on 64bit systems. Default is *False*.

• **package_args** *(str)* -- Arguments you want to pass to the package. Default is *None*.

Example:

```
upgrade_some_package:
    chocolatey.upgraded:
        - name: packagename
        - version: '12.04'
        - source: 'mychocolatey/source'
```

### 25.20.58 `salt.states.chronos_job`

Configure Chronos jobs via a salt proxy.

```
my_job:
    chronos_job.config:
        config:
            schedule: "R//PT2S"
            command: "echo 'hi'"
            owner: "me@example.com"
```

New in version 2015.8.2.

**salt.states.chronos_job.absent**(name)**

Ensure that the chronos job with the given name is not present.

**Parameters**

- **name** -- The app name

**Returns**

A standard Salt changes dictionary

**salt.states.chronos_job.config**(name, config)**

Ensure that the chronos job with the given name is present and is configured to match the given config values.

**Parameters**

- **name** -- The job name
- **config** -- The configuration to apply (dict)

**Returns**

A standard Salt changes dictionary
25.20.59  salt.states.cimc

A state module to manage Cisco UCS chassis devices.

codeauthor
Spencer Ervin <spencer_ervin@hotmail.com>
maturity
new
depends
none
platform
unix

About

This state module was designed to handle connections to a Cisco Unified Computing System (UCS) chassis. This module relies on the CIMC proxy module to interface with the device.

See also:

CIMC Proxy Module

salt.states.cimc.hostname(name, hostname=None)

Ensures that the hostname is set to the specified value.

New in version 2019.2.0.

name: The name of the module function to execute.
hostname(str): The hostname of the server.

SLS Example:

```
set_name:
  cimc.hostname:
    - hostname: foobar
```

salt.states.cimc.logging_levels(name, remote=None, local=None)

Ensures that the logging levels are set on the device. The logging levels must match the following options: emergency, alert, critical, error, warning, notice, informational, debug.

New in version 2019.2.0.

name: The name of the module function to execute.
remote(str): The logging level for SYSLOG logs.
local(str): The logging level for the local device.

SLS Example:

```
logging_levels:
  cimc.logging_levels:
    - remote: informational
    - local: notice
```
salt.states.cimc.ntp(name, servers)

Ensures that the NTP servers are configured. Servers are provided as an individual string or list format. Only four NTP servers will be reviewed. Any entries past four will be ignored.

name: The name of the module function to execute.

servers(str, list): The IP address or FQDN of the NTP servers.

SLS Example:

```
ntp_configuration_list:
  cimc.ntp:
    - servers:
      - foo.bar.com
      - 10.10.10.10

ntp_configuration_str:
  cimc.ntp:
    - servers: foo.bar.com
```

salt.states.cimc.power_configuration(name, policy=None, delayType=None, delayValue=None)

Ensures that the power configuration is configured on the system. This is only available on some C-Series servers.

New in version 2019.2.0.

name: The name of the module function to execute.

policy(str): The action to be taken when chassis power is restored after an unexpected power loss. This can be one of the following:
  - reset: The server is allowed to boot up normally when power is restored. The server can restart immediately or, optionally, after a fixed or random delay.
  - stay-off: The server remains off until it is manually restarted.
  - last-state: The server restarts and the system attempts to restore any processes that were running before power was lost.

delayType(str): If the selected policy is reset, the restart can be delayed with this option. This can be one of the following:
  - fixed: The server restarts after a fixed delay.
  - random: The server restarts after a random delay.

delayValue(int): If a fixed delay is selected, once chassis power is restored and the Cisco IMC has finished rebooting, the system waits for the specified number of seconds before restarting the server. Enter an integer between 0 and 240.

SLS Example:

```
reset_power:
  cimc.power_configuration:
    - policy: reset
    - delayType: fixed
    - delayValue: 0

power_off:
  cimc.power_configuration:
    - policy: stay-off
```
salt.states.cimc.syslog(name, primary=None, secondary=None)

Ensures that the syslog servers are set to the specified values. A value of None will be ignored.

name: The name of the module function to execute.
primary(str): The IP address or FQDN of the primary syslog server.
secondary(str): The IP address or FQDN of the secondary syslog server.

SLS Example:

```
syslog_configuration:
cimc.syslog:
  - primary: 10.10.10.10
  - secondary: foo.bar.com
```

salt.states.cimc.user(name, id='', user='', priv='', password='', status='active')

Ensures that a user is configured on the device. Due to being unable to verify the user password. This is a forced operation.

New in version 2019.2.0.

name: The name of the module function to execute.
id(int): The user ID slot on the device.
user(str): The username of the user.
priv(str): The privilege level of the user.
password(str): The password of the user.
status(str): The status of the user. Can be either active or inactive.

SLS Example:

```
user_configuration:
cimc.user:
  - id: 11
  - user: foo
  - priv: admin
  - password: mypassword
  - status: active
```

25.20.60 salt.states.cisconso

State module for Cisco NSO Proxy minions

New in version 2016.11.0.

For documentation on setting up the cisconso proxy minion look in the documentation for salt.proxy.cisconso.

salt.states.cisconso.value_present(name, datastore, path, config)

Ensure a specific value exists at a given path

Parameters

- name (str) -- The name for this rule
- datastore (DatastoreType (str enum)) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
• **path** (list, str OR tuple) -- The device path to set the value at, a list of element names in order, / separated
• **config** (dict) -- The new value at the given path

Examples:

```python
def enable_pap_auth:
    cisconso.config_present:
        - name: enable_pap_auth
        - datastore: running
        - path: devices/device/ex0/config/sys/interfaces/serial/ppp0/
          authentication
        - config:
            authentication:
                method: pap
                "list-name": foobar
```

### 25.20.61 salt.states.cloud

**Using states instead of maps to deploy clouds**

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```python
my-ec2-instance:
    cloud.profile:
        my-ec2-config
```

salt.states.cloud.absent(*name*, *onlyif=None*, *unless=None*)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

- **name**
  - The name of the instance to destroy
- **onlyif**
  - Do run the state only if is unless succeed
- **unless**
  - Do not run the state at least unless succeed

salt.states.cloud.present(*name*, *cloud_provider*, *onlyif=None*, *unless=None*, *opts=None*, **kwargs)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

- **name**
  - The name of the instance to create
- **cloud_provider**
  - The name of the cloud provider to use
- **onlyif**
  - Do run the state only if is unless succeed
- **unless**
  - Do not run the state at least unless succeed
opts
Any extra opts that need to be used

salt.states.cloud.profile(name, profile, onlyif=None, unless=None, opts=None, **kwargs)
Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used
to create an instance using a profile, this state will not verify the state of any of those arguments on an
existing instance. Stateful properties of an instance should be configured using their own individual state
(i.e., cloud.tagged, cloud.untagged, etc).

name
The name of the instance to create

profile
The name of the cloud profile to use

onlyif
Do run the state only if succeed

unless
Do not run the state at least unless succeed

kwargs
Any profile override or addition

opts
Any extra opts that need to be used

salt.states.cloud.volume_absent(name, provider=None, **kwargs)
Check that a block volume exists.

salt.states.cloud.volume_attached(name, server_name, provider=None, **kwargs)
Check if a block volume is attached.

salt.states.cloud.volume_detached(name, server_name=None, provider=None, **kwargs)
Check if a block volume is attached.

Returns True if server or Volume do not exist.

salt.states.cloud.volume_present(name, provider=None, **kwargs)
Check that a block volume exists.

25.20.62 salt.states.cmd

Execution of arbitrary commands

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under
certain circumstances.

A simple example to execute a command:

```
# Store the current date in a file
'date > /tmp/salt-run':
    cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```
'>' /var/log/messages/':
    cmd.run:
        - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```
Only run if the file specified by creates does not exist, in this case touch /tmp/foo if it does not exist:

```
touch /tmp/foo:
    cmd.run:
      - creates: /tmp/foo
```

creates also accepts a list of files, in which case this state will run if any of the files do not exist:

```
"echo 'foo' | tee /tmp/bar > /tmp/baz":
    cmd.run:
      - creates:
        - /tmp/bar
        - /tmp/baz
```

**Note:** The creates option was added to the cmd state in version 2014.7.0, and made a global requisite in 3001.

Sometimes when running a command that starts up a daemon, the init script doesn’t return properly which causes Salt to wait indefinitely for a response. In situations like this try the following:

```
run_installer:
    cmd.run:
      - name: /tmp/installer.bin > /dev/null 2>&1
```

Salt determines whether the cmd state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt's state system. Therefore, by default, the cmd state assumes that any command execution results in a changed state.

This means that if a cmd state is watched by another state then the state that's watching will always be executed due to the changed state in the cmd state.

**Using the "Stateful" Argument**

Many state functions in this module now also accept a stateful argument. If stateful is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. **If there's nothing in the stdout of the command, then assume no changes.** Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of '=').

2. **If it's JSON then it must be a JSON object (e.g., {})**. If it's key=value pairs then quoting may be used to include spaces. (Python's shlex module is used to parse the key=value string)

Two special keys or attributes are recognized in the output:

```
changed: bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)
comment: str  (i.e., any string)
```
So, only if changed is True then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. If there's a comment then it will be used as the comment of the state.

Here's an example of how one might write a shell script for use with a stateful command:

```bash
#!/bin/bash
#
echo "Working hard..."
# writing the state line
echo # an empty line here so the next line will be the last.
echo "changed=yes comment='something has changed' whatever=123"
```

And an example SLS file using this module:

```yaml
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful: True

Run only if myscript changed something:
  cmd.run:
    - name: echo hello
    - cwd: /
    - onchanges:
      - cmd: Run myscript

Note that if the second cmd.run state also specifies stateful: True it can then be watched by some other states as well.

4. The stateful argument can optionally include a test_name parameter.

This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.

New in version 2015.2.0.

```yaml
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful:
      - test_name: /path/to/myscript test

Run masterscript:
  cmd.script:
    - name: masterscript
    - source: salt://path/to/masterscript
    - cwd: /
    - stateful:
      - test_name: masterscript test
```
**Should I use `cmd.run` or `cmd.wait`?**

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to watch other states, and is executed when the state it is watching changes. Example:

```bash
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

cmd.wait itself do not do anything; all functionality is inside its `mod_watch` function, which is called by `watch` on changes.

The preferred format is using the `onchanges Requisite`, which works on `cmd.run` as well as on any other state. The example would then look as follows:

```bash
/usr/local/bin/postinstall.sh:
  cmd.run:
    - onchanges:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

**How do I create an environment from a pillar map?**

The map that comes from a pillar can be directly consumed by the `env` option! To use it, one may pass it like this. Example:

```bash
printenv:
  cmd.run:
    - env: {{ salt['pillar.get']('example:key', {}) }}

salt.states.cmd.call(name_func, args=(), kwarg=None, output_loglevel='debug', hide_output=False, use_vt=False, **kwargs)
```

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the `salt.renderers.pydsl` renderer.
In addition, the stateful argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it’s a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as result in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```python
{
    'name': name,
    'changes': {'retval': result},
    'result': True if result is None else bool(result),
    'comment': result if isinstance(result, str) else ''
}
```

```python
salt.states.cmd.mod_watch(name, **kwargs)
```

Execute a cmd function based on a watch call

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly.

Parameters for this function should be set by the state being triggered.

```python
salt.states.cmd.run(name, cwd=None, root=None, runas=None, shell=None, env=None, prepend_path=None, stateful=False, output_loglevel='debug', hide_output=False, timeout=None, ignore_timeout=False, use_vt=False, success_retcodes=None, success_stdout=None, success_stderr=None, **kwargs)
```

Run a command if certain circumstances are met. Use `cmd.wait` if you want to use the watch requisite.

**Note:** The **kwargs of `cmd.run` are passed down to one of the following exec modules:
- `cmdmod.run_all`: If used with default `runas`
- `cmdmod.run_chroot`: If used with non-root value for `runas`

For more information on what args are available for either of these, refer to the `cmdmod documentation`.

```python
name
```

The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

```python
cwd
```

The current working directory to execute the command in, defaults to `/root`

```python
root
```

Path to the root of the jail to use. If this parameter is set, the command will run inside a chroot

```python
runas
```

The user name (or uid) to run the command as

```python
shell
```

The shell to use for execution, defaults to the shell grain

```python
env
```

A list of environment variables to be set prior to execution. Example:

```python
script-foo:
  cmd.run:
    - env:
      - BATCH: 'yes'
```
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal '$PATH':

```yaml
script-bar:
  cmd.run:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```yaml
{# set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') #}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

Note: When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses Path as opposed to PATH for other systems.

prepend_path
$PATH segment to prepend (trailing ':' not necessary) to PATH. This is an easier alternative to the Jinja workaround.
New in version 2018.3.0.

stateful
The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

output_loglevel
[debug] Control the loglevel at which the output from the command is logged to the minion log.

Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

hide_output
[False] Suppress stdout and stderr in the state’s results.

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

timeout
If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill.

ignore_timeout
Ignore the timeout of commands, which is useful for running nohup processes.
New in version 2015.8.0.
creates
Only run if the file specified by creates do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

New in version 2014.7.0.

use_vt
[False] Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

bg
[False] If True, run command in background and do not await or deliver its results.

New in version 2016.3.6.

success_retcodes
This parameter allows you to specify a list of non-zero return codes that should be considered as successful. If the return code from the command matches any in the list, the state will have a True result instead of False.

New in version 2019.2.0.

success_stdout: This parameter will allow a list of strings that when found in standard out should be considered a success. If stdout returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

success_stderr: This parameter will allow a list of strings that when found in standard error should be considered a success. If stderr returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

Note: cmd.run supports the usage of reload_modules. This functionality allows you to force Salt to reload all modules. You should only use reload_modules if your cmd.run does some sort of installation (such as pip), if you do not reload the modules future items in your state which rely on the software being installed will fail.

```
getpip:
  cmd.run:
    - name: /usr/bin/python /usr/local/sbin/get-pip.py
    - unless: which pip
    - require:
      - pkg: python
      - file: /usr/local/sbin/get-pip.py
    - reload_modules: True
```

salt.states.cmd.script(name, source=None, template=None, cwd=None, runas=None, password=None, shell=None, env=None, stateful=False, timeout=None, use_vt=False, output_loglevel='debug', hide_output=False, defaults=None, context=None, success_retcodes=None, success_stdout=None, success_stderr=None, **kwargs)

Download a script and execute it with specified arguments.

source
The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

template
If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

name
Either "cmd arg1 arg2 arg3..." (cmd is not used) or a source "salt://..."
cwd
The current working directory to execute the command in, defaults to /root

runas
Specify an alternate user to run the command. The default behavior is to run as the user under which Salt is running. If running on a Windows minion you must also use the password argument, and the target user account must be in the Administrators group.

Note: For Windows users, specifically Server users, it may be necessary to specify your runas user using the User Logon Name instead of the legacy logon name. Traditionally, logons would be in the following format.

\[Domain/user\]
In the event this causes issues when executing scripts, use the UPN format which looks like the following.

\[user@domain.local\]
More information <https://github.com/saltstack/salt/issues/55080>

password
New in version 3000: Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

shell
The shell to use for execution. The default is set in grains['shell']

env
A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
    cmd.script:
    - env:
      - BATCH: 'yes'
```

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
    cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
    cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

Note: When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses Path as opposed to PATH for other systems.
saltenv
  [base] The Salt environment to use

stateful
  The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

timeout
  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

args
  String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: "arg1 'arg two' arg3"

depends
  Only run if the file specified by creates do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

  New in version 2014.7.0.

use_vt
  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.
  This is experimental.

dependencies
  New in version 2016.3.0.

  Overrides default context variables passed to the template.

defaults
  New in version 2016.3.0.

  Default context passed to the template.

output_loglevel
  [debug] Control the loglevel at which the output from the command is logged to the minion log.

  Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

hide_output
  [False] Suppress stdout and stderr in the state's results.

  Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

  New in version 2018.3.0.

success_retcodes
  This parameter allows you to specify a list of non-zero return codes that should be considered as successful. If the return code from the command matches any in the list, the state will have a True result instead of False.

  New in version 2019.2.0.

success_stdout: This parameter will allow a list of strings that when found in standard out should be considered a success. If stdout returned from the run matches any in the provided list, the return code will be overridden with zero.

  New in version 3004.

success_stderr: This parameter will allow a list of strings that when found in standard error should be considered a success. If stderr returned from the run matches any in the provided list, the return code will be overridden with zero.

  New in version 3004.
salt.states.cmd.wait(name, cwd=None, root=None, runas=None, shell=None, env=(), stateful=False, output_loglevel='debug', hide_output=False, use_vt=False, success_retcodes=None, success_stdout=None, success_stderr=None, **kwargs)

Run the given command only if the watch statement calls it.

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

**name**
The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**cwd**
The current working directory to execute the command in, defaults to /root

**root**
Path to the root of the jail to use. If this parameter is set, the command will run inside a chroot

**runas**
The user name to run the command as

**shell**
The shell to use for execution, defaults to /bin/sh

**env**
A list of environment variables to be set prior to execution. Example:

```yaml
script-foo:
    cmd.wait:
        - env:
            - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```yaml
script-bar:
    cmd.wait:
        - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
    cmd.run:
        - name: ls -l /
        - env:
            - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**Note:** When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses `Path` as opposed to `PATH` for other systems.
stateful
The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

creates
Only run if the file specified by creates do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

New in version 2014.7.0.

output_loglevel
[debug] Control the loglevel at which the output from the command is logged to the minion log.

Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

hid_output
[False] Suppress stdout and stderr in the state's results.

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

use_vt
Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

success_retcodes
This parameter allows you to specify a list of non-zero return codes that should be considered as successful. If the return code from the command matches any in the list, the state will have a True result instead of False.

New in version 2019.2.0.

success_stdout: This parameter will allow a list of strings that when found in standard out should be considered a success. If stdout returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

success_stderr: This parameter will allow a list of strings that when found in standard error should be considered a success. If stderr returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

salt.states.cmd.wait_call(name, func, args=(), kws=None, stateful=False, use_vt=False, output_loglevel='debug', hide_output=False, **kwargs)

salt.states.cmd.wait_script(name, source=None, template=None, cwd=None, runas=None, shell=None, env=None, stateful=False, use_vt=False, output_loglevel='debug', hide_output=False, success_retcodes=None, success_stdout=None, success_stderr=None, **kwargs)

Download a script from a remote source and execute it only if a watch statement calls it.

source
The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

template
If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

name
The command to execute, remember that the command will execute with the path and permissions of
the salt-minion.

cwd
The current working directory to execute the command in, defaults to /root

runas
The user name to run the command as

shell
The shell to use for execution, defaults to the shell grain

env
A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.wait_script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false
are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings.
More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal '$PATH':

```yaml
salt://scripts/bar.sh:
  cmd.wait_script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```yaml
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin' | join(':') }}
```

**Note:** When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses
Path as opposed to PATH for other systems.

stateful
The command being executed is expected to return data about executing a state. For more information,
see the *Using the "Stateful" Argument* section.

use_vt
Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.
This is experimental.

output_loglevel
[debug] Control the loglevel at which the output from the command is logged to the minion log.

**Note:** The command being run will still be logged at the debug loglevel regardless, unless quiet is
used for this value.
**hide_output**

[False] Suppress stdout and stderr in the state's results.

---

**Note:** This is separate from `output_loglevel`, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

**success_retcodes**

This parameter allows you to specify a list of non-zero return codes that should be considered as successful. If the return code from the command matches any in the list, the state will have a `True` result instead of `False`.

New in version 2019.2.0.

**success_stdout:** This parameter will allow a list of strings that when found in standard out should be considered a success. If stdout returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

**success_stderr:** This parameter will allow a list of strings that when found in standard error should be considered a success. If stderr returned from the run matches any in the provided list, the return code will be overridden with zero.

New in version 3004.

```
salt.states.cmd.watch(name, cwd=None, root=None, runas=None, shell=None, env=(), stateful=False, output_loglevel='debug', hide_output=False, use_vt=False, success_retcodes=None, success_stdout=None, success_stderr=None, **kwargs)
```

This function is an alias of `wait`.

Run the given command only if the watch statement calls it.

---

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

```
name

The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

cwd

The current working directory to execute the command in, defaults to `/root`

root

Path to the root of the jail to use. If this parameter is set, the command will run inside a chroot

runas

The user name to run the command as

shell

The shell to use for execution, defaults to `/bin/sh`

env

A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    - env:
      - BATCH: 'yes'
```

---

**Warning:** The above illustrates a common PyYAML pitfall, that *yes*, *no*, *on*, *off*, *true*, and *false* are all loaded as boolean `True` and `False` values, and must be enclosed in
quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal '$PATH':

```
script-bar:
  cmd.wait:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get'](PATH, '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin'] | join(':') }}
```

Note: When using environment variables on Windows, case-sensitivity matters, i.e. Windows uses Path as opposed to PATH for other systems.

### stateful
The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

### creates
Only run if the file specified by creates do not exist. If you specify a list of files then this state will only run if any of the files do not exist.

New in version 2014.7.0.

### output_loglevel
[debug] Control the loglevel at which the output from the command is logged to the minion log.

Note: The command being run will still be logged at the debug loglevel regardless, unless quiet is used for this value.

### hide_output
[False] Suppress stdout and stderr in the state’s results.

Note: This is separate from output_loglevel, which only handles how Salt logs to the minion log.

New in version 2018.3.0.

### use_vt
Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

### success_retcodes

New in version 3004.

25.20.63 salt.states.composer

Installation of Composer Packages

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

```
get-composer:
  cmd.run:
    - name: 'CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | 
      → php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/

install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer

/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true
```
salt.states.composer.installed(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True, env=None)

Verify that the correct versions of composer dependencies are present.

name
Directory location of the composer.json file.

composer
Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)

php
Location of the php executable to use with composer. (i.e. /usr/bin/php)

user
Which system user to run composer as.

New in version 2014.1.4.

prefer_source
--prefer-source option of composer.

prefer_dist
--prefer-dist option of composer.

no_scripts
--no-scripts option of composer.

no_plugins
--no-plugins option of composer.

optimize
--optimize-autoloader option of composer. Recommended for production.

no_dev
--no-dev option for composer. Recommended for production.

quiet
--quiet option for composer. Whether or not to return output from composer.

composer_home
$COMPOSER_HOME environment variable

always_check
If True, always run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.

env
A list of environment variables to be set prior to execution.

salt.states.composer.update(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', env=None)

Composer update the directory to ensure we have the latest versions of all project dependencies.

name
Directory location of the composer.json file.

composer
Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)

php
Location of the php executable to use with composer. (i.e. /usr/bin/php)

user
Which system user to run composer as.

New in version 2014.1.4.

prefer_source
--prefer-source option of composer.
prefer_dist
    --prefer-dist option of composer.
no_scripts
    --no-scripts option of composer.
no_plugins
    --no-plugins option of composer.
optimize
    --optimize-autoloader option of composer. Recommended for production.
no_dev
    --no-dev option for composer. Recommended for production.
quiet
    --quiet option for composer. Whether or not to return output from composer.
composer_home
    $COMPOSER_HOME environment variable
env
    A list of environment variables to be set prior to execution.

25.20.64  salt.states.consul

Consul Management

New in version 3005.

The consul module is used to create and manage Consul ACLs

```yaml
acl_present:
    consul.acl_present:
        - id: 38AC8470-4A83-4140-8DFD-F924CD32917F
        - name: acl_name
        - rules: node "" {policy = "write"} service "" {policy = "read"} key "_→reexec" {policy = "write"}
        - type: client
        - consul_url: http://localhost:8500

acl_delete:
    consul.acl_absent:
        - id: 38AC8470-4A83-4140-8DFD-F924CD32917F

salt.states.consul.acl_absent(name, id=None, token=None, consul_url='http://localhost:8500')
    Ensure the ACL is absent
    name
        Specifies a human-friendly name for the ACL token.
    id
        Specifies the ID of the ACL.
    token
        token to authenticate you Consul query
    consul_url
        [http://localhost:8500] consul URL to query

    Note: For more information https://www.consul.io/api/acl.html#delete-acl-token

salt.states.consul.acl_present(name, id=None, token=None, type='client', rules=''
    consul_url='http://localhost:8500')
```
Ensure the ACL is present

name
Specifies a human-friendly name for the ACL token.

id
Specifies the ID of the ACL.

type: client
Specifies the type of ACL token. Valid values are: client and management.

rules
Specifies rules for this ACL token.

consul_url
[
http://localhost:8500
] consul URL to query

Note: For more information https://www.consul.io/api/acl.html#create-acl-token, https://www.consul.io/api/acl.html#update-acl-token

25.20.65 salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- minute
- hour
- daymonth
- month
- dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

Warning: Any timing arguments not specified take a value of *. This means that setting hour to 5, while not defining the minute param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!

Additionally, the default user for these states is root. Therefore, if the cron job is for another user, it is necessary to specify that user with the user parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```
date > /tmp/crontest:
cron.present:
  - user: root
  - minute: 5
```

Is changed to this:

```
date > /tmp/crontest:
cron.present:
  - user: root
```

(continues on next page)
Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```
date > /tmp/crontest:
  cron.present:
    - identifier: SUPERCRON
    - user: root
    - minute: 7
    - hour: 2
```

New in version 2014.1.2.

And, some months later, you modify it:

```
superscript > /tmp/crontest:
  cron.present:
    - identifier: SUPERCRON
    - user: root
    - minute: 3
    - hour: 4
```

New in version 2014.1.2.

The old `date > /tmp/crontest` will be replaced by `superscript > /tmp/crontest`.

Additionally, Salt also supports running a cron every \( * / 5 \) minutes very similarly to the Unix convention of using \( * / 5 \) to have a job run every five minutes. In Salt, this looks like:

```
date > /tmp/crontest:
  cron.present:
    - minute: \( * / 5 \)
```

The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
  cron.present:
    - user: root
    - minute: random
    - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of \( * \) for unspecified temporal parameters, adding a parameter to the state and setting it
to random will change that value from * to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the random keyword will not modify it.

Added the opportunity to set a job with a special keyword like '@reboot' or '@hourly'. Quotes must be used, otherwise PyYAML will strip the '@' sign.

```
/path/to/cron/script:
cron.present:
  - user: root
  - special: '@hourly'
```

The script will be executed every reboot if cron daemon support this option.

```
/path/to/cron/otherscript:
cron.absent:
  - user: root
  - special: '@daily'
```

This counter part definition will ensure than a job with a special keyword is not set.

**salt.states.cron.absent(name, user='root', identifier=False, special=None, **kwargs)**

- **name**: The command that should be absent in the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.
- **identifier**: Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name.
- **special**: The special keyword used in the job (eg. @reboot, @hourly...). Quotes must be used, otherwise PyYAML will strip the '@' sign.

**salt.states.cron.env_absent(name, user='root')**

- **name**: The name of the environment variable to remove from the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.

**salt.states.cron.env_present(name, value=None, user='root')**

- **name**: The name of the environment variable to set in the user crontab.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.
- **value**: The value to set for the given environment variable.

**salt.states.cron.file(name, source_hash='', source_hash_name=None, user='root', template=None, context=None, replace=True, defaults=None, backup='', **kwargs)**

- Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.

25.20. state modules 4003
name

The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

If the file is hosted on an HTTP or FTP server then the `source_hash` argument is also required.

source_hash

This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file:

```
mmd5=e138491e9d5b97023cea823fe17bac22
```

source_hash_name

When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path `/tmp/foo.txt`, then the following line in a hash file would match:

```
acbd18db4cc2f85cedef654fccc4a4d8 foo.txt
```

However, sometimes a hash file will include multiple similar paths:

```
37b51d194a751e45b56f6524f2d51f2 ./dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8 ./dir2/foo.txt
73f75a4b7f6bb68e44cf984c85f6e88 ./dir3/foo.txt
```

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
foo_crontab:
cron.file:
  - name: https://mydomain.tld/dir2/foo.txt
  - source_hash: https://mydomain.tld/queries
  - source_hash_name: ./dir2/foo.txt
```

**Note:** This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using `foo.txt` would not match.

New in version 2016.3.5.

user

The user to whom the crontab should be assigned. This defaults to root.

template

If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.

context

Overrides default context variables passed to the template.

replace

If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.

defaults

Default context passed to the template.

backup

Overrides the default backup mode for the user’s crontab.

salt.states.cron.present(name, user='root', minute='*', hour='*', daymonth='*', month='*', dayweek='*', comment=None, commented=False, identifier=False, special=None)
Verifies that the specified cron job is present for the specified user. It is recommended to use identifier. Otherwise the cron job is installed twice if you change the name. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system's documentation. Most Unix-like systems' cron documentation can be found via the crontab man page: `man 5 crontab`.

- **name**: The command that should be executed by the cron job.
- **user**: The name of the user whose crontab needs to be modified, defaults to the root user.
- **minute**: The information to be set into the minute section, this can be any string supported by your cron system's the minute field. Default is `*`.
- **hour**: The information to be set in the hour section. Default is `*`.
- **daymonth**: The information to be set in the day of month section. Default is `*`.
- **month**: The information to be set in the month section. Default is `*`.
- **dayweek**: The information to be set in the day of week section. Default is `*`.
- **comment**: User comment to be added on line previous the cron job.
- **commented**: The cron job is set commented (prefixed with `#DISABLED#`). Defaults to False. New in version 2016.3.0.
- **identifier**: Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name.
- **special**: A special keyword to specify periodicity (eg. `@reboot`, `@hourly`). Quotes must be used, otherwise PyYAML will strip the '@' sign. New in version 2016.3.0.

### 25.20.66 salt.states.cryptdev

**Opening of Encrypted Devices**

Ensure that an encrypted device is mapped with the `mapped` function:

```yaml
mappedname:
  cryptdev.mapped:
    - device: /dev/sdb1
    - keyfile: /etc/keyfile.key
    - opts: size=256

swap:
  cryptdev.mapped:
    - device: /dev/sdx4
    - keyfile: /dev/urandom
    - opts: swap,cipher=aes-cbc-essiv:sha256,size=256
```

(continues on next page)
### mappedbyuuid:

- **cryptdev.mapped:**
  - **device:** UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
  - **keyfile:** /etc/keyfile.key
  - **config:** /etc/alternate-crypttab

New in version 2018.3.0.

salt.states.cryptdev.mapped(name, device, keyfile=None, opts=None, config='/etc/crypttab', persist=True, immediate=False, match_on='name')

Verify that a device is mapped.

- **name:** The name under which the device is to be mapped.
- **device:** The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314.
- **keyfile:** Either None if the password is to be entered manually on boot, or an absolute path to a keyfile. If the password is to be asked interactively, the mapping cannot be performed with immediate=True.
- **opts:** A list object of options or a comma delimited list.
- **config:** Set an alternative location for the crypttab, if the map is persistent, Default is /etc/crypttab.
- **persist:** Set if the map should be saved in the crypttab, Default is True.
- **immediate:** Set if the device mapping should be executed immediately. Requires that the keyfile not be None, because the password cannot be asked interactively. Note that options are not passed through on the initial mapping. Default is False.
- **match_on:** A name or list of crypttab properties on which this state should be applied. Default is name, meaning that the line is matched only by the name parameter. If the desired configuration requires two devices mapped to the same name, supply a list of parameters to match on.

salt.states.cryptdev.unmapped(name, config='/etc/crypttab', persist=True, immediate=False)

Ensure that a device is unmapped.

- **name:** The name to ensure is not mapped.
- **config:** Set an alternative location for the crypttab, if the map is persistent, Default is /etc/crypttab.
- **persist:** Set if the map should be removed from the crypttab. Default is True.
- **immediate:** Set if the device should be unmapped immediately. Default is False.
25.20.67 salt.states.csf

CSF Ip tables management

depends
  • csf utility

configuration
  See http://download.configserver.com/csf/install.txt for setup instructions.

Simply allow/deny rules:
  csf.rule_present:
    ip: 1.2.3.4
    method: allow

salt.states.csf.nics_skip(name, nics, ipv6)
  Alias for csf.nics_skipped

salt.states.csf.nics_skipped(name, nics, ipv6=False)
  name
      Meaningless arg, but required for state.
  nics
      A list of nics to skip.
  ipv6
      Boolean. Set to true if you want to skip the ipv6 interface. Default false (ipv4).

salt.states.csf.option_present(name, value, reload=False)
  Ensure the state of a particular option/setting in csf.
  name
      The option name in csf.conf
  value
      The value it should be set to.
  reload
      Boolean. If set to true, csf will be reloaded after.

salt.states.csf.ports_open(name, ports, proto='tcp', direction='in')
  Ensure ports are open for a protocol, in a direction. e.g. - proto='tcp', direction='in' would set the values for TCP_IN in the csf.conf file.
  ports
      A list of ports that should be open.
  proto
      The protocol. May be one of ‘tcp’, ‘udp’, ‘tcp6’, or ‘udp6’.
  direction
      Choose ‘in’, ‘out’, or both to indicate the port should be opened for inbound traffic, outbound traffic, or both.

salt.states.csf.rule_absent(name, method, port=None, proto='tcp', direction='in', port_origin='d',
                          ip_origin='s', ttl=None, reload=False)
  Ensure iptable is not present.
  name
      The ip address or CIDR for the rule.
  method
      The type of rule. Either ‘allow’ or ‘deny’.
  port
      Optional port to be open or closed for the iptables rule.
proto
  The protocol. Either 'tcp', 'udp'. Only applicable if port is specified.
direction
  The direction of traffic to apply the rule to. Either 'in', or 'out'. Only applicable if port is specified.
port_origin
  Specifies either the source or destination port is relevant for this rule. Only applicable if port is specified.
    Either 's', or 'd'.
ip_origin
  Specifies whether the ip in this rule refers to the source or destination ip. Either 's', or 'd'. Only applicable if port is specified.
ttl
  How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny() are used.
reload
  Reload the csf service after applying this rule. Default false.

salt.states.csf.rule_present(
  name, method, port=None, proto='tcp', direction='in', port_origin='d',
  ip_origin='s', ttl=None, comment='', reload=False)

Ensure iptable rule exists.

name
  The ip address or CIDR for the rule.
method
  The type of rule. Either 'allow' or 'deny'.
port
  Optional port to be open or closed for the iptables rule.
proto
  The protocol. Either 'tcp', or 'udp'. Only applicable if port is specified.
direction
  The direction of traffic to apply the rule to. Either 'in', or 'out'. Only applicable if port is specified.
port_origin
  Specifies either the source or destination port is relevant for this rule. Only applicable if port is specified.
    Either 's', or 'd'.
ip_origin
  Specifies whether the ip in this rule refers to the source or destination ip. Either 's', or 'd'. Only applicable if port is specified.
ttl
  How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny() are used.
comment
  An optional comment to appear after the rule as a #comment .
reload
  Reload the csf service after applying this rule. Default false.

salt.states.csf.testing_off(name, reload=False)

Ensure testing mode is enabled in csf.

reload
  Reload CSF after changing the testing status. Default false.

salt.states.csf.testing_on(name, reload=False)

Ensure testing mode is enabled in csf.

reload
  Reload CSF after changing the testing status. Default false.
25.20.68 salt.states.cyg

Installation of Cygwin packages.
A state module to manage cygwin packages. Packages can be installed or removed.

dos2unix:

cyg.installed

class salt.states.cyg.DictDiffer(current_dict, past_dict)
Calculate the difference between two dictionaries.
(1) items added
(2) items removed
(3) keys same in both but changed values
(4) keys same in both and unchanged values

added()
Return a set of additions to past_dict.

changed()
Return a set of the keys with changed values.

removed()
Return a set of things removed from past_dict.

same()
True if the two dicts are the same.

unchanged()
Return a set of the keys with unchanged values.

salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)
Make sure that a package is installed.

name
The name of the package to install

cyg_arch
[x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64

mirrors
[None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
cyg.installed:
  - mirrors:
    - http://mirror/without/public/key: ""

salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)
Make sure that a package is not installed.

name
The name of the package to uninstall

cyg_arch
[x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64

mirrors
[None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:
rsync:
cyg.removed:
  - mirrors:
    - http://mirror/without/public/key: 

salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)
Make sure all packages are up to date.
name
[None] No affect, salt fails poorly without the arg available
cyg_arch
[x86_64] The cygwin architecture to update. Current options are x86 and x86_64
mirrors
[None] List of mirrors to check. None will use a default mirror (kernel.org)
CLI Example:
rsync:
cyg.updated:
  - mirrors:
    - http://mirror/without/public/key: 

25.20.69 salt.states.ddns
Dynamic DNS updates
Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates.
depends
• dnspython

Note: The dnspython module is required when managing DDNS using a TSIG key. If you are not using a TSIG
defined, DDNS is allowed by ACLs based on IP address and the dnspython module is not required.

Example:
webserver:
ddns.present:
  - zone: example.com
  - ttl: 60
  - data: 111.222.333.444
  - nameserver: 123.234.345.456
  - keyfile: /srv/salt/dnspy_tsig_key.txt

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)
Ensures that the named DNS record is absent.
name
The host portion of the DNS record, e.g., 'webserver'. Name and zone are concatenated when the entry
is created unless name includes a trailing dot, so make sure that information is not duplicated in these
two arguments.
zone
The zone to check

data
Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and
dtype, if provided) will be purged.

rdtype
DNS resource type. If omitted, all types will be purged.

**kwargs
Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname). Note
that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow
the dnspython spec.

salt.states.ddns.present(name, zone, ttl, data, rdtype='A', **kwargs)
Ensures that the named DNS record is present with the given ttl.

name
The host portion of the DNS record, e.g., 'webserver'. Name and zone are concatenated when the entry
is created unless name includes a trailing dot, so make sure that information is not duplicated in these
two arguments.

zone
The zone to check/update

ttl
TTL for the record

data
Data for the DNS record. E.g., the IP address for an A record.

rdtype
DNS resource type. Default 'A'.

**kwargs
Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname). Note
that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow
the dnspython spec.

25.20.70 salt.states.debconfmod

Management of debconf selections

depends
• debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections
prior to package installation.

Available Functions

The debconfmod state has two functions, the set and set_file functions

set
Set debconf selections from the state itself

set_file
Set debconf selections from a file
nullmailer-debconf:

debconf.set:
  - name: nullmailer
  - data:
    'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
    'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}

ferm-debconf:

debconf.set:
  - name: ferm
  - data:
    'ferm/enable': {'type': 'boolean', 'value': True}

Note: Due to how PyYAML imports nested dicts (see here), the values in the data dict must be indented four spaces instead of two.

If you’re setting debconf values that requires dpkg-reconfigure, you can use the onchanges requisite to reconfigure your package:

set-default-shell:

debconf.set:
  - name: dash
  - data:
    'dash/sh': {'type': 'boolean', 'value': False}

reconfigure-dash:

cmd.run:
  - name: dpkg-reconfigure -f noninteractive dash
  - onchanges:
    - debconf: set-default-shell

Every time the set-default-shell state changes, the reconfigure-dash state will also run.

Note: For boolean types, the value should be true or false, not 'true' or 'false'.

salt.states.debconfmod.set(name, data, **kwargs)

Set debconf selections

```
<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}

name:
  The package name to set answers for.

data:
  A set of questions/answers for debconf. Note that everything under this must be indented twice.

question:
  The question the is being pre-answered
```
salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)

Set debconf selections from a file or a template

```yaml
<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections
<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections?saltenv=myenvironment
<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections.jinja2
    - template: jinja
    - context: some_value: "false"
```

source:
The location of the file containing the package selections

template
If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported

context
Overrides default context variables passed to the template.

defaults
Default context passed to the template.

25.20.71 salt.states.dellchassis

Manage chassis via Salt Proxies.

New in version 2015.8.2.

Below is an example state that sets basic parameters:

```yaml
my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - datacenter: dc-1-us
    - location: my-location
    - mode: 2
    - idrac_launch: 1
    - slot_names:
      - server-1: my-slot-name
      - server-2: my-other-slot-name
    - blade_power_states:
      - server-1: on
```

(continues on next page)
However, it is possible to place the entire set of chassis configuration data in pillar. Here's an example pillar structure:

```yaml
proxy:
  host: 10.27.20.18
  admin_username: root
  fallback_admin_username: root
  passwords:
    - super-secret
    - old-secret
  proxytype: fx2

chassis:
  name: fx2-1
  username: root
  password: saltstack1
  datacenter: london
  location: rack-1-shelf-3
  management_mode: 2
  idrac_launch: 0
  slot_names:
    - 'server-1': blade1
    - 'server-2': blade2

servers:
  server-1:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.132
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-2:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-3:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.20
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-4:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
    gateway: 172.17.17.1
```

(continues on next page)
And to go with it, here's an example state that pulls the data from the pillar stated above:

```yaml
{% set details = pillar.get('proxy:chassis', {}) %}

standup-step1:
  dellchassis.chassis:
    - name: {{ details['name'] }}
    - location: {{ details['location'] }}
    - mode: {{ details['management_mode'] }}
    - idrac_launch: {{ details['idrac_launch'] }}
    - slot_names:
      {% for entry in details['slot_names'] %}
        - {{ next(iter(entry)) }}: {{ entry[next(iter(entry))] }}
      {% endfor %}

blade_powercycle:
  dellchassis.chassis:
    - blade_power_states:
      - server-1: powercycle
      - server-2: powercycle
      - server-3: powercycle
      - server-4: powercycle

# Set idrac_passwords for blades. racadm needs them to be called 'server-x'
{% for k, v in details['servers'].iteritems() %}
  {{ k }}:
    dellchassis.blade_idrac:
      - idrac_password: {{ v['idrac_password'] }}
{% endfor %}

# Set management ip addresses, passwords, and snmp strings for switches
{% for k, v in details['switches'].iteritems() %}
  {{ k }}-switch-setup:
    dellchassis.switch:
      - name: {{ k }}
      - ip: {{ v['ip'] }}
      - netmask: {{ v['netmask'] }}
      - gateway: {{ v['gateway'] }}
      - password: {{ v['password'] }}
{% endfor %}
```
- snmp: {{ v['snmp'] }}
{% endfor %}

Note: This state module relies on the dracr.py execution module, which runs racadm commands on the chassis, blades, etc. The racadm command runs very slowly and, depending on your state, the proxy minion return might timeout before the racadm commands have completed. If you are repeatedly seeing minions timeout after state calls, please use the -t CLI argument to increase the timeout variable.

For example:

```
salt '*' state.sls my-dell-chasis-state-name -t 60
```

Note: The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take minutes to execute.

```
salt.states.dellchassis.blade_idrac(name, idrac_password=None, idrac_ipmi=None, idrac_ip=None, idrac_netmask=None, idrac_gateway=None, idrac_dnsname=None, idrac_dhcp=None)
```

Set parameters for iDRAC in a blade.

**Parameters**
- **idrac_password** -- Password to use to connect to the iDRACs directly (idrac_ipmi and idrac_dnsname must be set directly on the iDRAC. They can't be set through the CMC. If this password is present, use it instead of the CMC password)
- **idrac_ipmi** -- Enable/Disable IPMI over LAN
- **idrac_ip** -- Set IP address for iDRAC
- **idrac_netmask** -- Set netmask for iDRAC
- **idrac_gateway** -- Set gateway for iDRAC
- **idrac_dhcp** -- Turn on DHCP for iDRAC (True turns on, False does nothing because setting a static IP will disable DHCP).

**Returns**
A standard Salt changes dictionary

```
salt.states.dellchassis.chassis(name, chassis_name=None, password=None, datacenter=None, location=None, mode=None, idrac_launch=None, slot_names=None, blade_power_states=None)
```

Manage a Dell Chassis.

**chassis_name**
The name of the chassis.

**datacenter**
The datacenter in which the chassis is located

**location**
The location of the chassis.

**password**
Password for the chassis. Note: If this password is set for the chassis, the current implementation of this state will set this password both on the chassis and the iDrac passwords on any configured blades. If the password for the blades should be distinct, they should be set separately with the blade_idrac function.

**mode**
The management mode of the chassis. Viable options are:
- 0: None

---

**Note:** The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take minutes to execute.
Monitor

Manage and Monitor

Idrac_launch

The iDRAC launch method of the chassis. Viable options are:

- 0: Disabled (launch iDRAC using IP address)
- 1: Enabled (launch iDRAC using DNS name)

Slot_names

The names of the slots, provided as a list identified by their slot numbers.

Blade_power_states

The power states of a blade server, provided as a list and identified by their server numbers. Viable options are:

- on: Ensure the blade server is powered on.
- off: Ensure the blade server is powered off.
- powercycle: Power cycle the blade server.

Example:

```
my-dell-chassis:
dellchassis.chassis:
  - chassis_name: my-dell-chassis
  - location: my-location
  - datacenter: london
  - mode: 2
  - idrac_launch: 1
  - slot_names:
    - 1: my-slot-name
    - 2: my-other-slot-name
  - blade_power_states:
    - server-1: on
    - server-2: off
    - server-3: powercycle
```

Salt states.dellchassis.firmware_update(hosts=None, directory='', firmwarefile, host, directory)

State to update the firmware on host using the racadm command

firmwarefile

filename (string) starting with salt://

host

string representing the hostname supplied to the racadm command

directory

Directory name where firmwarefile will be downloaded

```
dell-chassis-firmware-update:
dellchassis.firmware_update:
  hosts:
    cmc:
      salt://firmware_cmc.exe
    server-1:
      salt://firmware.exe
directory: /opt/firmwares
```

Salt states.dellchassis.switch(name, ip=None, netmask=None, gateway=None, dhcp=None, password=None, snmp=None)

Manage switches in a Dell Chassis.

name

The switch designation (e.g. switch-1, switch-2)
ip
  The Static IP Address of the switch
netmask
  The netmask for the static IP
gateway
  The gateway for the static IP
dhcp
  True: Enable DHCP False: Do not change DHCP setup (disabling DHCP is automatic when a static IP is set)
password
  The access (root) password for the switch
snmp
  The SNMP community string for the switch

Example:

my-dell-chassis:
dellchassis.switch:
  - switch: switch-1
  - ip: 192.168.1.1
  - netmask: 255.255.255.0
  - gateway: 192.168.1.254
  - dhcp: True
  - password: secret
  - snmp: public

25.20.72 salt.states.disk

Disk monitoring state

Monitor the state of disk resources.

The disk.status function can be used to report that the used space of a filesystem is within the specified limits.

used_space:
disk.status:
  - name: /dev/xdal
  - maximum: 79%
  - minimum: 11%

It can be used with an onfail requisite, for example, to take additional action in response to or in preparation for other states.

storage_threshold:
disk.status:
  - name: /dev/xdal
  - maximum: 97%

clear_cache:
cmd.run:
  - name: rm -r /var/cache/app
  - onfail:
    - disk: storage_threshold

To use kilobytes (KB) for minimum and maximum rather than percents, specify the absolute flag:
```
used_space:
disk.status:
  - name: /dev/xdal
  - minimum: 1024 KB
  - maximum: 1048576 KB
  - absolute: True
```

gsalt.states.disk.status(name, maximum=None, minimum=None, absolute=False, free=False)

Return the current disk usage stats for the named mount point

**name**

Disk mount or directory for which to check used space

**maximum**

The maximum disk utilization

**minimum**

The minimum disk utilization

**absolute**

By default, the utilization is measured in percentage. Set the `absolute` flag to use kilobytes.

New in version 2016.11.0.

**free**

By default, `minimum & maximum` refer to the amount of used space. Set to `True` to evaluate the free space instead.

### 25.20.73 salt.states.docker_container

Management of Docker containers

New in version 2017.7.0.

**depends**

docker Python module

Note: Older releases of the Python bindings for Docker were called `docker-py` in PyPI. All releases of `docker`, and releases of `docker-py` >= 1.6.0 are supported. These python bindings can easily be installed using `pip.install`:

```
salt myminion pip.install docker
```

To upgrade from `docker-py` to `docker`, you must first uninstall `docker-py`, and then install `docker`:

```
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the `docker` state module (formerly called `dockerng`) in the 2017.7.0 release. When running the `docker_container.running` state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is `None`. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.

Note: To pull from a Docker registry, authentication must be configured. See [here](#) for more information on how to
configure access to docker registries in Pillar data.

```py
salt.states.docker_container.absent(name, force=False)
Ensure that a container is absent
name
    Name of the container
force
    [False] Set to True to remove the container even if it is running
Usage Examples:

mycontainer:
    docker_container.absent

multiple_containers:
    docker_container.absent:
        - names:
            - foo
            - bar
            - baz
```

```py
salt.states.docker_container.mod_watch(name, sfun=None, **kwargs)
The docker_container watcher, called to invoke the watch command.

Note: This state exists to support special handling of the watch requisite. It should not be called directly.
Parameters for this function should be set by the state being triggered.

salt.states.docker_container.run(name, image=None, bg=False, failhard=True, replace=False, force=False, skip_translate=None, ignore_collisions=False, validate_ip_addrs=True, client_timeout=60, **kwargs)
New in version 2018.3.0.

Note: If no tag is specified in the image name, and nothing matching the specified image is pulled on the
minion, the docker pull that retrieves the image will pull all tags for the image. A tag of latest is not
implicit for the pull. For this reason, it is recommended to specify the image in repo:tag notation.

Like the cmd.run state, only for Docker. Does the equivalent of a docker run and returns information
about the container that was created, as well as its output.

This state accepts the same arguments as docker_container.running, with the exception of
watch_action, start, and shutdown_timeout (though the force argument has a different meaning
in this state).

In addition, this state accepts the arguments from docker.logs, with the exception of follow, to control
how logs are returned.

Additionally, the following arguments are supported:
create
    A path or list of paths. Only run if one or more of the specified paths do not exist on the minion.
bg
    [False] If True, run container in background and do not await or deliver its results.
Note: This may not be useful in cases where other states depend on the results of this state. Also, the logs will be inaccessible once the container exits if `auto_remove` is set to `True`, so keep this in mind.

**failhard**

[True] If `True`, the state will return a `False` result if the exit code of the container is non-zero. When this argument is set to `False`, the state will return a `True` result regardless of the container’s exit code.

Note: This has no effect if `bg` is set to `True`.

**replace**

[False] If `True`, and if the named container already exists, this will remove the existing container. The default behavior is to return a `False` result when the container already exists.

**force**

[False] If `True`, and the named container already exists, and `replace` is also set to `True`, then the container will be forcibly removed. Otherwise, the state will not proceed and will return a `False` result.

CLI Examples:
salt myminion docker.run_container myuser/myimage command=/usr/local/bin/→myscript.sh

**USAGE EXAMPLE**

{\% set pkg_version = salt.pillar.get('pkg_version', '1.0-1') %}

build_package:
    docker_container.run:
    - image: myuser/builder:latest
    - binds: /home/myuser/builds:/build_dir
    - command: /scripts/build.sh {{ pkg_version }}
    - creates: /home/myuser/builds/myapp-{{ pkg_version }}.noarch.rpm
    - replace: True
    - networks:
    - mynet
    - require:
    - docker_network: mynet

salt.states.docker_container.running(name=image=None, skip_translate=None, skip_translation=None, skip_translation=None, validate_ip_addrs=True, force=False, watch_action='force', start=True, shutdown_timeout=None, client_timeout=60, networks=None, **kwargs)

Ensure that a container with a specific configuration is present and running

name
Name of the container

image
Image to use for the container

Note: This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the `docker_image.present` state should be used to manage the image.

Changed in version 2018.3.0: If no tag is specified in the image name, and nothing matching the specified image is pulled on the minion, the `docker pull` that retrieves the image will pull all tags for the image.
A tag of `latest` is no longer implicit for the pull. For this reason, it is recommended to specify the image in `repo:tag` notation.

**skip_translate**

This function translates Salt CLI or SLS input into the format which `docker-py` expects. However, in the event that Salt’s translation logic fails (due to potential changes in the Docker Remote API, or to bugs in the translation code), this argument can be used to exert granular control over which arguments are translated and which are not.

Pass this argument as a comma-separated list (or Python list) of arguments, and translation for each passed argument name will be skipped. Alternatively, pass `True` and all translation will be skipped.

Skipping translation allows for arguments to be formatted directly in the format which `docker-py` expects. This allows for API changes and other issues to be more easily worked around. An example of using this option to skip translation would be:

For example, imagine that there is an issue with processing the `port_bindings` argument, and the following configuration no longer works as expected:

```
mycontainer:
  docker_container.running:
    - image: 7.3.1611
    - port_bindings: 10.2.9.10:8080:80
```

By using `skip_translate`, you can forego the input translation and configure the port binding in the format `docker-py` needs:

```
mycontainer:
  docker_container.running:
    - image: 7.3.1611
    - skip_translate: port_bindings
    - port_bindings: {8080: [('10.2.9.10', 80)], '4193/udp': 9314}
```

See the following links for more information:

- `docker-py` Low-level API
- Docker Engine API

**ignore_collisions**

[False] Since many of `docker-py`'s arguments differ in name from their CLI counterparts (with which most Docker users are more familiar), Salt detects usage of these and aliases them to the `docker-py` version of that argument so that both CLI and API versions of a given argument are supported. However, if both the alias and the `docker-py` version of the same argument (e.g. `env` and `environment`) are used, an error will be raised. Set this argument to `True` to suppress these errors and keep the `docker-py` version of the argument.

**validate_ip_addrs**

[True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to `False`.

**force**

[False] Set this parameter to `True` to force Salt to re-create the container irrespective of whether or not it is configured as desired.

**watch_action**

[force] Control what type of action is taken when this state `watches` another state that has changes. The default action is `force`, which runs the state with `force` set to `True`, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals
can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage. For example:

```yaml
mycontainer:
  docker_container.running:
    - image: busybox
    - watch_action: SIGHUP
    - watch:
      - file: some_file
```

**Note:** If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

**start**

[True] Set to False to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the Django migrate and collectstatic commands. In instances such as this, the container only needs to be started the first time.

**shutdown_timeout**

If the container needs to be replaced, the container will be stopped using docker.stop. If a shutdown_timeout is not set, and the container was created using stop_timeout, that timeout will be used. If neither of these values were set, then a timeout of 10 seconds will be used.

Changed in version 2017.7.0: This option was renamed from stop_timeout to shutdown_timeout to accommodate the stop_timeout container configuration setting.

**client_timeout**

[60] Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

**Note:** This is only used if Salt needs to pull the requested image.

**NETWORK MANAGEMENT**

New in version 2018.3.0.

Changed in version 2019.2.0: If the networks option is used, any networks (including the default bridge network) which are not specified will be disconnected.

The networks argument can be used to ensure that a container is attached to one or more networks. Optionally, arguments can be passed to the networks. In the example below, net1 is being configured with arguments, while net2 and bridge are being configured without arguments:

```yaml
foo:
  docker_container.running:
    - image: myuser/myimage:foo
    - networks:
      - net1:
        - aliases:
          - bar
          - baz
        - ipv4_address: 10.0.20.50
      - net2
      - bridge
    - require:
```

(continues on next page)
The supported arguments are the ones from the docker-py's `connect_container_to_network` function (other than `container` and `net_id`).

**Important:** Unlike with the arguments described in the CONTAINER CONFIGURATION PARAMETERS section below, these network configuration parameters are not translated at all. Consult the `connect_container_to_network` documentation for the correct type/format of data to pass.

To start a container with no network connectivity (only possible in 2019.2.0 and later) pass this option as an empty list. For example:

```yaml
foo:
  docker_container.running:
    - image: myuser/myimage:foo
    - networks: []
```

CONTAINER CONFIGURATION PARAMETERS

---

**auto_remove** *(or rm)*

[False] Enable auto-removal of the container on daemon side when the container’s process exits (analogous to running a docker container with `--rm` on the CLI).

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - auto_remove: True
```

**binds**

Files/directories to bind mount. Each bind mount should be passed in one of the following formats:

- `<host_path>:`:<container_path> - host_path is mounted within the container as container_path with read-write access.
- `<host_path>:<container_path>:<selinux_context>` - host_path is mounted within the container as container_path with read-write access. Additionally, the specified selinux context will be set within the container.
- `<host_path>:<container_path>:<read_only>` - host_path is mounted within the container as container_path, with the read-only or read-write setting explicitly defined.
- `<host_path>:<container_path>:<read_only>,<selinux_context>` - host_path is mounted within the container as container_path, with the read-only or read-write setting explicitly defined. Additionally, the specified selinux context will be set within the container.

`<read_only>` can be either `rw` for read-write access, or `ro` for read-only access. When omitted, it is assumed to be read-write.

`<selinux_context>` can be `z` if the volume is shared between multiple containers, or `Z` if the volume should be private.

**Note:** When both `<read_only>` and `<selinux_context>` are specified, there must be a comma before `<selinux_context>`.

Binds can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
  docker_container.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /etc/foo.conf:/usr/local/etc/foo.conf:rw

However, in cases where both ro/rw and an selinux context are combined, the only option is to use a YAML list, like so:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro,Z
    - /home/myuser/conf/foo.conf:/etc/foo.conf:rw,Z

Since the second bind in the previous example is mounted read-write, the rw and comma can be dropped. For example:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro,Z
    - /home/myuser/conf/foo.conf:/etc/foo.conf:Z

blkio_weight
Block IO weight (relative weight), accepts a weight value between 10 and 1000.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - blkio_weight: 100

blkio_weight_device
Block IO weight (relative device weight), specified as a list of expressions in the format PATH:RATE

foo:
  docker_container.running:
  - image: bar/baz:latest
  - blkio_weight_device: /dev/sda:100

cap_add
List of capabilities to add within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
  docker_container.running:
- **image**: bar/baz:latest
- **cap_add**: SYS_ADMIN,MKNOD

**foo**:

```yaml
  docker_container.running:
  - image: bar/baz:latest
  - cap_add:
      - SYS_ADMIN
      - MKNOD
```

---

**Note**: This option requires Docker 1.2.0 or newer.

**cap_drop**

List of capabilities to drop within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

**foo**:

```yaml
  docker_container.running:
  - image: bar/baz:latest
  - cap_drop: SYS_ADMIN,MKNOD
```

**foo**:

```yaml
  docker_container.running:
  - image: bar/baz:latest
  - cap_drop: SYS_ADMIN
  - MKNOD
```

---

**Note**: This option requires Docker 1.2.0 or newer.

**command (or cmd)**

Command to run in the container

**foo**:

```yaml
  docker_container.running:
  - image: bar/baz:latest
  - command: bash
```

**cpuset_cpus (or cpuset)**

CPUs on which which to allow execution, specified as a string containing a range (e.g. `0-3`) or a comma-separated list of CPUs (e.g. `0,1`).

**foo**:

```yaml
  docker_container.running:
  - image: bar/baz:latest
  - cpuset_cpus: "0,1"
```

**cpuset_mems**

Memory nodes on which which to allow execution, specified as a string containing a range (e.g. `0-3`) or a comma-separated list of MEMs (e.g. `0,1`). Only effective on NUMA systems.
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpuset_mems: "0,1"

cpu_group
The length of a CPU period in microseconds
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_group: 100000

cpu_period
Microseconds of CPU time that the container can get in a CPU period
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_period: 50000

cpu_shares
CPU shares (relative weight), specified as an integer between 2 and 1024.
foo:
  docker_container.running:
    - image: bar/baz:latest
    - cpu_shares: 512

detach
[False] If True, run the container's command in the background (daemon mode)
foo:
  docker_container.running:
    - image: bar/baz:latest
    - detach: True

devices
List of host devices to expose within the container. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices: /dev/net/tun,/dev/xvda1:/dev/xvda1,/dev/xvdb1:/dev/
      xvdb1:r

foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices:
      - /dev/net/tun
      - /dev/xvda1:/dev/xvda1
      - /dev/xvdb1:/dev/xvdb1:r

device_read_bps
Limit read rate (bytes per second) from a device, specified as a list of expressions in the format
PATH:RATE, where RATE is either an integer number of bytes, or a string ending in kb, mb, or gb. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps: /dev/sda:1mb,/dev/sdb:5mb
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps:
      - /dev/sda:1mb
      - /dev/sdb:5mb
```

device_read_iops
Limit read rate (I/O per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_iops: /dev/sda:1000,/dev/sdb:500
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_iops:
      - /dev/sda:1000
      - /dev/sdb:500
```

device_write_bps
Limit write rate (bytes per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is either an integer number of bytes, or a string ending in kb, mb, or gb. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_bps: /dev/sda:1mb,/dev/sdb:5mb
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_bps:
      - /dev/sda:1mb
      - /dev/sdb:5mb
```

device_write_iops
Limit write rate (I/O per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
  docker_container.running:
   - image: bar/baz:latest
   - devices_write_iops: /dev/sda:1000, /dev/sdb:500

foo:
  docker_container.running:
   - image: bar/baz:latest
   - devices_write_iops:
     - /dev/sda:1000
     - /dev/sdb:500

dns
List of DNS nameservers. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
  docker_container.running:
   - image: bar/baz:latest
   - dns: 8.8.8.8, 8.8.4.4

foo:
  docker_container.running:
   - image: bar/baz:latest
   - dns:
     - 8.8.8.8
     - 8.8.4.4

Note: To skip IP address validation, use validate_ip_addrs=False

dns_opt
Additional options to be added to the container’s resolv.conf file. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
  docker_container.running:
   - image: bar/baz:latest
   - dns_opt: ndots:9

foo:
  docker_container.running:
   - image: bar/baz:latest
   - dns_opt:
     - ndots:9

dns_search
List of DNS search domains. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
  docker_container.running:
   - image: bar/baz:latest
   - dns_search: foo1.domain.tld, foo2.domain.tld
```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - dns_search:
      - foo1.domain.tld
      - foo2.domain.tld

domainname
The domain name to use for the container

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - domainname: domain.tld

```yaml
entrypoint
Entrypoint for the container

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - entrypoint: "mycmd --arg1 --arg2"

This argument can also be specified as a list:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - entrypoint:
      - mycmd
      - --arg1
      - --arg2

```yaml
environment
Either a list of variable/value mappings, or a list of strings in the format VARNAME=value. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment:
      - VAR1: value
      - VAR2: value

foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment: 'VAR1=value,VAR2=value'

foo:
  docker_container.running:
    - image: bar/baz:latest
    - environment:
      - VAR1=value
      - VAR2=value
```
extra_hosts
Additional hosts to add to the container's /etc/hosts file. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts: web1:10.9.8.7,web2:10.9.8.8
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts:
      - web1:10.9.8.7
      - web2:10.9.8.8
```

Note: To skip IP address validation, use `validate_ip_addrs=False`

Note: This option requires Docker 1.3.0 or newer.

group_add
List of additional group names and/or IDs that the container process will run as. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - group_add: web,network
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - group_add:
      - web
      - network
```

hostname
Hostname of the container. If not provided, the value passed as the container’s `name` will be used for the hostname.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - hostname: web1
```

Warning: hostname cannot be set if `network_mode` is set to `host`. The below example will result in an error:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
```
hostname: web1
network_mode: host

**interactive (or stdin_open)**

[False] Leave stdin open, even if not attached

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - interactive: True
```

**ipc_mode (or ipc)**

Set the IPC mode for the container. The default behavior is to create a private IPC namespace for the container, but this option can be used to change that behavior:

- container:<container_name_or_id> reuses another container shared memory, semaphores and message queues
- host: use the host’s shared memory, semaphores and message queues

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ipc_mode: container:foo
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ipc_mode: host
```

**Warning:** Using host gives the container full access to local shared memory and is therefore considered insecure.

**isolation**

Specifies the type of isolation technology used by containers

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - isolation: hyperv
```

**Note:** The default value on Windows server is process, while the default value on Windows client is hyperv. On Linux, only default is supported.

**labels**

Add metadata to the container. Labels can be set both with and without values, and labels with values can be passed either as key=value or key: value pairs. For example, while the below would be very confusing to read, it is technically valid, and demonstrates the different ways in which labels can be passed:

```yaml
mynet:
  docker_network.present:
    - labels:
```

(continues on next page)
The labels can also simply be passed as a YAML dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```yaml
foo:
  docker_network.present:
    - labels:
      foo: bar=baz
      hello: world
```

Changed in version 2018.3.0: Methods for specifying labels can now be mixed. Earlier releases required either labels with or without values.

**links**

Link this container to another. Links can be specified as a list of mappings or a comma-separated or Python list of expressions in the format `<container_name_or_id>:<link_alias>`. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      web1: link1
      web2: link2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links: web1:link1,web2:link2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      web1:link1
      web2:link2
```

**log_driver and log_opt**

Set container’s logging driver and options to configure that driver. Requires Docker 1.6 or newer.

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt:
      - syslog-address: tcp://192.168.0.42
      - syslog-facility: daemon
```

The `log_opt` can also be expressed as a comma-separated or YAML list of `key=value` pairs. The below two examples are equivalent to the above one:
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt: "syslog-address=tcp://192.168.0.42,syslog-
      → facility=daemon"

foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt:
        - syslog-address=tcp://192.168.0.42
        - syslog-facility=daemon

Note: The logging driver feature was improved in Docker 1.13 introducing option name changes. Please see Docker's Configure logging drivers documentation for more information.

lxc_conf
Additional LXC configuration parameters to set before starting the container. Either a list of variable/value mappings, or a list of strings in the format `VARNAME=value`. The below three examples are equivalent:

foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
        - lxc.utsname: docker
        - lxc.arch: x86_64

foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf: lxc.utsname=docker,lxc.arch=x86_64

foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
        - lxc.utsname=docker
        - lxc.arch=x86_64

Note: These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has been deprecated for some time.

mac_address
MAC address to use for the container. If not specified, a random MAC address will be used.

foo:
  docker_container.running:

(continues on next page)
- **image**: bar/baz:latest
- **mac_address**: 01:23:45:67:89:0a

**mem_limit** (or **memory**)

[0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - mem_limit: 512M
```

**mem_swappiness**

Tune a container's memory swappiness behavior. Accepts an integer between 0 and 100.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - mem_swappiness: 60
```

**memswap_limit** (or **memory_swap**)

[-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - memswap_limit: 1G
```

**network_disabled**

[False] If True, networking will be disabled within the container

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - network_disabled: True
```

**network_mode**

[bridge] One of the following:

- **bridge** - Creates a new network stack for the container on the docker bridge
- **none** - No networking (equivalent of the Docker CLI argument --net=none). Not to be confused with Python's None.
- **container:<name_or_id>** - Reuses another container's network stack
- **host** - Use the host's network stack inside the container

**Warning**: Using **host** mode gives the container full access to the hosts system’s services (such as D-bus), and is therefore considered insecure.

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - network_mode: "none"
```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - network_mode: container:web1

oom_kill_disable
Whether to disable OOM killer

foo:
  docker_container.running:
    - image: bar/baz:latest
    - oom_kill_disable: False

oom_score_adj
An integer value containing the score given to the container in order to tune OOM killer preferences

foo:
  docker_container.running:
    - image: bar/baz:latest
    - oom_score_adj: 500

pid_mode
Set to host to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

foo:
  docker_container.running:
    - image: bar/baz:latest
    - pid_mode: host

Note: This option requires Docker 1.5.0 or newer.

pids_limit
Set the container's PID limit. Set to -1 for unlimited.

foo:
  docker_container.running:
    - image: bar/baz:latest
    - pids_limit: 2000

port_bindings (or publish)
Bind exposed ports. Port bindings should be passed in the same way as the --publish argument to the docker run CLI command:
  • ip:hostPort:containerPort - Bind a specific IP and port on the host to a specific port within the container.
  • ip::containerPort - Bind a specific IP and an ephemeral port to a specific port within the container.
  • hostPort:containerPort - Bind a specific port on all of the host's interfaces to a specific port within the container.
  • containerPort - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.
Multiple bindings can be separated by commas, or expressed as a YAML list, and port ranges can be defined using dashes. The below two examples are equivalent:
foo:
  docker_container.running:
    - image: bar/baz:latest
    - port_bindings: "4505-4506:14505-14506,2123:2123/udp,8080"

Note: When specifying a protocol, it must be passed in the `containerPort` value, as seen in the examples above.

ports
A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports: 1111,2222/udp

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports:
      - 1111
      - 2222/udp

privileged
[False] If `True`, runs the exec process with extended privileges

foo:
  docker_container.running:
    - image: bar/baz:latest
    - privileged: True

publish_all_ports (or `publish_all`)
[False] Publish all ports to the host

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports: 8080
    - publish_all_ports: True

read_only
[False] If `True`, mount the container’s root filesystem as read only

foo:
  docker_container.running:
  
(continues on next page)
- **image**: bar/baz:latest
- **read_only**: True

### restart_policy (or restart)
Set a restart policy for the container. Must be passed as a string in the format `policy[:retry_count]` where `policy` is one of always, unless-stopped, or on-failure, and `retry_count` is an optional limit to the number of retries. The retry count is ignored when using the always or unless-stopped restart policy.

```json
foo:
  docker_container.running:
  - image: bar/baz:latest
  - restart_policy: on-failure:5

bar:
  docker_container.running:
  - image: bar/baz:latest
  - restart_policy: always
```

### security_opt (or security_opts):
Security configuration for MLS systems such as SELinux and AppArmor. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```json
foo:
  docker_container.running:
  - image: bar/baz:latest
  - security_opt: apparmor:unconfined

foo:
  docker_container.running:
  - image: bar/baz:latest
  - security_opt:ObjectLevel:unconfined
```

**Important**: Some security options can contain commas. In these cases, this argument must be passed as a Python list, as splitting by comma will result in an invalid configuration.

**Note**: See the documentation for security_opt at [https://docs.docker.com/engine/reference/run/#security-configuration](https://docs.docker.com/engine/reference/run/#security-configuration)

### shm_size
Size of /dev/shm

```json
foo:
  docker_container.running:
  - image: bar/baz:latest
  - shm_size: 128M
```

### stop_signal
Specify the signal docker will send to the container when stopping. Useful when running systemd as PID 1 inside the container.
foo:
  docker_container.running:
  - image: bar/baz:latest
  - stop_signal: SIGRTMIN+3

**Note:** This option requires Docker 1.9.0 or newer and docker-py 1.7.0 or newer.

New in version 2016.11.0.

**stop_timeout**

Timeout to stop the container, in seconds

```yaml
foo:
  docker_container.running:
  - image: bar/baz:latest
  - stop_timeout: 5
```

**Note:** In releases prior to 2017.7.0, this option was not set in the container configuration, but rather this timeout was enforced only when shutting down an existing container to replace it. To remove the ambiguity, and to allow for the container to have a stop timeout set for it, the old `stop_timeout` argument has been renamed to `shutdown_timeout`, while `stop_timeout` now refers to the container's configured stop timeout.

**storage_opt**

Storage driver options for the container. Can be either a list of strings in the format `option=value`, or a list of mappings between option and value. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt:
    - dm.basesize: 40G

foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt:
    - dm.basesize=40G

foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt: dm.basesize=40G
```

**sysctls (or sysctl)**

Set sysctl options for the container. Can be either a list of strings in the format `option=value`, or a list of mappings between option and value. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
  - image: bar/baz:latest
  - sysctls:
```

(continues on next page)
foo:
  docker_container.running:
    - image: bar/baz:latest
    - sysctls: fs.nr_open=1048576,kernel.pid_max=32768

foo:
  docker_container.running:
    - image: bar/baz:latest
    - sysctls:
      - fs.nr_open=1048576
      - kernel.pid_max=32768

tmpfs
  A map of container directories which should be replaced by tmpfs mounts and their corresponding
  mount options.

foo:
  docker_container.running:
    - image: bar/baz:latest
    - tmpfs:
      - /run: rw,noexec,nosuid,size=65536k

tty
  [False] Attach TTYs

foo:
  docker_container.running:
    - image: bar/baz:latest
    - tty: True

ulimits
  List of ulimits. These limits should be passed in the format
  <ulimit_name>:<soft_limit>:<hard_limit>, with the hard limit being optional. Can be
  expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits: nofile=1024:1024,nproc=60

foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits:
      - nofile=1024:1024
      - nproc=60

user
  User under which to run exec process
usersns_mode (or user_ns_mode)
Sets the user namespace mode, when the user namespace remapping option is enabled

volumes (or volume)
List of directories to expose as volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

volumes_from
Container names or IDs from which the container will get volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

volume_driver
sets the container’s volume driver

working_dir (or workdir)
Working directory inside the container
salt.states.docker_container.stopped

Ensure that a container (or containers) is stopped.

**name**
Name or ID of the container.

**containers**
 Run this state on more than one container at a time. The following two examples accomplish the same thing:

```yaml
stopped_containers:
  docker_container.stopped:
    - names:
      - foo
      - bar
      - baz
```

```yaml
stopped_containers:
  docker_container.stopped:
    - containers:
      - foo
      - bar
      - baz
```

However, the second example will be a bit quicker since Salt will stop all specified containers in a single run, rather than executing the state separately on each image (as it would in the first example).

**shutdown_timeout**
Timeout for graceful shutdown of the container. If this timeout is exceeded, the container will be killed. If this value is not passed, then the container's configured stop_timeout will be observed. If stop_timeout was also unset on the container, then a timeout of 10 seconds will be used.

**unpause**
[Boolean] Set to True to unpause any paused containers before stopping. If unset, then an error will be raised for any container that was paused.

**error_on_absent**
[Boolean] By default, this state will return an error if any of the specified containers are absent. Set this to False to suppress that error.

---

25.20.74 salt.states.docker_image

Management of Docker images

New in version 2017.7.0.

**depends**
- docker Python module

**Note:** Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using **pip install:**
To upgrade from `docker-py` to `docker`, you must first uninstall `docker-py`, and then install `docker`:

```
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the `docker` state module (formerly called `dockerng`) in the 2017.7.0 release.

**Note:** To pull from a Docker registry, authentication must be configured. See [here](#) for more information on how to configure access to docker registries in Pillar data.

```python
salt.states.docker_image.absent(name=None, images=None, force=False)
```

Ensure that an image is absent from the Minion. Image names can be specified either using `repo:tag` notation, or just the repo name (in which case a tag of `latest` is assumed).

**images**

Run this state on more than one image at a time. The following two examples accomplish the same thing:

```
remove_images:
  docker_image.absent:
    - names:
      - busybox
      - centos:6
      - nginx

remove_images:
  docker_image.absent:
    - images:
      - busybox
      - centos:6
      - nginx
```

However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

**force**

[False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

**Note:** This option can also be overridden by Pillar data. If the Minion has a pillar variable named `docker.running.force` which is set to `True`, it will turn on this option. This pillar variable can even be set at runtime. For example:

```
salt myminion state.sls docker_stuff pillar="{docker.force: True}""
```

If this pillar variable is present and set to `False`, then it will turn off this option.

For more granular control, setting a pillar variable named `docker.force.image_name` will affect only the named image.
salt.states.docker_image.mod_watch(name, sfun=None, **kwargs)

The docker_image watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the `watch` requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.docker_image.present(name, tag=None, build=None, load=None, force=False, insecure_registry=False, client_timeout=60, dockerfile=None, sls=None, base='opensuse/python', saltenv='base', pillarenv=None, pillar=None, **kwargs)

Changed in version 2018.3.0: The `tag` argument has been added. It is now required unless pulling from a registry.

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, loaded from a saved image, or built by running SLS files against a base image.

If none of the build, load, or sls arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless `force` is set to True. Here is an example of a state that will pull an image from the Docker Hub:

```yaml
myuser/myimage:
  docker_image.present:
    - tag: mytag
```

tag
Tag name for the image. Required when using build, load, or sls to create the image, but optional if pulling from a repository.

New in version 2018.3.0.

build
Path to directory on the Minion containing a Dockerfile

```yaml
myuser/myimage:
  docker_image.present:
    - build: /home/myuser/docker/myimage
    - tag: mytag
```

myuser/myimage:
  docker_image.present:
    - build: /home/myuser/docker/myimage
    - tag: mytag
    - dockerfile: Dockerfile.alternative

The image will be built using `docker.build` and the specified image name and tag will be applied to it.

New in version 2016.11.0.

Changed in version 2018.3.0: The `tag` must be manually specified using the `tag` argument.

load
Loads a tar archive created with `docker.save` (or the `docker save` Docker CLI command), and assigns it the specified repo and tag.
myuser/myimage:
docker_image.present:
    - load: salt://path/to/image.tar
    - tag: mytag

Changed in version 2018.3.0: The tag must be manually specified using the tag argument.

force
    [False] Set this parameter to True to force Salt to pull/build/load the image even if it is already present.

client_timeout
    Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response
    from the API.

dockerfile
    Allows for an alternative Dockerfile to be specified. Path to alternative Dockefile is relative to the build
    path for the Docker container.

    New in version 2016.11.0.

docker.sls_build

sls
    Allow for building of image with docker.sls_build by specifying the SLS files with which to build. This
    can be a list or comma-separated string.

myuser/myimage:
docker_image.present:
    - tag: latest
    - sls:
        - webapp1
        - webapp2
    - base: centos
    - saltenv: base

New in version 2017.7.0.

Changed in version 2018.3.0: The tag must be manually specified using the tag argument.

base
    Base image with which to start docker.sls_build

    New in version 2017.7.0.

saltenv
    Specify the environment from which to retrieve the SLS indicated by the mods parameter.

    New in version 2017.7.0.

    Changed in version 2018.3.0: Now uses the effective saltenv if not explicitly passed. In earlier versions,
    base was assumed as a default.

pillarenv
    Specify a Pillar environment to be used when applying states. This can also be set in the minion config
    file using the pillarenv option. When neither the pillarenv minion config option nor this CLI
    argument is used, all Pillar environments will be merged together.

    New in version 2018.3.0.

pillar
    Custom Pillar values, passed as a dictionary of key-value pairs

    Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar
    source.

    New in version 2018.3.0.
25.20.75  salt.states.docker_network

Management of Docker networks
New in version 2017.7.0.

Depends
docker Python module

Note: Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using pip install:

salt myminion pip.install docker

To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:

salt myminion pip.uninstall docker-py
salt myminion pip.install docker

These states were moved from the docker state module (formerly called dockerng) in the 2017.7.0 release.

salt.states.docker_network.absent(name)
Ensure that a network is absent.

name
Name of the network

Usage Example:

network_foo:
  docker_network.absent

salt.states.docker_network.present(name, skip_translate=None, ignore_collisions=False, validate_ip_addrs=True, containers=None, reconnect=True, **kwargs)

Changed in version 2018.3.0: Support added for network configuration options other than driver and driver_opts, as well as IPAM configuration.

Ensure that a network is present

Note: This state supports all arguments for network and IPAM pool configuration which are available for the release of docker-py installed on the minion. For that reason, the arguments described below in the NETWORK CONFIGURATION and IP ADDRESS MANAGEMENT (IPAM) sections may not accurately reflect what is available on the minion. The docker.get_client_args function can be used to check the available arguments for the installed version of docker-py (they are found in the network_config and ipam_config sections of the return data), but Salt will not prevent a user from attempting to use an argument which is unsupported in the release of Docker which is installed. In those cases, network creation be attempted but will fail.

name
Network name

skip_translate
This function translates Salt SLS input into the format which docker-py expects. However, in the event that Salt’s translation logic fails (due to potential changes in the Docker Remote API, or to bugs in the translation code), this argument can be used to exert granular control over which arguments are translated and which are not.
Pass this argument as a comma-separated list (or Python list) of arguments, and translation for each passed argument name will be skipped. Alternatively, pass True and all translation will be skipped.

Skipping translation allows for arguments to be formatted directly in the format which docker-py expects. This allows for API changes and other issues to be more easily worked around. See the following links for more information:
- docker-py Low-level API
- Docker Engine API

New in version 2018.3.0.

ignore_collisions
[Fake] Since many of docker-py’s arguments differ in name from their CLI counterparts (with which most Docker users are more familiar), Salt detects usage of these and aliases them to the docker-py version of that argument. However, if both the alias and the docker-py version of the same argument (e.g. options and driver_opts) are used, an error will be raised. Set this argument to True to suppress these errors and keep the docker-py version of the argument.

New in version 2018.3.0.

validate_ip_addrs
[True] For parameters which accept IP addresses/subnets as input, validation will be performed. To disable, set this to False.

New in version 2018.3.0.

containers
A list of containers which should be connected to this network.

Note: As of the 2018.3.0 release, this is not the recommended way of managing a container’s membership in a network, for a couple reasons:
1. It does not support setting static IPs, aliases, or links in the container’s IP configuration.
2. If a docker_container.running state replaces a container, it will not be reconnected to the network until the docker_network.present state is run again. Since containers often have require requisites to ensure that the network is present, this means that the docker_network.present state ends up being run before the docker_container.running, leaving the container unattached at the end of the Salt run.

For these reasons, it is recommended to use docker_container.running’s network management support.

reconnect
[True] If containers is not used, and the network is replaced, then Salt will keep track of the containers which were connected to the network and reconnect them to the network after it is replaced. Salt will first attempt to reconnect using the same IP the container had before the network was replaced. If that fails (for instance, if the network was replaced because the subnet was modified), then the container will be reconnected without an explicit IP address, and its IP will be assigned by Docker.

Set this option to False to keep Salt from trying to reconnect containers. This can be useful in some cases when managing static IPs in docker_container.running. For instance, if a network’s subnet is modified, it is likely that the static IP will need to be updated in the docker_container.running state as well. When the network is replaced, the initial reconnect attempt would fail, and the container would be reconnected with an automatically-assigned IP address. Then, when the docker_container.running state executes, it would disconnect the network again and reconnect using the new static IP. Disabling the reconnect behavior in these cases would prevent the unnecessary extra reconnection.

New in version 2018.3.0.

NETWORK CONFIGURATION ARGUMENTS

driver
Network driver
**mynet:**
```yaml
docker_network.present:
  - driver: macvlan
```

**driver_opts (or driver_opt, or options)**
Options for the network driver. Either a dictionary of option names and values or a Python list of strings in the format `varname=value`. The below three examples are equivalent:

```yaml
mynet:
docker_network.present:
  - driver: macvlan
  - driver_opts: macvlan_mode=bridge,parent=eth0
```

```yaml
mynet:
docker_network.present:
  - driver: macvlan
  - driver_opts:
    - macvlan_mode=bridge
    - parent=eth0
```

```yaml
mynet:
docker_network.present:
  - driver: macvlan
  - driver_opts:
    - macvlan_mode: bridge
    - parent: eth0
```

The options can also simply be passed as a dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```yaml
mynet:
docker_network.present:
  - driver: macvlan
  - driver_opts:
    macvlan_mode: bridge
    parent: eth0
```

**check_duplicate**
[True] If True, checks for networks with duplicate names. Since networks are primarily keyed based on a random ID and not on the name, and network name is strictly a user-friendly alias to the network which is uniquely identified using ID, there is no guaranteed way to check for duplicates. This option provides a best effort, checking for any networks which have the same name, but it is not guaranteed to catch all name collisions.

```yaml
mynet:
docker_network.present:
  - check_duplicate: False
```

**internal**
[False] If True, restricts external access to the network

```yaml
mynet:
docker_network.present:
  - internal: True
```

**labels**
Add metadata to the network. Labels can be set both with and without values, and labels with values can be passed either as `key=value` or `key: value` pairs. For example, while the below would be very confusing to read, it is technically valid, and demonstrates the different ways in which labels can be passed:

```yaml
mynet:
  docker_network.present:
    - labels:
      - foo
      - bar=baz
      - hello: world
```

The labels can also simply be passed as a YAML dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```yaml
foo:
  docker_network.present:
    - labels:
      - foo: '
      - bar: baz
      - hello: world
```

Changed in version 2018.3.0: Methods for specifying labels can now be mixed. Earlier releases required either labels with or without values.

**enable_ipv6 (or `ipv6`)**

[False] Enable IPv6 on the network

```yaml
mynet:
  docker_network.present:
    - enable_ipv6: True
```

**Note:** While it should go without saying, this argument must be set to `True` to configure an IPv6 subnet. Also, if this option is turned on without an IPv6 subnet explicitly configured, you will get an error unless you have set up a fixed IPv6 subnet. Consult the Docker IPv6 docs for information on how to do this.

**attachable**

[False] If `True`, and the network is in the global scope, non-service containers on worker nodes will be able to connect to the network.

```yaml
mynet:
  docker_network.present:
    - attachable: True
```

**Note:** This option cannot be reliably managed on CentOS 7. This is because while support for this option was added in API version 1.24, its value was not added to the inspect results until API version 1.26. The version of Docker which is available for CentOS 7 runs API version 1.24, meaning that while Salt can pass this argument to the API, it has no way of knowing the value of this config option in an existing Docker network.

**scope**

Specify the network’s scope (`local`, `global` or `swarm`)
**mynet:**
```
docker_network.present:
  - scope: local
```

*ingress*

[False] If True, create an ingress network which provides the routing-mesh in swarm mode

```
mynet:
docker_network.present:
  - ingress: True
```

**IP ADDRESS MANAGEMENT (IPAM)**

This state supports networks with either IPv4, or both IPv4 and IPv6. If configuring IPv4, then you can pass the `IPAM pool arguments` below as individual arguments. However, if configuring IPv4 and IPv6, the arguments must be passed as a list of dictionaries, in the `ipam_pools` argument (click `here` for some examples). These docs also have more information on these arguments.

**IPAM ARGUMENTS**

**ipam_driver**

IPAM driver to use, if different from the default one

```
mynet:
docker_network.present:
  - ipam_driver: foo
```

**ipam_opts**

Options for the IPAM driver. Either a dictionary of option names and values or a Python list of strings in the format `varname=value`. The below three examples are equivalent:

```
mynet:
docker_network.present:
  - ipam_driver: foo
  - ipam_opts: foo=bar,baz=qux
```

```
mynet:
docker_network.present:
  - ipam_driver: foo
  - ipam_opts:
    - foo: bar
    - baz: qux
```

```
mynet:
docker_network.present:
  - ipam_driver: foo
  - ipam_opts:
    - foo: bar
    - baz: qux
```

The options can also simply be passed as a dictionary, though this can be error-prone due to some *idiosyncrasies* with how PyYAML loads nested data structures:

```
mynet:
docker_network.present:
  - ipam_driver: macvlan
```

(continues on next page)
- **ipam_opts**:
  - **foo**: bar
  - **baz**: qux

**IPAM POOL ARGUMENTS**

**subnet**
Subnet in CIDR format that represents a network segment

**iprange (or ip_range)**
Allocate container IP from a sub-range within the subnet

**gateway**
IPv4 or IPv6 gateway for the master subnet

**aux_addresses (or aux_address)**
A dictionary of mapping container names to IP addresses which should be allocated for them should they connect to the network. Either a dictionary of option names and values or a Python list of strings in the format host=ipaddr.

**IPAM CONFIGURATION EXAMPLES**

Below is an example of an IPv4-only network (keep in mind that subnet is the only required argument).

```yaml
mynet:
  docker_network.present:
    - subnet: 10.0.20.0/24
    - iprange: 10.0.20.128/25
    - gateway: 10.0.20.254
    - aux_addresses:
      - foo.bar.tld: 10.0.20.50
      - hello.world.tld: 10.0.20.51
```

**Note:** The aux_addresses can be passed differently, in the same way that driver_opts and ipam_opts can.

This same network could also be configured this way:

```yaml
mynet:
  docker_network.present:
    - ipam_pools:
      - subnet: 10.0.20.0/24
        iprange: 10.0.20.128/25
        gateway: 10.0.20.254
        aux_addresses:
          foo.bar.tld: 10.0.20.50
          hello.world.tld: 10.0.20.51
```

Here is an example of a mixed IPv4/IPv6 subnet.

```yaml
mynet:
  docker_network.present:
    - ipam_pools:
      - subnet: 10.0.20.0/24
        gateway: 10.0.20.1
```

(continues on next page)
25.20.76 salt.states.docker_volume

Management of Docker volumes

New in version 2017.7.0.

depends
docker Python module

Note: Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using pip.install:

salt myminion pip.install docker

To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:

salt myminion pip.uninstall docker-py
salt myminion pip.install docker

These states were moved from the docker state module (formerly called dockerng) in the 2017.7.0 release.

salt.states.docker_volume.absent(name, driver=None)

Ensure that a volume is absent.
New in version 2015.8.4.
Changed in version 2017.7.0: This state was renamed from docker.volume_absent to docker_volume.absent

name
Name of the volume
Usage Examples:

volume_foo:
docker_volume.absent

salt.states.docker_volume.present(name, driver=None, driver_opts=None, force=False)

Ensure that a volume is present.
New in version 2015.8.4.
Changed in version 2015.8.6: This state no longer deletes and re-creates a volume if the existing volume's driver does not match the driver parameter (unless the force parameter is set to True).
Changed in version 2017.7.0: This state was renamed from docker.volume_present to docker_volume.present

name
Name of the volume
driver
Type of driver for that volume. If None and the volume does not yet exist, the volume will be created using Docker's default driver. If None and the volume does exist, this function does nothing, even if the existing volume's driver is not the Docker default driver. (To ensure that an existing volume's driver matches the Docker default, you must explicitly name Docker's default driver here.)
driver_opts
    Options for the volume driver
force
    [False] If the volume already exists but the existing volume's driver does not match the driver specified by the driver parameter, this parameter controls whether the function errors out (if False) or deletes and re-creates the volume (if True).

Usage Examples:

```
volume_foo:
    docker_volume.present

volume_bar:
    docker_volume.present
    - name: bar
    - driver: local
    - driver_opts:
        foo: bar

volume_bar:
    docker_volume.present
    - name: bar
    - driver: local
    - driver_opts:
        foo: bar
        option: value
```

## 25.20.77 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```
damian:
    drac.present:
        - name: damian
        - password: secret
        - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```
damian:
    drac.absent:
        - name: damian
```

Ensure DRAC network is in a consistent state

```
my_network:
    drac.network:
        - ip: 10.225.108.29
```

(continues on next page)
salt.states.drac.absent(name)
    Ensure a user does not exist on the Dell DRAC
    name:
        The users username

salt.states.drac.network(ip, netmask, gateway)
    Ensure the DRAC network settings are consistent

salt.states.drac.present(name, password, permission)
    Ensure the user exists on the Dell DRAC
    name:
        The users username
    password
        The password used to authenticate
    permission
        The permissions that should be assigned to a user

25.20.78 salt.states.dvs

Manage VMware distributed virtual switches (DVSs) and their distributed virtual portgroups (DVportgroups).

codeauthor
    Alexandru Bleotu <alexandru.bleotu@morganstaley.com>

Examples

Several settings can be changed for DVSs and DVportgroups. Here are two examples covering all of the settings. Fewer settings can be used

DVS

```json
    'name': 'dvs1',
    'max_mtu': 1000,
    'uplink_names': [
        'dvUplink1',
        'dvUplink2',
        'dvUplink3'
    ],
    'capability': {
        'portgroup_operation_supported': false,
        'operation_supported': true,
        'port_operation_supported': false
    },
    'lacp_api_version': 'multipleLag',
    'contact_email': 'foo@email.com',
    'product_info': {
        'version':
```
25.20. state modules

(continued from previous page)
Note: The mandatory attribute is: name.

Portgroup

'security_policy': {
    'allow_promiscuous': true,
    'mac_changes': false,
    'forged_transmits': true
},
'name': 'vmotion-v702',
'out_shaping': {
    'enabled': true,
    'average_bandwidth': 1500,
    'burst_size': 4096,
    'peak_bandwidth': 1500
},
'num_ports': 128,
'teaming': {
    'port_order': []}
'dvUplink2'
],
'standby': [
'dvUplink1'
]
},
'notify_switches': false,
'reverse_policy': true,
'rolling_order': false,
'policy': 'failover_explicit',
'failure_criteria': {
  'check_error_percent': true,
  'full_duplex': false,
  'check_duplex': false,
  'percentage': 50,
  'check_speed': 'minimum',
  'speed': 20,
  'check_beacon': true
}
},
'type': 'earlyBinding',
'vlan_id': 100,
'description': 'Managed by Salt. Random settings.'

Note: The mandatory attributes are: name, type.

Dependencies

- pyVmomi Python Module

PyVmomi

PyVmomi can be installed via pip:

```bash
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```bash
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

```python
salt.states.dvs.dvs_configured(name, dvs)
```

Configures a DVS.
Creates a new DVS, if it doesn’t exist in the provided datacenter or reconfigures it if configured differently.

dvs

DVS dict representations (see module sysdocs)
salt.states.dvs.portgroups_configured(name, dvs, portgroups)

Configures portgroups on a DVS.

Creates/updates/removes portgroups in a provided DVS
dvs

Name of the DVS

portgroups

Portgroup dict representations (see module sysdocs)
salt.states.dvs.uplink_portgroup_configured(name, dvs, uplink_portgroup)

Configures the uplink portgroup on a DVS. The state assumes there is only one uplink portgroup.
dvs

Name of the DVS

uplink_portgroup

Uplink portgroup dict representations (see module sysdocs)

25.20.79 salt.states.elasticsearch

State module to manage Elasticsearch.

New in version 2017.7.0.
salt.states.elasticsearch.alias_absent(name, index)

Ensure that the index alias is absent.

name

Name of the index alias to remove

index

Name of the index for the alias

salt.states.elasticsearch.alias_present(name, index, definition=None)

Ensure that the named index alias is present.

name

Name of the alias

index

Name of the index
definition

Example:

mytestalias:
  elasticsearch.alias_present:
    - index: testindex
    - definition:
      filter:
        term:
          user: kimchy

salt.states.elasticsearch.index_absent(name)

Ensure that the named index is absent.
name
   Name of the index to remove

salt.states.elasticsearch.index_present(name, definition=None)
   Ensure that the named index is present.
   name
      Name of the index to add
   definition
      Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html

Example:

```yaml
# Default settings
mytestindex:
   elasticsearch_index.present

# Extra settings
mytestindex2:
   elasticsearch_index.present:
      definition:
         settings:
            index:
               number_of_shards: 10
```

salt.states.elasticsearch.index_template_absent(name)
   Ensure that the named index template is absent.
   name
      Name of the index to remove

salt.states.elasticsearch.index_template_present(name, definition, check_definition=False)
   Ensure that the named index template is present.
   name
      Name of the index to add
   definition
      Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-templates.html
   check_definition
      If the template already exists and the definition is up to date

Example:

```yaml
mytestindex2_template:
   elasticsearch.index_template_present:
      definition:
         template: logstash-*
         order: 1
         settings:
            number_of_shards: 1
```

salt.states.elasticsearch.pipeline_absent(name)
   Ensure that the named pipeline is absent
   name
      Name of the pipeline to remove

salt.states.elasticsearch.pipeline_present(name, definition)
   Ensure that the named pipeline is present.
name
   Name of the index to add
definition
   Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/master/pipeline.html

Example:

```
<table>
<thead>
<tr>
<th>test_pipeline:</th>
</tr>
</thead>
<tbody>
<tr>
<td>elasticsearch.pipeline_present:</td>
</tr>
<tr>
<td>- definition:</td>
</tr>
<tr>
<td>description: example pipeline</td>
</tr>
<tr>
<td>processors:</td>
</tr>
<tr>
<td>- set:</td>
</tr>
<tr>
<td>field: collector_timestamp_millis</td>
</tr>
<tr>
<td>value: '{{ '{' }{'}_ingest.timestamp{'{'}{'} }' }}'</td>
</tr>
</tbody>
</table>
```

salt.states.elasticsearch.search_template_absent(name)
   Ensure that the search template is absent
name
   Name of the search template to remove

salt.states.elasticsearch.search_template_present(name, definition)
   Ensure that the named search template is present.
name
   Name of the search template to add
definition
   Required dict for creation parameters as per http://www.elastic.co/guide/en/elasticsearch/reference/current/search-template.html

Example:

```
<table>
<thead>
<tr>
<th>test_pipeline:</th>
</tr>
</thead>
<tbody>
<tr>
<td>elasticsearch.search_template_present:</td>
</tr>
<tr>
<td>- definition:</td>
</tr>
<tr>
<td>inline:</td>
</tr>
<tr>
<td>size: 10</td>
</tr>
</tbody>
</table>
```

25.20.80 salt.states.elasticsearch_index

State module to manage Elasticsearch indices

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use elasticsearch state instead

salt.states.elasticsearch_index.absent(name)
   Ensure that the named index is absent.
name
   Name of the index to remove

salt.states.elasticsearch_index.present(name, definition=None)
   New in version 2015.8.0.
   Changed in version 2017.3.0: Marked definition as optional.
   Ensure that the named index is present.
name
    Name of the index to add
definition
    Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html
Example:

```yaml
# Default settings
mytestindex:
  elasticsearch_index.present

# Extra settings
mytestindex2:
  elasticsearch_index.present:
    - definition:
      settings:
        index:
          number_of_shards: 10
```

---

25.20.81 salt.states.elasticsearch_index_template

State module to manage Elasticsearch index templates

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use elasticsearch state instead

salt.states.elasticsearch_index_template.absent(name)
    Ensure that the named index template is absent.
    name
        Name of the index to remove

table.states.elasticsearch_index_template.present(name, definition)
    New in version 2015.8.0.
    Changed in version 2017.3.0: Marked definition as required.
    Ensure that the named index template is present.
    name
        Name of the index to add
definition
        Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-templates.html
Example:

```yaml
mytestindex2_template:
  elasticsearch_index_template.present:
    - definition:
      template: logstash-*
      order: 1
      settings:
        number_of_shards: 1
```
25.20.82  salt.states.environ

Support for getting and setting the environment variables of the current salt process.

```python
salt.states.environ.setenv(name, value, false_unsets=False, clear_all=False, update_minion=False, permanent=False)
```

Set the salt process environment variables.

- **name**: The environment key to set. Must be a string.
- **value**: Either a string or dict. When string, it will be the value set for the environment key of `name` above. When a dict, each key/value pair represents an environment variable to set.
- **false_unsets**: If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False
- **clear_all**: USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False
- **update_minion**: If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False
- **permanent**: On Windows minions this will set the environment variable in the registry so that it is always added as a environment variable when applications open. If you want to set the variable to HKLM instead of HKCU just pass in "HKLM" for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.

Example:

```yaml
a_string_env:
environ.setenv:
    - name: foo
    - value: bar
    - update_minion: True

a_dict_env:
environ.setenv:
    - name: does_not_matter
    - value:
        foo: bar
        baz: quux
```

25.20.83  salt.states.eeselect

Management of Gentoo configuration using eeselect

A state module to manage Gentoo configuration via eeselect.

```python
salt.states.eeselect.set_(name, target, module_parameter=None, action_parameter=None)
```

Verify that the given module is set to the given target

- **name**: The name of the module
target
The target to be set for this module

module_parameter
additional params passed to the defined module

action_parameter
additional params passed to the defined action

```
profile:
eselect.set:
  - target: hardened/linux/amd64
```

### 25.20.84 salt.states.esxcluster

Manage VMware ESXi Clusters.

**Warning:** This module will be deprecated in a future release of Salt. VMware strongly recommends using the VMware Salt extensions instead of the ESX cluster module. Because the Salt extensions are newer and actively supported by VMware, they are more compatible with current versions of ESXi and they work well with the latest features in the VMware product line.

#### Dependencies

- pyVmomi Python Module

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See *Issue #29537* for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**salt.states.esxcluster.cluster_configured**(name, cluster_config)

Configures a cluster. Creates a new cluster, if it doesn't exist on the vCenter or reconfigures it if configured differently

Supported proxies: esxdatacenter, esxcluster

name
Name of the state. If the state is run in by an esxdatacenter proxy, it will be the name of the cluster.
cluster_config
Configuration applied to the cluster. Complex datastructure following the ESXClusterConfigSchema. Valid example is:

```yaml
drs:
  default_vm_behavior: fullyAutomated
  enabled: true
  vmotion_rate: 3
ha:
  admission_control
  _enabled: false
  default_vm_settings:
    isolation_response: powerOff
    restart_priority: medium
    enabled: true
  hb_ds_candidate_policy: userSelectedDs
  host_monitoring: enabled
  options:
  - key: das.ignoreinsufficienthbdatastore
    value: 'true'
  vm_monitoring: vmMonitoringDisabled
vm_swap_placement: vmDirectory
vsan:
  auto_claim_storage: false
  compression_enabled: true
  dedup_enabled: true
  enabled: true
```
salt.states.esxcluster.licenses_configured(name, licenses=None)
Configures licenses on the cluster entity
Checks if each license exists on the server:
  • if it doesn’t, it creates it
Check if license is assigned to the cluster:
  • if it’s not assigned to the cluster:
    − assign it to the cluster if there is space
    − error if there’s no space
  • if it’s assigned to the cluster nothing needs to be done
salt.states.esxcluster.vsan_datastore_configured(name, datastore_name)
Configures the cluster’s VSAN datastore
WARNING: The VSAN datastore is created automatically after the first ESXi host is added to the cluster; the state assumes that the datastore exists and errors if it doesn’t.

25.20.85 salt.states.esxdatacenter
Salt states to create and manage VMware vSphere datacenters (datacenters).

codeauthor
Alexandru Bleotu <alexandru.bleotu@morganstaley.com>

Warning: This module will be deprecated in a future release of Salt. VMware strongly recommends using the VMware Salt extensions instead of the ESX data center module. Because the Salt extensions are newer and
actively supported by VMware, they are more compatible with current versions of ESXi and they work well with the latest features in the VMware product line.

Dependencies

- pyVmomi Python Module

States

datacenter_configured

Makes sure a datacenter exists and is correctly configured.

If the state is run by an esxdatacenter minion, the name of the datacenter is retrieved from the proxy details, otherwise the datacenter has the same name as the state.

Supported proxies: esxdatacenter

Example:

1. Make sure that a datacenter named target_dc exists on the vCenter, using a esxdatacenter proxy:

Proxy minion configuration (connects passthrough to the vCenter):

```
proxy:
  proxysqltype: esxdatacenter
datacenter: target_dc
  vcenter: vcenter.fake.com
  mechanism: sspi
  domain: fake.com
  principal: host
```

State configuration:

```
datacenter_state:
esxdatacenter.datacenter_configured
```

salt.states.esxdatacenter.datacenter_configured(name)

Makes sure a datacenter exists.

If the state is run by an esxdatacenter minion, the name of the datacenter is retrieved from the proxy details, otherwise the datacenter has the same name as the state.

Supported proxies: esxdatacenter
name:

Datacenter name. Ignored if the proxytype is esxdatacenter.
25.20.86 salt.states.esxi

Manage VMware ESXi Hosts.

**Warning:** This module will be deprecated in a future release of Salt. VMware strongly recommends using the VMware Salt extensions instead of the ESXi module. Because the Salt extensions are newer and actively supported by VMware, they are more compatible with current versions of ESXi and they work well with the latest features in the VMware product line.

**Dependencies**

- pyVmomi Python Module
- ESXCLI

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.
Note: Be aware that some functionality in this state module may depend on the type of license attached to the ESXi host.

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.

Please see the vSphere Comparison page for more information.

About

This state module was written to be used in conjunction with Salt's ESXi Proxy Minion. For a tutorial on how to use Salt's ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

salt.states.esxi.coredump_configured(name, enabled, dump_ip, host_vnic='vmk0', dump_port=6500)

Ensures a host's core dump configuration.

name
Name of the state.

dumped
Sets whether or not ESXi core dump collection should be enabled. This is a boolean value set to True or False to enable or disable core dumps.

Note that ESXi requires that the core dump must be enabled before any other parameters may be set. This also affects the changes results in the state return dictionary. If enabled is False, we can't obtain any previous settings to compare other state variables, resulting in many old references returning None.

Once enabled is True the changes dictionary comparisons will be more accurate. This is due to the way the system coredump network configuration command returns data.

dump_ip
The IP address of host that will accept the dump.

host_vnic
Host VNic port through which to communicate. Defaults to vmk0.

dump_port
TCP port to use for the dump. Defaults to 6500.

Example:

```yaml
configure-host-coredump:
esxi.coredump_configured:
  - enabled: True
  - dump_ip: 'my-coredump-ip.example.com'
```

salt.states.esxi.diskgroups_configured(name, diskgroups, erase_disks=False)

Configures the disk groups to use for vsan.

This function will do the following:
1. Check whether or not all disks in the diskgroup spec exist, and raises and errors if they do not.
2. Create diskgroups with the correct disk configurations if diskgroup (identified by the cache disk canonical name) doesn't exist
3. Adds extra capacity disks to the existing diskgroup

Example:
name
Mandatory state name
diskgroups
Disk group representation containing scsi disk addresses. Scsi addresses are expected for disks in the
diskgroup:
erase_disks
Specifies whether to erase all partitions on all disks member of the disk group before the disk group is
created. Default value is False.

salt.states.esxi.host_cache_configured(name, enabled, datastore, swap_size='100%',
dedicated_backing_disk=False, erase_backing_disk=False)

Configures the host cache used for swapping.

It will do the following:
1. Checks if backing disk exists
2. Creates the VMFS datastore if doesn't exist (datastore partition will be created and use the entire disk)
3. Raises an error if dedicated_backing_disk is True and partitions already exist on the backing
disk
4. Configures host_cache to use a portion of the datastore for caching (either a specific size or a percentage
of the datastore)

Examples

Percentage swap size (can't be 100%)

```json
{
    'enabled': true,
    'datastore': {
        'backing_disk_scsi_addr': 'vmhba1:C0:T0:L0',
        'vmfs_version': 5,
        'name': 'hostcache'
    },
    'dedicated_backing_disk': false,
    'swap_size': '98%',
}
```

Fixed sized swap size

```json
{
    'enabled': true,
    'datastore': {
        'backing_disk_scsi_addr': 'vmhba0:C0:T0:L0',
        'vmfs_version': 5,
        'name': 'hostcache'
    },
    'dedicated_backing_disk': true
}
```
'swap_size': '10GiB',
}

name
   Mandatory state name.

enabled
   Specifies whether the host cache is enabled.

datastore
   Specifies the host cache datastore.

swap_size
   Specifies the size of the host cache swap. Can be a percentage or a value in GiB. Default value is 100%.

dedicated_backing_disk
   Specifies whether the backing disk is dedicated to the host cache which means it must have no other partitions. Default is False

erase_backing_disk
   Specifies whether to erase all partitions on the backing disk before the datastore is created. Default value is False.

salt.states.esxi.ntp_configured(name, service_running, ntp_servers=None, service_policy=None, service_restart=False, update_datetime=False)

Ensures a host's NTP server configuration such as setting NTP servers, ensuring the NTP daemon is running or stopped, or restarting the NTP daemon for the ESXi host.
	name
   Name of the state.

service_running
   Ensures the running state of the ntp daemon for the host. Boolean value where True indicates that ntpd should be running and False indicates that it should be stopped.

ntp_servers
   A list of servers that should be added to the ESXi host's NTP configuration.

service_policy
   The policy to set for the NTP service.

   Note: When setting the service policy to off or on, you must quote the setting. If you don't, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

service_restart
   If set to True, the ntp daemon will be restarted, regardless of its previous running state. Default is False.

update_datetime
   If set to True, the date/time on the given host will be updated to UTC. Default setting is False. This option should be used with caution since network delays and execution delays can result in time skews.

Example:

```python
configure_host-ntp:
   esxi.ntp_configured:
      - service_running: True
      - ntp_servers:
         - 192.174.1.100
         - 192.174.1.200
      - service_policy: 'on'
      - service_restart: True
```
salt.states.esxi.password_present(name, password)

Ensures the given password is set on the ESXi host. Passwords cannot be obtained from host, so if a password
is set in this state, the vsphere.update_host_password function will always run (except when using
test=True functionality) and the state's changes dictionary will always be populated.

The username for which the password will change is the same username that is used to authenticate against
the ESXi host via the Proxy Minion. For example, if the pillar definition for the proxy username is defined as root,
then the username that the password will be updated for via this state is root.

name

Name of the state.

password

The new password to change on the host.

Example:

```
configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'
```

salt.states.esxi.ssh_configured(name, service_running, ssh_key=None, ssh_key_file=None,
  service_policy=None, service_restart=False, certificate_verify=None)

Manage the SSH configuration for a host including whether or not SSH is running or the presence of a given
SSH key. Note: Only one ssh key can be uploaded for root. Uploading a second key will replace any existing
key.

name

Name of the state.

service_running

Ensures whether or not the SSH service should be running on a host. Represented as a boolean value
where True indicates that SSH should be running and False indicates that SSH should stopped.

In order to update SSH keys, the SSH service must be running.

ssh_key

Public SSH key to added to the authorized_keys file on the ESXi host. You can use ssh_key or
ssh_key_file, but not both.

ssh_key_file

File containing the public SSH key to be added to the authorized_keys file on the ESXi host. You can use
ssh_key_file or ssh_key, but not both.

service_policy

The policy to set for the NTP service.

Note: When setting the service policy to off or on, you must quote the setting. If you don't, the yaml
parser will set the string to a boolean, which will cause trouble checking for stateful changes and will
error when trying to set the policy on the ESXi host.

service_restart

If set to True, the SSH service will be restarted, regardless of its previous running state. Default is
False.

certificate_verify

If set to True, the SSL connection must present a valid certificate. Default is True.

Example:

```
configure-host-ssh:
  esxi.ssh_configured:
    - service_running: True
    - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
```

(continues on next page)
- **service_policy**: 'on'
- **service_restart**: True
- **certificate_verify**: True

salt.states.esxi.syslog_configured(
    name, syslog_configs, firewall=True, reset_service=True,
    reset_syslog_config=False, reset_configs=None)

Ensures the specified syslog configuration parameters. By default, this state will reset the syslog service after any new or changed parameters are set successfully.

- **name**: Name of the state.
- **syslog_configs**: Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--))

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size, and default-timeout.

Each syslog_config option also needs a configuration value to set. For example, loghost requires URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas

- **firewall**: Enable the firewall rule set for syslog. Defaults to True.
- **reset_service**: After a successful parameter set, reset the service. Defaults to True.
- **reset_syslog_config**: Resets the syslog service to its default settings. Defaults to False. If set to True, default settings defined by the list of syslog configs in reset_configs will be reset before running any other syslog settings.

- **reset_configs**: A comma-delimited list of parameters to reset. Only runs if reset_syslog_config is set to True. If reset_syslog_config is set to True, but no syslog configs are listed in reset_configs, then reset_configs will be set to all by default.

See syslog_configs parameter above for a list of valid options.

Example:

```yaml
configure-host-syslog:
  esxi.syslog_configured:
    - syslog_configs:
        default-timeout: 120
    - firewall: True
    - reset_service: True
    - reset_syslog_config: True
    - reset_configs: loghost,default-timeout
```

salt.states.esxi.vmotion_configured(name, enabled, device='vmk0')

Configures a host's VMotion properties such as enabling VMotion and setting the device VirtualNic that VMotion will use.

- **name**: Name of the state.
enabled
Ensures whether or not VMotion should be enabled on a host as a boolean value where True indicates that VMotion should be enabled and False indicates that VMotion should be disabled.

device
The device that uniquely identifies the VirtualNic that will be used for VMotion for the host. Defaults to vmk0.

Example:

```yaml
configure-vmotion:
esxi.vmotion_configured:
  - enabled: True
  - device: sample-device
```

salt.states.esxi.vsan_configured(name, enabled, add_disks_to_vsan=False)
Configures a host's VSAN properties such as enabling or disabling VSAN, or adding VSAN-eligible disks to the VSAN system for the host.

name
Name of the state.

enabled
Ensures whether or not VSAN should be enabled on a host as a boolean value where True indicates that VSAN should be enabled and False indicates that VSAN should be disabled.

add_disks_to_vsan
If set to True, any VSAN-eligible disks for the given host will be added to the host's VSAN system. Default is False.

Example:

```yaml
configure-host-vsan:
esxi.vsan_configured:
  - enabled: True
  - add_disks_to_vsan: True
```

25.20.87 salt.states.esxvm
Salt state to create, update VMware ESXi Virtual Machines.

Warning: This module will be deprecated in a future release of Salt. VMware strongly recommends using the VMware Salt extensions instead of the ESX VSM module. Because the Salt extensions are newer and actively supported by VMware, they are more compatible with current versions of ESXi and they work well with the latest features in the VMware product line.

Dependencies

- pyVmomi
- jsonschema
States

vm_configured

Enforces correct virtual machine configuration. Creates, updates and registers a virtual machine.

This state identifies the action which should be taken for the virtual machine and applies that action via the create, update, register state functions.

Supported proxies: esxvm

Example:

1. Get the virtual machine my_vm status with an esxvm proxy:

Proxy minion configuration for esxvm proxy:

```yaml
proxy:
  proxytype: esxvm
  datacenter: my_dc
  vcenter: vcenter.fake.com
  mechanism: sspi
  domain: fake.com
  principal: host
```

State configuration:

```yaml
myvm_state:
  esxvm.vm_configured:
    - vm_name: my_vm
    - cpu: {{ 'count': 4, 'cores_per_socket': 2 }}
    - memory: {{ 'size': 16384, 'unit': 'MB' }}
    - image: rhel7_64Guest
    - version: vmx-12
    - interfaces: {{ []
        ['adapter': 'Network adapter 1',
         'name': 'my_pg1',
         'switch_type': 'distributed',
         'adapter_type': 'vmxnet3',
         'mac': '00:50:56:00:01:02,
         'connectable': { 'start_connected': true,
                         'allow_guest_control': true,
                         'connected': true} },
        ['adapter': 'Network adapter 2',
         'name': 'my_pg2',
         'switch_type': 'distributed',
         'adapter_type': 'vmxnet3',
         'mac': '00:50:56:00:01:03',
         'connectable': { 'start_connected': true,
                         'allow_guest_control': true,
                         'connected': true} }
    ] }}
    - disks: {{ []
        ['adapter': 'Hard disk 1',
         'unit': 'MB',
...}}
Here is a representation of the Salt documentation you provided:

```json
{
    'size': 51200,
    'filename': 'my_vm/sda.vmdk',
    'datastore': 'my_datastore',
    'address': '0:0',
    'thin_provision': true,
    'eagerly_scrub': false,
    'controller': 'SCSI controller 0'},

{ 'adapter': 'Hard disk 2',
  'unit': 'MB',
  'size': 10240,
  'filename': 'my_vm/sdb.vmdk',
  'datastore': 'my_datastore',
  'address': '0:1',
  'thin_provision': true,
  'eagerly_scrub': false,
  'controller': 'SCSI controller 0'}

- `scsi_devices`: {{{
    'adapter': 'SCSI controller 0',
    'type': 'paravirtual',
    'bus_sharing': 'no_sharing',
    'bus_number': 0}
  }}

- `serial_ports`: {{{
    'adapter': 'Serial port 1',
    'type': 'network',
    'yield': false,
    'backing': {
        'uri': 'my_uri',
        'direction': 'server',
        'filename': 'my_file'},
    'connectable': {
        'start_connected': true,
        'allow_guest_control': true,
        'connected': true}}
  }}

- `datacenter`: {{ 'my_dc' }}
- `datastore`: 'my_datastore'
- `placement`: {{ {'cluster': 'my_cluster'} }}
- `cd_dvd_drives`: {{ [] }}
- `advanced_configs`: {{ {'my_param': '1'} }}
- `template`: false
- `tools`: false
- `power_on`: false
- `deploy`: false
```
vm_updated

Updates a virtual machine to a given configuration.

vm_created

Creates a virtual machine with a given configuration.

vm_registered

Registers a virtual machine with its configuration file path.

Dependencies

pyVmomi

PyVmomi can be installed via pip:

```
    pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using
version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency
in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported
range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the
following:

```
    pip install pyVmomi==6.0.0.2016.4
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against. To be able
to connect through SSPI you must use pyvmomi 6.0.0.2016.4 or above. The ESXVM State Module was tested with
this version.

About

This state module was written to be used in conjunction with Salt’s ESXi Proxy Minion For a tutorial on how to
use Salt's ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency
installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a
larger state example.

```
salt.states.esxvm.vm_cloned(name)
```

    Clones a virtual machine from a template virtual machine if it doesn't exist and a template is defined.

```
salt.states.esxvm.vm_configured(name, vm_name, cpu, memory, image, version, interfaces, disks,
scsi_devices, serial_ports, datacenter, datastore, placement,
cd_dvd_drives=None, sata_controllers=None, advanced_configs=None,
template=None, tools=True, power_on=False, deploy=False)
```
Selects the correct operation to be executed on a virtual machine, non existing machines will be created, existing ones will be updated if the config differs.

```python
salt.states.esxvm.vm_created(name, vm_name, cpu, memory, image, version, interfaces, disks,
    scsi_devices, serial_ports, datacenter, datastore, placement,
    ide_controllers=None, sata_controllers=None, cd_dvd_drives=None,
    advanced_configs=None, power_on=False)
```

Creates a virtual machine with the given properties if it doesn't exist.

```python
salt.states.esxvm.vm_registered(vm_name, datacenter, placement, vm_file, power_on=False)
```

Registers a virtual machine if the machine files are available on the main datastore.

```python
salt.states.esxvm.vm_updated(name, vm_name, cpu, memory, image, version, interfaces, disks,
    scsi_devices, serial_ports, datacenter, datastore, cd_dvd_drives=None,
    sata_controllers=None, advanced_configs=None, power_on=False)
```

Updates a virtual machine configuration if there is a difference between the given and deployed configuration.

**25.20.88 salt.states.etcd_mod**

Manage etcd Keys

New in version 2015.8.0.

```
depends
• python-etcd or etcd3-py
```

This state module supports setting and removing keys from etcd.

**Configuration**

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

In order to choose whether to use etcd API v2 or v3, you can put the following configuration option in the same place as your etcd configuration. This option defaults to true, meaning you will use v2 unless you specify otherwise.

```
etcd.require_v2: True
```

When using API v3, there are some specific options available to be configured within your etcd profile. They are defaulted to the following...
**etcd.encode_keys**: False
**etcd.encode_values**: True
**etcd.raw_keys**: False
**etcd.raw_values**: False
**etcd.unicode_errors**: "surrogateescape"

`etcd.encode_keys` indicates whether you want to pre-encode keys using msgpack before adding them to etcd.

**Note**: If you set `etcd.encode_keys` to True, all recursive functionality will no longer work. This includes `tree` and `ls` and all other methods if you set `recurse/recursive` to True. This is due to the fact that when encoding with msgpack, keys like `/salt` and `/salt/stack` will have differing byte prefixes, and etcd v3 searches recursively using prefixes.

`etcd.encode_values` indicates whether you want to pre-encode values using msgpack before adding them to etcd. This defaults to True to avoid data loss on non-string values wherever possible.

`etcd.raw_keys` determines whether you want the raw key or a string returned.

`etcd.raw_values` determines whether you want the raw value or a string returned.

`etcd.unicode_errors` determines what you policy to follow when there are encoding/decoding errors.

**Note**: The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to True.

Be aware that setting `pillar_opts` to True has security implications as this makes all master configuration settings available in all minion's pillars.

Etcd profile configuration can be overridden using following arguments: `host`, `port`, `username`, `password`, `ca`, `client_key` and `client_cert`. The v3 specific arguments can also be used for overriding if you are using v3.

```yaml
my-value:
  etcd.set:
    - name: /path/to/key
    - value: value
    - host: 127.0.0.1
    - port: 2379
    - username: user
    - password: pass
```

### Available Functions

- **set**

  This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

```yaml
/foo/bar/baz:
  etcd.set:
    - value: foo
    - profile: my_etcd_config
```
• **wait_set**
  Performs the same functionality as `set` but only if a watch requisite is True.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_set:
    - value: foo
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

• **rm**
  This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

```yaml
/foo/bar/baz:
  etcd.rm:
    - profile: my_etcd_config
```

• **wait_rm**
  Performs the same functionality as `rm` but only if a watch requisite is True.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

salt.states.etcd_mod.directory(name, profile=None, **kwargs)
Create a directory in etcd.

- **name**
  The etcd directory name, for example: `/foo/bar/baz`.

- **profile**
  Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

```yaml
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

salt.states.etcd_mod.mod_watch(name, **kwargs)
The etcd watcher, called to invoke the watch command. When called, execute a etcd function based on a watch call requisite.

**Note**: This state exists to support special handling of the `watch requisite`. It should not be called directly.
Parameters for this function should be set by the state being triggered.

```python
salt.states.etcd_mod.rm(name, recurse=False, profile=None, **kwargs)

Deletes a key from etcd

- **name**
  The etcd key name to remove, for example /foo/bar/baz.

- **recurse**
  Optional, defaults to False. If True performs a recursive delete.

- **profile**
  Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

```python
salt.states.etcd_mod.set_(name, value, profile=None, **kwargs)

Set a key in etcd

- **name**
  The etcd key name, for example: /foo/bar/baz.

- **value**
  The value the key should contain.

- **profile**
  Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

```python
salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None, **kwargs)

Deletes a key from etcd only if the watch statement calls it. This function is also aliased as wait_rm.

- **name**
  The etcd key name to remove, for example /foo/bar/baz.

- **recurse**
  Optional, defaults to False. If True performs a recursive delete, see: https://python-etcd.readthedocs.io/en/latest/#delete-a-key.

- **profile**
  Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

```

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

```python
salt.states.etcd_mod.wait_set(name, value, profile=None, **kwargs)

Set a key in etcd only if the watch statement calls it. This function is also aliased as wait_set.

- **name**
  The etcd key name, for example: /foo/bar/baz.

- **value**
  The value the key should contain.

- **profile**
  The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to None.

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001

25.20.89 salt.states.ethtool

Configuration of network device

New in version 2016.11.0.

codeauthor

25.20.90 salt.states.event

Send events through Salt’s event system during state runs

**salt.states.event**

This function is an alias of **send**.

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the **event.send** execution module of the same name, with the additional argument:

**param show_changed**

- If True, state will show as changed with the data argument as the change value.
- If False, shows as unchanged.

Example:

```python
mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"
```

salt.states.event**mod_watch**

This function is an alias of **send**.

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the **event.send** execution module of the same name, with the additional argument:

**param show_changed**

- If True, state will show as changed with the data argument as the change value.
- If False, shows as unchanged.

Example:

```python
mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"
```
salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, show_changed=True, **kwargs)

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the event.send execution module of the same name, with the additional argument:

**Parameters**

show_changed -- If True, state will show as changed with the data argument as the change value. If False, shows as unchanged.

Example:

```yaml
# ...snip bunch of states above

mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"

# ...snip bunch of states below
```

salt.states.event.wait(name, sfun=None, data=None)

Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:

```yaml
# Stand up a new web server.
apache:
  pkg:
    - installed
    - name: httpd
  service:
    - running
    - enable: True
    - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
  event:
    - wait
    - name: mycompany/loadbalancer/pool/update
    - data:
      new_web_server_ip: {{ grains['ipv4'] | first() }}
    - watch:
      - pkg: apache
```
25.20.91 salt.states.file

Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed. Regular files can be enforced with the `file.managed` state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of `file.managed` which makes use of the jinja templating system would look like this:

```
/etc/http/conf/http.conf:
  file.managed:
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - attrs: ai
    - template: jinja
    - defaults:
      custom_var: "default value"
      other_var: 123
    {% if grains["os"] == 'Ubuntu' %}
      - context:
        custom_var: "override"
    {%- endif %}
```

It is also possible to use the `py renderer` as a templating option. The template would be a Python script which would need to contain a function called `run()`, which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

```
def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context])
    # Arguments as globals
    return '

'.join(lines)
```

**Note:** The `defaults` and `context` arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. [More information.](#)

If using a template, any user-defined template variables in the file defined in `source` must be passed in using the `defaults` and/or `context` arguments. The general best practice is to place default values in `defaults`, with conditional overrides going into `context`, as seen above.

The template will receive a variable `custom_var`, which would be accessed in the template using `{{ custom_var }}`. If the operating system is Ubuntu, the value of the variable `custom_var` would be `override`, otherwise it is the default `default value`.

The `source` parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserv. Here's an example:

```
/etc/foo.conf:
  file.managed:
    - source:
```

(continues on next page)
- salt://foo.conf.{{ grains['fqdn'] }}
- salt://foo.conf.fallback
- user: foo
- group: users
- mode: 644
- attrs: i
- backup: minion

Note: Salt supports backing up managed files via the backup option. For more details on this functionality please review the backup_mode documentation.

The source parameter can also specify a file in another Salt environment. In this example foo.conf in the dev environment will be used instead.

/etc/foo.conf:
  file.managed:
  - source:
    - 'salt://foo.conf?saltenv=dev'
    - user: foo
    - group: users
    - mode: '0644'
    - attrs: i

Warning: When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

The names parameter, which is part of the state compiler, can be used to expand the contents of a single state declaration into multiple, single state declarations. Each item in the names list receives its own individual state name and is converted into its own low-data structure. This is a convenient way to manage several files with similar attributes.

salt_master_conf:
  file.managed:
  - user: root
  - group: root
  - mode: '0644'
  - names:
    - /etc/salt/master.d/master.conf:
      - source: salt://saltmaster/master.conf
    - /etc/salt/minion.d/minion-99.conf:
      - source: salt://saltmaster/minion.conf

Note: There is more documentation about this feature in the Names declaration section of the Highstate docs.

Special files can be managed via the mknod function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and FIFO pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions.
In most cases the creation of some special files require root permissions on the minion. This would require that the
minion to be run as the root user. Here is an example of a character device:

```
/var/named/chroot/dev/random:
  file.mknod:
    - ntype: c
    - major: 1
    - minor: 8
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
    - group: named
    - mode: 660
```

Directories can be managed via the directory function. This function can create and enforce the permissions on
a directory. A directory statement will look like this:

```
/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can
do so by adding a recurse directive:

```
/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode
```
As a default, mode will resolve to dir_mode and file_mode, to specify both directory and file permissions, use this form:

```
/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - file_mode: 744
    - dir_mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode
```

Symlinks can be easily created; the symlink function is very simple and only takes a few arguments:

```
/etc/grub.conf:
  file.symlink:
    - target: /boot/grub/grub.conf
```

Recursive directory management can also be set via the recurse function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using recurse would look something like this:

```
/opt/code/flask:
  file.recurse:
    - source: salt://code/flask
    - include_empty: True
```

A more complex recurse example:

```
{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
  file.recurse:
    - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
    - user: {{ site_user }}
    - dir_mode: 2775
    - file_mode: '0644'
    - template: jinja
    - source: salt://project/templates_dir
    - include_empty: True
```

Retention scheduling can be applied to manage contents of backup directories. For example:

```
/var/backups/example_directory:
  file.retention_schedule:
    - strftime_format: example_name_%Y%m%dT%H%M%S.tar.bz2
    - retain:
      most_recent: 5
```

(continues on next page)
salt.states.file.absent(name, **kwargs)

Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module. If a directory is supplied, it will be recursively deleted.

If only the contents of the directory need to be deleted but not the directory itself, use \texttt{file.directory} with clean=True

name

The path which should be deleted

salt.states.file.accumulated(name, filename, text, **kwargs)

Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

name

Accumulator name

filename

Filename which would receive this accumulator (see file.managed state documentation about name)

text

String or list for adding in accumulator

require_in / watch_in

One of them required for sure we fill up accumulator before we manage the file. Probably the same as filename

Example:

Given the following:

\begin{verbatim}
animals_doing_things:
  file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: 'jumps over the lazy dog.'
    - require_in:
      - file: animal_file

animal_file:
  file.managed:
    - name: /tmp/animal_file.txt
    - source: salt://animal_file.txt
    - template: jinja
\end{verbatim}

One might write a template for animal_file.txt like the following:

\begin{verbatim}
The quick brown fox{% for animal in accumulator['animals_doing_things'] %} →{{ animal }}{% endfor %}
\end{verbatim}

Collectively, the above states and template file will produce:

\begin{verbatim}
The quick brown fox jumps over the lazy dog.
\end{verbatim}

Multiple accumulators can be "chained" together.
Note: The ‘accumulator’ data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, ignore_whitespace=True)

Ensure that some text appears at the end of a file.

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

name

The location of the file to append to.

text

The text to be appended, which can be a single string or a list of strings.

makedirs

If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.

source

A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

See the source_hash parameter description for file.managed function for more details and examples.

template

The named templating engine will be used to render the appended-to file. Defaults to jinja. The following templates are supported:

- cheetah
- genshi
- jinja
- mako
sources
A list of source files to append. If the files are hosted on an HTTP or FTP server, the source_hashes argument is also required.

source_hashes
A list of source_hashes corresponding to the sources list specified in the sources argument.

defaults
Default context passed to the template.

context
Overrides default context variables passed to the template.

ignore_whitespace
New in version 2015.8.4.
Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to False if you want to change this behavior.

Multi-line example:

```
/etc/motd:
  file.append:
    - text:
      | Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
      - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.append:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - append
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 0.9.5.

salt.states.file.blockreplace(name, marker_start='## start managed zone --', marker_end='## end managed zone --', source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content='", append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True, append_newline=None, insert_before_match=None, insert_after_match=None)

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.
Changed in version 2017.7.5, 2018.3.1: append_newline argument added. Additionally, to improve idempotence, if the string represented by marker_end is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove append_newline: False from the SLS and have the block properly replaced if the end of the content block is immediately followed by the marker_end (i.e. no newline before the marker).

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits.

**Note:** This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

Additionally, you can use file.accumulated and target this state. All accumulated data dictionaries' content will be added in the content block.

**name**
Filesistem path to the file to be edited

**marker_start**
The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output.

**marker_end**
The line content identifying the end of the content block. As of versions 2017.7.5 and 2018.3.1, everything up to the text matching the marker will be replaced, so it's important to ensure that your marker includes the beginning of the text you wish to replace.

**content**
The content to be used between the two lines identified by marker_start and marker_end.

**source**
The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```yaml
file_override_example:
  file.blockreplace:
    - name: /etc/example.conf
      source:
        - salt://file_that_does_not_exist
        - salt://file_that_exists
```

**source_hash**
This can be one of the following:
1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:
<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

See the `source_hash` parameter description for `file.managed` function for more details and examples.

**template**

Templating engine to be used to render the downloaded file. The following engines are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**context**

Overrides default context variables passed to the template

**defaults**

Default context passed to the template

**append_if_not_found**

If markers are not found and this option is set to `True`, the content block will be appended to the file.

**prepend_if_not_found**

If markers are not found and this option is set to `True`, the content block will be prepended to the file.

**insert_before_match**

If markers are not found, this parameter can be set to a regex which will insert the block before the first found occurrence in the file.

New in version 3001.

**insert_after_match**

If markers are not found, this parameter can be set to a regex which will insert the block after the first found occurrence in the file.

New in version 3001.

**backup**

The file extension to use for a backup of the file if any edit is made. Set this to `False` to skip making a backup.

**show_changes**

Controls how changes are presented. If `True`, the `Changes` section of the state return will contain a unified diff of the changes made. If `False`, then it will contain a boolean (`True` if any changes were made, otherwise `False`).

**append_newline**

Controls whether or not a newline is appended to the content block. If the value of this argument is `True` then a newline will be added to the content block. If it is `False`, then a newline will not be added to the content block. If it is unspecified, then a newline will only be added to the content block if it does not already end in a newline.

New in version 2017.7.5, 2018.3.1.

Example of usage with an accumulator and with a variable:
Salt Documentation, Release 3006.3

```python
{% set myvar = 42 %}
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
      marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-
      marker_end: "# END managed zone {{ myvar }} --"
      content: 'First line of content'
      append_if_not_found: True
      backup: '.bak'
      show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
      name: my-accumulator-{{ myvar }}
      text: "text 2"
      require_in:
        - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
      name: my-accumulator-{{ myvar }}
      text: |
        text 3
        text 4
      require_in:
        - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-

salt.states.file.cached(name, source_hash='', source_hash_name=None, skip_verify=False, saltenv='base', use_etag=False)

New in version 2017.7.3.
Changed in version 3005.

Ensures that a file is saved to the minion’s cache. This state is primarily invoked by other states to ensure that we do not re-download a source file if we do not need to.

name

The URL of the file to be cached. To cache a file from an environment other than base, either use the saltenv argument or include the saltenv in the URL (e.g. salt://path/to/file.conf?saltenv=dev).

Note: A list of URLs is not supported, this must be a single URL. If a local file is passed here, then the state will obviously not try to download anything, but it will compare a hash if one is specified.
source_hash
See the documentation for this same argument in the `file.managed` state.

**Note:** For remote files not originating from the `salt://` fileserver, such as http(s) or ftp servers, this state will not re-download the file if the locally-cached copy matches this hash. This is done to prevent unnecessary downloading on repeated runs of this state. To update the cached copy of a file, it is necessary to update this hash.

source_hash_name
See the documentation for this same argument in the `file.managed` state.

skip_verify
See the documentation for this same argument in the `file.managed` state.

**Note:** Setting this to `True` will result in a copy of the file being downloaded from a remote (http(s), ftp, etc.) source each time the state is run.

saltenv
Used to specify the environment from which to download a file from the Salt fileserver (i.e. those with `salt://` URL).

use_etag
If `True`, remote http/https file sources will attempt to use the ETag header to determine if the remote file needs to be downloaded. This provides a lightweight mechanism for promptly refreshing files changed on a web server without requiring a full hash comparison via the `source_hash` parameter.

New in version 3005.
This state will in most cases not be useful in SLS files, but it is useful when writing a state or remote-execution module that needs to make sure that a file at a given URL has been downloaded to the cachedir. One example of this is in the `archive.extracted` state:

```
result = __states__['file.cached'](source_match, 
    source_hash=source_hash, 
    source_hash_name=source_hash_name, 
    skip_verify=skip_verify, 
    saltenv=__env__)
```

This will return a dictionary containing the state's return data, including a `result` key which will state whether or not the state was successful. Note that this will not catch exceptions, so it is best used within a `try/except`.

Once this state has been run from within another state or remote-execution module, the actual location of the cached file can be obtained using `cp.is_cached`:

```
cached = __salt__['cp.is_cached'](source_match, saltenv=__env__)
```

This function will return the cached path of the file, or an empty string if the file is not present in the minion cache.

salt.states.file.comment(name, regex, char='#', backup='.bak', ignore_missing=False)

New in version 0.9.5.
Changed in version 3005.
Comment out specified lines in a file.

name
The full path to the file to be edited
regex

A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^foo$). Note that you _need_ the leading ^, otherwise each time you run highstate, another comment char will be inserted.

char

The character to be inserted at the beginning of a line in order to comment it out

backup

The file will be backed up before edit with this file extension

| Warning: This backup will be overwritten each time sed /comment/uncomment is called. Meaning the backup will only be useful after the first invocation. |

Set to False/None to not keep a backup.

ignore_missing

Ignore a failure to find the regex in the file. This is useful for scenarios where a line must only be commented if it is found in the file.

New in version 3005.

Usage:

```
/etc/fstab:
  file.comment:
    - regex: ^bind 127.0.0.1
```

salt.states.file.copy_(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, dir_mode=None, subdir=False, **kwargs)

If the file defined by the source option exists on the minion, copy it to the named path. The file will not be overwritten if it already exists, unless the force option is set to True.

| Note: This state only copies files from one location on a minion to another location on the same minion. For copying files from the master, use a file.managed state. |

name

The location of the file to copy to

source

The location of the file to copy to the location specified with name

force

If the target location is present then the file will not be moved, specify "force: True" to overwrite the target file

makedirs

If the target subdirectories don’t exist create them

preserve

New in version 2015.5.0.

Set preserve: True to preserve user/group ownership and mode after copying. Default is False. If preserve is set to True, then user/group/mode attributes will be ignored.

user

New in version 2015.5.0.

The user to own the copied file, this defaults to the user salt is running as on the minion. If preserve is set to True, then this will be ignored
group
New in version 2015.5.0.

The group to own the copied file, this defaults to the group salt is running as on the minion. If `preserve` is set to `True` or on Windows this will be ignored.

mode
New in version 2015.5.0.

The permissions to set on the copied file, aka 644, ‘0775’, ‘4664’. If `preserve` is set to `True`, then this will be ignored. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

dir_mode
New in version 3006.0.

If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

The default mode for new files and directories corresponds to the umask of the salt process. Not enforced for existing files and directories.

subdir
New in version 2015.5.0.

If the name is a directory then place the file inside the named directory.

Note: The copy function accepts paths that are local to the Salt minion. This function does not support salt://, http://, or the other additional file paths that are supported by `states.file.managed` and `states.file.recurse`.

Usage:

```
# Use 'copy', not 'copy_'
/etc/example.conf:
  file.copy:
    - source: /tmp/example.conf
```

salt.states.file.decode(name, encoded_data=None, contents_pillar=None, encoding_type='base64', checksum='md5')

Decode an encoded file and write it to disk

New in version 2016.3.0.

name
Path of the file to be written.

encoded_data
The encoded file. Either this option or `contents_pillar` must be specified.

contents_pillar
A Pillar path to the encoded file. Uses the same path syntax as `pillar.get`. The `hashutil.base64_encodefile` function can load encoded content into Pillar. Either this option or `encoded_data` must be specified.

encoding_type
The type of encoding.

checksum
The hashing algorithm to use to generate checksums. Wraps the `hashutil.digest` execution function.

Usage:
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - contents_pillar: mypillar:thefile

# or

write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: Z2V0IHNhbHRlZAo=

Be careful with multi-line strings that the YAML indentation is correct. E.g.,

```yaml
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data:
      {{ salt.pillar.get('path:to:data') | indent(8) }}
```

salt.states.file.directory(name=None, user=None, group=None, recurse=None, max_depth=None, dir_mode=None, file_mode=None, makedirs=False, clean=False, require=None, exclude_pat=None, follow_symlinks=False, force=False, backupname=None, allow_symlink=True, children_only=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False, **kwargs)

Ensure that a named directory is present and has the right perms

name
The location to create or manage a directory, as an absolute path

user
The user to own the directory; this defaults to the user salt is running as on the minion

group
The group ownership set for the directory; this defaults to the group salt is running as on the minion. On Windows, this is ignored

recurse
Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left unchanged respectively. directories will be left unchanged respectively. If silent is defined, individual file/directory change notifications will be suppressed.

Example:

```
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
```
Leave files or directories unchanged:

```
    /var/log/httpd:
        file.directory:
            - user: root
            - group: root
            - dir_mode: 755
            - file_mode: 644
            - recurse:
                - user
                - group
                - mode
                - ignoreDirs
```

New in version 2015.5.0.

**max_depth**

Limit the recursion depth. The default is no limit=None. 'max_depth' and 'clean' are mutually exclusive.

New in version 2016.11.0.

**dir_mode / mode**

The permissions mode to set any directories created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**file_mode**

The permissions mode to set any files created if 'mode' is run in 'recurse'. This defaults to dir_mode. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**makedirs**

If the directory is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean**

Remove any files that are not referenced by a required file state. See examples below for more info.

If this option is set then everything in this directory will be deleted unless it is required. 'clean' and 'max_depth' are mutually exclusive.

**require**

Require other resources such as packages or files.

**exclude_pat**

When 'clean' is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks**

If the desired path is a symlink (or recurse is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

Changed in version 3001.1: If set to False symlinks permissions are ignored on Linux systems because it does not support permissions modification. Symlinks permissions are always 0o777 on Linux.

**force**
If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname**

If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink**

If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

**children_only**

If children_only is True the base of a path is excluded when performing a recursive operation. In case of /path/to/base, base will be ignored while all of /path/to/base/* are still operated on.

**win_owner**

The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.

**win_perms**

A dictionary containing permissions to grant and their propagation. For example:

```python
{'Administrators': {'perms': 'full_control', 'applies_to': 'this_folder_only'}}
```

Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to is optional and defaults to this_folder_subfolder_files.

New in version 2017.7.0.

**windeny_perms**

A dictionary containing permissions to deny and their propagation. For example:

```python
{'Administrators': {'perms': 'full_control', 'applies_to': 'this_folder_only'}}
```

Can be a single basic perm or a list of advanced perms.

New in version 2017.7.0.

**win_inheritance**

True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

**win_perms_reset**

If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

New in version 2018.3.0.

Here's an example using the above win_* parameters:

```yaml
create_config_dir:
  file.directory:
    - name: 'C:\config'
    - win_owner: Administrators
    - win_perms:
      # Basic Permissions
      dev_ops:
        perms: full_control
```

(continues on next page)
# List of advanced permissions

- **appuser**
  - perms: read_attributes, read_ea, create_folders, read_permissions
  - applies_to: this_folder_only

- **joe_snuffy**
  - perms: read
  - applies_to: this_folder_files

- **fred_snuffy**
  - perms: full_control
  - win_deny_perms:
  - win_inheritance: False

For **clean**: True there is no mechanism that allows all states and modules to enumerate the files that they manage, so for file.directory to know what files are managed by Salt, a file state targeting managed files is required. To use a contrived example, the following states will always have changes, despite the file named okay being created by a Salt state:

```yaml
silly_way_of_creating_a_file:
  cmd.run:
    - name: mkdir -p /tmp/dont/do/this && echo "seriously" > /tmp/dont/do/this/okay
      - unless: grep seriously /tmp/dont/do/this/okay

will_always_clean:
  file.directory:
    - name: /tmp/dont/do/this
    - clean: True
```

Because `cmd.run` has no way of communicating that it’s creating a file, `will_always_clean` will remove the newly created file. Of course, every time the states run the same thing will happen - the `silly_way_of_creating_a_file` will create the file and `will_always_clean` will always remove it. Over and over again, no matter how many times you run it.

To make this example work correctly, we need to add a file state that targets the file, and a require between the file states:

```yaml
silly_way_of_creating_a_file:
  cmd.run:
    - name: mkdir -p /tmp/dont/do/this && echo "seriously" > /tmp/dont/do/this/okay
      - unless: grep seriously /tmp/dont/do/this/okay

file.managed:
  - name: /tmp/dont/do/this/okay
    - create: False
    - replace: False
    - require_in:
      - file: will_always_clean
```

Now there is a file state that `clean` can check, so running those states will work as expected. The file will be created with the specific contents, and `clean` will ignore the file because it is being managed by a Salt
file state. Note that if require_in was placed under cmd.run, it would not work, because the requisite is for the cmd, not the file.

```yaml
silly_way_of_creating_a_file:
  cmd.run:
    - name: mkdir -p /tmp/dont/do/this && echo "seriously" > /tmp/dont/do/this/okay
    - unless: grep seriously /tmp/dont/do/this/okay
      # This part should be under file.managed
    - require_in:
      - file: will_always_clean
  file.managed:
    - name: /tmp/dont/do/this/okay
    - create: False
    - replace: False
```

Any other state that creates a file as a result, for example pkgrepo, must have the resulting files referenced in a file state in order for clean: True to ignore them. Also note that the requisite (require_in vs require) works in both directions:

```yaml
clean_dir:
  file.directory:
    - name: /tmp/a/better/way
    - require:
      - file: a_better_way

a_better_way:
  file.managed:
    - name: /tmp/a/better/way/truely
    - makedirs: True
    - contents: a much better way
```

Works the same as this:

```yaml
clean_dir:
  file.directory:
    - name: /tmp/a/better/way
    - clean: True

a_better_way:
  file.managed:
    - name: /tmp/a/better/way/truely
    - makedirs: True
    - contents: a much better way
    - require_in:
      - file: clean_dir
```

A common mistake here is to forget the state name and id are both required for requisites:

```yaml
# Correct:
/path/to/some/file:
  file.managed:
    - contents: Cool
    - require_in:
```

(continues on next page)
salt.states.file.exists(name, **kwargs)

Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt’s purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

This function does not create the file if it doesn’t exist, it will return an error.

name
Absolute path which must exist

salt.states.file.hardlink(name, target, force=False, makedirs=False, user=None, group=None, dir_mode=None, **kwargs)

Create a hard link. If the file already exists and is a hard link pointing to any location other than the specified target, the hard link will be replaced. If the hard link is a regular file or directory then the state will return False. If the regular file is desired to be replaced with a hard link pass force: True

name
The location of the hard link to create

target
The location that the hard link points to

force
If the name of the hard link exists and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the hard link file will be deleted to make room for the hard link, unless backupname is set, when it will be renamed

makedirs
If the location of the hard link does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

user
The user to own any directories made if makedirs is set to true. This defaults to the user salt is running as on the minion

group
The group ownership set on any directories made if makedirs is set to true. This defaults to the group salt is running as on the minion. On Windows, this is ignored

dir_mode
If directories are to be created, passing this option specifies the permissions for those directories.
salt.states.file.keyvalue(name, key=None, value=None, key_values=None, separator='=',
    append_if_not_found=False, prepend_if_not_found=False, search_only=False,
    show_changes=True, ignore_if_missing=False, count=1, uncomment=None,
    key_ignore_case=False, value_ignore_case=False, create_if_missing=False)

Key/Value based editing of a file.

New in version 3001.

This function differs from file.replace in that it is able to search for keys, followed by a customizable
separator, and replace the value with the given value. Should the value be the same as the one already in the
file, no changes will be made.

Either supply both key and value parameters, or supply a dictionary with key / value pairs. It is an error to
supply both.

name  
Name of the file to search/replace in.

key  
Key to search for when ensuring a value. Use in combination with a value parameter.

value  
Value to set for a given key. Use in combination with a key parameter.

key_values  
Dictionary of key / value pairs to search for and ensure values for. Used to specify multiple key / values
at once.

separator  
Separator which separates key from value.

append_if_not_found  
Append the key/value to the end of the file if not found. Note that this takes precedence over
prepend_if_not_found.

prepend_if_not_found  
Prepend the key/value to the beginning of the file if not found. Note that append_if_not_found
takes precedence.

show_changes  
Show a diff of the resulting removals and inserts.

ignore_if_missing  
Return with success even if the file is not found (or not readable).

count  
Number of occurrences to allow (and correct), default is 1. Set to -1 to replace all, or set to 0 to remove
all lines with this key regardless of its value.

Note: Any additional occurrences after count are removed. A count of -1 will only replace all occurrences
that are currently uncommented already. Lines commented out will be left alone.

uncomment  
Disregard and remove supplied leading characters when finding keys. When set to None, lines that are
commented out are left for what they are.

Note: The argument to uncomment is not a prefix string. Rather; it is a set of characters, each of which are
stripped.

key_ignore_case  
Keys are matched case insensitively. When a value is changed the matched key is kept as-is.

value_ignore_case  
Values are checked case insensitively, trying to set e.g. 'Yes' while the current value is 'yes', will not
result in changes when value_ignore_case is set to True.
create_if_missing
Create the file if the destination file is not found.
New in version 3007.0.

An example of using file.keyvalue to ensure sshd does not allow for root to login with a password and at the same time setting the login-grace time to 1 minute and disabling all forwarding:

```python
sshd_config_harden:
  file.keyvalue:
    - name: /etc/ssh/sshd_config
      key_values:
        permitrootlogin: 'without-password'
        LoginGraceTime: '1m'
        DisableForwarding: 'yes'
      separator: ''
      uncomment: '# '
      key_ignore_case: True
      append_if_not_found: True
```

The same example, except for only ensuring PermitRootLogin is set correctly. Thus being able to use the shorthand key and value parameters instead of key_values.

```python
sshd_config_harden:
  file.keyvalue:
    - name: /etc/ssh/sshd_config
      key: PermitRootLogin
      value: without-password
      separator: ''
      uncomment: '# '
      key_ignore_case: True
      append_if_not_found: True
```

Note: Notice how the key is not matched case-sensitively, this way it will correctly identify both 'PermitRootLogin' as well as 'permitrootlogin'.

salt.states.file.line(name, content=None, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True, create=False, user=None, group=None, file_mode=None)

Line-focused editing of a file.
New in version 2015.8.0.

Note: file.line exists for historic reasons, and is not generally recommended. It has a lot of quirks. You may find file.replace to be more suitable.

file.line is most useful if you have single lines in a file, potentially a config file, that you would like to manage. It can remove, add, and replace lines.

name
Files system path to the file to be edited.

content
Content of the line. Allowed to be empty if mode=delete.
match
Match the target line for an action by a fragment of a string or regular expression.
If neither before nor after are provided, and match is also None, match falls back to the content value.

mode
Defines how to edit a line. One of the following options is required:
• ensure
  If line does not exist, it will be added. If before and after are specified either zero lines, or lines that contain the content line are allowed to be in between before and after. If there are lines, and none of them match then it will produce an error.
• replace
  If line already exists, it will be replaced.
• delete
  Delete the line, if found.
• insert
  Nearly identical to ensure. If a line does not exist, it will be added.
The differences are that multiple (and non-matching) lines are allowed between before and after, if they are specified. The line will always be inserted right before before. insert also allows the use of location to specify that the line should be added at the beginning or end of the file.

Note: If mode=insert is used, at least one of the following options must also be defined: location, before, or after. If location is used, it takes precedence over the other two options.

location
In mode=insert only, whether to place the content at the beginning or end of a the file. If location is provided, before and after are ignored. Valid locations:
• start
  Place the content at the beginning of the file.
• end
  Place the content at the end of the file.

before
Regular expression or an exact case-sensitive fragment of the string. Will be tried as both a regex and a part of the line. Must match exactly one line in the file. This value is only used in ensure and insert modes. The content will be inserted just before this line, matching its indent unless indent=False.

after
Regular expression or an exact case-sensitive fragment of the string. Will be tried as both a regex and a part of the line. Must match exactly one line in the file. This value is only used in ensure and insert modes. The content will be inserted directly after this line, unless before is also provided. If before is not matched, indentation will match this line, unless indent=False.

show_changes
Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True

Note: Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

backup
Create a backup of the original file with the extension: "Year-Month-Day-Hour-Minutes-Seconds".

quiet
Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and
nothing really happened.

**indent**

Keep indentation with the previous line. This option is not considered when the `delete` mode is specified. Default is True.

**create**

Create an empty file if doesn't exist.

New in version 2016.11.0.

**user**

The user to own the file, this defaults to the user salt is running as on the minion.

New in version 2016.11.0.

**group**

The group ownership set for the file, this defaults to the group salt is running as on the minion On Windows, this is ignored.

New in version 2016.11.0.

**file_mode**

The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

New in version 2016.11.0.

If an equal sign (=) appears in an argument to a Salt command, it is interpreted as a keyword argument in the format of `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```yaml
update_config:
  file.line:
    - name: /etc/myconfig.conf
    - mode: ensure
    - content: my key = my value
    - before: somekey.*?
```

Examples:

Here's a simple config file.

```ini
[some_config]
# Some config file
# this line will go away

here=False
away=True
goodybe=away
```

And an sls file:

```yaml
remove_lines:
  file.line:
    - name: /some/file.conf
    - mode: delete
    - match: away
```

This will produce:

```ini
[some_config]
# Some config file
```

(continues on next page)
here=False
away=True
goodbye=away

If that state is executed 2 more times, this will be the result:

```yaml
[some_config]
# Some config file
here=False
```

Given that original file with this state:

```yaml
replace_things:
  file.line:
    - name: /some/file.conf
    - mode: replace
    - match: away
    - content: here
```

Three passes will this state will result in this file:

```yaml
[some_config]
# Some config file
here
here
here
```

Each pass replacing the first line found.

Given this file:

```yaml
insert after me
something
insert before me
```

The following state:

```yaml
insert_a_line:
  file.line:
    - name: /some/file.txt
    - mode: insert
    - after: insert after me
    - before: insert before me
    - content: thrice
```

If this state is executed 3 times, the result will be:

```yaml
insert after me
something
thrice
```

(continues on next page)
If the mode is ensure instead, it will fail each time. To succeed, we need to remove the incorrect line between before and after:

<table>
<thead>
<tr>
<th>insert after me</th>
</tr>
</thead>
<tbody>
<tr>
<td>insert before me</td>
</tr>
</tbody>
</table>

With an ensure mode, this will insert thrice the first time and make no changes for subsequent calls. For something simple this is fine, but if you have instead blocks like this:

```plaintext
Begin SomeBlock
foo = bar
End

Begin AnotherBlock
another = value
End
```

And given this state:

```yaml
ensure_someblock:
  file.line:
  - name: /some/file.conf
  - mode: ensure
  - after: Begin SomeBlock
  - content: this should be my content
  - before: End
```

This will fail because there are multiple `End` lines. Without that problem, it still would fail because there is a non-matching line, `foo = bar`. Ensure only allows either zero, or the matching line present to be present in between `before` and `after`.

### salt.states.file.managed

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

- **name**
  - The location of the file to manage, as an absolute path.

- **source**
  - The source file to download to the minion, this source file can be hosted on either the salt master server (`salt://`), the salt minion local file system (`/`), or on an HTTP or FTP server (`http(s)://`, `ftp://`).
Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed. If source is left blank or None, please also set replaced to False to make your intention explicit.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored. Source list functionality only supports local files and remote files hosted on the salt master server or retrievable via HTTP, HTTPS, or FTP.

```yaml
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

**Using a Source Hash File**

The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/
```

25.20. state modules 4109
The following lines are all supported formats:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8bcc06a
/etc/resolv.conf
ead48423703509d37c4a90e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

### Inserting the Source Hash in the SLS Data

The `source_hash` can be specified as a simple checksum, like so:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
tomdroid-src-0.7.3.tar.gz
    - source_hash: 79eef25f9b0b2c642c62b7f737d4f53f
```

**Note:** Releases prior to 2016.11.0 must also include the hash type, like in the below example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
tomdroid-src-0.7.3.tar.gz
    - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

`source_hash` is ignored if the file hosted is not on a HTTP, HTTPS or FTP server.

### Known issues:

If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/
tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz/+md5
```

**source_hash_name**

When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path `/tmp/foo.txt`, then the following line in a hash file would match:

```
acbd18db4cc2f85cedef654fccc4a4d8  foo.txt
```

However, sometimes a hash file will include multiple similar paths:
In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
/tmp/foo.txt:
  file.managed:
    - source: https://mydomain.tld/dir2/foo.txt
    - source_hash: https://mydomain.tld/hashes
    - source_hash_name: ./dir2/foo.txt
```

**Note:** This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using `foo.txt` would not match.

New in version 2016.3.5.

**keep_source**

Set to `False` to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

**user**

The user to own the file, this defaults to the user salt is running as on the minion.

**group**

The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored.

**mode**

The permissions to set on this file, e.g. 644, 0775, or 4664.

The default mode for new files and directories corresponds to the umask of the salt process. The mode of existing files and directories will only be changed if `mode` is specified.

**Note:** This option is not supported on Windows.

Changed in version 2016.11.0: This option can be set to `keep`, and Salt will keep the mode from the Salt fileserver. This is only supported when the `source` URL begins with `salt://`, or for files local to the minion. Because the `source` option cannot be used with any of the `contents` options, setting the `mode` to `keep` is also incompatible with the `contents` options.

**Note:** `keep` does not work with salt-ssh.

As a consequence of how the files are transferred to the minion, and the inability to connect back to the master with salt-ssh, salt is unable to stat the file as it exists on the fileserver and thus cannot mirror the mode on the salt-ssh minion.

**attrs**

The attributes to have on this file, e.g. `a`, `i`. The attributes can be any or a combination of the following characters: `aAcCdDeijPsStTu`.
**Note:** This option is **not** supported on Windows.

New in version 2018.3.0.

**template**
If this setting is applied, the named templating engine will be used to render the downloaded file. The following templates are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

**makedirs**
If set to `True`, then the parent directories will be created to facilitate the creation of the named file. If `False`, and the parent directory of the destination file doesn't exist, the state will fail.

**dir_mode**
If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**replace**
If set to `False` and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

**context**
Overrides default context variables passed to the template.

**defaults**
Default context passed to the template.

**backup**
Override the default backup mode for this specific file. See backup_mode documentation for more details.

**show_changes**
Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made.

**create**
If set to `False`, then the file will only be managed if the file already exists on the system.

**contents**
Specify the contents of the file. Cannot be used in combination with `source`. Ignores hashes and does not use a templating engine.

This value can be either a single string, a multiline YAML string or a list of strings. If a list of strings, then the strings will be joined together with newlines in the resulting file. For example, the below two example states would result in identical file contents:

```
/path/to/file1:
  file.managed:
    - contents:
      - This is line 1
      - This is line 2

/path/to/file2:
  file.managed:
    - contents: |
      This is line 1
```

(continues on next page)
This is line 2

**contents_pillar**

New in version 0.17.0.

Changed in version 2016.11.0: contents_pillar can also be a list, and the pillars will be concatenated together to form one file.

Operates like *contents*, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

For example, the following could be used to deploy an SSH private key:

```yaml
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - attrs: a
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate `/home/deployer/.ssh/id_rsa` with the contents of `pillar['userdata']['deployer']['id_rsa']`. An example of this pillar setup would be like so:

```yaml
userdata:
  deployer:
    id_rsa: |
      -----BEGIN RSA PRIVATE KEY-----
      MIIEowIBAAKCAQEAoQiwO3JhBquPAalQF9qP1llZNXVjYMIswrMe2HcWUVBgh+vYU7sCwx/
      dH6+VvNwmCoqmNnP+8gTPKGl1vgA0b3AnMT623dMXjVKwnEagZPRJIxDynB/
      HaAre9euNiY3LvIez8TWSeMfT+rWvIKVBpvwlgGrfgz70m0pqux+UyFbAGLin+GpxzZAMafpZw4sBIIruissZj/j/shPqb8p9M5leO4Z3rjkCP1cxI
      -----END RSA PRIVATE KEY-----
```

**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

To avoid the hassle of creating an indented multiline YAML string, the `file_tree external pillar` can be used instead. However, this will not work for binary files in Salt releases before 2015.8.4.

**contents_grains**

New in version 2014.7.0.

Operates like *contents*, but draws from a value stored in grains, using the grains path syntax used in `grains.get`. This functionality works similarly to `contents_pillar`, but with grains.

For example, the following could be used to deploy a "message of the day" file:
**write_motd:**
```
file.managed:
  - name: /etc/motd
  - contents_grains: motd
```

This would populate `/etc/motd` file with the contents of the `motd` grain. The `motd` grain is not a default grain, and would need to be set prior to running the state:

```
salt '*' grains.set motd 'Welcome! This system is managed by Salt.'
```

**contents_newline**
New in version 2014.7.0.

Changed in version 2015.8.4: This option is now ignored if the contents being deployed contain binary data.

If `True`, files managed using `contents`, `contents_pillar`, or `contents_grains` will have a newline added to the end of the file if one is not present. Setting this option to `False` will ensure the final line, or entry, does not contain a new line. If the last line, or entry in the file does contain a new line already, this option will not remove it.

**contents_delimiter**
New in version 2015.8.4.

Can be used to specify an alternate delimiter for `contents_pillar` or `contents_grains`. This delimiter will be passed through to `pillar.get` or `grains.get` when retrieving the contents.

**encoding**
If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See [https://docs.python.org/3/library/codecs.html#standard-encodings](https://docs.python.org/3/library/codecs.html#standard-encodings) for the list of available encodings.

New in version 2017.7.0.

**encoding_errors**
Error encoding scheme. Default is `'strict'`. See [https://docs.python.org/2/library/codecs.html#codec-base-classes](https://docs.python.org/2/library/codecs.html#codec-base-classes) for the list of available schemes.

New in version 2017.7.0.

**allow_empty**
New in version 2015.8.4.

If set to `False`, then the state will fail if the contents specified by `contents_pillar` or `contents_grains` are empty.

**follow_symlinks**
New in version 2014.7.0.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

**check_cmd**
New in version 2014.7.0.

The specified command will be run with an appended argument of a *temporary* file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

For example, the following could be used to verify sudoers before making changes:

```
/etc/sudoers:
  file.managed:
    - user: root
```
(continues on next page)
NOTE: This check_cmd functions differently than the requisite check_cmd.

tmp_dir
Directory for temp file created by check_cmd. Useful for checkers dependent on config file location (e.g. daemons restricted to their own config directories by an apparmor profile).

/etc/dhcp/dhcpd.conf:
file.managed:
  - user: root
  - group: root
  - mode: 0755
  - tmp_dir: '/etc/dhcp'
  - contents: "# Managed by Salt"
  - check_cmd: dhcpd -t -cf

/tmp
Suffix for temp file created by check_cmd. Useful for checkers dependent on config file extension (e.g. the init-checkconf upstart config checker).

/etc/init/test.conf:
file.managed:
  - user: root
  - group: root
  - mode: 0440
  - tmp_ext: '.conf'
  - contents:
    - 'description "Salt Minion"
    - 'start on started mountall'
    - 'stop on shutdown'
    - 'respawn'
    - 'exec salt-minion'
  - check_cmd: init-checkconf -f

skip_verify
If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.0.

selinux
Allows setting the selinux user, role, type, and range of a managed file.

/tmp/selinux.test
file.managed:
  - user: root
  - selinux:
    seuser: system_u
    serole: object_r
    setype: system_conf_t

(continues on next page)
**serange**: s0

New in version 3000.

**win_owner**
The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.

**win_perms**
A dictionary containing permissions to grant and their propagation. For example: 
{"Administrators": {"perms": 'full_control'}}
Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to does not apply to file objects.

New in version 2017.7.0.

**win_deny_perms**
A dictionary containing permissions to deny and their propagation. For example: 
{"Administrators": {"perms": 'full_control'}}
Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to does not apply to file objects.

New in version 2017.7.0.

**win_inheritance**
True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

**win_perms_reset**
If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

New in version 2018.3.0.

Here's an example using the above win_* parameters:

```yaml
create_config_file:
  file.managed:
    - name: C:\config\settings.cfg
      source: salt://settings.cfg
      win_owner: Administrators
      win_perms:
        # Basic Permissions
        dev_ops:
          perms: full_control
        # List of advanced permissions
        appuser:
          perms:
            - read_attributes
            - read_ea
            - create_folders
            - read_permissions
        joe_snuffy:
          perms: read
      win_deny_perms:
      fred_snuffy:
        perms: full_control
      win_inheritance: False
```

verify_ssl
If False, remote https file sources (https://) and source_hash will not attempt to validate the servers certificate. Default is True.

New in version 3002.

use_etag
If True, remote http/https file sources will attempt to use the ETag header to determine if the remote file needs to be downloaded. This provides a lightweight mechanism for promptly refreshing files changed on a web server without requiring a full hash comparison via the source_hash parameter.

New in version 3005.

salt.states.file.missing(name, **kwargs)
Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.

name
Absolute path which must NOT exist

salt.states.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')
Create a special file similar to the 'nix mknod command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of 'nix mknod. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.

name
name of the file

ntype
node type 'p' (fifo pipe), 'c' (character device), or 'b' (block device)

major
major number of the device does not apply to a fifo pipe

minor
minor number of the device does not apply to a fifo pipe

user
owning user of the device/pipe

group
owning group of the device/pipe

mode
permissions on the device/pipe

Usage:

```
/dev/chr:
  file.mknod:
    - ntype: c
    - major: 180
    - minor: 31
    - user: root
    - group: root
    - mode: 660

/dev/blk:
  file.mknod:
    - ntype: b
    - major: 8
```
- **minor**: 999
- **user**: root
- **group**: root
- **mode**: 660

/dev/fifo:
file.mknod:
- **ntype**: p
- **user**: root
- **group**: root
- **mode**: 660

New in version 0.17.0.

**salt.states.file.mod_beacon**(name, **kwargs)

Create a beacon to monitor a file based on a beacon state argument.

**Note**: This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

**salt.states.file.mod_run_check_cmd**(cmd, filename, **check_cmd_opts)**

Execute the check_cmd logic.

Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True

**salt.states.file.not_cached**(name, saltenv='base')

New in version 2017.7.3.

Ensures that a file is not present in the minion's cache, deleting it if found. This state is primarily invoked by other states to ensure that a fresh copy is fetched.

name

The URL of the file to be removed from cache. To remove a file from cache in an environment other than base, either use the saltenv argument or include the saltenv in the URL (e.g. salt://path/to/file.conf?saltenv=dev).

**Note**: A list of URLs is not supported, this must be a single URL. If a local file is passed here, the state will take no action.

**saltenv**

Used to specify the environment from which to download a file from the Salt fileserver (i.e. those with salt:// URL).

**salt.states.file.patch**(name, source=None, source_hash=None, source_hash_name=None, skip_verify=False, template=None, context=None, defaults=None, options='', reject_file=None, strip=None, saltenv=None, **kwargs)**

Ensure that a patch has been applied to the specified file or directory.

Changed in version 2019.2.0: The hash and dry_run_first options are now ignored, as the logic which determines whether or not the patch has already been applied no longer requires them. Additionally, this state now supports patch files that modify more than one file. To use these sort of patches, specify a directory (and, if necessary, the strip option) instead of a file.

**Note**: A suitable patch executable must be available on the minion. Also, keep in mind that the pre-check
this state does to determine whether or not changes need to be made will create a temp file and send all patch output to that file. This means that, in the event that the patch would not have applied cleanly, the comment included in the state results will reference a temp file that will no longer exist once the state finishes running.

name
The file or directory to which the patch should be applied

source
The patch file to apply

Changed in version 2019.2.0: The source can now be from any file source supported by Salt (salt://, http://, https://, ftp://, etc.). Templating is also now supported.

source_hash
Works the same way as in file.managed.
New in version 2019.2.0.

source_hash_name
Works the same way as in file.managed
New in version 2019.2.0.

skip_verify
Works the same way as in file.managed
New in version 2019.2.0.

template
Works the same way as in file.managed
New in version 2019.2.0.

context
Works the same way as in file.managed
New in version 2019.2.0.

defaults
Works the same way as in file.managed
New in version 2019.2.0.

options
Extra options to pass to patch. This should not be necessary in most cases.

Note: For best results, short opts should be separate from one another. The -N and -r, and -o options are used internally by this state and cannot be used here. Additionally, instead of using -pN or --strip=N, use the strip option documented below.

reject_file
If specified, any rejected hunks will be written to this file. If not specified, then they will be written to a temp file which will be deleted when the state finishes running.

Important: The parent directory must exist. Also, this will overwrite the file if it is already present.

New in version 2019.2.0.

strip
Number of directories to strip from paths in the patch file. For example, using the below SLS would instruct Salt to use -p1 when applying the patch:

/exemple/myfile.conf:
    file.patch:
        (continues on next page)
New in version 2019.2.0: In previous versions, `-p1` would need to be passed as part of the `options` value.

**saltenv**
Specify the environment from which to retrieve the patch file indicated by the `source` parameter. If not provided, this defaults to the environment from which the state is being executed.

**Note:** Ignored when the patch file is from a non-salt:// source.

**Usage:**

```
# Equivalent to ``patch --forward /opt/myfile.txt myfile.patch``
```

```
/opt/myfile.txt:
  file.patch:
    - source: salt://myfile.patch
```

### salt.states.file.prepend

```python
salt.states.file.prepend(name, text=None, makedirs=False, source=None, source_hash=None,
                         template='jinja', sources=None, source_hashes=None, defaults=None,
                         context=None, header=None)
```

Ensure that some text appears at the beginning of a file

The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

**name**
The location of the file to append to.

**text**
The text to be appended, which can be a single string or a list of strings.

**makedirs**
If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.

**source**
A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see `s3.get` state documentation). File retrieval from Openstack Swift object storage is supported via `swift://container/object_path` URLs (see `swift.get` documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

**source_hash**
This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

```
<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
See the `source_hash` parameter description for `file.managed` function for more details and examples.

**template**

The named templating engine will be used to render the appended-to file. Defaults to `jinja`. The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**sources**

A list of source files to append. If the files are hosted on an HTTP or FTP server, the `source_hashes` argument is also required.

**source_hashes**

A list of `source_hashes` corresponding to the sources list specified in the `sources` argument.

**defaults**

Default context passed to the template.

**context**

Overrides default context variables passed to the template.

**ignore_whitespace**

New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to `False` if you want to change this behavior.

Multi-line example:

```
/etc/motd:
file.prepend:
  text: | Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
  - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
file.prepend:
  text:
    - Trust no one unless you have eaten much salt with him.
    - "Salt is born of the purest of parents: the sun and the sea."
```

Optionally, require the text to appear exactly as specified (order and position). Combine with multi-line or multiple lines of input.
Gather text from multiple template files:

```
/etc/motd:
  file:
    - prepend
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 2014.7.0.

salt.states.file.pruned(name, recurse=False, ignore_errors=False, older_than=None)

New in version 3006.0.

Ensure that the named directory is absent. If it exists and is empty, it will be deleted. An entire directory tree can be pruned of empty directories as well, by using the `recurse` option.

- **name**
  The directory which should be deleted if empty.

- **recurse**
  If set to `True`, this option will recursive deletion of empty directories. This is useful if nested paths are all empty, and would be the only items preventing removal of the named root directory.

- **ignore_errors**
  If set to `True`, any errors encountered while attempting to delete a directory are ignored. This AUTOMATICALLY ENABLES the `recurse` option since it’s not terribly useful to ignore errors on the removal of a single directory. Useful for pruning only the empty directories in a tree which contains non-empty directories as well.

- **older_than**
  When `older_than` is set to a number, it is used to determine the number of days which must have passed since the last modification timestamp before a directory will be allowed to be removed. Setting the value to 0 is equivalent to leaving it at the default of `None`.

salt.states.file.recurse(name, source, keep_source=True, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, replace=True, defaults=None, include_empty=False, backup='', include_pat=None, exclude_pat=None, maxdepth=None, keep_symlinks=False, force_symlinks=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, **kwargs)

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

- **name**
  The directory to set the recursion in

- **source**
  The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs
**keep_source**
Set to False to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

**clean**
Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**
Require other resources such as packages or files

**user**
The user to own the directory. This defaults to the user salt is running as on the minion

**group**
The group ownership set for the directory. This defaults to the group salt is running as on the minion.

On Windows, this is ignored

**dir_mode**
The permissions mode to set on any directories created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

---

**Note**: This option is not supported on Windows.

**file_mode**
The permissions mode to set on any files created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

---

**Note**: This option is not supported on Windows.

Changed in version 2016.11.0: This option can be set to keep, and Salt will keep the mode from the Salt files server. This is only supported when the source URL begins with salt://, or for files local to the minion. Because the source option cannot be used with any of the contents options, setting the mode to keep is also incompatible with the contents options.

**sym_mode**
The permissions mode to set on any symlink created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

---

**Note**: This option is not supported on Windows.

**template**
If this setting is applied, the named templating engine will be used to render the downloaded file. The following templates are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy
**Note:** The template option is required when recursively applying templates.

**replace**
If set to `False` and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

**context**
Overides default context variables passed to the template.

**defaults**
Default context passed to the template.

**include_empty**
Set this to `True` if empty directories should also be created (default is `False`).

**backup**
Overides the default backup mode for all replaced files. See backup_mode documentation for more details.

**include_pat**
When copying, include only this pattern, or list of patterns, from the source. Default is glob match; if prefixed with `E@`, then regexp match. Example:

- `include_pat: hello*` :: glob matches 'hello01', 'hello02'
  ... but not 'otherhello'
- `include_pat: E@hello` :: regexp matches 'otherhello', 'hello01' ...

Changed in version 3001: List patterns are now supported

- `include_pat:
  - hello01
  - hello02`

**exclude_pat**
Exclude this pattern, or list of patterns, from the source when copying. If both `include_pat` and `exclude_pat` are supplied, then it will apply conditions cumulatively. i.e. first select based on `include_pat`, and then within that result apply `exclude_pat`.

Also, when 'clean=True', exclude this pattern from the removal list and preserve in the destination. Example:

- `exclude_pat: APPDATA*` :: glob matches APPDATA.01, APPDATA.02,.. for exclusion
- `exclude_pat: E@(APPDATA)|(TEMPDATA)` :: regexp matches APPDATA or TEMPDATA for exclusion

Changed in version 3001: List patterns are now supported

- `exclude_pat:
  - APPDATA.01
  - APPDATA.02`

**maxdepth**
When copying, only copy paths which are of depth `maxdepth` from the source path. Example:

- `maxdepth: 0` :: Only include files located in the source directory
- `maxdepth: 1` :: Only include files located in the source or immediate subdirectories
keep_symlinks
Keep symlinks when copying from the source. This option will cause the copy operation to terminate at
the symlink. If desire behavior similar to rsync, then set this to True. This option is not taken in account
if fileserver_followsymlinks is set to False.

force_symlinks
Force symlink creation. This option will force the symlink creation. If a file or directory is obstruct-
ing symlink creation it will be recursively removed so that symlink creation can proceed. This op-
tion is usually not needed except in special circumstances. This option is not taken in account if
fileserver_followsymlinks is set to False.

win_owner
The owner of the symlink and directories if makedirs is True. If this is not passed, user will be used.
If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.7.

win_perms
A dictionary containing permissions to grant

New in version 2017.7.7.

win_deny_perms
A dictionary containing permissions to deny

New in version 2017.7.7.

win_inheritance
True to inherit permissions from parent, otherwise False

New in version 2017.7.7.

salt.states.file.rename(name, source, force=False, makedirs=False, **kwargs)
If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it
already exists unless the force option is set to True.

name
The location of the file to rename to

source
The location of the file to move to the location specified with name

force
If the target location is present then the file will not be moved, specify "force: True" to overwrite the
target file

makedirs
If the target subdirectories don’t exist create them

salt.states.file.replace(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False,
preprend_if_not_found=False, not_found_content=None, backup='.bak',
show_changes=True, ignore_if_missing=False, backslash_literal=False)
Maintain an edit in a file.

New in version 0.17.0.

name
Filesystem path to the file to be edited. If a symlink is specified, it will be resolved to its target.

pattern
A regular expression, to be matched using Python’s re.search().

Note: If you need to match a literal string that contains regex special characters, you may want to use
salt’s custom Jinja filter, regex_escape.

{{ 'http://example.com?foo=bar%20baz' | regex_escape }}
**repl**
The replacement text

**count**
Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.

**flags**
A list of flags defined in the `re` module documentation from the Python standard library. Each list item should be a string that will correlate to the human-friendly flag name. E.g., `['IGNORECASE', 'MULTILINE']`. Optionally, flags may be an int, with a value corresponding to the XOR (`|`) of all the desired flags. Defaults to 8 (which equates to `['MULTILINE']`).

**Note:** `file.replace` reads the entire file as a string to support multiline regex patterns. Therefore, when using anchors such as `^` or `$` in the pattern, those anchors may be relative to the line OR relative to the file. The default for `file.replace` is to treat anchors as relative to the line, which is implemented by setting the default value of `flags` to `['MULTILINE']`. When overriding the default value for `flags`, if 'MULTILINE' is not present then anchors will be relative to the file. If the desired behavior is for anchors to be relative to the line, then simply add 'MULTILINE' to the list of flags.

**bufsize**
How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.

**append_if_not_found**
If set to `True`, and pattern is not found, then the content will be appended to the file.

New in version 2014.7.0.

**prepend_if_not_found**
If set to `True` and pattern is not found, then the content will be prepended to the file.

New in version 2014.7.0.

**not_found_content**
Content to use for append/prepend if not found. If `None` (default), uses `repl`. Useful when `repl` uses references to group in pattern.

New in version 2014.7.0.

**backup**
The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**show_changes**
Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Returns a boolean or a string.

**ignore_if_missing**
New in version 2016.3.4.

Controls what to do if the file is missing. If set to `False`, the state will display an error raised by the execution module. If set to `True`, the state will simply report no changes.

**backslash_literal**
New in version 2016.11.7.

Interpret backslashes as literal backslashes for the `repl` and not escape characters. This will help when using append/prepend so that the backslashes are not interpreted for the `repl` on the second run of the state.

For complex regex patterns, it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML’s multiline string syntax.

```yaml
complex_search_and_replace:
  file.replace:
```

(continues on next page)
Note: When using YAML multiline string syntax in `pattern:`, make sure to also use that syntax in the `repl:` part, or you might loose line feeds.

When regex capture groups are used in `pattern:`, their captured value is available for reuse in the `repl:` part as a backreference (ex. `\1`).

```
add_login_group_to_winbind_ssh_access_list:
  file.replace:
    - name: '/etc/security/pam_winbind.conf'
    - pattern: '^(require_membership_of =)\([^\n]+\n\)
    - repl: '\1, append-new-group-to-line'
```

Note: The `file.replace` state uses Python's `re` module. For more advanced options, see https://docs.python.org/2/library/re.html

```
salt.states.file.retention_schedule(name, retain, strptime_format=None, timezone=None)
Apply retention scheduling to backup storage directory.
New in version 2016.11.0.
Changed in version 3006.0.

Parameters
- name -- The filesystem path to the directory containing backups to be managed.
- retain -- Delete the backups, except for the ones we want to keep. The N below should be an integer but may also be the special value of `all`, which keeps all files matching the criteria. All of the retain options default to None, which means to not keep files based on this criteria.
  - most_recent N
    - Keep the most recent N files.
  - first_of_hour N
    - For the last N hours from now, keep the first file after the hour.
  - first_of_day N
    - For the last N days from now, keep the first file after midnight. See also timezone.
  - first_of_week N
    - For the last N weeks from now, keep the first file after Sunday midnight.
  - first_of_month N
    - For the last N months from now, keep the first file after the start of the month.
  - first_of_year N
    - For the last N years from now, keep the first file after the start of the year.
- strptime_format -- A python strptime format string used to first match the filenames of backups and then parse the filename to determine the datetime of the file.
  https://docs.python.org/2/library/datetime.html#datetime.datetime.strptime
```

25.20. state modules
to None, which considers all files in the directory to be backups eligible for deletion and uses `os.path.getmtime()` to determine the datetime.

- `timezone` -- The timezone to use when determining midnight. This is only used when datetime is pulled from `os.path.getmtime()`. Defaults to None which uses the timezone from the locale.

Usage example:

```
/var/backups/example_directory:
file.retention_schedule:
  - retain:
      most_recent: 5
      first_of_hour: 4
      first_of_day: 7
      first_of_week: 6  # NotImplemented yet.
      first_of_month: 6
      first_of_year: all
  - strftime_format: example_name_%Y%m%dT%H%M%S.tar.bz2
  - timezone: None
```

salt.states.file.serialize(name=None, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, backup='', makedirs=False, show_changes=True, create=True, merge_if_exists=False, encoding=None, encoding_errors='strict', serializer=None, serializer_opts=None, deserializer_opts=None, **kwargs)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

- **name**
  - The location of the file to create

- **dataset**
  - The dataset that will be serialized

- **dataset_pillar**
  - Operates like `dataset`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

  - New in version 2015.8.0.

- **serializer** (or `formatter`)

  - Write the data as this format. See the list of `serializer modules` for supported output formats.

  - Changed in version 3002: `serializer` argument added as an alternative to `formatter`. Both are accepted, but using both will result in an error.

- **encoding**

  - If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See [https://docs.python.org/3/library/codecs.html#standard-encodings](https://docs.python.org/3/library/codecs.html#standard-encodings) for the list of available encodings.

  - New in version 2017.7.0.

- **encoding_errors**

  - Error encoding scheme. Default is `'strict'`. See [https://docs.python.org/2/library/codecs.html#codec-base-classes](https://docs.python.org/2/library/codecs.html#codec-base-classes) for the list of available schemes.

  - New in version 2017.7.0.

- **user**

  - The user to own the directory, this defaults to the user salt is running as on the minion

- **group**

  - The group ownership set for the directory, this defaults to the group salt is running as on the minion
mode
The permissions to set on this file, e.g. 644, 0775, or 4664.
The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

Note: This option is not supported on Windows.
 backup
Overrides the default backup mode for this specific file.
 makedirs
Create parent directories for destination file.
 New in version 2014.1.3.
 show_changes
Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.
 create
Default is True, if create is set to False then the file will only be managed if the file already exists on the system.
 merge_if_exists
Default is False, if merge_if_exists is True then the existing file will be parsed and the dataset passed in will be merged with the existing content
 New in version 2014.7.0.
 serializer_opts
Pass through options to serializer. For example:

/etc/dummy/package.yaml
  file.serialize:
    - serializer: yaml
    - serializer_opts:
      - explicit_start: True
      - default_flow_style: True
      - indent: 4

The valid opts are the additional opts (i.e. not the data being serialized) for the function used to serialize the data. Documentation for the these functions can be found in the list below:
  • For yaml: yaml.dump()
  • For json: json.dumps()
  • For python: pprint.pformat()
  • For msgpack: Run python -c 'import msgpack; help(msgpack.Packer)' to see the available options (encoding, unicode_errors, etc.)
 deserializer_opts
Like serializer_opts above, but only used when merging with an existing file (i.e. when merge_if_exists is set to True).
The options specified here will be passed to the deserializer to load the existing data, before merging with the specified data and re-serializing.

/etc/dummy/package.yaml
  file.serialize:
    - serializer: yaml
    - serializer_opts:
      - explicit_start: True
The valid opts are the additional opts (i.e., not the data being deserialized) for the function used to deserializethe data. Documentation for these functions can be found in the list below:

- For **yaml**: `yaml.load()`  
  - For **json**: `json.loads()`

However, note that not all arguments are supported. For example, when deserializing JSON, arguments like `parse_float` and `parse_int` which accept a callable object cannot be handled in an SLS file.

New in version 2019.2.0.

For example, this state:

```json
/file.serialize:
  - dataset:
    name: naive
    description: A package using naive versioning
    author: A confused individual <iam@confused.com>
    dependencies:
      express: '>= 1.2.0'
      optimist: '>= 0.1.0'
    engine: node 0.4.1
    serializer: json
```

will manage the file `/etc/dummy/package.json`:

```json
{
  "author": "A confused individual <iam@confused.com>",
  "dependencies": {
    "express": ">= 1.2.0",
    "optimist": ">= 0.1.0"
  },
  "description": "A package using naive versioning",
  "engine": "node 0.4.1",
  "name": "naive"
}
```

salt.states.file.shortcut(name, target, arguments=None, working_dir=None, description=None, icon_location=None, force=False, backupname=None, makedirs=False, user=None, **kwargs)

Create a Windows shortcut

If the file already exists and is a shortcut pointing to any location other than the specified target, the shortcut will be replaced. If it is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a shortcut pass `force: True`, if it is to be renamed, pass a `backupname`.

- **name**
  The location of the shortcut to create. Must end with either ".lnk" or ".url"
- **target**
  The location that the shortcut points to
arguments
Any arguments to pass in the shortcut

working_dir
Working directory in which to execute target

description
Description to set on shortcut

icon_location
Location of shortcut’s icon

force
If the name of the shortcut exists and is not a file and force is set to False, the state will fail. If force is set to True, the link or directory in the way of the shortcut file will be deleted to make room for the shortcut, unless backupname is set, when it will be renamed

backupname
If the name of the shortcut exists and is not a file, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

makedirs
If the location of the shortcut does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory. Setting this to True will also create the parent for backupname if necessary.

user
The user to own the file, this defaults to the user salt is running as on the minion

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=None, atomic=False, disallow_copy_and_unlink=False, inherit_user_and_group=False, **kwargs)

Create a symbolic link (symlink, soft link)

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If an entry with the same name exists then the state will return False. If the existing entry is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

name
The location of the symlink to create

target
The location that the symlink points to

force
If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the existing entry in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed

Changed in version 3000: Force will now remove all types of existing file system entries, not just files, directories and symlinks.

backupname
If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first. An absolute path OR a basename file/directory name must be provided. The latter will be placed relative to the symlink destination’s parent directory.

makedirs
If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

user
The user to own the file, this defaults to the user salt is running as on the minion unless the link already
exists and \texttt{inherit\_user\_and\_group} is set

\textbf{group}
The group ownership set for the file, this defaults to the group salt is running as on the minion unless the link already exists and \texttt{inherit\_user\_and\_group} is set. On Windows, this is ignored

\textbf{mode}
The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

\textbf{win\_owner}
The owner of the symlink and directories if \texttt{makedirs} is True. If this is not passed, \texttt{user} will be used. If \texttt{user} is not passed, the account under which Salt is running will be used.

New in version 2017.7.7.

\textbf{win\_perms}
A dictionary containing permissions to grant

New in version 2017.7.7.

\textbf{win\_deny\_perms}
A dictionary containing permissions to deny

New in version 2017.7.7.

\textbf{win\_inheritance}
True to inherit permissions from parent, otherwise False

New in version 2017.7.7.

\textbf{atomic}
Use atomic file operation to create the symlink.

New in version 3006.0.

\textbf{disallow\_copy\_and\_unlink}
Only used if \texttt{backupname} is used and the name of the symlink exists and is not a symlink. If set to True, the operation is offloaded to the \texttt{file.rename} execution module function. This will use \texttt{os.rename} underneath, which will fail in the event that \texttt{src} and \texttt{dst} are on different filesystems. If False (the default), \texttt{shutil.move} will be used in order to fall back on a "copy then unlink" approach, which is required for moving across filesystems.

New in version 3006.0.

\textbf{inherit\_user\_and\_group}
If set to True, the link already exists, and either \texttt{user} or \texttt{group} are not set, this parameter will inform Salt to pull the user and group information from the existing link and use it where \texttt{user} or \texttt{group} is not set. The \texttt{user} and \texttt{group} parameters will override this behavior.

New in version 3006.0.

\texttt{salt.states.file.tidied(name, age=0, matches=None, rmdir=False, size=0, exclude=None, full_path_match=False, followlinks=False, time_comparison='atime', age_size_logical_operator='OR', age_size_only=None, rmlinks=True, **kwargs)}

Changed in version 3005,3006.0.

Remove unwanted files based on specific criteria.

The default operation uses an OR operation to evaluate age and size, so a file that is too large but is not old enough will still get tidied. If neither age nor size is given all files which match a pattern in matches will be removed.

\textbf{NOTE}: The regex patterns in this function are used in \texttt{re.match()}, so there is an implicit "beginning of string" anchor (^) in the regex and it is unanchored at the other end unless explicitly entered ($).

\textbf{name}
The directory tree that should be tidied
age
Maximum age in days after which files are considered for removal

matches
List of regular expressions to restrict what gets removed. Default: ['.*']

rmdirs
Whether or not it's allowed to remove directories

size
Maximum allowed file size. Files greater or equal to this size are removed. Doesn't apply to directories or symbolic links

exclude
List of regular expressions to filter the matches parameter and better control what gets removed.

New in version 3005.

full_path_match
Match the matches and exclude regex patterns against the entire file path instead of just the file or directory name. Default: False

New in version 3005.

followlinks
This module will not descend into subdirectories which are pointed to by symbolic links. If you wish to force it to do so, you may give this option the value True. Default: False

New in version 3005.

time_comparison
Default: atime. Options: atime/mtime/ctime. This value is used to set the type of time comparison made using age. The default is to compare access times (atime) or the last time the file was read. A comparison by modification time (mtime) uses the last time the contents of the file was changed. The ctime parameter is the last time the contents, owner, or permissions of the file were changed.

New in version 3005.

age_size_logical_operator
This parameter can change the default operation (OR) to an AND operation to evaluate age and size. In that scenario, a file that is too large but is not old enough will NOT get tidied. A file will need to fulfill BOTH conditions in order to be tidied. Accepts OR or AND.

New in version 3006.0.

age_size_only
This parameter can trigger the reduction of age and size conditions which need to be satisfied down to ONLY age or ONLY size. By default, this parameter is None and both conditions will be evaluated using the logical operator defined in age_size_logical_operator. The parameter can be set to age or size in order to restrict evaluation down to that specific condition. Path matching and exclusions still apply.

New in version 3006.0.

rmlinks
Whether or not it's allowed to remove symbolic links

New in version 3006.0.

```
cleanup:
  file.tidied:
    - name: /tmp/salt_test
    - rmdirs: True
    - matches:
      - foo
      - b.*r
```
salt.states.file.touch(name, atime=None, mtime=None, makedirs=False)

Replicate the 'nix "touch" command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don't care about atime or mtime, you should use file.managed instead, as it is more feature-complete. (Just leave out the source/template/contents arguments, and it will just create the file and/or check its permissions, without messing with contents)

**name**
- name of the file

**atime**
- atime of the file

**mtime**
- mtime of the file

**makedirs**
- whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
  file.touch
```

New in version 0.9.5.

salt.states.file.uncomment(name, regex, char='#', backup='.bak')

Uncomment specified commented lines in a file

**name**
- The full path to the file to be edited

**regex**
- A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between comment() and uncomment()). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend "^[ t"]"

**char**
- The character to remove in order to uncomment a line

**backup**
- The file will be backed up before edit with this file extension;

**Warning:** This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:

```
/etc/adduser.conf:
  file.uncomment:
    - regex: EXTRA_GROUPS
```

New in version 0.9.5.
25.20.92 salt.states.firewall

State to check firewall configurations
New in version 2016.3.0.

```python
salt.states.firewall.check(name, port=None, **kwargs)
```

Checks if there is an open connection from the minion to the defined host on a specific port.

- **name**
  - host name or ip address to test connection to
- **port**
  - The port to test the connection on
- **kwargs**
  - Additional parameters, parameters allowed are:
    - `proto` (tcp or udp)
    - `family` (ipv4 or ipv6)
    - `timeout`

```yaml
testgoogle:
  firewall.check:
    - name: 'google.com'
    - port: 80
    - proto: 'tcp'
```

25.20.93 salt.states.firewalld

Management of firewalld
New in version 2015.8.0.

The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp. It will be applied permanently and directly before restart/reload.

```yaml
public:
  firewalld.present:
    - name: public
    - block_icmp:
      - echo-reply
      - echo-request
    - default: False
    - masquerade: True
    - ports:
      - 22/tcp
      - 25/tcp
```

The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```yaml
my_zone:
  firewalld.present:
    - name: public
    - masquerade: True
    - port_fwd:
      - 22:2222:tcp
      - 80:443:tcp:192.168.0.1
```
The following example binds the public zone to interface eth0 and to all packets coming from the 192.168.1.0/24 subnet. It also removes the zone from all other interfaces or sources.

```yaml
public:
  firewalld.present:
    - name: public
      interfaces:
        - eth0
      sources:
        - 192.168.1.0/24
```

Here, we define a new service that encompasses TCP ports 4505 4506:

```yaml
saltmaster:
  firewalld.service:
    - name: saltmaster
    - ports:
      - 4505/tcp
      - 4506/tcp
```

To make this new service available in a zone, the following can be used, which would allow access to the salt master from the 10.0.0.0/8 subnet:

```yaml
saltzone:
  firewalld.present:
    - name: saltzone
    - services:
      - saltmaster
    - sources:
      - 10.0.0.0/8
```

Another way of implementing the same rule above using rich rules is demonstrated here:

```yaml
saltzone:
  firewalld.present:
    - name: saltzone
    - rich_rules:
      - rule service name="saltmaster" accept
      - sources:
        - 10.0.0.0/8
```

The format of rich rules is the same as:

```
firewall-cmd --list-rich-rules
```

with an example output of:

```
rule protocol value="icmp" accept
rule protocol value="ipv6-icmp" accept
rule service name="snmp" accept
```

```python
class salt.states.firewalld.ForwardingMapping(srcport, destport, protocol, destaddr)
```

Represents a port forwarding statement mapping a local port to a remote port for a specific protocol (TCP or UDP)
**todict()**

Returns a pretty dictionary meant for command line output.

```python
salt.states.firewalld.present(name, block_icmp=None, prune_block_icmp=False, default=None, masquerade=False, ports=None, prune_ports=False, port_fwd=None, prune_port_fwd=False, services=None, prune_services=False, interfaces=None, prune_interfaces=False, sources=None, prune_sources=False, rich_rules=None, prune_rich_rules=False)
```

Ensure a zone has specific attributes.

- **name**
  - The zone to modify.
- **default**
  - [None] Set this zone as the default zone if True.
- **masquerade**
  - [False] Enable or disable masquerade for a zone.
- **block_icmp**
  - [None] List of ICMP types to block in the zone.
- **prune_block_icmp**
  - [False] If True, remove all but the specified block_icmp from the zone.
- **ports**
  - [None] List of ports to add to the zone.
- **prune_ports**
  - [False] If True, remove all but the specified ports from the zone.
- **port_fwd**
  - [None] List of port forwards to add to the zone.
- **prune_port_fwd**
  - [False] If True, remove all but the specified port_fwd from the zone.
- **services**
  - [None] List of services to add to the zone.
- **prune_services**
  - [False] If True, remove all but the specified services from the zone. .. note:: Currently defaults to True for compatibility, but will be changed to False in a future release.
- **interfaces**
  - [None] List of interfaces to add to the zone.
- **prune_interfaces**
  - [False] If True, remove all but the specified interfaces from the zone.
- **sources**
  - [None] List of sources to add to the zone.
- **prune_sources**
  - [False] If True, remove all but the specified sources from the zone.
- **rich_rules**
  - [None] List of rich rules to add to the zone.
- **prune_rich_rules**
  - [False] If True, remove all but the specified rich rules from the zone.

```python
salt.states.firewalld.service(name, ports=None, protocols=None)
```

Ensure the service exists and encompasses the specified ports and protocols.

New in version 2016.11.0.
25.20.94  salt.states.gem

Installation of Ruby modules packaged as gems

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```
addressable:
  gem.installed:
    - user: rvm
    - ruby: jruby@jgemset
```

`salt.states.gem.installed(name, ruby=None, gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None, source=None)`

Make sure that a gem is installed.

- `name` The name of the gem to install
- `ruby`: None
  Only for RVM or rbenv installations: the ruby version and gemset to target.
- `gem_bin`: None
  Custom gem command to run instead of the default. Use this to install gems to a non-default ruby install.
  If you are using rvm or rbenv use the ruby argument instead.
- `user`: None
  The user under which to run the `gem` command
  New in version 0.17.0.
- `version` [None] Specify the version to install for the gem. Doesn't play nice with multiple gems at once
- `rdoc` [False] Generate RDoc documentation for the gem(s).
- `ri` [False] Generate RI documentation for the gem(s).
- `pre_releases` [False] Install pre-release version of gem(s) if available.
- `proxy` [None] Use the specified HTTP proxy server for all outgoing traffic. Format: `http://hostname[[:port]]`
- `source` [None] Use the specified HTTP gem source server to download gem. Format: `http://hostname[[:port]]`

`salt.states.gem.removed(name, ruby=None, user=None, gem_bin=None)`

Make sure that a gem is not installed.

- `name` The name of the gem to uninstall
- `gem_bin` [None] Full path to `gem` binary to use.
- `ruby` [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- `user`: None
  The user under which to run the `gem` command
  New in version 0.17.0.

`salt.states.gem.sources_add(name, ruby=None, user=None)`

Make sure that a gem source is added.
name
The URL of the gem source to be added
ruby: None
For RVM or rbenv installations: the ruby version and gemset to target.
user: None
The user under which to run the gem command
New in version 0.17.0.

salt.states.gem.sources_remove(name, ruby=None, user=None)
Make sure that a gem source is removed.
name
The URL of the gem source to be removed
ruby: None
For RVM or rbenv installations: the ruby version and gemset to target.
user: None
The user under which to run the gem command
New in version 0.17.0.

25.20.95 salt.states.git
States to manage git repositories and git configuration

Important: Before using git over ssh, make sure your remote host fingerprint exists in your ~/.ssh/known_hosts file.

Changed in version 2015.8.8: This state module now requires git 1.6.5 (released 10 October 2009) or newer.

salt.states.git.cloned(name, target, branch=None, user=None, password=None, identity=None, https_user=None, https_pass=None, output_encoding=None)
New in version 2018.3.3,2019.2.0.
Ensure that a repository has been cloned to the specified target directory. If not, clone that repository. No fetches will be performed once cloned.
name
Address of the remote repository
target
Name of the target directory where repository should be cloned
branch
Remote branch to check out. If unspecified, the default branch (i.e. the one to the remote HEAD points) will be checked out.

Note: The local branch name will match the remote branch name. If the branch name is changed, then that branch will be checked out locally, but keep in mind that remote repository will not be fetched. If your use case requires that you keep the clone up to date with the remote repository, then consider using git.latest.

user
User under which to run git commands. By default, commands are run by the user under which the minion is running.
password
Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.
**identity**

Path to a private key to use for ssh URLs. Works the same way as in `git.latest`, see that state’s documentation for more information.

**https_user**

HTTP Basic Auth username for HTTPS (only) clones

**https_pass**

HTTP Basic Auth password for HTTPS (only) clones

**output_encoding**

Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

```python
salt.states.git.config_set(name, value=None, multivar=None, repo=None, user=None, password=None, output_encoding=None, **kwargs)
```

New in version 2014.7.0.

Changed in version 2015.8.0: Renamed from `git.config` to `git.config_set`. For earlier versions, use `git.config`.

Ensure that a config value is set to the desired value(s)

**name**

Name of the git config value to set

**value**

Set a single value for the config item

**multivar**

Set multiple values for the config item

**Note:** The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

New in version 2015.8.0.

**repo**

Location of the git repository for which the config value should be set. Required unless `global` is set to `True`.

**user**

User under which to run git commands. By default, the commands are run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**global**

[False] If `True`, this will set a global git config option

**output_encoding**

Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.
New in version 2018.3.1.

Local Config Example:

```yaml
# Single value
mylocalrepo:
  git.config_set:
    - name: user.email
    - value: foo@bar.net
    - repo: /path/to/repo

# Multiple values
mylocalrepo:
  git.config_set:
    - name: mysection.myattribute
    - multivar:
      - foo
      - bar
      - baz
    - repo: /path/to/repo
```

Global Config Example (User ``foo``):

```yaml
mylocalrepo:
  git.config_set:
    - name: user.name
    - value: Foo Bar
    - user: foo
    - global: True
```

salt.states.git.config_unset(name, value_regex=None, repo=None, user=None, password=None, output_encoding=None, **kwargs)

New in version 2015.8.0.

Ensure that the named config key is not present

**name**

The name of the configuration key to unset. This value can be a regex, but the regex must match the entire key name. For example, `foo\.` would not match all keys in the `foo` section, it would be necessary to use `foo\..+` to do so.

**value_regex**

Regex indicating the values to unset for the matching key(s)

**all**

[False] If True, unset all matches

**repo**

Location of the git repository for which the config value should be set. Required unless `global` is set to True.

**user**

User under which to run git commands. By default, commands are run by the user under which the minion is running.

**password**
Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms. New in version 2016.3.4.

`global`  
[False] If `True`, this will set a global git config option

`output_encoding`  
Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

**Examples:**

```yaml
# Value matching 'baz'
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - value_regex: 'baz'
    - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
  git.config_unset:
    - name: 'foo\..+'
    - all: True

# Ensure that global config value is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - global: True
```

```python
canopystates.git.detached(name, rev, target, remote='origin', user=None, password=None, force_clone=False, force_checkout=False, fetch_remote=True, hard_reset=False, submodules=False, identity=None, https_user=None, https_pass=None, output_encoding=None, **kwargs)
```

New in version 2016.3.0.

Make sure a repository is cloned to the given target directory and is a detached HEAD checkout of the commit ID resolved from `rev`.

- `name`  
  Address of the remote repository.

- `rev`  
  The branch, tag, or commit ID to checkout after clone. If a branch or tag is specified it will be resolved to a commit ID and checked out.
target
   Name of the target directory where repository is about to be cloned.
remote
   [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the
   initial remote name. If the repository already exists, and a remote by this name is not present, one will
   be added.
user
   User under which to run git commands. By default, commands are run by the user under which the
   minion is running.
password
   Windows only. Required when specifying user. This parameter will be ignored on non-
   Windows platforms.
   New in version 2016.3.4.
force_clone
   [False] If the target directory exists and is not a git repository, then this state will fail. Set this
   argument to True to remove the contents of the target directory and clone the repo into it.
force_checkout
   [False] When checking out the revision ID, the state will fail if there are unwritten changes. Set this
   argument to True to discard unwritten changes when checking out.
fetch_remote
   [True] If False a fetch will not be performed and only local refs will be reachable.
hard_reset
   [False] If True a hard reset will be performed before the checkout and any uncommitted modifications
   to the working directory will be discarded. Untracked files will remain in place.

Note: Changes resulting from a hard reset will not trigger requisites.

submodules
   [False] Update submodules
identity
   A path on the minion (or a SaltStack fileserver URL, e.g. salt://path/to/identity_file) to a
   private key to use for SSH authentication.
https_user
   HTTP Basic Auth username for HTTPS (only) clones
https_pass
   HTTP Basic Auth password for HTTPS (only) clones
output_encoding
   Use this option to specify which encoding to use to decode the output from any git commands which
   are run. This should not be needed in most cases.

Note: This should only be needed if the files in the repository were created with filenames using an
encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.
salt.states.git.latest(name, target, rev='HEAD', branch=None, user=None, password=None,
   update_head=True, force_checkout=False, force_clone=False, force_fetch=False,
   force_reset=False, submodules=False, bare=False, mirror=False, remote='origin',
   fetch_tags=True, sync_tags=True, depth=None, identity=None, https_user=None,
   https_pass=None, refspec_branch='', refspec_tag='', output_encoding=None,
   **kwargs)

Make sure the repository is cloned to the given directory and is up-to-date.
name
Address of the remote repository, as passed to git clone

Note: From the Git documentation, there are two URL formats supported for SSH authentication. The below two examples are equivalent:

```bash
# ssh:// URL
ssh://user@server/project.git

# SCP-like syntax
user@server:project.git
```

A common mistake is to use an ssh:// URL, but with a colon after the domain instead of a slash. This is invalid syntax in Git, and will therefore not work in Salt. When in doubt, confirm that a git clone works for the URL before using it in Salt.

It has been reported by some users that SCP-like syntax is incompatible with git repos hosted on Atlas-sian Stash/BitBucket Server. In these cases, it may be necessary to use ssh:// URLs for SSH authentication.

rev
[HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to <remote>/<rev>, unless rev refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If rev is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.

Changed in version 2015.8.0: If not specified, rev now defaults to the remote repository’s HEAD.

target
Name of the target directory where repository is about to be cloned

branch
Name of the local branch into which to checkout the specified rev. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.

New in version 2015.8.0.

Note: If this argument is not specified, this means that Salt will not change the local branch if the repository is reset to another branch/tag/SHA1. For example, assume that the following state was run initially:

```yaml
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
```

This would have cloned the HEAD of that repo (since a rev wasn’t specified), and because branch is not specified, the branch in the local clone at /var/www/foo would be whatever the default branch is on the remote repository (usually master, but not always). Now, assume that it becomes necessary to switch this checkout to the dev branch. This would require rev to be set, and probably would also require force_reset to be enabled:

```yaml
foo_app:
  git.latest:
```

(continues on next page)
The result of this state would be to perform a hard-reset to origin/dev. Since branch was not specified though, while /var/www/foo would reflect the contents of the remote repo's dev branch, the local branch would still remain whatever it was when it was cloned. To make the local branch match the remote one, set `branch` as well, like so:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - branch: dev
    - force_reset: True
```

This may seem redundant, but Salt tries to support a wide variety of use cases, and doing it this way allows for the use case where the local branch doesn’t need to be strictly managed.

**user**

Local system user under which to run git commands. By default, commands are run by the user under which the minion is running.

**Note:** This is not to be confused with the username for http(s)/SSH authentication.

New in version 0.17.0.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**update_head**

[True] If set to False, then the remote repository will be fetched (if necessary) to ensure that the commit to which `rev` points exists in the local checkout, but no changes will be made to the local HEAD.

New in version 2015.8.3.

**force_checkout**

[False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

**force_clone**

[False] If the `target` directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.

**force_fetch**

[False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to True to force the fetch even if it is a non-fast-forward update.

New in version 2015.8.0.

**force_reset**

[False] If the update is not a fast-forward, this state will fail. Set this argument to True to force a
hard-reset to the remote revision in these cases.

Changed in version 2019.2.0: This option can now be set to `remote-changes`, which will instruct Salt not to discard local changes if the repo is up-to-date with the remote repository.

**submodules**

[False] Update submodules on clone or branch change

**bare**

[False] Set to True if the repository is to be a bare clone of the remote repository.

**mirror**

Set to True if the repository is to be a mirror of the remote repository. This implies that bare set to True, and thus is incompatible with rev.

**remote**

[origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

**fetch_tags**

[True] If True, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

**sync_tags**

[True] If True, then Salt will delete tags which exist in the local clone but are not found on the remote repository.

New in version 2018.3.4.

**depth**

Defines depth in history when git a clone is needed in order to ensure latest. E.g. `depth: 1` is useful when deploying from a repository with a long history. Use rev to specify branch or tag. This is not compatible with revision IDs.

Changed in version 2019.2.0: This option now supports tags as well as branches, on Git 1.8.0 and newer.

**identity**

Path to a private key to use for ssh URLs. This can be either a single string, or a list of strings. For example:

```
# Single key
git@github.com:user/repo.git:
  git.latest:
    - user: deployer
    - identity: /home/deployer/.ssh/id_rsa

# Two keys
git@github.com:user/repo.git:
  git.latest:
    - user: deployer
    - identity:
      - /home/deployer/.ssh/id_rsa
      - /home/deployer/.ssh/id_rsa_alternate
```

If multiple keys are specified, they will be tried one-by-one in order for each git command which needs to authenticate.

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.
Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Changed in version 2016.3.0: Key can now be specified as a SaltStack fileserver URL (e.g. `salt:// path/to/identity_file`).

**https_user**

HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https_pass**

HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

**refspec_branch**

[*] A glob expression defining which branches to retrieve when fetching. See `git-fetch(1)` for more information on how refspecs work.

New in version 2017.7.0.

**refspec_tag**

[*] A glob expression defining which tags to retrieve when fetching. See `git-fetch(1)` for more information on how refspecs work.

New in version 2017.7.0.

**output_encoding**

Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

Note: This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

Note: Clashing ID declarations can be avoided when including different branches from the same git repository in the same SLS file by using the `name` argument. The example below checks out the `gh-pages` and `gh-pages-prod` branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts` ssh key required to perform the git checkout.

```
<table>
<thead>
<tr>
<th>gitlab.example.com:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssh_known_hosts:</td>
</tr>
<tr>
<td>- present</td>
</tr>
<tr>
<td>- user: root</td>
</tr>
<tr>
<td>- enc: ecdsa</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>git-website-staging:</th>
</tr>
</thead>
<tbody>
<tr>
<td>git.latest:</td>
</tr>
<tr>
<td>- name: <a href="mailto:git@gitlab.example.com">git@gitlab.example.com</a>:user/website.git</td>
</tr>
<tr>
<td>- rev: gh-pages</td>
</tr>
<tr>
<td>- target: /usr/share/nginx/staging</td>
</tr>
<tr>
<td>- identity: /root/.ssh/website_id_rsa</td>
</tr>
<tr>
<td>- require:</td>
</tr>
<tr>
<td>- pkg: git</td>
</tr>
<tr>
<td>- ssh_known_hosts:</td>
</tr>
</tbody>
</table>
```

(continues on next page)
**salt.states.git.present***(name, force=False, bare=True, template=None, separate_git_dir=None, shared=None, user=None, password=None, output_encoding=None)***

Ensure that a repository exists in the given directory

**Warning:** If the minion has Git 2.5 or later installed, name points to a worktree, and force is set to True, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

- **name**
  Path to the directory
  Changed in version 2015.8.0: This path must now be absolute

- **force**
  [False] If True, and if name points to an existing directory which does not contain a git repository, then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

- **bare**
  [True] If True, and a repository must be initialized, then the repository will be a bare repository.

**Note:** This differs from the default behavior of **git.init**, make sure to set this value to False if a bare repo is not desired.

- **template**
  If a new repository is initialized, this argument will specify an alternate template directory.
  New in version 2015.8.0.

- **separate_git_dir**
  If a new repository is initialized, this argument will specify an alternate $GIT_DIR
  New in version 2015.8.0.

- **shared**
  Set sharing permissions on git repo. See git-init(1) for more details.
  New in version 2015.5.0.
**user**
User under which to run git commands. By default, commands are run by the user under which the minion is running.

New in version 0.17.0.

**password**
Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**output_encoding**
Use this option to specify which encoding to use to decode the output from any git commands which are run. This should not be needed in most cases.

**Note:** This should only be needed if the files in the repository were created with filenames using an encoding other than UTF-8 to handle Unicode characters.

New in version 2018.3.1.

---

### 25.20.96 salt.states.github

**Github User State Module**

New in version 2016.3.0.

This state is used to ensure presence of users in the Organization.

#### **ensure user test is present in github:**

```python
github.present:
- name: 'Example TestUser1'
- email: example@domain.com
- username: 'gitexample'
```

**salt.states.github.absent**(*name*, **profile**='github', **kwargs)

Ensure a github user is absent

```python
ensure user test is absent in github:
github.absent:
- name: 'Example TestUser1'
- email: example@domain.com
- username: 'gitexample'
```

The following parameters are required:

**name**
Github handle of the user in organization

#### **salt.states.github.present**(*name*, **profile**='github', **kwargs)

Ensure a user is present

```python
ensure user test is present in github:
github.present:
- name: 'gitexample'
```

The following parameters are required:
name

This is the github handle of the user in the organization.

**salt.states.github.repo_absent**(name, profile='github', **kwargs)

Ensure a repo is absent.

Example:

```python
ensure repo test is absent in github:
github.repo_absent:
  - name: 'test'
```

The following parameters are required:

name

This is the name of the repository in the organization.

New in version 2016.11.0.

**salt.states.github.repo_present**(name, description=None, homepage=None, private=None, has_issues=None, has_wiki=None, has_downloads=None, auto_init=False, gitignore_template=None, license_template=None, teams=None, profile='github', **kwargs)

Ensure a repository is present.

name

This is the name of the repository.

description

The description of the repository.

homepage

The URL with more information about the repository.

private

The visibility of the repository. Note that private repositories require a paid GitHub account.

has_issues

Whether to enable issues for this repository.

has_wiki

Whether to enable the wiki for this repository.

has_downloads

Whether to enable downloads for this repository.

auto_init

Whether to create an initial commit with an empty README.

gitignore_template

The desired language or platform for a .gitignore, e.g "Haskell".

license_template

The desired LICENSE template to apply, e.g "mit" or "mozilla".

teams

The teams for which this repo should belong to, specified as a dict of team name to permission ('pull', 'push' or 'admin').

New in version 2017.7.0.

Example:

```python
Ensure repo my-repo is present in github:
github.repo_present:
  - name: 'my-repo'
  - description: 'My very important repository'
```

New in version 2016.11.0.
salt.states.github.team_absent(name, profile='github', **kwargs)
Ensure a team is absent.

Example:

```
ensure team test is present in github:
    github.team_absent:
        - name: 'test'
```

The following parameters are required:

name
This is the name of the team in the organization.
New in version 2016.11.0.

salt.states.github.team_present(name, description=None, repo_names=None, privacy='secret', permission='pull', members=None, enforce_mfa=False, no_mfa_grace_seconds=0, profile='github', **kwargs)
Ensure a team is present

name
This is the name of the team in the organization.
description
The description of the team.
repo_names
The names of repositories to add the team to.
privacy
The level of privacy for the team, can be 'secret' or 'closed'. Defaults to secret.
permission
The default permission for new repositories added to the team, can be 'pull', 'push' or 'admin'. Defaults to pull.
members
The members belonging to the team, specified as a dict of member name to optional configuration. Options include 'enforce_mfa_from' and 'mfa_exempt'.
enforce_mfa
Whether to enforce MFA requirements on members of the team. If True then all members without mfa_exempt: True configured will be removed from the team. Note that no_mfa_grace_seconds may be set to allow members a grace period.
no_mfa_grace_seconds
The number of seconds of grace time that a member will have to enable MFA before being removed from the team. The grace period will begin from enforce_mfa_from on the member configuration, which defaults to 1970/01/01.

Example:

```
Ensure team test is present in github:
    github.team_present:
        - name: 'test'
        - members:
            user1: {}
            user2: {}

Ensure team test_mfa is present in github:
    github.team_present:
        - name: 'test_mfa'
        - members:
            user1:
```
(continues on next page)
New in version 2016.11.0.

25.20.97 salt.states.glance_image

Management of OpenStack Glance Images

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.glanceng for setup instructions

Example States

create image:
  glance_image.present:
    - name: cirros
    - filename: cirros.raw
    - image_format: raw

delete image:
  glance_image.absent:
    - name: cirros

salt.states.glance_image.absent(name, auth=None)
  Ensure image does not exist
  name
    Name of the image

salt.states.glance_image.present(name, auth=None, **kwargs)
  Ensure image exists and is up-to-date
  name
    Name of the image
  enabled
    Boolean to control if image is enabled
description
    An arbitrary description of the image
25.20.98  salt.states.glassfish

Manage Glassfish/Payara server .. versionadded:: 2016.11.0

Management of glassfish using its RESTful API You can setup connection parameters like this

- server:
  - ssl: true
  - url: localhost
  - port: 4848
  - user: admin
  - password: changeit

salt.states.glassfish.connection_factory_absent(name, both=True, server=None)
Ensures the transaction factory is absent.

name
Name of the connection factory

both
Delete both the pool and the resource, defaults to true

salt.states.glassfish.connection_factory_present(name, restype='connection_factory',
description='', enabled=True, min_size=1, max_size=250, resize_quantity=2,
idle_timeout=300, wait_timeout=60,
reconnect_on_failure=False,
transaction_support='',
connection_validation=False, server=None)
Ensures that the Connection Factory is present

name
Name of the connection factory

restype
Type of the connection factory, can be either connection_factory, queue_connection_factory or `topic_connection_factory`, defaults to connection_factory

description
Description of the connection factory

enabled
Is the connection factory enabled? defaults to true

min_size
Minimum and initial number of connections in the pool, defaults to 1

max_size
Maximum number of connections that can be created in the pool, defaults to 250

resize_quantity
Number of connections to be removed when idle_timeout expires, defaults to 2

idle_timeout
Maximum time a connection can remain idle in the pool, in seconds, defaults to 300

wait_timeout
Maximum time a caller can wait before timeout, in seconds, defaults to 60

reconnect_on_failure
Close all connections and reconnect on failure (or reconnect only when used), defaults to false

transaction_support
Level of transaction support, can be either XATransaction, LocalTransaction or NoTransaction

connection_validation
Connection validation is required, defaults to false
salt.states.glassfish.\texttt{destination_absent}(name, server=None)

Ensures that the JMS Destination doesn't exists

\texttt{name}

Name of the JMS Destination

salt.states.glassfish.\texttt{destination_present}(name, physical, restype='queue', description='', enabled=True, server=None)

Ensures that the JMS Destination Resource (queue or topic) is present

\texttt{name}

The JMS Queue/Topic name

\texttt{physical}

The Physical destination name

\texttt{restype}

The JMS Destination resource type, either \texttt{queue} or \texttt{topic}, defaults is \texttt{queue}

\texttt{description}

A description of the resource

\texttt{enabled}

Defaults to True

salt.states.glassfish.\texttt{jdbc_datasource_absent}(name, both=True, server=None)

Ensures the JDBC Datasource doesn't exists

\texttt{name}

Name of the datasource

\texttt{both}

Delete both the pool and the resource, defaults to true

salt.states.glassfish.\texttt{jdbc_datasource_present}(name, description='', enabled=True, restype='datasource', vendor='mysql', sql_url='', sql_user='', sql_password='', min_size=8, max_size=32, resize_quantity=2, idle_timeout=300, wait_timeout=60, non_transactional=False, transaction_isolation='', isolation_guaranteed=True, server=None)

Ensures that the JDBC Datasource exists

\texttt{name}

Name of the datasource

\texttt{description}

Description of the datasource

\texttt{enabled}

Is the datasource enabled? defaults to true

\texttt{restype}

Resource type, can be \texttt{datasource}, \texttt{xa_datasource}, \texttt{connection_pool_datasource} or \texttt{driver}, defaults to \texttt{datasource}

\texttt{vendor}

SQL Server type, currently supports \texttt{mysql}, \texttt{postgresql} and \texttt{mssql}, defaults to \texttt{mysql}

\texttt{sql_url}

URL of the server in jdbc form

\texttt{sql_user}

Username for the server

\texttt{sql_password}

Password for that username

\texttt{min_size}

Minimum and initial number of connections in the pool, defaults to 8
max_size
   Maximum number of connections that can be created in the pool, defaults to 32
resize_quantity
   Number of connections to be removed when idle_timeout expires, defaults to 2
idle_timeout
   Maximum time a connection can remain idle in the pool, in seconds, defaults to 300
wait_timeout
   Maximum time a caller can wait before timeout, in seconds, defaults to 60
non_transactional
   Return non-transactional connections
transaction_isolation
   Defaults to the JDBC driver default
isolation_guaranteed
   All connections use the same isolation level

salt.states.glassfish.system_properties_absent(name, server=None)
   Ensures that the system property doesn’t exists
   name
      Name of the system property

salt.states.glassfish.system_properties_present(server=None, **kwargs)
   Ensures that the system properties are present
   properties
      The system properties

25.20.99 salt.states.glusterfs

Manage GlusterFS pool.
salt.states.glusterfs.add_volume_bricks(name, bricks)
   Add brick(s) to an existing volume
   name
      Volume name
   bricks
      List of bricks to add to the volume

```
myvolume:
   glusterfs.add_volume_bricks:
      - bricks:
         - host1:/srv/gluster/drive1
         - host2:/srv/gluster/drive2

Replicated Volume:
   glusterfs.add_volume_bricks:
      - name: volume2
      - bricks:
         - host1:/srv/gluster/drive2
         - host2:/srv/gluster/drive3
```
salt.states.glusterfs.max_op_version(name)
   New in version 2019.2.0.
   Add brick(s) to an existing volume
   name
      Volume name
myvolume:
    glusterfs.max_op_version:
        - name: volume1
        - version: 30707

salt.states.glusterfs.op_version(name, version)
New in version 2019.2.0.
Add brick(s) to an existing volume
name
    Volume name
version
    Version to which the cluster.op-version should be set

myvolume:
    glusterfs.op_version:
        - name: volume1
        - version: 30707

salt.states.glusterfs.peered(name)
Check if node is peered.
name
    The remote host with which to peer.

peer-cluster:
    glusterfs.peered:
        - name: two

peer-clusters:
    glusterfs.peered:
        - names:
            - one
            - two
            - three
            - four

salt.states.glusterfs.started(name)
Check if volume has been started
name
    name of the volume

mycluster:
    glusterfs.started: []

salt.states.glusterfs.volume_present(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False, arbiter=False)
Ensure that the volume exists
name
    name of the volume
bricks
    list of brick paths
replica
    replica count for volume
arbiter
use every third brick as arbiter (metadata only)

New in version 2019.2.0.

start
ensure that the volume is also started

```yaml
myvolume:
  glusterfs.volume_present:
    - bricks:
        - host1:/srv/gluster/drive1
        - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.volume_present:
    - name: volume2
      - bricks:
          - host1:/srv/gluster/drive2
          - host2:/srv/gluster/drive3
        - replica: 2
        - start: True

Replicated Volume with arbiter brick:
  glusterfs.volume_present:
    - name: volume3
      - bricks:
          - host1:/srv/gluster/drive2
          - host2:/srv/gluster/drive3
          - host3:/srv/gluster/drive4
        - replica: 3
        - arbiter: True
        - start: True
```

25.20.100 salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

```yaml
localdesktop_wm_prefs:
  gnomedesktop.wm_preferences:
    - user: username
    - audible_bell: false
    - action_double_click_titlebar: 'toggle-maximize'
    - visual_bell: true
    - num_workspaces: 6

localdesktop_lockdown:
  gnomedesktop.desktop_lockdown:
    - user: username
    - disable_user_switching: true

localdesktop_interface:
  gnomedesktop.desktop_interface:
    - user: username
```

(continues on next page)
- `clock_show_date`: true
- `clock_format`: 12h

`salt.states.gnomedesktop.desktop_interface`:

```python
salt.states.gnomedesktop.desktop_interface(name, user=None, automatic_mnemonics=None, buttons_have_icons=None, can_change_accels=None, clock_format=None, clock_show_date=None, clock_show_seconds=None, cursor_blink=None, cursor_blink_time=None, cursor_blink_timeout=None, cursor_size=None, cursor_theme=None, document_font_name=None, enable_animations=None, font_name=None, gtk_color_palette=None, gtk_color_scheme=None, gtk_im_module=None, gtk_im_preedit_style=None, gtk_im_status_style=None, gtk_key_theme=None, gtk_theme=None, gtk_timeout_initial=None, gtk_timeout_repeat=None, icon_theme=None, menubar_accel=None, menubar_detachable=None, menus_have_icons=None, menus_have_tearoff=None, monospace_font_name=None, show_input_method_menu=None, show_unicode_menu=None, text_scaling_factor=None, toolbar_detachable=None, toolbar_icons_size=None, toolbar_style=None, toolkit_accessibility=None, **kwargs)
```

desktop_interface: sets values in the org.gnome.desktop.interface schema

`salt.states.gnomedesktop.desktop_lockdown`:

```python
salt.states.gnomedesktop.desktop_lockdown(name, user=None, disable_application_handlers=None, disable_command_line=None, disable_lock_screen=None, disable_log_out=None, disable_print_setup=None, disable_printing=None, disable_save_to_disk=None, disable_user_switching=None, user_administration_disabled=None, **kwargs)
```

desktop_lockdown: sets values in the org.gnome.desktop.lockdown schema

`salt.states.gnomedesktop.wm_preferences`:

```python
salt.states.gnomedesktop.wm_preferences(name, user=None, action_double_click_titlebar=None, action_middle_click_titlebar=None, action_right_click_titlebar=None, application_based=None, audible_bell=None, auto_raise=None, auto_raise_delay=None, button_layout=None, disable_workarounds=None, focus_mode=None, focus_new_windows=None, mouse_button_modifier=None, num_workspaces=None, raise_on_click=None, resize_with_right_button=None, theme=None, titlebar_font=None, titlebar_uses_system_font=None, visual_bell=None, visual_bell_type=None, workspace_names=None, **kwargs)
```

wm_preferences: sets values in the org.gnome.desktop.wm.preferences schema
25.20.101 salt.states.gpg

Management of the GPG keychains

New in version 2016.3.0.

```python
salt.states.gpg.absent(name, keys=None, user=None, gnupghome=None, **kwargs)
```

Ensure GPG public key is absent in keychain

- **name**: The unique name or keyid for the GPG public key.
- **keys**: The keyId or keyIds to add to the GPG keychain.
- **user**: Remove GPG keys from the specified user’s keychain.
- **gnupghome**: Override GNUPG Home directory

```python
salt.states.gpg.present(name, keys=None, user=None, keyserver=None, gnupghome=None, trust=None, **kwargs)
```

Ensure GPG public key is present in keychain

- **name**: The unique name or keyid for the GPG public key.
- **keys**: The keyId or keyIds to add to the GPG keychain.
- **user**: Add GPG keys to the specified user’s keychain.
- **keyserver**: The keyserver to retrieve the keys from.
- **gnupghome**: Override GNUPG Home directory
- **trust**: Trust level for the key in the keychain, ignored by default. Valid trust levels: expired, unknown, not_trusted, marginally, fully, ultimately

25.20.102 salt.states.grafana

Manage Grafana Dashboards

This module uses `elasticsearch`, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

```python
mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash
```

```bash
# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
```

(continues on next page)
- rows_from_pillar:
  - systemhealth
  - requests

# Passing hosts in
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows:
    - collapse: false
effective: true
    height: 150px
title: System Health
panels:
  - aliasColors: {}
    id: 200000
    annotate:
      enable: false
    bars: false
datasource: null
effective: true
error: false
fill: 7

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

**salt.states.grafana.dashboard_absent**(name, hosts=None, profile='grafana')

Ensure the named grafana dashboard is deleted.

**name**
Name of the grafana dashboard.

**profile**
A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

**salt.states.grafana.dashboard_present**(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.

**name**
Name of the grafana dashboard.

**dashboard**
A dict that defines a dashboard that should be managed.
dashboard_from_pillar
A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
rows
A list of grafana rows.
rows_from_pillar
A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
profile
A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

25.20.103  salt.states.grafana4_dashboard

Manage Grafana v4.0 Dashboards
New in version 2017.7.0.

configuration
This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_user: admin
  grafana_password: admin
  grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_token: token
  grafana_timeout: 3
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

Ensure minimum dashboard is managed:
grafana4_dashboard.present:
  - name: insightful-dashboard
  - base_dashboards_from_pillar:
    - default_dashboard
  - base_rows_from_pillar:
    - default_row
  - base_panels_from_pillar:
    - default_panel
  - dashboard:
    rows:
      - title: Usage
        panels:
          - targets:
            - target: alias(constantLine(50), 'max')
title: Imaginary

type: graph

salt.states.grafana4_dashboard.absent(name, orgname=None, profile='grafana')

Ensure the named grafana dashboard is absent.

name
Name of the grafana dashboard.

orgname
Name of the organization in which the dashboard should be present.

profile
Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

salt.states.grafana4_dashboard.present(name, base_dashboards_from_pillar=None,
    base_panels_from_pillar=None,
    base_rows_from_pillar=None,
    dashboard=None,
    orgname=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.

name
Name of the grafana dashboard.

base_dashboards_from_pillar
A pillar key that contains a list of dashboards to inherit from

base_panels_from_pillar
A pillar key that contains a list of panels to inherit from

base_rows_from_pillar
A pillar key that contains a list of rows to inherit from

dashboard
A dict that defines a dashboard that should be managed.

orgname
Name of the organization in which the dashboard should be present.

profile
Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

25.20.104  salt.states.grafana4_datasource

Manage Grafana v4.0 data sources
New in version 2017.7.0.

collection
This state requires a configuration profile to be configured in the minion config, minion pillar, or
master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```yaml
grafana:
    grafana_url: http://grafana.localhost
    grafana_user: admin
    grafana_password: admin
    grafana_timeout: 3
```

Example configuration using token based authentication:
The behavior of this module is to create data sources if the do not exists, and to update data sources if the already exists.

Ensure influxdb data source is present:

```yaml
grafana4_datasource.present:
  - name: influxdb
  - type: influxdb
  - url: http://localhost:8086
  - access: proxy
  - basic_auth: true
  - basic_auth_user: myuser
  - basic_auth_password: mypass
  - is_default: true
```

salt.states.grafana4_datasource.absent(name, orgname=None, profile='grafana')

Ensure that a data source is absent.

name
Name of the data source to remove.

orgname
Name of the organization from which the data source should be absent.

profile
Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

salt.states.grafana4_datasource.present(name, type, url, access=None, user=None, password=None, database=None, basic_auth=None, basic_auth_user=None, basic_auth_password=None, tls_auth=None, json_data=None, is_default=None, with_credentials=None, type_logo_url=None, orgname=None, profile='grafana')

Ensure that a data source is present.

name
Name of the data source.

type
Type of the datasourc (‘graphite’, ‘influxdb’ etc.).

access
Use proxy or direct. Default: proxy

url
The URL to the data source API.

user
Optional - user to authenticate with the data source.

password
Optional - password to authenticate with the data source.

database
Optional - database to use with the data source.

basic_auth
Optional - set to True to use HTTP basic auth to authenticate with the data source.

basic_auth_user
Optional - HTTP basic auth username.
**basic_auth_password**
Optional - HTTP basic auth password.

**json_data**
Optional - additional json data to post (eg. "timeInterval").

**is_default**
Optional - set data source as default.

**with_credentials**
Optional - Whether credentials such as cookies or auth headers should be sent with cross-site requests.

**type_logo_url**
Optional - Logo to use for this datasource.

**orgname**
Name of the organization in which the data source should be present.

**profile**
Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

### 25.20.105 `salt.states.grafana4_org`

Manage Grafana v4.0 orgs

New in version 2017.7.0.

**configuration**
This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```
grafana:
    grafana_url: http://grafana.localhost
    grafana_user: admin
    grafana_password: admin
    grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
    grafana_url: http://grafana.localhost
    grafana_token: token
    grafana_timeout: 3
```

**Ensure foobar org is present:**

```yaml
grafana4_org.present:
    - name: foobar
    - theme: ""
    - home_dashboard_id: 0
    - timezone: "utc"
    - address1: ""
    - address2: ""
    - city: ""
    - zip_code: ""
    - state: ""
    - country: ""
```

`salt.states.grafana4_org.absent(name, profile='grafana')`
Ensure that a org is present.
name
   Name of the org to remove.
profile
   Configuration profile used to connect to the Grafana instance. Default is 'grafana'.
salt.states.grafana4_org.present(name, users=None, theme=None, home_dashboard_id=None, timezone=None, address1=None, address2=None, city=None, zip_code=None, address_state=None, country=None, profile='grafana')

Ensure that an organization is present.
name
   Name of the org.
users
   Optional - Dict of user/role associated with the org. Example:
   
   ```yaml
   users:
     foo: Viewer
     bar: Editor
   ```
theme
   Optional - Selected theme for the org.
home_dashboard_id
   Optional - Home dashboard for the org.
timezone
   Optional - Timezone for the org (one of: "browser", "utc", or ").
address1
   Optional - address1 of the org.
address2
   Optional - address2 of the org.
city
   Optional - city of the org.
zip_code
   Optional - zip_code of the org.
address_state
   Optional - state of the org.
country
   Optional - country of the org.
profile
   Configuration profile used to connect to the Grafana instance. Default is 'grafana'.

25.20.106 salt.states.grafana4_user

Manage Grafana v4.0 users
New in version 2017.7.0.
configuration
   This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the 'grafana' key by default, if defined.

Example configuration using basic authentication:

```yaml
grafana:
  grafana_url: http://grafana.localhost
  grafana_user: admin
```
(continues on next page)
Salt Documentation, Release 3006.3

Example configuration using token based authentication:

```
grafana:
  grafana_url: http://grafana.localhost
  grafana_token: token
  grafana_timeout: 3
```

Ensure foobar user is present:
```
grafana4_user.present:
  - name: foobar
  - password: mypass
  - email: "foobar@localhost"
  - fullname: Foo Bar
  - is_admin: true
```

salt.states.grafana4_user.absent(name, profile='grafana')

Ensure that a user is present.
```
salt.states.grafana4_user.present(name, password, email, is_admin=False, fullname=None, theme=None, profile='grafana')
```

Ensure that a user is present.
```
name
password
email
is_admin
fullname
theme
profile
```

Configuration profile used to connect to the Grafana instance. Default is 'grafana'.
## 25.20.107 `salt.states.grafana_dashboard`

Manage Grafana v2.0 Dashboards

New in version 2016.3.0.

```yaml
grafana:
  grafana_timeout: 3
  grafana_token: qwertyuiop
  grafana_url: 'https://url.com'
```

### Ensure minimum dashboard is managed:

```yaml
grafana_dashboard.present:
  - name: insightful-dashboard
  - base_dashboards_from_pillar:
    - default_dashboard
  - base_rows_from_pillar:
    - default_row
  - base_panels_from_pillar:
    - default_panel
  - dashboard:
    rows:
      - title: Usage
        panels:
          - targets:
            - target: alias(constantLine(50), 'max')
        title: Imaginary
        type: graph
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

**salt.states.grafana_dashboard.absent** *(name, profile='grafana')*

Ensure the named grafana dashboard is absent.

- **name**
  Name of the grafana dashboard.

- **profile**
  A pillar key or dict that contains grafana information

**salt.states.grafana_dashboard.present** *(name, base_dashboards_from_pillar=None, base_panels_from_pillar=None, base_rows_from_pillar=None, dashboard=None, profile='grafana')*

Ensure the grafana dashboard exists and is managed.

- **name**
  Name of the grafana dashboard.

- **base_dashboards_from_pillar**
  A pillar key that contains a list of dashboards to inherit from

- **base_panels_from_pillar**
  A pillar key that contains a list of panels to inherit from

- **base_rows_from_pillar**
  A pillar key that contains a list of rows to inherit from

- **dashboard**
  A dict that defines a dashboard that should be managed.
profile
A pillar key or dict that contains grafana information

25.20.108 salt.states.grafana_datasource

Manage Grafana v2.0 data sources

New in version 2016.3.0.

```
grafana:
  grafana_timeout: 3
  grafana_token: qwertyuiop
  grafana_url: 'https://url.com'
```

Ensure influxdb data source is present:
```
salt.states.grafana_datasource.present:
  - name: influxdb
  - type: influxdb
  - url: http://localhost:8086
  - access: proxy
  - basic_auth: true
  - basic_auth_user: myuser
  - basic_auth_password: mypass
  - is_default: true
```

```
salt.states.grafana_datasource.absent(name, profile='grafana')
  Ensure that a data source is present.
  name
  Name of the data source.
```

```
salt.states.grafana_datasource.present(name, type, url, access='proxy', user='', password='',
  database='', basic_auth=False, basic_auth_user='',
  basic_auth_password='', is_default=False, json_data=None,
  profile='grafana')
  Ensure that a data source is present.
  name
  Name of the data source.
  type
  Which type of data source it is ('graphite', 'influxdb' etc.).
  url
  The URL to the data source API.
  user
  Optional - user to authenticate with the data source
  password
  Optional - password to authenticate with the data source
  basic_auth
  Optional - set to True to use HTTP basic auth to authenticate with the data source.
  basic_auth_user
  Optional - HTTP basic auth username.
  basic_auth_password
  Optional - HTTP basic auth password.
  is_default
  Default: False
25.20.109  salt.states.grains

Manage grains on the minion

This state allows for grains to be set.

Grains set or altered with this module are stored in the 'grains' file on the minions, By default, this file is located at: /etc/salt/grains

Note: This does NOT override any grains set in the minion config file.

salt.states.grains.absent(name, destructive=False, delimiter=':', force=False)

New in version 2014.7.0.

Delete a grain from the grains config file

name
  The grain name

destructive
  If destructive is True, delete the entire grain. If destructive is False, set the grain’s value to None. Defaults to False.

force
  If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False.

New in version 2015.8.2.

delimiter
  A delimiter different from the default can be provided.

Changed in version 2015.8.2.

This state now support nested grains and complex values. It is also more conservative: if a grain has a value that is a list or a dict, it will not be removed unless the force parameter is True.

salt.states.grains.append(name, value, convert=False, delimiter=': ')

New in version 2014.7.0.

Append a value to a list in the grains config file. The grain that is being appended to (name) must exist before the new value can be added.

name
  The grain name

value
  The value to append

convert
  If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

delimiter
  A delimiter different from the default can be provided.

New in version 2015.8.2.
salt.states.grains.exists(name, delimiter=":")
Ensure that a grain is set
name
The grain name
delimiter
A delimiter different from the default can be provided.
Check whether a grain exists. Does not attempt to check or set the value.
salt.states.grains.list_absent(name, value, delimiter=":")
delete
A value from a grain formed as a list.
New in version 2014.1.0.
name
The grain name.
value
The value to delete from the grain list.
delimiter
A delimiter different from the default : can be provided.
New in version 2015.8.2.
The grain should be list type
roles:
grains.list_absent:
- value: db
For multiple grains, the syntax looks like:
roles:
grains.list_absent:
- value:
  - web
  - dev
salt.states.grains.list_present(name, value, delimiter=":")
New in version 2014.1.0.
Ensure the value is present in the list-type grain. Note: If the grain that is provided in name is not present on the system, this new grain will be created with the corresponding provided value.
name
The grain name.
value
The value is present in the list type grain.
delimiter
A delimiter different from the default : can be provided.
New in version 2015.8.2.
The grain should be list type
roles:
grains.list_present:
- value: web
For multiple grains, the syntax looks like:

```yaml
roles:
    grains.list_present:
      - value:
        - web
        - dev
```

`salt.states.grains.make_hashable(list_grain, result=None)`

Ensure that a list grain is hashable.

- `list_grain`: The list grain that should be hashable
- `result`: This function is recursive, so it must be possible to use a sublist as parameter to the function. Should not be used by a caller outside of the function.

Make it possible to compare two list grains to each other if the list contains complex objects.

`salt.states.grains.present(name, value, delimiter=':', force=False)`

Ensure that a grain is set

- `name`: The grain name
- `value`: The value to set on the grain
- `force`: If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False
  - New in version 2015.8.2.
- `delimiter`: A delimiter different from the default can be provided.
  - New in version 2015.8.2.

It is now capable to set a grain to a complex value (ie. lists and dicts) and supports nested grains as well.

If the grain does not yet exist, a new grain is set to the given value. For a nested grain, the necessary keys are created if they don’t exist. If a given key is an existing value, it will be converted, but an existing value different from the given key will fail the state.

If the grain with the given name exists, its value is updated to the new value unless its existing or provided value is complex (list or dict). Use `force: True` to overwrite.

```yaml
cheese:
    grains.present:
      - value: edam

nested_grain_with_complex_value:
    grains.present:
      - name: icinga:Apache SSL
      - value:
        - command: check_https
        - params: -H localhost -p 443 -S

with,a,custom,delimiter:
    grains.present:
```

(continues on next page)
- value: yay
  - delimiter: ','

25.20.110 salt.states.group

Management of user groups

The group module is used to create and manage group settings, groups can be either present or absent. User/Group names can be passed to the adduser, deluser, and members parameters. adduser and deluser can be used together but not with members.

In Windows, if no domain is specified in the user or group name (i.e. DOMAIN\username) the module will assume a local user or group.

<table>
<thead>
<tr>
<th>cheese:</th>
</tr>
</thead>
<tbody>
<tr>
<td>group.present:</td>
</tr>
<tr>
<td>- gid: 7648</td>
</tr>
<tr>
<td>- system: True</td>
</tr>
<tr>
<td>- addusers:</td>
</tr>
<tr>
<td>- user1</td>
</tr>
<tr>
<td>- users2</td>
</tr>
<tr>
<td>- delusers:</td>
</tr>
<tr>
<td>- foo</td>
</tr>
</tbody>
</table>

cheese:

<table>
<thead>
<tr>
<th>group.present:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- gid: 7648</td>
</tr>
<tr>
<td>- system: True</td>
</tr>
<tr>
<td>- members:</td>
</tr>
<tr>
<td>- foo</td>
</tr>
<tr>
<td>- bar</td>
</tr>
<tr>
<td>- user1</td>
</tr>
<tr>
<td>- user2</td>
</tr>
</tbody>
</table>

salt.states.group.absent(name, local=False)

Ensure that the named group is absent

Parameters

- name (str) -- The name of the group to remove
- local (Only on systems with lgroupdel available) -- Ensure the group account is removed locally ignoring global account management (default is False).

Example:

```
# Removes the local group `db_admin`

db_admin:

  group.absent
```

salt.states.group.present(name, gid=None, system=False, addusers=None, delusers=None, members=None, non_unique=False, local=False)

Changed in version 3006.0.
Ensure that a group is present

**Parameters**

- **name (str)** -- The name of the group to manage
- **gid (str)** -- The group id to assign to the named group; if left empty, then the next available group id will be assigned. Ignored on Windows
- **system (bool)** -- Whether or not the named group is a system group. This is essentially the `-r` option of `groupadd`. Ignored on Windows
- **addusers (list)** -- List of additional users to be added as a group members. Cannot conflict with names in delusers. Cannot be used in conjunction with members.
- **delusers (list)** -- Ensure these user are removed from the group membership. Cannot conflict with names in addusers. Cannot be used in conjunction with members.
- **members (list)** -- Replace existing group members with a list of new members. Cannot be used in conjunction with addusers or delusers.
- **non_unique (bool)** -- Allow creating groups with duplicate (non-unique) GIDs
  
  New in version 3006.0.
- **local** (Only on systems with `lgroupadd` available) -- Create the group account locally ignoring global account management (default is False).
  
  New in version 3007.0.

**Example:**

```yaml
# Adds DOMAIN\db_admins and Administrators to the local db_admin group
# Removes Users
db_admin:
  group.present:
    - addusers:
      - DOMAIN\db_admins
      - Administrators
    - delusers:
      - Users

# Ensures only DOMAIN\domain_admins and the local Administrator are members of the local Administrators group. All other users are removed
Administrators:
  group.present:
    - members:
      - DOMAIN\domain_admins
      - Administrator
```

### 25.20.111 salt.states.heat

**Management of Heat**

New in version 2017.7.0.

**depends**

- `heat` Python module

**configuration**

See `salt.modules.heat` for setup instructions.

The heat module is used to create, show, list and delete Heat staks. Stack can be set as either absent or deploy.
heat.deployed:
  - name:
  - template: #Required
  - environment:
    - params: {}
    - poll: 5
    - rollback: False
    - timeout: 60

heat.absent:
  - name:
  - poll: 5

mysql:
  heat.deployed:
    • template: salt://templates/mysql.heat.yaml
    • params: image: Debian 7
    • rollback: True

New in version 2017.7.5,2018.3.1: The spelling mistake in parameter environment was corrected to environment. The environment spelling mistake has been removed in Salt 3000.

salt.states.heat.absent(name, poll=5, timeout=60, profile=None)
Ensure that the named stack is absent
name
  The name of the stack to remove
poll
  Poll (in sec.) and report events until stack complete
timeout
  Stack creation timeout in minutes
profile
  Profile to use

salt.states.heat.deployed(name, template=None, environment=None, params=None, poll=5,
                        rollback=False, timeout=60, update=False, profile=None, **connection_args)
Deploy stack with the specified properties
name
  The name of the stack
template
  File of template
environment
  File of environment
params
  Parameter dict used to create the stack
poll
  Poll (in sec.) and report events until stack complete
rollback
  Enable rollback on create failure
timeout
  Stack creation timeout in minutes
profile
  Profile to use
New in version 2017.7.5,2018.3.1: The spelling mistake in parameter *enviroment* was corrected to *environment*. The *enviroment* spelling mistake has been removed in Salt 3000.

25.20.112 **salt.states.helm**

salt.states.helm.*release_absent*(name, namespace=None, flags=None, kvflags=None)

Make sure the release name is absent.

* name
  * (string) The release name to uninstall.
* namespace
  * (string) The namespace scope for this request.
* flags
  * (list) Flags in argument of the command without values. ex: ['help', '--help']
* kvflags
  * (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

```bash
helm_release_is_absent:
  helm.release_absent:
    - name: release_name

# In dry-run mode.
helm_release_is_absent_dry-run:
  helm.release_absent:
    - name: release_name
    - flags:
      - dry-run
```

salt.states.helm.*release_present*(name, chart, values=None, version=None, namespace=None, set=None, flags=None, kvflags=None)

Make sure the release name is present.

* name
  * (string) The release name to install.
* chart
  * (string) The chart to install.
* values
  * (string) Absolute path to the values.yaml file.
* version
  * (string) The exact chart version to install. If this is not specified, the latest version is installed.
* namespace
  * (string) The namespace scope for this request.
* set
  * (string or list) Set a values on the command line.
* flags
  * (list) Flags in argument of the command without values. ex: ['help', '--help']
* kvflags
  * (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

```bash
helm_release_is_present:
  helm.release_present:
    - name: release_name
```

(continues on next page)
- chart: repo/chart

# In dry-run mode.
helm_release_is_present_dry-run:
  helm.release_present:
    - name: release_name
    - chart: repo/chart
    - flags:
      - dry-run

# With values.yaml file.
helm_release_is_present_values:
  helm.release_present:
    - name: release_name
    - chart: repo/chart
    - kvflags:
      values: /path/to/values.yaml

salt.states.helm.repo_managed(name, present=None, absent=None, prune=False, repo_update=False, namespace=None, flags=None, kvflags=None)

Make sure the repository is updated.

name
  (string) Not used.
present
  (list) List of repository to be present. It's a list of dict: [{'name': 'local_name', 'url': 'repository_url'}]
absent
  (list) List of local name repository to be absent.
prune
  (boolean - default: False) If True, all repository already present but not in the present list would be removed.
repo_update
  (boolean - default: False) If True, the Helm repository is updated after a repository add or remove.
namespace
  (string) The namespace scope for this request.
flags
  (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags
  (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

helm.repository_is_managed:
  helm.repo_managed:
    - present:
      - name: local_name_1
      - url: repository_url
    - absent:
      - local_name_2

salt.states.helm.repo_updated(name, namespace=None, flags=None, kvflags=None)

Make sure the repository is updated. To execute after a repository changes.

name
  (string) Not used.
namespace
    (string) The namespace scope for this request.
flags
    (list) Flags in argument of the command without values. ex: ['help', '--help']
kvflags
    (dict) Flags in argument of the command with values. ex: {'v': 2, '--v': 4}

Example:

```
helm_repository_is_updated:
    helm.repo_updated
```

25.20.113 salt.states.hg

Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known_hosts, and the remote host has this host's public key.

```
https://bitbucket.org/example_user/example_repo:
	hg.latest:
    - rev: tip
    - target: /tmp/example_repo
```

```
salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False, update_head=True)
```

Make sure the repository is cloned to the given directory and is up to date

**name**
    Address of the remote repository as passed to "hg clone"

**rev**
    The remote branch, tag, or revision hash to clone/pull

**target**
    Target destination directory path on minion to clone into

**clean**
    Force a clean update with -C (Default: False)

**user**
    Name of the user performing repository management operations

    New in version 0.17.0.

**identity**
    Private SSH key on the minion server for authentication (ssh://)

    New in version 2015.5.0.

**force**
    Force hg to clone into pre-existing directories (deletes contents)

**opts**
    Include additional arguments and options to the hg command line

**update_head**
    Should we update the head if new changes are found? Defaults to True

    New in version 2017.7.0.
25.20.114 salt.states.highstate_doc

To be used with processors in module `highstate_doc`.

salt.states.highstate_doc.note(name, source=None, contents=None, **kwargs)

Add content to a document generated using `highstate_doc.render`.

This state does not perform any tasks on the host. It only is used in highstate_doc lowstate processors to include extra documents.

```yaml
{{sls}} example note:
  highstate_doc.note:
    - name: example note
    - require_in:
      - pkg: somepackage
    - contents:
      example `highstate_doc.note`
  
This state does not do anything to the system! It is only used by a `processor` you can use `requisites` and `order` to move your docs around the rendered file.

  .. this message appear above the `pkg: somepackage` state.
  - source: salt://{{tpldir}}/also_include_a_file.md

{{sls}} extra help:
  highstate_doc.note:
    - name: example
    - order: 0
    - source: salt://{{tpldir}}/HELP.md
```

25.20.115 salt.states.host

Management of addresses and names in hosts file

The `/etc/hosts` file can be managed to contain definitions for specific hosts:

```yaml
salt-master:
  host.present:
    - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```yaml
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
```

**Note:** Changing the names in `host.present` does not cause an update to remove the old entry.
You can replace all existing names for a particular IP address:

```
server1:
  host.present:
    - ip:
      - 192.168.0.42
      - 192.168.0.43
      - 192.168.0.44
    - names:
      - server1
```

Or delete all existing names for an address:

```
127.0.1.1:
  host.only:
    - hostnames:
      - foo.example.com
      - foo
```

You can also include comments:

```
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
    - comment: A very important comment
```

salt.states.host.absent(name, ip)
Ensure that the named host is absent

- name
  The host to remove
- ip
  The ip addr(s) of the host to remove

salt.states.host.only(name, hostnames)
Ensure that only the given hostnames are associated with the given IP address.

New in version 2016.3.0.

- name
  The IP address to associate with the given hostnames.
- hostnames
  Either a single hostname or a list of hostnames to associate with the given IP address in the given order. Any other hostname associated with the IP address is removed. If no hostnames are specified, all hostnames associated with the given IP address are removed.

salt.states.host.present(name, ip, comment='', clean=False)
Ensures that the named host is present with the given ip

- name
  The host to assign an ip to
**ip**
The ip addr(s) to apply to the host. Can be a single IP or a list of IP addresses.

**comment**
A comment to include for the host entry

New in version 3001.

**clean**
Remove any entries which don’t match those configured in the ip option. Default is False.

New in version 2018.3.4.

### 25.20.116 salt.states.http

HTTP monitoring states

Perform an HTTP query and statefully return the result

New in version 2015.5.0.

```python
salt.states.http.query(name, match=None, match_type='string', status=None, status_type='string', wait_for=None, **kwargs)
```

Perform an HTTP query and statefully return the result

Passes through all the parameters described in the `utils.http.query function`:

- **name**
The name of the query.

- **match**
  Specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text.

- **match_type**
  Specifies the type of pattern matching to use on match. Default is string, but can also be set to pcre to use regular expression matching if a more complex pattern matching is required.

  **Note:** Despite the name of match_type for this argument, this setting actually uses Python’s `re.search()` function rather than Python’s `re.match()` function.

- **status**
The status code for a URL for which to be checked. Can be used instead of or in addition to the match setting. This can be passed as an individual status code or a list of status codes.

- **status_type**
  Specifies the type of pattern matching to use for status. Default is string, but can also be set to pcre to use regular expression matching if a more complex pattern matching is required. Additionally, if a list of strings representing statuses is given, the type list can be used.

New in version 3000.

  **Note:** Despite the name of match_type for this argument, this setting actually uses Python’s `re.search()` function rather than Python’s `re.match()` function.

If both match and status options are set, both settings will be checked. However, note that if only one option is True and the other is False, then False will be returned. If this case is reached, the comments in the return data will contain troubleshooting information.

For more information about the http.query state, refer to the [HTTP Tutorial](#).
query_example:
http.query:
  - name: 'http://example.com/
  - status: 200

query_example2:
http.query:
  - name: 'http://example.com/
  - status:
    - 200
    - 201
  - status_type: list

salt.states.http.wait_for_successful_query(name, wait_for=300, **kwargs)
Like query but, repeat and wait until match/match_type or status is fulfilled. State returns result from last
query state in case of success or if no successful query was made within wait_for timeout.
name
  The name of the query.
wait_for
  Total time to wait for requests that succeed.
request_interval
  Optional interval to delay requests by N seconds to reduce the number of requests sent.

Note: All other arguments are passed to the http.query state.

25.20.117 salt.states.icinga2

Icinga2 state
New in version 2017.7.0.
depends
  • Icinga2 Python module
configuration
  See salt.modules.icinga2 for setup instructions.
The icinga2 module is used to execute commands. Its output may be stored in a file or in a grain.

command_id:
  icinga2.generate_ticket:
    - name: domain.tld
    - output: '/tmp/query_id.txt'

salt.states.icinga2.generate_cert(name)
Generate an icinga2 certificate and key on the client.
name
  The domain name for which this certificate and key will be generated
salt.states.icinga2.generate_ticket(name, output=None, grain=None, key=None, overwrite=True)
Generate an icinga2 ticket on the master.
name
  The domain name for which this ticket will be generated

output
  grain: output in a grain other: the file to store results None: output to the result comment (default)

grain:
  grain to store the output (need output=grain)

key:
  the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.

overwrite:
  The file or grain will be overwritten if it already exists (default)

salt.states.icinga2.node_setup(name, master, ticket)
  Setup the icinga2 node.

  name
  The domain name for which this certificate will be saved

  master
  Icinga2 master node for which this certificate will be saved

  ticket
  Authentication ticket generated on icinga2 master
salt.states.icinga2.request_cert(name, master, ticket, port='5665')
  Request CA certificate from master icinga2 node.

  name
  The domain name for which this certificate will be saved

  master
  Icinga2 master node for which this certificate will be saved

  ticket
  Authentication ticket generated on icinga2 master

  port
  Icinga2 port, defaults to 5665

salt.states.icinga2.save_cert(name, master)
  Save the certificate on master icinga2 node.

  name
  The domain name for which this certificate will be saved

  master
  Icinga2 master node for which this certificate will be saved

25.20.118 salt.states.idem

Idem Support

This state provides access to idem states

New in version 3002.

salt.states.idem.state(name, sls, acct_file=None, acct_key=None, acct_profile=None, cache_dir=None, render=None, runtime=None, source_dir=None, test=False)
  Execute an idem sls file through a salt state

  sls
  A list of idem sls files or sources

  acct_file
  Path to the acct file used in generating idem ctx parameters. Defaults to the value in the ACCT_FILE environment variable.
acct_key
Key used to decrypt the acct file. Defaults to the value in the ACCT_KEY environment variable.

acct_profile
Name of the profile to add to idem's ctx.acct parameter. Defaults to the value in the ACCT_PROFILE environment variable.

cache_dir
The location to use for the cache directory.

render
The render pipe to use, this allows for the language to be specified (jinja|yaml).

runtime
Select which execution runtime to use (serial|parallel).

source_dir
The directory containing sls files.

cheese:

idem.state:
- runtime: parallel
- sls:
  - idem_state.sls
  - sls_source

Maturity
new

Depends
acct, pop, pop-config, idem

Platform
all

25.20.119 salt.states.ifttt

Trigger an event in IFTTT

This state is useful for trigging events in IFTTT.

New in version 2015.8.0.

ifttt-event:

ifttt.trigger_event:
- event: TestEvent
- value1: 'This state was executed successfully.'
- value2: 'Another value we can send.'
- value3: 'A third value we can send.'

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

ifttt:
  secret_key: bzMRb-KKIAaNOwKEEw792J7Eb-B3z7muhdhYblJn4V6

salt.states.ifttt.trigger_event(name, event, value1=None, value2=None, value3=None)

Trigger an event in IFTTT.

ifttt-event:
  ifttt.trigger_event:
    - event: TestEvent

(continues on next page)
The following parameters are required:

- **name**
  The unique name for this event.

- **event**
  The name of the event to trigger in IFTTT.

The following parameters are optional:

- **value1**
  One of the values that we can send to IFTTT.

- **value2**
  One of the values that we can send to IFTTT.

- **value3**
  One of the values that we can send to IFTTT.

25.20.120 **salt.states.incron**

Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: **path**, **mask**, and **cmd**. The **user** whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the **path** declaration is the unique factor, so if an existing cron that looks like this:

```
Watch for modifications in /home/user:
incron.present:
  - user: root
  - path: /home/user
  - mask:
    - IN_MODIFY
  - cmd: 'echo $$ $@'
```

Is changed to this:

```
Watch for modifications and access in /home/user:
incron.present:
  - user: root
  - path: /home/user
  - mask:
    - IN_MODIFY
    - IN_ACCESS
  - cmd: 'echo $$ $@'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.
salt.states.incron.absent(name, path, mask, cmd, user='root')

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.

- **name**: Unique comment describing the entry
- **path**: The path that should be watched
- **user**: The name of the user who's crontab needs to be modified, defaults to the root user
- **mask**: The mask of events that should be monitored for
- **cmd**: The cmd that should be executed

salt.states.incron.present(name, path, mask, cmd, user='root')

Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: `man 5 incrontab`.

- **name**: Unique comment describing the entry
- **path**: The path that should be watched
- **user**: The name of the user who's crontab needs to be modified, defaults to the root user
- **mask**: The mask of events that should be monitored for
- **cmd**: The cmd that should be executed

25.20.121 salt.states.influxdb08_database

**Management of Influxdb 0.8 databases**

(compatible with InfluxDB version 0.5-0.8)

New in version 2014.7.0.

salt.states.influxdb08_database.absent(name, user=None, password=None, host=None, port=None)

Ensure that the named database is absent

- **name**: The name of the database to remove
- **user**: The user to connect as (must be able to remove the database)
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

salt.states.influxdb08_database.present(name, user=None, password=None, host=None, port=None)

Ensure that the named database is present
name
    The name of the database to create

user
    The user to connect as (must be able to remove the database)

password
    The password of the user

host
    The host to connect to

port
    The port to connect to

25.20.122 salt.states.influxdb08_user

Management of InfluxDB 0.8 users

(compatible with InfluxDB version 0.5-0.8)

New in version 2014.7.0.

salt.states.influxdb08_user.absent(name, database=None, user=None, password=None, host=None, port=None)

Ensure that the named cluster admin or database user is absent.

name
    The name of the user to remove
database
    The database to remove the user from
user
    The user to connect as (must be able to remove the user)
password
    The password of the user
host
    The host to connect to
port
    The port to connect to

salt.states.influxdb08_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)

Ensure that the cluster admin or database user is present.

name
    The name of the user to manage
passwd
    The password of the user
database
    The database to create the user in
user
    The user to connect as (must be able to create the user)
password
    The password of the user
host
    The host to connect to
port
    The port to connect to
25.20.123 salt.states.influxdb_continuous_query

Management of Influxdb continuous queries

New in version 2017.7.0.
(compatible with InfluxDB version 0.9+)

salt.states.influxdb_continuous_query.absent(name, database, **client_args)
  Ensure that given continuous query is absent.
  name
    Name of the continuous query to remove.
  database
    Name of the database that the continuous query was defined on.

salt.states.influxdb_continuous_query.present(name, database, query, resample_time=None, coverage_period=None, **client_args)
  Ensure that given continuous query is present.
  name
    Name of the continuous query to create.
  database
    Database to create continuous query on.
  query
    The query content
  resample_time
    [None] Duration between continuous query resampling.
  coverage_period
    [None] Duration specifying time period per sample.

25.20.124 salt.states.influxdb_database

Management of Influxdb databases

(compatible with InfluxDB version 0.9+)

salt.states.influxdb_database.absent(name, **client_args)
  Ensure that given database is absent.
  name
    Name of the database to remove.

salt.states.influxdb_database.present(name, **client_args)
  Ensure that given database is present.
  name
    Name of the database to create.
25.20.125 salt.states.influxdb_retention_policy

Management of Influxdb retention policies

New in version 2017.7.0.
(compatible with InfluxDB version 0.9+)

salt.states.influxdb_retention_policy.absent(name, database, **client_args)
Ensure that given retention policy is absent.
name
Name of the retention policy to remove.
database
Name of the database that the retention policy was defined on.

salt.states.influxdb_retention_policy.convert_duration(duration)
Convert the a duration string into XXhYYmZZs format
duration
Duration to convert
Returns: duration_string
String representation of duration in XXhYYmZZs format

salt.states.influxdb_retention_policy.present(name, database, duration='7d', replication=1, default=False, **client_args)
Ensure that given retention policy is present.
name
Name of the retention policy to create.
database
Database to create retention policy on.

25.20.126 salt.states.influxdb_user

Management of InfluxDB users

(compatible with InfluxDB version 0.9+)

salt.states.influxdb_user.absent(name, **client_args)
Ensure that given user is absent.
name
The name of the user to manage

salt.states.influxdb_user.present(name, passwd, admin=False, grants=None, **client_args)
Ensure that given user is present.
name
Name of the user to manage
passwd
Password of the user
admin
[False] Whether the user should have cluster administration privileges or not.
grants
Optional - Dict of database:privilege items associated with the user. Example:
grants:
    foo_db: read bar_db: all
Example:
example user present in influxdb:
```yaml
influxdb_user.present:
  - name: example
  - passwd: somepassword
  - admin: False
  - grants:
    foo_db: read
    bar_db: all
```

25.20.127 salt.states.infoblox_a

Infoblox A record management.

functions accept api_opts:

    api_verifyssl: verify SSL [default to True or pillar value]
    api_url: server to connect to [default to pillar value]
    api_username: [default to pillar value]
    api_password: [default to pillar value]

```
salt.states.infoblox_a.absent(name=None, ipv4addr=None, **api_opts)

Ensure infoblox A record is removed.
```

State example:
```
salt.states.infoblox_a.absent:
  - name: example-ha-0.domain.com

salt.states.infoblox_a.absent:
  - name:
    - ipv4addr: 127.0.23.23
```

```
salt.states.infoblox_a.present(name=None, ipv4addr=None, data=None, ensure_data=True, **api_opts)

Ensure infoblox A record.
```

When you wish to update a hostname ensure name is set to the hostname of the current record. You can give a new name in the data.name.

State example:
```
salt.states.infoblox_a.present:
  - name: example-ha-0.domain.com
  - data:
    name: example-ha-0.domain.com
    ipv4addr: 123.0.31.2
    view: Internal
```

25.20.128 salt.states.infoblox_cname

Infoblox CNAME management.

functions accept api_opts:

api_verifyssl: verify SSL [default to True or pillar value] api_url: server to connect to [default to pillar value] api_username: [default to pillar value] api_password: [default to pillar value]
salt.states.infoblox_cname.absent(name=None, canonical=None, **api_opts)
Ensure the CNAME with the given name or canonical name is removed

salt.states.infoblox_cname.present(name=None, data=None, ensure_data=True, **api_opts)
Ensure the CNAME with the given data is present.

name
CNAME of record
data
raw CNAME api data see: https://INFOBLOX/wapidoc
State example:

```
infoblox_cname.present:
- name: example-ha-0.domain.com
- data:
  name: example-ha-0.domain.com
  canonical: example.domain.com
  zone: example.com
  view: Internal
  comment: Example comment
```

infoblox_cname.present:
- name: example-ha-0.domain.com
- data:
  name: example-ha-0.domain.com
  canonical: example.domain.com
  zone: example.com
  view: Internal
  comment: Example comment
  api_url: https://INFOBLOX/wapi/v1.2.1
  api_username: username
  api_password: passwd

25.20.129 salt.states.infoblox_host_record

Infoblox host record management.

functions accept api_opts:

api_verifyssl: verify SSL [default to True or pillar value] api_url: server to connect to [default to pillar value] api_username: [default to pillar value] api_password: [default to pillar value]
salt.states.infoblox_host_record.absent(name=None, ipv4addr=None, mac=None, **api_opts)
Ensure the host with the given Name ipv4addr or mac is removed.

State example:
infoblox_host_record.absent:
- name: hostname.of.record.to.remove

infoblox_host_record.absent:
- name:
  - ipv4addr: 192.168.0.1

infoblox_host_record.absent:
- name:
  - mac: 12:02:12:31:23:43

salt.states.infoblox_host_record.present(name=None, data=None, ensure_data=True, **api_opts)
This will ensure that a host with the provided name exists. This will try to ensure that the state of the host
matches the given data If the host is not found then one will be created.

When trying to update a hostname ensure name is set to the hostname of the current record. You can give a
new name in the data.name.

Avoid race conditions, use func:nextavailableip:
  - func:nextavailableip:network/ZG54dfgsrDFEFfsfsLzA:10.0.0.0/8/default
  - func:nextavailableip:10.0.0.0/8
  - func:nextavailableip:10.0.0.0/8,externalconfigure_for_dns
  - func:nextavailableip:10.0.3-10.0.0.10

State Example:

```
# this would update `original_hostname.example.ca` to changed `data`.
infoblox_host_record.present:
- name: original_hostname.example.ca
- data: {
  'name': 'hostname.example.ca',
  'aliases': ['hostname.math.example.ca'],
  'extattrs': [{'Business Contact': {'value': 'EXAMPLE@example.ca'}}],
  'ipv4addrs': [{'configure_for_dhcp': True,
                 'ipv4addr': 'func:nextavailableip:129.97.139.0/24',

               ]
  }
```

25.20.130 salt.states.infoblox_range

Infoblox host record management.

functions accept api_opts:

  api_verifysl: verify SSL [default to True or pillar value] api_url: server to connect to [default to pillar value] api_username: [default to pillar value] api_password: [default to pillar value]
salt.states.infoblox_range.absent(name=None, start_addr=None, end_addr=None, data=None, **api_opts)

Ensure the range is removed

Supplying the end of the range is optional.

State example:
infoblox_range.absent:
  - name: 'vlan10'

infoblox_range.absent:
  - name: 
    - start_addr: 127.0.1.20

salt.states.infoblox_range.present(name=None, start_addr=None, end_addr=None, data=None, **api_opts)

Ensure range record is present.

infoblox_range.present:
  - start_addr: '129.97.150.160', end_addr: '129.97.150.170',

Verbose state example:

infoblox_range.present:
  - data: 
    
    'always_update_dns': False,
    'authority': False,
    'comment': 'range of IP addresses used for salt.. was used for ghost images deployment',
    'ddns_generate_hostname': True,
    'deny_all_clients': False,
    'deny_bootp': False,
    'disable': False,
    'email_list': [],
    'enable_ddns': False,
    'enable_dhcp_thresholds': False,
    'enable_email_warnings': False,
    'enable_ifmap_publishing': False,
    'enable_snmp_warnings': False,
    'end_addr': '129.97.150.169',
    'exclude': [],
    'extattrs': {},
    'fingerprint_filter_rules': [],
    'high_water_mark': 95,
    'high_water_mark_reset': 85,
    'ignore_dhcp_option_list_request': False,
    'lease_scavenge_time': -1,
    'logic_filter_rules': [],
    'low_water_mark': 0,
    'low_water_mark_reset': 10,
    'mac_filter_rules': [],
    'member': { '_struct': 'dhcpmember',
      'ipv4addr': '129.97.128.9',
      'name': 'cn-dhcp-mc.example.ca'},
    'ms_options': [],
    'nac_filter_rules': [],
    'name': 'ghost-range',
    'network': '129.97.150.0/24',
    'network_view': 'default',
    'option_filter_rules': [],
    'options': [{'name': 'dhcp-lease-time',

25.20.131 salt.states.ini_manage

Manage ini files

maintainer
<akilesh1597@gmail.com>

maturity
new

depends
re

platform
all

salt.states.ini_manage.options_absent(name, sections=None, separator='=')

/home/saltminion/api-paste.ini:
ini.options_absent:
- separator: '=
- sections:
  test:
- testkey
- secondoption

**test1:**
- testkey1

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

```python
call.states.ini_manage.options_present(name, sections=None, separator='=', strict=False)
```

```ini
/home/saltminion/api-paste.ini:
ini.options_present:
- separator: '
- strict: True
- sections:
  test:
  - testkey: 'testval'
  - secondoption: 'secondvalue'
  - test1:
    - testkey1: 'testval121'
```

options present in file and not specified in sections dict will be untouched, unless strict: True flag is used
changes dict will contain the list of changes made

```python
call.states.ini_manage.sections_absent(name, sections=None, separator='=')
```

```ini
/home/saltminion/api-paste.ini:
ini.sections_absent:
- separator: '
- sections:
  - test
  - test1
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

```python
call.states.ini_manage.sections_present(name, sections=None, separator='=')
```

```ini
/home/saltminion/api-paste.ini:
ini.sections_present:
- separator: '
- sections:
  - section_one
  - section_two
```

This will only create empty sections. To also create options, use options_present state
options present in file and not specified in sections will be deleted changes dict will contain the sections that changed
25.20.132 salt.states.ipmi

Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```yaml
<table>
<thead>
<tr>
<th>ipmi.config:</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_host: 127.0.0.1</td>
</tr>
<tr>
<td>api_user: admin</td>
</tr>
<tr>
<td>api_pass: apassword</td>
</tr>
<tr>
<td>api_port: 623</td>
</tr>
<tr>
<td>api_kg: None</td>
</tr>
</tbody>
</table>
```

Every call can override the config defaults:

```yaml
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None

ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
```

```python
salt.states.ipmi.boot_device(name='default', **kwargs)
  Request power state change
  name = default
  • network -- Request network boot
  • hd -- Boot from hard drive
  • safe -- Boot from hard drive, requesting 'safe mode'
  • optical -- boot from CD/DVD/BD drive
  • setup -- Boot into setup utility
  • default -- remove any IPMI directed boot device request

kwargs
  • api_host=localhost
  • api_user=admin
  • api_pass=
  • api_port=623
  • api_kg=None

salt.states.ipmi.power(name='power_on', wait=300, **kwargs)
  Request power state change
  name
  Ensure power state one of:
  • power_on -- system turn on
  • power_off -- system turn off (without waiting for OS)
  • shutdown -- request OS proper shutdown
  • reset -- reset (without waiting for OS)
```
• `boot` -- If system is off, then 'on', else 'reset'

`wait`

wait X seconds for the job to complete before forcing. (defaults to 300 seconds)

`kwargs`

• `api_host=localhost`
• `api_user=admin`
• `api_pass=`
• `api_port=623`
• `api_kg=None`

`salt.states.ipmi.user_absent(name, channel=14, **kwargs)`

Remove user Delete all user (uid) records having the matching name.

`name`

string name of user to delete

`channel`

channel to remove user access from defaults to 14 for auto.

`kwargs`

• `api_host=localhost`
• `api_user=admin`
• `api_pass=`
• `api_port=623`
• `api_kg=None`

`salt.states.ipmi.user_present(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)`

Ensure IPMI user and user privileges.

`name`

name of user (limit 16 bytes)

`uid`

user id number (1 to 7)

`password`

user password (limit 16 bytes)

`channel`

ipmi channel defaults to 14 for auto

`callback`

User Restricted to Callback

False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.

True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they 'call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

`link_auth`

User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

`ipmi_msg`

User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, 'IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.) ipmi_msg

`privilege_level`
25.20.133 salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

```yaml
setname:
  ipset.set_present:
    - set_type: bitmap:ip
    - range: 192.168.0.0/16
    - comment: True

setname:
  ipset.set_absent:
    - set_type: bitmap:ip
    - range: 192.168.0.0/16
    - comment: True

setname_entries:

  ipset.absent:
    - set_name: setname
```

(continues on next page)
salt.states.ipset.absent(name, entry=None, entries=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Remove a entry or entries from a chain

name
A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

family
Network family, ipv4 or ipv6.

salt.states.ipset.flush(name, family='ipv4', **kwargs)

New in version 2014.7.0.

Flush current ipset set

family
Networking family, either ipv4 or ipv6

salt.states.ipset.present(name, entry=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Append a entry to a set

name
A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

traceback:  File "...",
 func: apply_ipset_set_diff,
 line: 53,
 msg: Unable to find entry index for 192.168.0.3

entry
A single entry to add to a set or a list of entries to add to a set

family
Network family, ipv4 or ipv6.

salt.states.ipset.set_absent(name, family='ipv4', **kwargs)

New in version 2014.7.0.

Verify the set is absent.

family
Networking family, either ipv4 or ipv6

salt.states.ipset.set_present(name, set_type, family='ipv4', **kwargs)

New in version 2014.7.0.

Verify the set exists.

name
A user-defined set name.

set_type
The type for the set.

family
Networking family, either ipv4 or ipv6
25.20.134 salt.states.iptables

Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```
httpd:
  iptables.append:
    - table: filter

    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True

(continues on next page)
- **connstate**: NEW
  - **dport**: 80
  - **protocol**: tcp
  - **sport**: 1025:65535
  - **save**: True

**httpd**:

```bash
iptables.delete:
- **table**: filter
- **family**: ipv6
- **chain**: INPUT
- **jump**: ACCEPT
- **match**: state
- **connstate**: NEW
- **dport**: 80
- **protocol**: tcp
- **sport**: 1025:65535
- **save**: True
```

**default to accept**:

```bash
iptables.set_policy:
- **chain**: INPUT
- **policy**: ACCEPT
```

**Note**: Whereas `iptables` will accept `-p --proto[c[o[l]]]` as synonyms of `--protocol`, if `--proto` appears in an `iptables` command after the appearance of `-m policy`, it is interpreted as the `--proto` option of the policy extension (see the `iptables-extensions(8)` man page).

Example rules for IPSec policy:

**accept_esp_in**:

```bash
iptables.append:
- **table**: filter
- **chain**: INPUT
- **jump**: ACCEPT
- **source**: 10.20.0.0/24
- **destination**: 10.10.0.0/24
- **in-interface**: eth0
- **match**: policy
- **dir**: in
- **pol**: ipsec
- **reqid**: 1
- **proto**: esp
```

**accept_esp_forward_in**:

```bash
iptables.append:
- **use**:
  - **iptables**: accept_esp_in
  - **chain**: FORWARD
```

**accept_esp_out**:

```bash
iptables.append:
```
- table: filter
  chain: OUTPUT
  jump: ACCEPT
  source: 10.10.0.0/24
  destination: 10.20.0.0/24
  out-interface: eth0
  match: policy
dir: out
pol: ipsec
reqid: 1
proto: esp

accept_esp_forward_out:

iptables.append:
  use:
    - iptables: accept_esp_out
  chain: FORWARD
  
salt.states.iptables.append(name, table='filter', family='ipv4', **kwargs)

New in version 0.17.0.

Add a rule to the end of the specified chain. If the rule is already present anywhere in the chain, its position is not changed.

name
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
table
The table that owns the chain which should be modified
family
Network family, ipv4 or ipv6.
save
If set to a true value, the new iptables rules for the given family will be saved to a file.

If the value is True, rules are saved to an OS-dependent file that will be loaded during system startup, resulting in the firewall rule remaining active across reboots if possible.

Note that loading the iptables rules during system startup may require non-default packages to be installed. On Debian-derived systems, the iptables-persistent package is required.

If the value is a string, it is taken to be a filename to which the rules will be saved. Arranging for the rules to be loaded during system startup must be done separately.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.
salt.states.iptables.chain_absent(name, table='filter', family='ipv4')

New in version 2014.1.0.

Verify the chain is absent.

table
The table to remove the chain from

family
Networking family, either ipv4 or ipv6

salt.states.iptables.chain_present(name, table='filter', family='ipv4')

New in version 2014.1.0.

Verify the chain is exist.

name
A user-defined chain name.

table
The table to own the chain.

family
Networking family, either ipv4 or ipv6

salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)

New in version 2014.1.0.

Delete a rule from a chain if present. If the rule is already absent, this is not an error and nothing is changed.

name
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

table
The table that owns the chain that should be modified

family
Networking family, either ipv4 or ipv6

save
If set to a true value, the new iptables rules for the given family will be saved to a file. See the append state for more details.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)

New in version 2014.1.0.

Flush current iptables state

table
The table that owns the chain that should be modified

family
Networking family, either ipv4 or ipv6

chain
The chain to be flushed. All the chains in the table if none is given.

salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)

New in version 2014.1.0.

Insert a rule into a chain. If the rule is already present anywhere in the chain, its position is not changed.

name
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
table
   The table that owns the chain that should be modified
family
   Networking family, either ipv4 or ipv6
position
   The numerical representation of where the rule should be inserted into the chain. Note that -1 is not a supported position value.
save
   If set to a true value, the new iptables rules for the given family will be saved to a file. See the append state for more details.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

canonical

table
   The table that owns the chain that should be modified
family
   Networking family, either ipv4 or ipv6
        
position
   The numerical representation of where the rule should be inserted into the chain. Note that -1 is not a supported position value.
save
   If set to a true value, the new iptables rules for the given family will be saved to a file. See the append state for more details.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

canonical

25.20.135 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses the jboss-cli.sh script from a JBoss or Wildfly installation and parses its output to determine the execution result.

In order to run each state, a jboss_config dictionary with the following properties must be passed:

```
jboss:
   cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
   controller: 10.11.12.13:9999
   cli_user: 'jbossadm'
   cli_password: 'jbossadm'
```

If the controller doesn't require a password, then the cli_user and cli_password parameters are optional.

Since same dictionary with configuration will be used in all the states, it may be more convenient to move JBoss configuration and other properties to the pillar.

Example of application deployment from local filesystem:
application_deployed:
  jboss7.deployed:
    - salt_source:
        target_file: '/tmp/webapp.war'
    - jboss_config: {{ pillar['jboss'] }}

For the sake of brevity, examples for each state assume that jboss_config is contained in the pillar.

salt.states.jboss7.bindings_exist(name, jboss_config, bindings, profile=None)

Ensures that given JNDI binding are present on the server. If a binding doesn’t exist on the server it will be created. If it already exists its value will be changed.

jboss_config:
  Dict with connection properties (see state description)
bindings:
  Dict with bindings to set.
profile:
  The profile name (domain mode only)

Example:

jndi_entries_created:
  jboss7.bindings_exist:
    - bindings:
        'java:global/sampleapp/environment': 'DEV'
        'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.properties'
    - jboss_config: {{ pillar['jboss'] }}

salt.states.jboss7.datasource_exists(name, jboss_config, datasource_properties, recreate=False, profile=None)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn’t exist, it is created, otherwise only the properties that are different will be updated.

name
  Datasource property name
jboss_config
  Dict with connection properties (see state description)
datasource_properties
  Dict with datasource properties
recreate
  [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not me possible to remove it.
profile
  [None] The profile name for this datasource (domain mode only)

Example:

sampleDS:
  jboss7.datasource_exists:
    - recreate: False
    - datasource_properties:
      driver-name: mysql
      connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
      jndi-name: 'java:jboss/datasources/sampleDS'
      user-name: sampleuser
      password: secret

(continues on next page)
salt.states.jboss7.deployed(name, jboss_config, salt_source= None)

Ensures that the given application is deployed on server.

jboss_config:
Dict with connection properties (see state description)
salt_source:
How to find the artifact to be deployed.
target_file:
Where to look in the minion's file system for the artifact to be deployed (e.g. '/tmp/application-web-0.39.war'). When source is specified, also specifies where to save the retrieved file.
source:
(optional) File on salt master (e.g. salt://application-web-0.39.war). If absent, no files will be retrieved and the artifact in target_file will be used for the deployment.
undeploy:
(optional) Regular expression to match against existing deployments. When present, if there is a deployment that matches the regular expression, it will be undeployed before the new artifact is deployed.
undeploy_force:
(optional) If True, the artifact will be undeployed although it has not changed.

Examples:

Deployment of a file from minion's local file system:

    application_deployed:
        jboss7.deployed:
            - salt_source:
                target_file: '/tmp/webapp.war'
            - jboss_config: {{ pillar['jboss'] }}

It is assumed that /tmp/webapp.war was made available by some other means. No applications will be undeployed; if an existing deployment that shares that name exists, then it will be replaced with the updated version.

Deployment of a file from the Salt master's file system:

    application_deployed:
        jboss7.deployed:
            - salt_source:
                source: salt://application-web-0.39.war
                target_file: '/tmp/application-web-0.39.war'
                undeploy: 'application-web-.*'
            - jboss_config: {{ pillar['jboss'] }}

Here, application-web-0.39.war file is downloaded from Salt file system to /tmp/application-web-0.39.war file on minion. Existing deployments are checked if any of them matches 'application-web-.*' regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

If the source parameter of salt_source is specified, it can use any protocol that the file states use. This includes
not only downloading from the master but also HTTP, HTTPS, FTP, Amazon S3, and OpenStack Swift.

```python
salt.states.jboss7.reloaded(name, jboss_config, timeout=60, interval=5)
```
Reloads configuration of jboss server.

**jboss_config:**
Dict with connection properties (see state description)

**timeout:**
Time to wait until jboss is back in running state. Default timeout is 60s.

**interval:**
Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:
- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloads configuration
- Waits for server to reload and be in running state

Example:
```
configuration_reloaded:
  jboss7.reloaded:
    - jboss_config: {{ pillar['jboss'] }}
```

### 25.20.136 salt.states.jenkins

**Management of Jenkins**

New in version 2016.3.0.

```python
salt.states.jenkins.absent(name, **kwargs)
```
Ensure the job is absent from the Jenkins configured jobs

**name**
The name of the Jenkins job to remove

```python
salt.states.jenkins.present(name, config=None, **kwargs)
```
Ensure the job is present in the Jenkins configured jobs

**name**
The unique name for the Jenkins job

**config**
The Salt URL for the file to use for configuring the job

### 25.20.137 salt.states.junos

**State modules to interact with Junos devices.**

**maturity**
new

**dependencies**
- junos-eznc, jxmlease

**Note:** Those who wish to use junos-eznc (PyEZ) version >= 2.1.0, must use the latest salt code from github until the next release.
Refer to `junos` for information on connecting to junos proxy.

```python
salt.states.junos-cli(name, **kwargs)
```

Executes the CLI commands and returns the text output.

```python
show version:
  junos-cli:
    - format: xml

get software version of device:
  junos-cli:
    - name: show version
    - format: text
    - dest: /home/user/show_version.log
```

Parameters

- **Required**
  - `name`: The command that need to be executed on Junos CLI (default = None)

- **Optional**
  - **kwargs**: Keyworded arguments which can be provided like-
    - `format`: Format in which to get the CLI output. (text or xml, default = 'text')
    - `timeout`: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - `dest`: The destination file where the CLI output can be stored. (default = None)

```python
salt.states.junos.commit(name, **kwargs)
```

Commits the changes loaded into the candidate configuration.

```python
commit the changes:
  junos.commit:
    - confirm: 10
```

Parameters

- **Optional**
  - **kwargs**: Keyworded arguments which can be provided like-
    - `timeout`: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - `comment`: Provide a comment to the commit. (default = None)
    - `confirm`: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbaclined in the given time unless the commit is confirmed.
    - `sync`: On dual control plane systems, requests that the candidate configuration on one control plane be copied to the other control plane, checked for correct syntax, and committed on both Routing Engines. (default = False)
    - `force_sync`: On dual control plane systems, force the candidate configuration on one control plane to be copied to the other control plane.
    - `full`: When set to True requires all the daemons to check and evaluate the new configuration.
    - `detail`: When true return commit detail.

```python
salt.states.junos.commit_check(name)
```

Perform a commit check on the configuration.
**perform commit check:**

```
junos.commit_check
```

```
salt.states.junos.diff(name, d_id=0, **kwargs)
```

Changed in version 3001.

Gets the difference between the candidate and the current configuration.

```
get the diff:

junos.diff:
  - d_id: 10
```

**Parameters**

- **Optional**
  - `d_id`: The rollback diff id (d_id) value [0-49]. (default = 0)

```
salt.states.junos.file_copy(name, dest=None, **kwargs)
```

Copies the file from the local device to the junos device.

```
/home/m2/info.txt:

junos.file_copy:
  - dest: info_copy.txt
```

**Parameters**

- **Required**
  - `name`: The source path where the file is kept.
  - `dest`: The destination path where the file will be copied.

```
salt.states.junos.get_table(name, table, table_file, **kwargs)
```

New in version 3001.

Retrieve data from a Junos device using Tables/Views

```
get route details:

junos.get_table:
  - table: RouteTable
  - table_file: routes.yml

get interface details:

junos.get_table:
  - table: EthPortTable
  - table_file: ethport.yml
  - table_args:
    interface_name: ge-0/0/0
```

**name** (required)
- task definition

**table** (required)
- Name of PyEZ Table

**file**
- YAML file that has the table specified in table parameter

**path:**
- Path of location of the YAML file. defaults to op directory in jnpr.junos.op

**target:**
- if command need to run on FPC, can specify fpc target
key:
  To overwrite key provided in YAML
key_items:
  To select only given key items
filters:
  To select only filter for the dictionary from columns
template_args:
  key/value pair which should render Jinja template command

salt.states.junos.install_config(name, **kwargs)
  Loads and commits the configuration provided.

Install the mentioned config:
junos.install_config:
  - name: salt://configs/interface.set
  - timeout: 100
  - diffs_file: '/var/log/diff'

Install the mentioned config:
junos.install_config:
  - path: salt://configs/interface.set
  - timeout: 100
  - template_vars:
    interface_name: lo0
    description: Creating interface via SaltStack.

name
  Path where the configuration/template file is present. If the file has a *.conf extension, the content is treated as text format. If the file has a *.xml extension, the content is treated as XML format. If the file has a *.set extension, the content is treated as Junos OS set commands
template_vars
  The dictionary of data for the Jinja variables present in the Jinja template
timeout
  [30] Set NETCONF RPC timeout. Can be used for commands which take a while to execute.
overwrite
  [False] Set to True if you want this file is to completely replace the configuration file. Sets action to override

---

**Note:** This option cannot be used if format is "set".

merge
  [False] If set to True will set the load-config action to merge. the default load-config action is 'replace' for xml/json/text config
comment
  Provide a comment to the commit. (default = None)
confirm
  Provide time in minutes for commit confirmation. If this option is specified, the commit will be rolled back in the given time unless the commit is confirmed.
diffs_file
  Path to the file where the diff (difference in old configuration and the committed configuration) will be stored.
salt.states.junos.install_os(name, **kwargs)
Installs the given image on the device. After the installation is complete the device is rebooted, if reboot=True is given as a keyworded argument.

```
salt://images/junos_image.tgz:
junos.install_os:
    - timeout: 100
    - reboot: True
```

Parameters
- Required --
  - name: Path where the image file is present on the proxy minion.
- Optional --
  - kwargs: keyworded arguments to be given such as timeout, reboot etc
    - timeout: Set NETCONF RPC timeout. Can be used to RPCs which take a while to execute. (default = 30 seconds)
    - reboot: Whether to reboot after installation (default = False)
    - no_copy: When True the software package will not be SCP'd to the device. (default = False)

salt.states.junos.load(name, **kwargs)
Loads the configuration provided onto the junos device.

```
Install the mentioned config:
junos.load:
    - name: salt://configs/interface.set
```

```
Install the mentioned config:
junos.load:
    - name: salt://configs/interface.set
    - template_vars:
        interface_name: lo0
        description: Creating interface via SaltStack.
```

Sample template:

```
set interfaces {{ interface_name }} unit 0
```

name
Path where the configuration/template file is present. If the file has a *.conf extension, the content is treated as text format. If the file has a *.xml extension, the content is treated as XML format. If the file has a *.set extension, the content is treated as Junos OS set commands.

overwrite
[False] Set to True if you want this file is to completely replace the configuration file.

Note: This option cannot be used if format is "set".

merge
[False] If set to True will set the load-config action to merge. the default load-config action is 'replace' for xml/json/text config
update
[False] Compare a complete loaded configuration against the candidate configuration. For each hierarchy level or configuration object that is different in the two configurations, the version in the loaded configuration replaces the version in the candidate configuration. When the configuration is later committed, only system processes that are affected by the changed configuration elements parse the new configuration. This action is supported from PyEZ 2.1 (default = False)

template_vars
Variables to be passed into the template processing engine in addition to those present in __pillar__, __opts__, __grains__, etc. You may reference these variables in your template like so: {{ template_vars['var_name'] }}

salt.states.junos.lock(name)
Attempts an exclusive lock on the candidate configuration. This is a non-blocking call.

Note: Any user who wishes to use lock, must necessarily unlock the configuration too. Ensure unlock is called in the same orchestration run in which the lock is called.

```
live the config:
---
junos.lock
```

salt.states.junos.resultdecorator(function)

salt.states.junos.rollback(name, d_id, **kwargs)
Rollbacks the committed changes.

```
rollback the changes:
---
junos.rollback:
  - id: 5
```

Parameters
Optional
- id:
  - d_id: The rollback id value [0-49]. (default = 0) (this variable cannot be named id, it conflicts with the state compiler’s internal id)
  - kwargs: Keyworded arguments which can be provided like-
    - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - comment: Provide a comment to the commit. (default = None)
    - confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbacked in the given time unless the commit is confirmed.
    - diffs_file: Path to the file where any diffs will be written. (default = None)

salt.states.junos.rpc(name, dest=None, format='xml', args=None, **kwargs)
Executes the given rpc. The returned data can be stored in a file by specifying the destination path with dest as an argument

```
get-interface-information:
---
junos.rpc:
  - dest: /home/user/rpc.log
  - interface_name: lo0
```

fetch interface information with terse:
**junos.rpc:**
- **name:** get-interface-information
- **terse:** True

Parameters

- **Required**
  - name: The rpc to be executed. (default = None)
- **Optional**
  - dest: Destination file where the rpc output is stored. (default = None) Note that the file will be stored on the proxy minion. To push the files to the master use the salt’s following execution module: `cp.push`
  - format: The format in which the rpc reply must be stored in file specified in the dest (used only when dest is specified) (default = xml)
  - kwargs: keywarded arguments taken by rpc call like-
    - timeout: 30 Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - filter: Only to be used with 'get-config' rpc to get specific configuration.
    - terse: Amount of information you want.
    - interface_name: Name of the interface whose information you want.

**salt.states.junos.set_hostname**(name, **kwargs)**

Changes the hostname of the device.

```python
device_name:
    junos.set_hostname:
    - comment: "Host-name set via saltstack."
```

Parameters

- **Required**
  - name: The name to be set. (default = None)
- **Optional**
  - kwargs: Keywarded arguments which can be provided like-
    - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    - comment: Provide a comment to the commit. (default = None)
    - confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbacked in the given time unless the commit is confirmed.

**salt.states.junos.shutdown**(name, **kwargs)**

Shuts down the device.

```python
shut the device:
    junos.shutdown:
    - in_min: 10
```

Parameters

- **Optional**
  - kwargs:
    - reboot: Whether to reboot instead of shutdown. (default=False)
    - at: Specify time for reboot. (To be used only if reboot=yes)
    - in_min: Specify delay in minutes for shutdown
salt.states.junos.unlock(name)

Unlocks the candidate configuration.

```
unlock the config:
    junos.unlock
```

salt.states.junos.zeroize(name)

Resets the device to default factory settings.

```
reset my device:
    junos.zeroize
```

name: can be anything

25.20.138 salt.states.kapacitor

Kapacitor state module.

**configuration**

This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```
kapacitor.unsafe_ssl: 'false'
kapacitor.protocol: 'http'
kapacitor.host: 'localhost'
kapacitor.port: 9092
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

New in version 2016.11.0.

salt.states.kapacitor.task_absent(name)

Ensure that a task is absent from Kapacitor.

name

Name of the task.

salt.states.kapacitor.task_present(name, tick_script, task_type='stream', database=None, retention_policy='default', enable=True, dbrps=None)

Ensure that a task is present and up-to-date in Kapacitor.

name

Name of the task.

tick_script

Path to the TICK script for the task. Can be a salt:// source.

task_type

Task type. Defaults to 'stream'

dbrps

A list of databases and retention policies in "dbname","rpname" format to fetch data from. For backward compatibility, the value of 'database' and 'retention_policy' will be merged as part of dbrps.

New in version 2019.2.0.

database

Which database to fetch data from. Defaults to None, which will use the default database in InfluxDB.

retention_policy

Which retention policy to fetch data from. Defaults to 'default'.

25.20. state modules 4217
enable
Whether to enable the task or not. Defaults to True.

25.20.139 salt.states.kernelpkg

Manage kernel packages and active kernel version

Example state to install the latest kernel from package repositories:

```yaml
install-latest-kernel:
    kernelpkg.latest_installed: []
```

Example state to boot the system if a new kernel has been installed:

```yaml
boot-latest-kernel:
    kernelpkg.latest_active:
        - at_time: 1
```

Example state chaining the install and reboot operations:

```yaml
install-latest-kernel:
    kernelpkg.latest_installed: []

boot-latest-kernel:
    kernelpkg.latest_active:
        - at_time: 1
        - onchanges:
            - kernelpkg: install-latest-kernel
```

Chaining can also be achieved using wait/listen requisites:

```yaml
install-latest-kernel:
    kernelpkg.latest_installed: []

boot-latest-kernel:
    kernelpkg.latest_wait:
        - at_time: 1
        - listen:
            - kernelpkg: install-latest-kernel
```

salt.states.kernelpkg.latest_active(name, at_time=None, **kwargs)
Initiate a reboot if the running kernel is not the latest one installed.

Note: This state does not install any patches. It only compares the running kernel version number to other kernel versions also installed in the system. If the running version is not the latest one installed, this state will reboot the system.

See kernelpkg.upgrade and latest_installed() for ways to install new kernel packages.

This module does not attempt to understand or manage boot loader configurations. It is possible to have a new kernel installed, but a boot loader configuration that will never activate it. For this reason, it would not be advisable to schedule this state to run automatically.
Because this state function may cause the system to reboot, it may be preferable to move it to the very end of the state run. See `latest_wait()` for a waitable state that can be called with the `listen` requisite.

```
name
    Arbitrary name for the state. Does not affect behavior.

at_time
    The wait time in minutes before the system will be rebooted.
```

```
salt.states.kernelpkg.latest_installed(name, **kwargs)
    Ensure that the latest version of the kernel available in the repositories is installed.
```

Note: This state only installs the kernel, but does not activate it. The new kernel should become active at the next reboot. See `kernelpkg.needs_reboot` for details on how to detect this condition, and `latest_active()` to initiate a reboot when needed.

```
salt.states.kernelpkg.latest_wait(name, at_time=None, **kwargs)
    Initiate a reboot if the running kernel is not the latest one installed. This is the waitable version of `latest_active()` and will not take any action unless triggered by a watch or listen requisite.
```

Note: Because this state function may cause the system to reboot, it may be preferable to move it to the very end of the state run using `listen` or `listen_in` requisites.

```
   system-up-to-date:
       pkg.uptodate:
           - refresh: true

   boot-latest-kernel:
       kernelpkg.latest_wait:
           - at_time: 1
           - listen:
               - pkg: system-up-to-date
```

```
name
    Arbitrary name for the state. Does not affect behavior.

at_time
    The wait time in minutes before the system will be rebooted.
```

```
salt.states.kernelpkg.mod_watch(name, sfun, **kwargs)
    Execute a kernelpkg state based on a watch or listen call
```
25.20.140 salt.states.keyboard

Management of keyboard layouts

The keyboard layout can be managed for the system:

```
us:
  keyboard.system
```

Or it can be managed for XOrg:

```
us:
  keyboard.xorg
```

salt.states.keyboard.system(name)
Set the keyboard layout for the system name
  The keyboard layout to use

salt.states.keyboard.xorg(name)
Set the keyboard layout for XOrg layout
  The keyboard layout to use

25.20.141 salt.states.keystone

Management of Keystone users

depends
  • keystoneclient Python module

collection
  See salt.modules.keystone for setup instructions.

**Keystone tenants:**
  keystone.tenant_present:
    - names:
      - admin
      - demo
      - service

**Keystone roles:**
  keystone.role_present:
    - names:
      - admin
      - Member

admin:
  keystone.user_present:
    - password: R00T_4CC3SS
    - email: admin@domain.com
    - roles:

(continues on next page)

nova service:
    keystone.service_present:
      - name: nova
      - service_type: compute
      - description: OpenStack Compute Service

salt.states.keystone.endpoint_absent
    name, region=None, profile=None, interface=None, **connection_args

Ensure that the endpoint for a service doesn't exist in Keystone catalog
name
    The name of the service whose endpoints should not exist
region (optional)
    The region of the endpoint. Defaults to RegionOne.
interface
    The interface type, which describes the visibility of the endpoint. (for V3 API)
salt.states.keystone.endpoint_present
    name, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, url=None, interface=None, **connection_args

Ensure the specified endpoints exists for service
name
   The Service name
publicurl
   The public url of service endpoint (for V2 API)
internalurl
   The internal url of service endpoint (for V2 API)
adminurl
   The admin url of the service endpoint (for V2 API)
region
   The region of the endpoint
url
   The endpoint URL (for V3 API)
interface
   The interface type, which describes the visibility of the endpoint. (for V3 API)
salt.states.keystone.project_absent(name, profile=None, **connection_args)
Ensure that the keystone project is absent. Alias for tenant_absent from V2 API to fulfill V3 API naming
convention.
New in version 2016.11.0.
name
   The name of the project that should not exist

```
delte_nova:
    keystone.project_absent:
       - name: nova
```
salt.states.keystone.project_present(name, description=None, enabled=True, profile=None, **connection_args)
Ensures that the keystone project exists Alias for tenant_present from V2 API to fulfill V3 API naming con-
vention.
New in version 2016.11.0.
name
   The name of the project to manage
description
   The description to use for this project
enabled
   Availability state for this project

```
nova:
    keystone.project_present:
       - enabled: True
       - description: 'Nova Compute Service'
```
salt.states.keystone.role_absent(name, profile=None, **connection_args)
Ensure that the keystone role is absent.
name
   The name of the role that should not exist
salt.states.keystone.role_present(name, profile=None, **connection_args)
'Ensures that the keystone role exists
name
   The name of the role that should be present
salt.states.keystone.service_absent(name, profile=None, **connection_args)

Ensure that the service doesn’t exist in Keystone catalog

name

The name of the service that should not exist

salt.states.keystone.service_present(name, service_type, description=None, profile=None, **connection_args)

Ensure service present in Keystone catalog

name

The name of the service

service_type

The type of Openstack Service

description (optional)

Description of the service

salt.states.keystone.tenant_absent(name, profile=None, **connection_args)

Ensure that the keystone tenant is absent.

name

The name of the tenant that should not exist

salt.states.keystone.tenant_present(name, description=None, enabled=True, profile=None, **connection_args)

Ensures that the keystone tenant exists

name

The name of the tenant to manage

description

The description to use for this tenant

enabled

Availability state for this tenant

salt.states.keystone.user_absent(name, profile=None, **connection_args)

Ensure that the keystone user is absent.

name

The name of the user that should not exist

salt.states.keystone.user_present(name, password, email, tenant=None, enabled=True, roles=None, profile=None, password_reset=True, project=None, **connection_args)

Ensure that the keystone user is present with the specified properties.

name

The name of the user to manage

password

The password to use for this user.

password_reset

Whether or not to reset password after initial set. Defaults to True.

email

The email address for this user

tenant

The tenant (name) for this user

**Note:** If the user already exists and a different password was set for the user than the one specified here, the password for the user will be updated. Please set the password_reset option to False if this is not the desired behavior.
**project**  
The project (name) for this user (overrides tenant in api v3)

**enabled**  
Availability state for this user

**roles**  
The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.:

```yaml
roles:
  admin:   # tenant
    - admin  # role
  service:
    - admin
    - Member
```

---

## 25.20.142 salt.states.keystone_domain

**Management of OpenStack Keystone Domains**

New in version 2018.3.0.

**depends**  
shade

**configuration**  
see `salt.modules.keystoneng` for setup instructions

**Example States**

```yaml
create domain:
  keystone_domain.present:
    - name: domain1

create domain with optional params:
  keystone_domain.present:
    - name: domain1
    - enabled: False
    - description: 'my domain'

delete domain:
  keystone_domain.absent:
    - name: domain1
```

**salt.states.keystone_domain.absent(name, auth=None)**  
Ensure domain does not exist  
**name**  
Name of the domain

**salt.states.keystone_domain.present(name, auth=None, **kwargs)**  
Ensure domain exists and is up-to-date  
**name**  
Name of the domain  
**enabled**  
Boolean to control if domain is enabled
description
An arbitrary description of the domain

25.20.143 salt.states.keystone_endpoint

Management of OpenStack Keystone Endpoints

New in version 2018.3.0.

depends
shade

configuration
see salt.modules.keystoneng for setup instructions

Example States

create endpoint:
  keystone_endpoint.present:
  - name: public
  - url: https://example.org:9292
  - region: RegionOne
  - service_name: glance

destroy endpoint:
  keystone_endpoint.absent:
  - name: public
  - url: https://example.org:9292
  - region: RegionOne
  - service_name: glance

create multiple endpoints:
  keystone_endpoint.absent:
  - names:
    - public
    - admin
    - internal
  - url: https://example.org:9292
  - region: RegionOne
  - service_name: glance

salt.states.keystone_endpoint.absent(name, service_name, auth=None, **kwargs)
Ensure an endpoint does not exists

name
  Interface name
url
  URL of the endpoint
service_name
  Service name or ID
region
  The region name to assign the endpoint

salt.states.keystone_endpoint.present(name, service_name, auth=None, **kwargs)
Ensure an endpoint exists and is up-to-date
name
  Interface name
url
  URL of the endpoint
service_name
  Service name or ID
region
  The region name to assign the endpoint
enabled
  Boolean to control if endpoint is enabled

25.20.144  salt.states.keystone_group

Management of OpenStack Keystone Groups

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.keystoneng for setup instructions

Example States

create group:
  keystone_group.present:
    - name: group1

delete group:
  keystone_group.absent:
    - name: group1

create group with optional params:
  keystone_group.present:
    - name: group1
    - domain: domain1
    - description: 'my group'

salt.states.keystone_group.absent(name, auth=None, **kwargs)
  Ensure group does not exist
  name
    Name of the group
domain
    The name or id of the domain

salt.states.keystone_group.present(name, auth=None, **kwargs)
  Ensure an group exists and is up-to-date
  name
    Name of the group
domain
    The name or id of the domain
description
    An arbitrary description of the group
25.20.145  salt.states.keystone_project

Management of OpenStack Keystone Projects

New in version 2018.3.0.

depends
    shade

configuration
    see salt.modules.keystoneng for setup instructions

Example States

```yaml
create project:
    keystone_project.present:
        - name: project1

delete project:
    keystone_project.absent:
        - name: project1

create project with optional params:
    keystone_project.present:
        - name: project1
        - domain: domain1
        - enabled: False
        - description: 'my project'
```

```
salt.states.keystone_project.absent(name, auth=None, **kwargs)
    Ensure a project does not exists
        name
            Name of the project
        domain
            The name or id of the domain

salt.states.keystone_project.present(name, auth=None, **kwargs)
    Ensure a project exists and is up-to-date
        name
            Name of the project
        domain
            The name or id of the domain
        description
            An arbitrary description of the project
```
25.20.146 salt.states.keystone_role

Management of OpenStack Keystone Roles

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.keystoneng for setup instructions

Example States

**create role:**
  keystoneng.present:
    - name: role1

**delete role:**
  keystoneng.absent:
    - name: role1

**create role with optional params:**
  keystoneng.present:
    - name: role1
    - description: 'my group'

salt.states.keystone_role.absent(name, auth=None, **kwargs)
  Ensure role does not exist
  name
    Name of the role

salt.states.keystone_role.present(name, auth=None, **kwargs)
  Ensure an role exists
  name
    Name of the role
description
    An arbitrary description of the role

25.20.147 salt.states.keystone_role_grant

Management of OpenStack Keystone Role Grants

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.keystoneng for setup instructions

Example States

**create group:**
  keystoneng.group.present:
(continues on next page)
delete group:
    keystone_group.absent:
        - name: group1

create group with optional params:
    keystone_group.present:
        - name: group1
        - domain: domain1
        - description: 'my group'

salt.states.keystone_role_grant.absent(name, auth=None, **kwargs)

salt.states.keystone_role_grant.present(name, auth=None, **kwargs)

25.20.148  salt.states.keystone_service

Management of OpenStack Keystone Services

New in version 2018.3.0.

depends
    shade

configuration
    see salt.modules.keystoneng for setup instructions

Example States

create service:
    keystone_service.present:
        - name: glance
        - type: image

delete service:
    keystone_service.absent:
        - name: glance

create service with optional params:
    keystone_service.present:
        - name: glance
        - type: image
        - enabled: False
        - description: 'OpenStack Image'

salt.states.keystone_service.absent(name, auth=None)

    Ensure service does not exist

    name
        Name of the service

salt.states.keystone_service.present(name, auth=None, **kwargs)

    Ensure an service exists and is up-to-date
name
   Name of the group
type
   Service type
enabled
   Boolean to control if service is enabled
description
   An arbitrary description of the service

25.20.149 salt.states.keystone_user

Management of OpenStack Keystone Users

New in version 2018.3.0.

depends
   shade
configuration
   see salt.modules.keystoneng for setup instructions

Example States

create user:
   keystone_user.present:
      - name: user1

delete user:
   keystone_user.absent:
      - name: user1

create user with optional params:
   keystone_user.present:
      - name: user1
      - domain: domain1
      - enabled: False
      - password: password123
      - email: "user1@example.org"
      - description: 'my user'

salt.states.keystone_user.absent(name, auth=None, **kwargs)
   Ensure user does not exists
   name
      Name of the user
domain
      The name or id of the domain

salt.states.keystone_user.present(name, auth=None, **kwargs)
   Ensure domain exists and is up-to-date
   name
      Name of the domain
domain
      The name or id of the domain
enabled
   Boolean to control if domain is enabled
description
An arbitrary description of the domain

password
The user password

email
The users email address

25.20.150 salt.states.keystore

State management of a java keystore

salt.states.keystore.managed(name, passphrase, entries, force_remove=False)

Create or manage a java keystore.

Parameters
- name -- The path to the keystore file
- passphrase -- The password to the keystore
- entries -- A list containing an alias, certificate, and optional private_key. The certificate and private_key can be a file or a string
- force_remove -- If True will cause the state to remove any entries found in the keystore which are not defined in the state. The default is False. Example:

```python
define_keystore:
    keystore.managed:
        - name: /path/to/keystore
        - passphrase: changeit
        - force_remove: True
        - entries:
            - alias: hostname1
              certificate: /path/to/cert.crt
            - alias: remotehost
              certificate: /path/to/cert2.crt
              private_key: /path/to/key2.key
            - alias: pillarhost
              certificate: {{ salt.pillar.get('path:to:cert') }}
```

```plaintext
- entries:
  - alias: hostname2
    certificate: /path/to/cert.crt
    private_key: /path/to/key.key
  - alias: stringhost
    certificate: |
    ======BEGIN CERTIFICATE=====
    MIICjCCAXsCAg36MA0GCSqGSIb3QEBBQUAMIGbMQswCQYDVQQGEwJKUDEOMAwG
    2VguKv4SWjRFoRkIfILHXOqVviMhSlNy2ioFLy7JcPZb+v3ftDGywUqcBiVDoea0
    ======END CERTIFICATE=====
```
25.20.151 salt.states.kmod

Loading and unloading of kernel modules

The Kernel modules on a system can be managed cleanly with the kmod state module:

```
add_kvm:
    kmod.present:
        - name: kvm_amd
remove_beep:
    kmod.absent:
        - name: pcspkr
```

Multiple modules can be specified for both kmod.present and kmod.absent.

```
add_sound:
    kmod.present:
        - mods:
            - snd_hda_codec_hdm
            - snd_hda_CODEC
            - snd_hwdep
            - snd_hda_core
            - snd_pcm
            - snd_timer
            - snd
```

```
salt.states.kmod.absent(name, persist=False, comment=True, mods=None)
    Verify that the named kernel module is not loaded
    name
        The name of the kernel module to verify is not loaded
    persist
        Remove module from /etc/modules (or /etc/modules-load.d/salt_managed.conf if the systemd key is present in Grains.
    comment
        Comment out module in /etc/modules rather than remove it
    mods
        A list of modules to verify are unloaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.

```
salt.states.kmod.present(name, persist=False, mods=None)
    Ensure that the specified kernel module is loaded
    name
        The name of the kernel module to verify is loaded
    persist
        Also add module to /etc/modules (or /etc/modules-load.d/salt_managed.conf if the systemd key is present in Grains.
    mods
        A list of modules to verify are loaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.
```
25.20.152 salt.states.kubernetes

Manage kubernetes resources as salt states

NOTE: This module requires the proper pillar values set. See salt.modules.kubernetesmod for more information.

Warning: Configuration options will change in 2019.2.0.

The kubernetes module is used to manage different kubernetes resources.

```yaml
my-nginx:
  kubernetes.deployment_present:
    - namespace: default
      metadata:
        app: frontend
      spec:
        replicas: 1
      template:
        metadata:
          labels:
            run: my-nginx
        spec:
          containers:
            - name: my-nginx
              image: nginx
              ports:
                - containerPort: 80

my-mariadb:
  kubernetes.deployment_absent:
    - namespace: default

# kubernetes deployment as specified inside of
# a file containing the definition of the the
# deployment using the official kubernetes format
redis-master-deployment:
  kubernetes.deployment_present:
    - name: redis-master
      source: salt://k8s/redis-master-deployment.yml
      require:
        - pip: kubernetes-python-module

# kubernetes service as specified inside of
# a file containing the definition of the the
# service using the official kubernetes format
redis-master-service:
  kubernetes.service_present:
    - name: redis-master
      source: salt://k8s/redis-master-service.yml
      require:
        - kubernetes.deployment_present: redis-master
```

(continues on next page)
# Kubernetes deployment as specified inside of
# a file containing the definition of the the
# plus some jinja directives

```yaml
nginx-source-template:
  kubernetes.deployment_present:
    - source: salt://k8s/nginx.yml.jinja
    - template: jinja
    require:
      - pip: kubernetes-python-module
```

# Kubernetes secret

k8s-secret:
  kubernetes.secret_present:
    - name: top-secret
      data:
        key1: value1
        key2: value2
        key3: value3
```

New in version 2017.7.0.

salt.states.kubernetes.configmap_absent(name, namespace='default', **kwargs)

Ensures that the named configmap is absent from the given namespace.

- name
  The name of the configmap
- namespace
  The namespace holding the configmap. The 'default' one is going to be used unless a different one is specified.

salt.states.kubernetes.configmap_present(name, namespace='default', data=None, source=None, template=None, **kwargs)

Ensures that the named configmap is present inside of the specified namespace with the given data. If the configmap exists it will be replaced.

- name
  The name of the configmap.
- namespace
  The namespace holding the configmap. The 'default' one is going to be used unless a different one is specified.
- data
  The dictionary holding the configmaps.
- source
  A file containing the data of the configmap in plain format.
- template
  Template engine to be used to render the source file.

salt.states.kubernetes.deployment_absent(name, namespace='default', **kwargs)

Ensures that the named deployment is absent from the given namespace.

- name
  The name of the deployment
- namespace
  The name of the namespace
salt.states.kubernetes.deployment_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)

Ensures that the named deployment is present inside of the specified namespace with the given metadata and spec. If the deployment exists it will be replaced.

- **name**
  - The name of the deployment.

- **namespace**
  - The namespace holding the deployment. The 'default' one is going to be used unless a different one is specified.

- **metadata**
  - The metadata of the deployment object.

- **spec**
  - The spec of the deployment object.

- **source**
  - A file containing the definition of the deployment (metadata and spec) in the official kubernetes format.

- **template**
  - Template engine to be used to render the source file.

salt.states.kubernetes.namespace_absent(name, **kwargs)

Ensures that the named namespace is absent.

- **name**
  - The name of the namespace

salt.states.kubernetes.namespace_present(name, **kwargs)

Ensures that the named namespace is present.

- **name**
  - The name of the namespace.

salt.states.kubernetes.node_label_absent(name, node, **kwargs)

Ensures that the named label is absent from the node.

- **name**
  - The name of the label

- **node**
  - The name of the node

salt.states.kubernetes.node_label_folder_absent(name, node, **kwargs)

Ensures the label folder doesn't exist on the specified node.

- **name**
  - The name of label folder

- **node**
  - The name of the node

salt.states.kubernetes.node_label_present(name, node, value, **kwargs)

Ensures that the named label is set on the named node with the given value. If the label exists it will be replaced.

- **name**
  - The name of the label.

- **value**
  - Value of the label.

- **node**
  - Node to change.

salt.states.kubernetes.pod_absent(name, namespace='default', **kwargs)

Ensures that the named pod is absent from the given namespace.

- **name**
  - The name of the pod
namespace
The name of the namespace

salt.states.kubernetes.pod_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)

Ensures that the named pod is present inside of the specified namespace with the given metadata and spec. If the pod exists it will be replaced.

name
The name of the pod.

namespace
The namespace holding the pod. The 'default' one is going to be used unless a different one is specified.

metadata
The metadata of the pod object.

spec
The spec of the pod object.

source
A file containing the definition of the pod (metadata and spec) in the official kubernetes format.

template
Template engine to be used to render the source file.

salt.states.kubernetes.secret_absent(name, namespace='default', **kwargs)

Ensures that the named secret is absent from the given namespace.

name
The name of the secret

namespace
The name of the namespace

salt.states.kubernetes.secret_present(name, namespace='default', data=None, source=None, template=None, **kwargs)

Ensures that the named secret is present inside of the specified namespace with the given data. If the secret exists it will be replaced.

name
The name of the secret.

namespace
The namespace holding the secret. The 'default' one is going to be used unless a different one is specified.

data
The dictionary holding the secrets.

source
A file containing the data of the secret in plain format.

template
Template engine to be used to render the source file.

salt.states.kubernetes.service_absent(name, namespace='default', **kwargs)

Ensures that the named service is absent from the given namespace.

name
The name of the service

namespace
The name of the namespace

salt.states.kubernetes.service_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)

Ensures that the named service is present inside of the specified namespace with the given metadata and spec. If the deployment exists it will be replaced.

name
The name of the service.
namespace
   The namespace holding the service. The 'default' one is going to be used unless a different one is specified.
metadata
   The metadata of the service object.
spec
   The spec of the service object.
source
   A file containing the definition of the service (metadata and spec) in the official kubernetes format.
template
   Template engine to be used to render the source file.

25.20.153  salt.states.layman

Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

sunrise:
   layman.present

salt.states.layman.absent(name)
   Verify that the overlay is absent
name
   The name of the overlay to delete

salt.states.layman.present(name)
   Verify that the overlay is present
name
   The name of the overlay to add

25.20.154  salt.states.ldap

Manage entries in an LDAP database

New in version 2016.3.0.

The states.ldap state module allows you to manage LDAP entries and their attributes.
salt.states.ldap.managed(name, entries, connect_spec=None)
   Ensure the existence (or not) of LDAP entries and their attributes

Example:

ldap:///
ldap.managed:
   - connect_spec:
     bind:
       method: sasl
     - entries:
       # make sure the entry doesn't exist
       - cn=foo,ou=users,dc=example,dc=com:
- **delete_others**: True

  # make sure the entry exists with only the specified attribute values
  - `cn=admin,dc=example,dc=com`:
    - **delete_others**: True
    - **replace**:
      - `cn`
      - admin
      - **description**:
        - LDAP administrator
      - **objectClass**:
        - simpleSecurityObject
        - organizationalRole
      - **userPassword**:
        - `{{pillar.ldap_admin_password}}`

  # make sure the entry exists, its olcRootDN attribute has only the specified value, the olcRootDN attribute doesn't exist, and all other attributes are ignored
  - `olcDatabase={1}hdb,cn=config`
    - **replace**:
      - `olcRootDN`
      - `cn=admin,dc=example,dc=com`
      # the admin entry has its own password attribute
      - **olcRootPW**: `[]`

  # note the use of 'default'. also note how you don't have to use list syntax if there is only one attribute value
  - `cn=foo,ou=users,dc=example,dc=com`:
    - **delete_others**: True
    - **default**:
      - **userPassword**: changeme
      - **shadowLastChange**: 0
      # keep sshPublicKey if present, but don't create # the attribute if it is missing
      - **sshPublicKey**: `[]`
    - **replace**:
      - `cn`: foo
      - `uid`: foo
      - `uidNumber`: 1000
      - `gidNumber`: 1000
      - `gecos`: Foo Bar
      - `givenName`: Foo
      - `sn`: Bar
      - `homeDirectory`: /home/foo
      - `loginShell`: /bin/bash
      - **objectClass**:
        - inetOrgPerson
        - posixAccount
        - top
Parameters

- **name** -- The URL of the LDAP server. This is ignored if `connect_spec` is either a connection object or a dict with a 'url' entry.
- **entries** -- A description of the desired state of zero or more LDAP entries.

`entries` is an iterable of dicts. Each of these dict's keys are the distinguished names (DNs) of LDAP entries to manage. Each of these dicts is processed in order. A later dict can reference an LDAP entry that was already mentioned in an earlier dict, which makes it possible for later dicts to enhance or alter the desired state of an LDAP entry.

The DNs are mapped to a description of the LDAP entry's desired state. These LDAP entry descriptions are themselves iterables of dicts. Each dict in the iterable is processed in order. They contain directives controlling the entry's state. The key names the directive type and the value is state information for the directive. The specific structure of the state information depends on the directive type.

The structure of `entries` looks like this:

```
[{dn1: [{directive1: directive1_state,
         directive2: directive2_state},
         {directive3: directive3_state}],
  dn2: [{directive4: directive4_state,
         directive5: directive5_state}],
  {dn3: [{directive6: directive6_state}]]
```

These are the directives:

- **'delete_others'**
  Boolean indicating whether to delete attributes not mentioned in this dict or any of the other directive dicts for this DN. Defaults to False.

  If you don't want to delete an attribute if present, but you also don't want to add it if it is missing or modify it if it is present, you can use either the 'default' directive or the 'add' directive with an empty value list.

- **'default'**
  A dict mapping an attribute name to an iterable of default values for that attribute. If the attribute already exists, it is left alone. If not, it is created using the given list of values.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- **'add'**
  Attribute values to add to the entry. This is a dict mapping an attribute name to an iterable of values to add.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- **'delete'**
  Attribute values to remove from the entry. This is a dict mapping an attribute name to an iterable of values to delete from the attribute. If the iterable is empty, all of the attribute's values are deleted.
- 'replace'
  Attributes to replace. This is a dict mapping an attribute name to an iterable of values. Any existing values for the attribute are deleted, then the given values are added. The iterable may be empty.

In the above directives, the iterables of attribute values may instead be `None`, in which case an empty list is used, or a scalar such as a string or number, in which case a new list containing the scalar is used.

Note that if all attribute values are removed from an entry, the entire entry is deleted.

- `connect_spec` -- See the description of the `connect_spec` parameter of the `ldap3.connect` function in the `ldap3` execution module. If this is a dict and the 'url' entry is not specified, the 'url' entry is set to the value of the `name` parameter.

Returns

A dict with the following keys:

- 'name'
  This is the same object passed to the `name` parameter.

- 'changes'
  This is a dict describing the changes made (or, in test mode, the changes that would have been attempted). If no changes were made (or no changes would have been attempted), then this dict is empty. Only successful changes are included.

  Each key is a DN of an entry that was changed (or would have been changed). Entries that were not changed (or would not have been changed) are not included. The value is a dict with two keys:

  - 'old'
    The state of the entry before modification. If the entry did not previously exist, this key maps to `None`. Otherwise, the value is a dict mapping each of the old entry's attributes to a list of its values before any modifications were made. Unchanged attributes are excluded from this dict.

  - 'new'
    The state of the entry after modification. If the entry was deleted, this key maps to `None`. Otherwise, the value is a dict mapping each of the entry's attributes to a list of its values after the modifications were made. Unchanged attributes are excluded from this dict.

Example 'changes' dict where a new entry was created with a single attribute containing two values:

```json
{'dn1': {'old': None,
         'new': {'attr1': ['val1', 'val2']}}}
```

Example 'changes' dict where a new attribute was added to an existing entry:

```json
{'dn1': {'old': {},
         'new': {'attr2': ['val3']}}}
```

- 'result'
  One of the following values:
  - `True` if no changes were necessary or if all changes were applied successfully.
  - `False` if at least one change was unable to be applied.
  - `None` if changes would be applied but it is in test mode.
25.20.155 salt.states.libcloud_dns

Manage DNS records and zones using libcloud

codeauthor
Anthony Shaw <anthonyshaw@apache.org>

New in version 2016.11.0.

Create and delete DNS records or zones through Libcloud. Libcloud's DNS system supports over 20 DNS providers including Amazon, Google, GoDaddy, Softlayer

This module uses libcloud, which can be installed via package, or pip.

configuration
This module uses a configuration profile for one or multiple DNS providers

```
libcloud_dns:
  profile1:
    driver: godaddy
    key: 2orgk34kgk34g
  profile2:
    driver: route53
    key: blah
    secret: blah
```

Example:

```
my-zone:
  libcloud_dns.zone_present:
    - name: mywebsite.com
    - profile: profile1

my-website:
  libcloud_dns.record_present:
    - name: www
    - zone: mywebsite.com
    - type: A
    - data: 12.34.32.3
    - profile: profile1
    - require:
      - libcloud_dns: my-zone
```

depends
apache-libcloud

salt.states.libcloud_dns.record_absent(name, zone, type, data, profile)

Ensures a record is absent.

Parameters

- **name** (str) -- Record name without the domain name (e.g. www). Note: If you want to create a record for a base domain name, you should specify empty string ('') for this argument.
- **zone** (str) -- Zone where the requested record is created, the domain name
- **type** (str) -- DNS record type (A, AAAA, ...).
- **data** (str) -- Data for the record (depends on the record type).
- **profile** (str) -- The profile key
salt.states.libcloud_dns.record_present(name, zone, type, data, profile)

Ensures a record is present.

Parameters
- **name** (str) -- Record name without the domain name (e.g. www). Note: If you want to create a record for a base domain name, you should specify empty string ("") for this argument.
- **zone** (str) -- Zone where the requested record is created, the domain name
- **type** (str) -- DNS record type (A, AAAA, ...).
- **data** (str) -- Data for the record (depends on the record type).
- **profile** (str) -- The profile key

salt.states.libcloud_dns.state_result(result, message, name, changes=None)

salt.states.libcloud_dns.zone_absent(domain, profile)

Ensures a record is absent.

Parameters
- **domain** (str) -- Zone name, i.e. the domain name
- **profile** (str) -- The profile key

salt.states.libcloud_dns.zone_present(domain, type, profile)

Ensures a record is present.

Parameters
- **domain** (str) -- Zone name, i.e. the domain name
- **type** (str) -- Zone type (master / slave), defaults to master
- **profile** (str) -- The profile key

25.20.156 salt.states.libcloud_loadbalancer

Apache Libcloud Load Balancer State

Manage load balancers using libcloud

codeauthor
Anthony Shaw <anthonyshaw@apache.org>

Apache Libcloud load balancer management for a full list of supported clouds, see http://libcloud.readthedocs.io/en/latest/loadbalancer/supported_providers.html

Clouds include Amazon ELB, ALB, Google, Aliyun, CloudStack, Softlayer

New in version 2018.3.0.

configuration

This module uses a configuration profile for one or multiple Cloud providers

```yaml
libcloud_loadbalancer:
  profile_test1:
    driver: gce
    key: G00G0123456789ABCXY
    secret: mysecret
  profile_test2:
    driver: alb
    key: 12345
    secret: mysecret
```
Example:

Using States to deploy a load balancer with extended arguments to specify region

```yaml
lb_test:
  libcloud_loadbalancer.balancer_present:
    name: example
    port: 80
    protocol: http
    profile: google
    ex_region: us-east1
```

depends

apache-libcloud

salt.states.libcloud_loadbalancer.balancer_absent(name, profile, **libcloud_kwargs)

Ensures a load balancer is absent.

Parameters

- name (str) -- Load Balancer name
- profile (str) -- The profile key

salt.states.libcloud_loadbalancer.balancer_present(name, port, protocol, profile, algorithm=None, members=None, **libcloud_kwargs)

Ensures a load balancer is present.

Parameters

- name (str) -- Load Balancer name
- port (str) -- Port the load balancer should listen on, defaults to 80
- protocol (str) -- Loadbalancer protocol, defaults to http.
- profile (str) -- The profile key
- algorithm (str) -- Load balancing algorithm, defaults to ROUND_ROBIN. See Algorithm type in Libcloud documentation for a full listing.
- members (list of dict (ip, port)) -- An optional list of members to create on deployment

salt.states.libcloud_loadbalancer.member_absent(ip, port, balancer_id, profile, **libcloud_kwargs)

Ensure a load balancer member is absent, based on IP and Port

Parameters

- ip (str) -- IP address for the member
- port (int) -- Port for the member
- balancer_id (str) -- id of a load balancer you want to detach the member from
- profile (str) -- The profile key

salt.states.libcloud_loadbalancer.member_present(ip, port, balancer_id, profile, **libcloud_kwargs)

Ensure a load balancer member is present

Parameters

- ip (str) -- IP address for the new member
- port (int) -- Port for the new member
- balancer_id (str) -- id of a load balancer you want to attach the member to
- profile (str) -- The profile key

salt.states.libcloud_loadbalancer.state_result(result, message, name, changes=None)
25.20.157 salt.states.libcloud_storage

Apache Libcloud Storage State

Manage cloud storage using libcloud

codeauthor
Anthony Shaw <anthonyshaw@apache.org>

Apache Libcloud Storage (object/blob) management for a full list of supported clouds, see http://libcloud.readthedocs.io/en/latest/storage/supported_providers.html

Clouds include Amazon S3, Google Storage, Aliyun, Azure Blobs, Ceph, OpenStack swift

New in version 2018.3.0.

configuration

This module uses a configuration profile for one or multiple Storage providers

```
libcloud_storage:
  profile_test1:
    driver: google_storage
    key: G00G0123456789ABCXYZ
    secret: mysecret
  profile_test2:
    driver: s3
    key: 12345
    secret: mysecret
```

Examples

Creating a container and uploading a file

```
web_things:
  libcloud_storage.container_present:
    name: my_container_name
    profile: profile1
  libcloud_storage.object_present:
    name: my_file.jpg
    container: my_container_name
    path: /path/to/local/file.jpg
    profile: profile1
```

Downloading a file

This example will download the file from the remote cloud and keep it locally

```
web_things:
  libcloud_storage.file_present:
    name: my_file.jpg
    container: my_container_name
    path: /path/to/local/file.jpg
    profile: profile1
```
depends

    apache-libcloud

salt.states.libcloud_storage.

    container_absent(name, profile)

Ensures a container is absent.

    Parameters
        • name (str) -- Container name
        • profile (str) -- The profile key

salt.states.libcloud_storage.

    container_present(name, profile)

Ensures a container is present.

    Parameters
        • name (str) -- Container name
        • profile (str) -- The profile key

salt.states.libcloud_storage.

    file_present(container, name, path, profile, overwrite_existing=False)

Ensures a object is downloaded locally.

    Parameters
        • container (str) -- Container name
        • name (str) -- Object name in cloud
        • path (str) -- Local path to file
        • profile (str) -- The profile key
        • overwrite_existing (bool) -- Replace if already exists

salt.states.libcloud_storage.

    object_absent(container, name, profile)

Ensures a object is absent.

    Parameters
        • container (str) -- Container name
        • name (str) -- Object name in cloud
        • profile (str) -- The profile key

salt.states.libcloud_storage.

    object_present(container, name, path, profile)

Ensures a object is present.

    Parameters
        • container (str) -- Container name
        • name (str) -- Object name in cloud
        • path (str) -- Local path to file
        • profile (str) -- The profile key

salt.states.libcloud_storage.

    state_result(result, message, name, changes)

25.20.158  salt.states.linux_acl

Linux File Access Control Lists

The Linux ACL state module requires the getfacl and setfacl binaries.

Ensure a Linux ACL is present

    root:
      acl.present:
        - name: /root
        - acl_type: user
        - acl_name: damian
        - perms: rwx
Ensure a Linux ACL does not exist

```yaml
root:
  acl.absent:
    - name: /root
    - acl_type: user
    - acl_name: damian
    - perms: rwx
```

Ensure a Linux ACL list is present

```yaml
root:
  acl.list_present:
    - name: /root
    - acl_type: user
    - acl_names:
      - damian
      - homer
    - perms: rwx
```

Ensure a Linux ACL list does not exist

```yaml
root:
  acl.list_absent:
    - name: /root
    - acl_type: user
    - acl_names:
      - damian
      - homer
    - perms: rwx
```

**Warning:** The effective permissions of Linux file access control lists (ACLs) are governed by the "effective rights mask" (the `mask` line in the output of the `getfacl` command) combined with the `perms` set by this module: any permission bits (for example, r=read) present in an ACL but not in the mask are ignored. The mask is automatically recomputed when setting an ACL, so normally this isn't important. However, if the file permissions are changed (with `chmod` or `file.managed`, for example), the mask will generally be set based on just the group bits of the file permissions.

As a result, when using `file.managed` or similar to control file permissions as well as this module, you should set your group permissions to be at least as broad as any permissions in your ACL. Otherwise, the two state declarations will each register changes each run, and if the `file` declaration runs later, your ACL will be ineffective.

```
salt.states.linux_acl.absent(name, acl_type, acl_name='', perms='', recurse=False)
```
Ensure a Linux ACL does not exist

name
  The acl path

acl_type
  The type of the acl is used for, it can be 'user' or 'group'

acl_name
  The user or group

perms
  Remove the permissions eg.: rwx
recurse
Set the permissions recursive in the path

```python
salt.states.linux_acl.list_absent(name, acl_type, acl_names=None, recurse=False)
```
Ensure a Linux ACL list does not exist

- Takes a list of acl names and remove them from the given path
- name
  - The acl path
- acl_type
  - The type of the acl is used for, it can be 'user' or 'group'
- acl_names
  - The list of users or groups
- perms
  - Remove the permissions eg.: rwx
- recurse
  - Set the permissions recursive in the path

```python
salt.states.linux_acl.list_present(name, acl_type, acl_names=None, perms='', recurse=False, force=False)
```
Ensure a Linux ACL list is present

- Takes a list of acl names and add them to the given path
- name
  - The acl path
- acl_type
  - The type of the acl is used for it can be 'user' or 'group'
- acl_names
  - The list of users or groups
- perms
  - Set the permissions eg.: rwx
- recurse
  - Set the permissions recursive in the path
- force
  - Wipe out old permissions and ensure only the new permissions are set

```python
salt.states.linux_acl.present(name, acl_type, acl_name='', perms='', recurse=False, force=False)
```
Ensure a Linux ACL is present

- The acl path
- acl_type
  - The type of the acl is used for it can be 'user' or 'group'
- acl_name
  - The user or group
- perms
  - Set the permissions eg.: rwx
- recurse
  - Set the permissions recursive in the path
- force
  - Wipe out old permissions and ensure only the new permissions are set
25.20.159  salt.states.locale

Management of languages/locales

Manage the available locales and the system default:

```yaml
us_locale:
  locale.present:
    - name: en_US.UTF-8

default_locale:
  locale.system:
    - name: en_US.UTF-8
    - require:
      - locale: us_locale
```

salt.states.locale.present(name)

Generate a locale if it is not present

New in version 2014.7.0.

**name**

The name of the locale to be present. Some distributions require the charmap to be specified as part of the locale at this point.

salt.states.locale.system(name)

Set the locale for the system

**name**

The name of the locale to use

25.20.160  salt.states.logadm

Management of logs using Solaris logadm.

**maintainer**

Jorge Schrauwen <sjorge@blackdot.be>

**maturity**

new

**depends**

salt.modulus.logadm

**platform**

Oracle Solaris, Sun Solaris, illumos

New in version 2017.7.0.

.. note::

   TODO

salt.states.logadm.remove(name, log_file=None)

Remove a log from the logadm configuration

**name**

[string] entryname

**log_file**

[string] (optional) log file path
Note: If log_file is specified it will be used instead of the entry name.

```python
salt.states.logadm.rotate(name, **kwargs)
```
Add a log to the logadm configuration

- **name**
  - [string] alias for entryname
- **kwargs**
  - [boolean|string|int] optional additional flags and parameters

### 25.20.161 `salt.states.logrotate`

Module for managing logrotate.

New in version 2017.7.0.

```python
salt.states.logrotate.set_(name, key, value, setting=None, conf_file='/etc/logrotate.conf')
```
Set a new value for a specific configuration line.

- **key** *(str)* -- The command or block to configure.
- **value** *(str)* -- The command value or command of the block specified by the key parameter.
- **setting** *(str)* -- The command value for the command specified by the value parameter.
- **conf_file** *(str)* -- The logrotate configuration file.

Example of usage with only the required arguments:

```
logrotate.rotate:
logrotate.set:
  - key: rotate
  - value: 2
```

Example of usage specifying all available arguments:

```
logrotate.wtmp.rotate:
logrotate.set:
  - key: /var/log/wtmp
  - value: rotate
  - setting: 2
  - conf_file: /etc/logrotate.conf
```

### 25.20.162 `salt.states.loop`

Loop state

Allows for looping over execution modules.

New in version 2017.7.0.

In both examples below, the execution module function `boto_elb.get_instance_health` returns a list of dicts. The condition checks the state-key of the first dict in the returned list and compares its value to the string `InService`. 
**wait_for_service_to_be_healthy:**
```python
loop.until:
    - name: boto_elb.get_instance_health
    - condition: m_ret[0]['state'] == 'InService'
    - period: 5
    - timeout: 20
    - m_args:
      - {{ elb }}
    - m_kwargs:
      - keyid: {{ access_key }}
      - key: {{ secret_key }}
      - instances: "{{ instance }}"
```

**Warning:** This state allows arbitrary python code to be executed through the condition parameter which is literally evaluated within the state. Please use caution.

Changed in version 3000.

A version that does not use eval is now available. It uses either the python operator to compare the result of the function called in `name`, which can be one of the following: lt, le, eq (default), ne, ge, gt. Alternatively, `compare_operator` can be filled with a function from an execution module in `__salt__` or `__utils__` like the example below. The function `data.subdict_match` checks if the expected expression matches the data returned by calling the name function (with passed args and kwargs).

**Wait for service to be healthy:**
```python
loop.until_no_eval:
    - name: boto_elb.get_instance_health
    - expected: '0:state:InService'
    - compare_operator: data.subdict_match
    - period: 5
    - timeout: 20
    - args:
      - {{ elb }}
    - kwargs:
      - keyid: {{ access_key }}
      - key: {{ secret_key }}
      - instances: "{{ instance }}"
```

salt.states.loop.until(name, m_args=None, m_kwargs=None, condition=None, period=1, timeout=60)

Loop over an execution module until a condition is met.

**Parameters**
- `name (str)` -- The name of the execution module
- `m_args (list)` -- The execution module's positional arguments
- `m_kwargs (dict)` -- The execution module's keyword arguments
- `condition (str)` -- The condition which must be met for the loop to break. This should contain `m_ret` which is the return from the execution module.
- `period (int or float)` -- The number of seconds to wait between executions
- `timeout (int or float)` -- The timeout in seconds

salt.states.loop.until_no_eval(name, expected, compare_operator='eq', timeout=60, period=1, init_wait=0, args=None, kwargs=None)

Generic waiter state that waits for a specific salt function to produce an expected result. The state fails if
the function does not exist or raises an exception, or does not produce the expected result within the allotted retries.

Parameters
- **name** *(str)* -- Name of the module.function to call
- **expected** -- Expected return value. This can be almost anything.
- **compare_operator** *(str)* -- Operator to use to compare the result of the module.function call with the expected value. This can be anything present in __salt__ or __utils__. Will be called with 2 args: result, expected.
- **timeout** *(int or float)* -- Abort after this amount of seconds (excluding init_wait).
- **period** *(int or float)* -- Time (in seconds) to wait between attempts.
- **init_wait** *(int or float)* -- Time (in seconds) to wait before trying anything.
- **args** *(list)* -- args to pass to the salt module.function.
- **kwargs** *(dict)* -- kwargs to pass to the salt module.function.

New in version 3000.

25.20.163 salt.states.lvm

Management of Linux logical volumes

A state module to manage LVMs

```python
/dev/sda:
    lvm.pv_present

my_vg:
    lvm.vg_present:
        - devices: /dev/sda

lvroot:
    lvm.lv_present:
        - vgname: my_vg
        - size: 10G
        - stripes: 5
        - stripesize: 8K
```

salt.states.lvm.lv_absent(name, vgname=None)

Remove a given existing Logical Volume from a named existing volume group

- **name** The Logical Volume to remove
- **vgname** The name of the Volume Group on which the Logical Volume resides

salt.states.lvm.lv_present(name, vgname=None, size=None, extents=None, snapshot=None, pv='', thinvolume=False, thinpool=False, force=False, resizefs=False, **kwargs)

Ensure that a Logical Volume is present, creating it if absent.

- **name** The name of the Logical Volume
- **vgname** The name of the Volume Group on which the Logical Volume resides
- **size** The size of the Logical Volume in megabytes, or use a suffix such as S, M, G, T, P for 512 byte sectors, megabytes, gigabytes or terabytes respectively. The suffix is case insensitive.
extents
The number of logical extents allocated to the Logical Volume. It can be a percentage allowed by lvcreate's syntax, in this case it will set the Logical Volume initial size and won't be resized.

snapshot
The name of the snapshot

pv
The Physical Volume to use

kwargs
Any supported options to lvcreate. See linux_lvm for more details. New in version 2016.11.0.

thinvolume
Logical Volume is thinly provisioned

thinpool
Logical Volume is a thin pool New in version 2018.3.0.

force
Assume yes to all prompts New in version 3002.

resizefs
Use fsadm to resize the logical volume filesystem if needed

salt.states.lvm.pv_absent(name)
Ensure that a Physical Device is not being used by lvm

name
The device name to initialize.

salt.states.lvm.pv_present(name, **kwargs)
Set a Physical Device to be used as an LVM Physical Volume

name
The device name to initialize.

kwargs
Any supported options to pvcreate. See linux_lvm for more details.

salt.states.lvm.vg_absent(name)
Remove an LVM volume group

name
The volume group to remove

salt.states.lvm.vg_present(name, devices=None, **kwargs)
Create an LVM Volume Group

name
The Volume Group name to create

devices
A list of devices that will be added to the Volume Group

kwargs
Any supported options to vgcreate. See linux_lvm for more details.
25.20.164 salt.states.lvs_server

Management of LVS (Linux Virtual Server) Real Server

**salt.states.lvs_server.absent** *(name, protocol=None, service_address=None, server_address=None)*

Ensure the LVS Real Server in specified service is absent.

- **name**
  - The name of the LVS server.
- **protocol**
  - The service protocol (only support tcp, udp and fwmark service).
- **service_address**
  - The LVS service address.
- **server_address**
  - The LVS real server address.

**salt.states.lvs_server.present** *(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)*

Ensure that the named service is present.

- **name**
  - The LVS server name
- **protocol**
  - The service protocol
- **service_address**
  - The LVS service address
- **server_address**
  - The real server address.
- **packet_forward_method**
  - The LVS packet forwarding method (dr for direct routing, tunnel for tunneling, nat for network access translation).
- **weight**
  - The capacity of a server relative to the others in the pool.

```
lvsrs:
  lvs_server.present:
    - protocol: tcp
    - service_address: 1.1.1.1:80
    - server_address: 192.168.0.11:8080
    - packet_forward_method: dr
    - weight: 10
```

25.20.165 salt.states.lvs_service

Management of LVS (Linux Virtual Server) Service

**salt.states.lvs_service.absent** *(name, protocol=None, service_address=None)*

Ensure the LVS service is absent.

- **name**
  - The name of the LVS service
- **protocol**
  - The service protocol
- **service_address**
  - The LVS service address
salt.states.lvs_service.present(name, protocol=None, service_address=None, scheduler='wlc')

Ensure that the named service is present.

name
The LVS service name

protocol
The service protocol

service_address
The LVS service address

scheduler
Algorithm for allocating TCP connections and UDP datagrams to real servers.

```text
lvstest:
  lvs_service.present:
    - service_address: 1.1.1.1:80
    - protocol: tcp
    - scheduler: rr
```

25.20.166 salt.states.lxc

Manage Linux Containers

salt.states.lxc.absent(name, stop=False, path=None)

Ensure a container is not present, destroying it if present

name
Name of the container to destroy

stop
stop before destroying default: false

New in version 2015.5.2.

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```text
web01:
  lxc.absent
```

salt.states.lxc.edited_conf(name, lxc_conf=None, lxc_conf_unset=None)

Warning: This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface).

Issue #35523 was opened to track the addition of a suitable replacement or fix.

Edit LXC configuration options

Deprecated since version 2015.5.0.

path
path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
setconf:
  lxc.edited_conf:
    - name: ubuntu
    - lxc_conf:
      - network.ipv4.ip: 10.0.3.6
    - lxc_conf_unset:
      - lxc.utsname

salt.states.lxc.frozen(name, start=True, path=None)

New in version 2015.5.0.

Ensure that a container is frozen

Note: This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use `lxc.present`.

name
  The name of the container
path
  path to the container parent default: /var/lib/lxc (system default)
  New in version 2015.8.0.
start
  [True] Start container first, if necessary. If False, then this state will fail if the container is not running.

web01:
  lxc.frozen
web02:
  lxc.frozen:
    - start: False

salt.states.lxc.present(name, running=None, clone_from=None, snapshot=False, profile=None,
    network_profile=None, template=None, options=None, image=None, config=None,
    fstype=None, size=None, backing=None, vgname=None, lvname=None,
    thinpool=None, path=None)

Changed in version 2015.8.0: The lxc.created state has been renamed to lxc.present, and the lxc.cloned state has been merged into this state.

Create the named container if it does not exist
name
  The name of the container to be created
path
  path to the container parent default: /var/lib/lxc (system default)
  New in version 2015.8.0.
running
  [False]
    • If True, ensure that the container is running
    • If False, ensure that the container is stopped
    • If None, do nothing with regards to the running state of the container
  New in version 2015.8.0.
clone_from
  Create named container as a clone of the specified container
**snapshot**
[False] Use Copy On Write snapshots (LVM). Only supported with `clone_from`.

**profile**
Profile to use in container creation (see the *LXC Tutorial* for more information). Values in a profile will be overridden by the parameters listed below.

**network_profile**
Network Profile to use in container creation (see the *LXC Tutorial* for more information). Values in a profile will be overridden by the parameters listed below.

New in version 2015.5.2.

**Container Creation Arguments**

**template**
The template to use. For example, `ubuntu` or `fedora`. For a full list of available templates, check out the `lxc.templates` function.

Conflicts with the `image` argument.

**options**
New in version 2015.5.0.

Template-specific options to pass to the `lxc-create` command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```yaml
web01:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64
```

Remember to double-indent the options, due to how *PyYAML* works.

For available template options, refer to the `lxc` template scripts which are usually located under `/usr/share/lxc/templates`, or run `lxc-create -t <template> -h`.

**image**
A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing**
The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**fstype**
Filesystem type to use on LVM logical volume

**size**
Size of the volume to create. Only applicable if `backing` is set to `lvm`.

**vgname**
[lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**lvname**
Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

---

**Note:**
The `download` template requires the following three parameters to be defined in `options`:
- `dist` - The name of the distribution
- `release` - Release name/version
- `arch` - Architecture of the container

The available images can be listed using the `lxc.images` function.
thinpool
    Name of a pool volume that will be used for thin-provisioning this container. Only applicable if
    backing is set to lvm.

salt.states.lxc.running(name, restart=False, path=None)
    Changed in version 2015.5.0: The lxc.started state has been renamed to lxc.running
    Ensure that a container is running

    **Note:** This state does not enforce the existence of the named container, it just starts the container
    if it is not running. To ensure that the named container exists, use lxc.present.

    **name**
    The name of the container

    **path**
    path to the container parent default: /var/lib/lxc (system default)
    New in version 2015.8.0.

    **restart**
    [False] Restart container if it is already running

    **web01:**
    lxc.running

    **web02:**
    lxc.running:
        - restart: True

salt.states.lxc.set_pass(name, **kwargs)
    Deprecated since version 2015.5.0.
    This state function has been disabled, as it did not conform to design guidelines. Specifically, due to
    the fact that lxc.set_password uses chpasswd(8) to set the password, there was no method to make this
    action idempotent (in other words, the password would be changed every time). This makes this state
    redundant, since the following state will do the same thing:

    **setpass:**
    module.run:
        - name: set_pass
        - m_name: root
        - password: secret

salt.states.lxc.stopped(name, kill=False, path=None)
    Ensure that a container is stopped

    **Note:** This state does not enforce the existence of the named container, it just stops the container
    if it running or frozen. To ensure that the named container exists, use lxc.present, or use the lxc.absent
    state to ensure that the container does not exist.

    **name**
    The name of the container

    **path**
    path to the container parent default: /var/lib/lxc (system default)
kill
[False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

New in version 2015.5.0.

web01:
  lxc.stopped

25.20.167 salt.states.lxd

Manage LXD profiles.
New in version 2019.2.0.

maintainer
  René Jochum <rene@jochums.at>

maturity
  new

depends
  python-pylxd

platform
  Linux

salt.states.lxd.authenticate(name, remote_addr, password, cert, key, verify_cert=True)
  Authenticate with a remote peer.
  remote_addr:
    An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
    Examples:
      https://myserver.lan:8443 /var/lib/mysocket.sock
  password:
    The PaSsW0rD
  cert:
    PEM Formatted SSL Zertifikate.
    Examples:
      /root/.config/lxc/client.crt
  key:
    PEM Formatted SSL Key.
    Examples:
      /root/.config/lxc/client.key
  verify_cert
    [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

name:
  Ignore this. This is just here for salt.

salt.states.lxd.configManaged(name, value, force_password=False)
  Manage a LXD Server config setting.
  name:
    The name of the config key.
  value:
    Its value.
force_password

[False] Set this to True if you want to set the password on every run.

As we can’t retrieve the password from LXD we can’t check if the current one is the same as the given one.

```
salt.states.lxd.init(name, storage_backend='dir', trust_password=None, network_address=None, network_port=None, storage_create_device=None, storage_create_loop=None, storage_pool=None, done_file='%SALT_CONFIG_DIR%/lxd_initialized')
```

Initializes the LXD Daemon, as LXD doesn’t tell if its initialized we touch the done_file and check if it exist.

This can only be called once per host unless you remove the done_file.

name :
Ignore this. This is just here for salt.

storage_backend :
Storage backend to use (zfs or dir, default: dir)

trust_password :
Password required to add new clients

network_address
[None] Address to bind LXD to (default: none)

network_port
[None] Port to bind LXD to (Default: 8443)

storage_create_device
[None] Setup device based storage using this DEVICE

storage_create_loop
[None] Setup loop based storage with this SIZE in GB

storage_pool
[None] Storage pool to use or create

done_file :
Path where we check that this method has been called, as it can run only once and there’s currently no way to ask LXD if init has been called.

25.20.168 salt.states.lxd_container

Manage LXD containers.

New in version 2019.2.0.

maintainer
René Jochum <rene@jochums.at>

maturity
new

depends
python-pylxd

platform
Linux

```
salt.states.lxd_container.absent(name, stop=False, remote_addr=None, cert=None, key=None, verify_cert=True)
```

Ensure a LXD container is not present, destroying it if present

name :
The name of the container to destroy

stop :
stop before destroying default: false
remote_addr:
    An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
    Examples:
    https://myserver.lan:8443 /var/lib/mysocket.sock
cert:
    PEM Formatted SSL Zertifikate.
    Examples:
    ~/.config/lxc/client.crt
defkey:
    PEM Formatted SSL Key.
    Examples:
    ~/.config/lxc/client.key
verify_cert
    [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as
    LXD normally uses self-signed certificates.

salt.states.lxd_container.frozen(name, start=True, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is frozen, start and freeze it if start is true

name:
    The name of the container to freeze
start:
    start and freeze it
remote_addr:
    An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
    Examples:
    https://myserver.lan:8443 /var/lib/mysocket.sock
cert:
    PEM Formatted SSL Zertifikate.
    Examples:
    ~/.config/lxc/client.crt
defkey:
    PEM Formatted SSL Key.
    Examples:
    ~/.config/lxc/client.key
verify_cert
    [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as
    LXD normally uses self-signed certificates.

salt.states.lxd_container.migrated(name, remote_addr, cert, key, verify_cert, src_remote_addr, stop_and_start=False, src_cert=None, src_key=None, src_verify_cert=None)

Ensure a container is migrated to another host

If the container is running, it either must be shut down first (use stop_and_start=True) or criu must be installed
on the source and destination machines.

For this operation both certs need to be authenticated, use lxd.authenticate <salt.states.lxd.
authenticate to authenticate your cert(s).

name:
    The container to migrate
remote_addr:
    An URL to the destination remote Server
    Examples:
    https://myserver.lan:8443 /var/lib/mysocket.sock
cert:
  PEM Formatted SSL Zertifikate.
  Examples:
    ~/.config/lxc/client.crt
key:
  PEM Formatted SSL Key.
  Examples:
    ~/.config/lxc/client.key
verify_cert
  [True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
src_remote_addr:
  An URL to the source remote Server
  Examples:
    https://myserver.lan:8443 /var/lib/mysocket.sock
stop_and_start:
  Stop before migrating and start after
src_cert:
  PEM Formatted SSL Zertifikate, if None we copy "cert"
  Examples:
    ~/.config/lxc/client.crt
src_key:
  PEM Formatted SSL Key, if None we copy "key"
  Examples:
    ~/.config/lxc/client.key
src_verify_cert:
  Wherever to verify the cert, if None we copy "verify_cert"
salt.states.lxd_container.present(name, running=None, source=None, profiles=None, config=None, devices=None, architecture='x86_64', ephemeral=False, restart_on_change=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Create the named container if it does not exist

name
  The name of the container to be created

running
  [None]
    • If True, ensure that the container is running
    • If False, ensure that the container is stopped
    • If None, do nothing with regards to the running state of the container

source
  [None] Can be either a string containing an image alias:
    "xenial/amd64"
  or an dict with type "image" with alias:
    {"type": "image",
     "alias": "xenial/amd64"}
  or image with "fingerprint":
    {"type": "image",
     "fingerprint": "SHA-256"}
or image with "properties":

```json
{"type": "image",
 "properties": {
   "os": "ubuntu",
   "release": "14.04",
   "architecture": "x86_64"
 }
}
```

or none:

```

or copy:

```json
{"type": "copy",
 "source": "my-old-container"
}
```

profiles

```
[['default']] List of profiles to apply on this container
```

config:

A config dict or None (None = unset).

Can also be a list:

```json
[{
'key': 'boot.autostart', 'value': 1},
{
'key': 'security.privileged', 'value': '1'}]
```

devices:

A device dict or None (None = unset).

architecture

```
['x86_64'] Can be one of the following:
```

- unknown
- i686
- x86_64
- armv7l
- aarch64
- ppc
- ppc64
- ppc64le
- s390x

ephemeral

```
[False] Destroy this container after stop?
```

restart_on_change

```
[False] Restart the container when we detect changes on the config or its devices?
```

remote_addr:

```
An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
```

Examples:

```
https://myserver.lan:8443 /var/lib/mysocket.sock
```

cert:

```
PEM Formatted SSL Zertifikate.
```

Examples:
```
~/.config/lxc/client.crt
```

key:

```
PEM Formatted SSL Key.
```

Examples:
Salt Documentation, Release 3006.3

```
-/.config/lxc/client.key

verify_cert
[True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.running(name, restart=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is running and restart it if restart is True
name:
The name of the container to start/restart.
restart:
restart the container if it is already started.
remote_addr:
An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples:
https://myserver.lan:8443 /var/lib/mysocket.sock
cert:
PEM Formatted SSL Zertifikate.
Examples:
-/.config/lxc/client.crt
key:
PEM Formatted SSL Key.
Examples:
-/.config/lxc/client.key
verify_cert
[True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.

salt.states.lxd_container.stopped(name, kill=False, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure a LXD container is stopped, kill it if kill is true else stop it
name:
The name of the container to stop
kill:
kill if true
remote_addr:
An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples:
https://myserver.lan:8443 /var/lib/mysocket.sock
cert:
PEM Formatted SSL Zertifikate.
Examples:
-/.config/lxc/client.crt
key:
PEM Formatted SSL Key.
Examples:
-/.config/lxc/client.key
verify_cert
[True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
```

salt.states.lxd_image.absent(name, remote_addr=None, cert=None, key=None, verify_cert=True)

name:
An alias or fingerprint of the image to check and delete.

remote_addr:
An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
Examples:
https://myserver.lan:8443 /var/lib/mysocket.sock

cert:
PEM Formatted SSL Zertifikate.
Examples:
~/.config/lxc/client.crt

key:
PEM Formatted SSL Key.
Examples:
~/.config/lxc/client.key

verify_cert
[True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as
LXD normally uses self-signed certificates.

salt.states.lxd_image.present(name, source, aliases=None, public=None, auto_update=None, remote_addr=None, cert=None, key=None, verify_cert=True)

Ensure an image exists, copy it else from source

name:
An alias of the image, this is used to check if the image exists and it will be added as alias to the image
on copy/create.

source:
Source dict.

For an LXD to LXD copy:

```
source:
  type: lxd
  name: ubuntu/xenial/amd64  # This can also be a fingerprint.
  remote_addr: https://images.linuxcontainers.org:8443
  cert: ~/.config/lxc/client.crt
  key: ~/.config/lxc/client.key
  verify_cert: False
```

From file:
source:
  type: file
  filename: salt://lxd/files/busybox.tar.xz
saltenv: base

From simplestreams:

source:
  type: simplestreams
  server: https://cloud-images.ubuntu.com/releases
  name: xenial/amd64

From an URL:

source:
  type: url
  url: https://dl.stgraber.org/lxd

aliases :
  List of aliases to append, can be empty.

public :
  Make this image public available on this instance?
  None on source_type LXD means copy source None on source_type file means False

auto_update :
  Try to auto-update from the original source?
  None on source_type LXD means copy source source_type file does not have auto-update.

remote_addr :
  An URL to a remote Server, you also have to give cert and key if you provide remote_addr!
  Examples:
    https://myserver.lan:8443 /var/lib/mysocket.sock

cert :
  PEM Formatted SSL Zertifikate.
  Examples:
    ~/.config/lxc/client.crt

Examples:
-./config/lxc/client.key

verify_cert
[True] Wherever to verify the cert, this is by default True but in the most cases you want to set it off as LXD normally uses self-signed certificates.
See the lxd-docs for the details about the config and devices dicts. See the requests-docs for the SSL stuff.
25.20.171 salt.states.mac_assistive

Allows you to manage assistive access on macOS minions with 10.9+

Install, enable and disable assistive access on macOS minions

```
/usr/bin/osascript:
    assistive.installed:
        - enabled: True
```

```
salt.states.mac_assistive.installed(name, enabled=True)

    Make sure that we have the given bundle ID or path to command installed in the assistive access panel.

    name
        The bundle ID or path to command

    enable
        Should assistive access be enabled on this application?
```

25.20.172 salt.states.mac_keychain

Installing of certificates to the keychain

Install certificates to the macOS keychain

```
/mnt/test.p12:
    keychain.installed:
        - password: test123
```

```
salt.states.mac_keychain.default_keychain(name, domain='user', user=None)

    Set the default keychain to use

    name
        The chain in which to use as the default

    domain
        The domain to use valid values are user|system|common|dynamic, the default is user

    user
        The user to run as

salt.states.mac_keychain.installed(name, password, keychain='/Library/Keychains/System.keychain', **kwargs)

    Install a p12 certificate file into the macOS keychain

    name
        The certificate to install

    password
        The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section

    keychain
        The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain

    allow_any
        Allow any application to access the imported certificate without warning

    keychain_password
        If your keychain is likely to be locked pass the password and it will be unlocked before running the import
```
salt.states.mac_keychain.uninstalled(name, password,  
    keychain='~/Library/Keychains/System.keychain',  
    keychain_password=None)

Uninstall a p12 certificate file from the macOS keychain
name
    The certificate to uninstall, this can be a path for a .p12 or the friendly name
password
    The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section
cert_name
    The friendly name of the certificate, this can be used instead of giving a certificate
keychain
    The keychain to remove the certificate from, this defaults to /Library/Keychains/System.keychain
keychain_password
    If your keychain is likely to be locked pass the password and it will be unlocked before running the import

25.20.173 salt.states.mac_xattr

Allows you to manage extended attributes on files or directories
Install, enable and disable assistive access on macOS minions

/path/to/file:
    xattr.exists:
        - attributes:
            - com.file.attr=test
            - com.apple.quarantine=0x00001111

salt.states.mac_xattr.delete(name, attributes)
    Make sure the given attributes are deleted from the file/directory
name
    The path to the file/directory
attributes
    The attributes that should be removed from the file/directory, this is accepted as an array.

salt.states.mac_xattr.exists(name, attributes)
    Make sure the given attributes exist on the file/directory
name
    The path to the file/directory
attributes
    The attributes that should exist on the file/directory, this is accepted as an array, with key and value split with an equals sign, if you want to specify a hex value then add 0x to the beginning of the value.
25.20.174 salt.states.macdefaults

Writing/reading defaults from a macOS minion

salt.states.macdefaults.absent(name, domain, user=None)
   Make sure the defaults value is absent
   name
   The key of the given domain to remove
   domain
   The name of the domain to remove from
   user
   The user to write the defaults to

salt.states.macdefaults.write(name, domain, value, vtype='string', user=None)
   Write a default to the system
   name
   The key of the given domain to write to
   domain
   The name of the domain to write to
   value
   The value to write to the given key
   vtype
   The type of value to be written, valid types are string, data, int[eger], float, bool[ean], date, array, array-add, dict, dict-add
   user
   The user to write the defaults to

25.20.175 salt.states.macpackage

Installing of mac pkg files

Install any kind of pkg, dmg or app file on macOS:

```
/mnt/test.pkg:
   macpackage.installed:
      - store: True

/mnt/test.dmg:
   macpackage.installed:
      - dmg: True

/mnt/xcode.dmg:
   macpackage.installed:
      - dmg: True
      - app: True
      - target: /Applications/Xcode.app
      - version_check: xcodebuild -version=Xcode 7.1

salt.states.macpackage.installed(name, target='LocalSystem', dmg=False, store=False, app=False, mpkg=False, force=False, allow_untrusted=False, version_check=None)
```

Install a Mac OS Package from a pkg or dmg file, if given a dmg file it will first be mounted in a temporary location
name
   The pkg or dmg file to install
target
   The location in which to install the package. This can be a path or LocalSystem
dmg
   Is the given file a dmg file?
store
   Should the pkg be installed as if it was from the Mac OS Store?
app
   Is the file a .app? If so then we'll just copy that to /Applications/ or the given target
mpkg
   Is the file a .mpkg? If so then we'll check all of the .pkg files found are installed
force
   Force the package to be installed even if its already been found installed
allow_untrusted
   Allow the installation of untrusted packages
version_check
   The command and version that we want to check against, the version number can use regex.
   
   ```
   version_check: python --version_check=2.7.\[0-9]\]
   ```

25.20.176 salt.states.makeconf
Management of Gentoo make.conf

A state module to manage Gentoo's make.conf file

**makeopts:**

```makeconf.present:
   - value: '-j3'
```

salt.states.makeconf.absent(name)
Verify that the variable is not in the make.conf.

name
   The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
salt.states.makeconf.present(name, value=None, contains=None, excludes=None)
Verify that the variable is in the make.conf and has the provided settings. If value is set, contains and excludes will be ignored.

name
   The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
value
   Enforce that the value of the variable is set to the provided value
contains
   Enforce that the value of the variable contains the provided value
excludes
   Enforce that the value of the variable does not contain the provided value.
25.20.177 salt.states.marathon_app

Configure Marathon apps via a salt proxy.

```
my_app:
  marathon_app.config:
    - config:
        cmd: "while [ true ]; do echo 'Hello Marathon'; sleep 5; done"
        cpus: 0.1
        mem: 10
        instances: 3
```

New in version 2015.8.2.

**salt.states.marathon_app.absent(name)**

Ensure that the marathon app with the given id is not present.

- **Parameters**
  - name -- The app name/id

- **Returns**
  - A standard Salt changes dictionary

**salt.states.marathon_app.config(name, config)**

Ensure that the marathon app with the given id is present and is configured to match the given config values.

- **Parameters**
  - name -- The app name/id
  - config -- The configuration to apply (dict)

- **Returns**
  - A standard Salt changes dictionary

**salt.states.marathon_app.running(name, restart=False, force=True)**

Ensure that the marathon app with the given id is present and restart if set.

- **Parameters**
  - name -- The app name/id
  - restart -- Restart the app
  - force -- Override the current deployment

- **Returns**
  - A standard Salt changes dictionary

25.20.178 salt.states.mdadm_raid

Managing software RAID with mdadm

- **depends**
  - mdadm

A state module for creating or destroying software RAID devices.

```
/dev/md0:
  raid.present:
    - level: 5
    - devices:
      - /dev/xvdd
      - /dev/xvde
      - /dev/xvdf
```

salt.states.mdadm_raid.absent(name)
  Verify that the raid is absent
    name
      The name of raid device to be destroyed

```
/dev/md0:
  raid:
    - absent
```

salt.states.mdadm_raid.present(name, level, devices, **kwargs)
  Verify that the raid is present
  Changed in version 2014.7.0.
    name
      The name of raid device to be created
    level
      The RAID level to use when creating the raid.
    devices
      A list of devices used to build the array.
    kwargs
      Optional arguments to be passed to mdadm.
  Example:

```
/dev/md0:
  raid.present:
    - level: 5
    - devices:
      - /dev/xvdd
      - /dev/xvde
      - /dev/xvdf
    - chunk: 256
    - run: True
```

25.20.179 salt.states.memcached

States for Management of Memcached Keys

New in version 2014.1.0.

salt.states.memcached.absent(name, value=None, host='127.0.0.1', port=11211, time=0)
  Ensure that a memcached key is not present.
    name
      The key
    value
      [None] If specified, only ensure that the key is absent if it matches the specified value.
    host
      The memcached server IP address
    port
      The memcached server port
foo:
    memcached.absent

bar:
    memcached.absent:
    - host: 10.0.0.1

salt.states.memcached.managed(name, value=None, host='127.0.0.1', port=11211, time=0, min_compress_len=0)

Manage a memcached key.
name
    The key to manage
value
    The value to set for that key
host
    The memcached server IP address
port
    The memcached server port

foo:
    memcached.managed:
    - value: bar

25.20.180 salt.states.modjk

State to control Apache modjk

salt.states.modjk.worker_activated(name, workers=None, profile='default')

Activate all the workers in the modjk load balancer
Example:

loadbalancer:
    modjk.worker_activated:
    - workers:
      - app1
      - app2

salt.states.modjk.worker_disabled(name, workers=None, profile='default')

Disable all the workers in the modjk load balancer
Example:

loadbalancer:
    modjk.worker_disabled:
    - workers:
      - app1
      - app2

salt.states.modjk.worker_recover(name, workers=None, profile='default')

Recover all the workers in the modjk load balancer
Example:
salt.states.modjk.worker_stopped(name, workers=None, profile='default')

Stop all the workers in the modjk load balancer

Example:

```yaml
loadbalancer:
    modjk.worker_stopped:
        - workers:
            - app1
            - app2
```

25.20.181 salt.states.modjk_worker

Manage modjk workers

Send commands to a modjk load balancer via the peer system.

This module can be used with the prereq requisite to remove/add the worker from the load balancer before deploying/restarting service.

Mandatory Settings:

- The minion needs to have permission to publish the modjk.* functions (see here for information on configuring peer publishing permissions)
- The modjk load balancer must be configured as stated in the modjk execution module documentation

salt.states.modjk_worker.activate(name, lbn, target, profile='default', tgt_type='glob')

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Activate the named worker from the lbn load balancers at the targeted minions

Example:

```yaml
disable-before-deploy:
    modjk_worker.activate:
        - name: {{ grains['id'] }}
        - lbn: application
        - target: 'roles:balancer'
        - tgt_type: grain
```

salt.states.modjk_worker.disable(name, lbn, target, profile='default', tgt_type='glob')

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:
disable-before-deploy:
  modjk_worker.disable:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain

salt.states.modjk_worker.stop(name, lbn, target, profile='default', tgt_type='glob')

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Stop the named worker from the lbn load balancers at the targeted minions. The worker won't get any traffic from the lbn

Example:

disable-before-deploy:
  modjk_worker.stop:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain

25.20.182 salt.states.module

Execution of Salt modules from within states

Note: As of the 3005 release, you no longer need to opt-in to the new style of calling module.run. The following config can be removed from /etc/salt/minion:

use_superseded:
  - module.run

Both 'new' and 'legacy' styles of calling module.run are supported.

With module.run these states allow individual execution module calls to be made via states. Here's a contrived example, to show you how it's done:

# New Style
test.random_hash:
  module.run:
    - test.random_hash:
      - size: 42
      - hash_type: sha256

# Legacy Style
test.random_hash:
  module.run:
    - size: 42
    - hash_type: sha256
In the new style, the state ID (test.random_hash, in this case) is irrelevant when using module.run. It could have very well been written:

```
Generate a random hash:
  module.run:
      - test.random_hash:
          - size: 42
          - hash_type: sha256
```

For a simple state like that it's not a big deal, but if the module you're using has certain parameters, things can get cluttered, fast. Using the contrived custom module (stuck in /srv/salt/_modules/foo.py, or your configured file_roots):

```
def bar(name, names, fun, state, saltenv):
    return "Name: {name} Names: {names} Fun: {fun} State: {state} Saltenv: {saltenv}".format(**locals())
```

Your legacy state has to look like this:

```
# Legacy style
Unfortunate example:
  module.run:
      - name: foo.bar
      - m_name: Some name
      - m_names:
          - Such names
          - very wow
      - m_state: Arkansas
      - m_fun: Such fun
      - m_saltenv: Salty
```

With the new style it's much cleaner:

```
# New style
Better:
  module.run:
      - foo.bar:
          - name: Some name
          - names:
              - Such names
              - very wow
          - state: Arkansas
          - fun: Such fun
          - saltenv: Salty
```

The new style also allows multiple modules in one state. For instance, you can do this:

```
Do many things:
  module.run:
      - test.random_hash:
          - size: 10
          - hash_type: md5
      # Note the `:` at the end
      - test.true:
```

(continues on next page)
- test.arg:
  - this
  - has
  - args
  - and: kwargs
  - isn't: that neat?
  # Note the `:` at the end, too
- test.version:
- test.fib:
  - 4

Where in the legacy style you would have had to split your states like this:

test.random_hash:
  module.run:
    - size: 10
    - hash_type: md5
test.nop:
  module.run
test.arg:
  module.run:
    - args:
      - this
      - has
      - args
    - kwargs:
      and: kwargs
      isn't: that neat?
test.version:
  module.run

Another difference is that in the legacy style, unconsumed arguments to the module state were simply passed into the module function being executed:

show off module.run with args:
  module.run:
    - name: test.random_hash
    - size: 42
    - hash_type: sha256

The new style is much more explicit, with the arguments and keyword arguments being nested under the name of the function:

show off module.run with args:
  module.run:
    # Note the lack of `name: `, and trailing `:`
    - test.random_hash:
      - size: 42
      - hash_type: sha256
If the function takes *args, they can be passed in as well:

```python
args and kwargs:
  module.run:
    - test.arg:
      - isn't
      - this
      - fun
      - this: that
    - salt: stack
```

Modern Examples

Here are some other examples using the modern `module.run`:

```python
fetch_out_of_band:
  module.run:
    - git.fetch:
      - cwd: /path/to/my/repo
      - user: myuser
      - opts: '--all'

A more complex example:

```python
eventsviewer:
  module.run:
    - task.create_task:
      - name: events-viewer
      - user_name: System
      - action_type: Execute
      - cmd: 'c:\netops\scripts\events_viewer.bat'
      - trigger_type: 'Daily'
      - start_date: '2017-1-20'
      - start_time: '11:59PM'
```

It is sometimes desirable to trigger a function call after a state is executed, for this the `module.wait` state can be used:

```python
add example to hosts:
  file.append:
    - name: /etc/hosts
    - text: 203.0.113.13 example.com

# New Style
mine.send:
  module.wait:
    # Again, note the trailing `:`
    - hosts.list_hosts:
    - watch:
      - file: add example to hosts
```
Legacy (Default) Examples

If you're using the legacy module.run, due to how the state system works, if a module function accepts an argument called name, then m_name must be used to specify that argument, to avoid a collision with the name argument.

Here is a list of keywords hidden by the state system, which must be prefixed with m_:

- fun
- name
- names
- state
- saltenv

For example:

```yaml
disable_nfs:
  module.run:
    - name: service.disable
    - m_name: nfs
```

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

```yaml
mine.send:
  module.run:
    - func: network.ip_addrs
    - kwargs:
      interface: eth0
```

```yaml
cloud.create:
  module.run:
    - func: cloud.create
    - provider: test-provider
    - m_names:
      - test-vlad
    - kwargs:
      ssh_username: 'ubuntu',
      image: 'ami-8d6d9daa',
      securitygroup: 'default',
      size: 'c3.large',
      location: 'ap-northeast-1',
      delvol_on_destroy: 'True'
```

Other modules take the keyword arguments using this style:

```yaml
mac_enable_ssh:
  module.run:
    - name: system.set_remote_login
    - enable: True
```

Another example that creates a recurring task that runs a batch file on a Windows system:
eventsviewer:
  module.run:
    - name: task.create_task
      - m_name: 'events-viewer'
      - user_name: System
      - kwargs: {
          action_type: 'Execute',
          cmd: 'c:\netops\scripts\events_viewer.bat',
          trigger_type: 'Daily',
          start_date: '2017-1-20',
          start_time: '11:59PM'
      }

salt.states.module.mod_watch(**kwargs)

This function is an alias of run.

Run a single module function or a range of module functions in a batch. Supersedes module.run function, which requires m_ prefix to function-specific parameters.

Parameters

- returner -- Specify a common returner for the whole batch to send the return data
- kwargs -- Pass any arguments needed to execute the function(s)

some_id_of_state:
  module.run:
    - network.ip_addrs:
      - interface: eth0
    - cloud.create:
      - names:
        - test-isbm-1
        - test-isbm-2
      - ssh_username: sles
      - image: sles12sp2
      - securitygroup: default
      - size: 'c3.large'
      - location: ap-northeast-1
      - delvol_on_destroy: True

return

salt.states.module.run(**kwargs)

Run a single module function or a range of module functions in a batch. Supersedes module.run function, which requires m_ prefix to function-specific parameters.

Parameters

- returner -- Specify a common returner for the whole batch to send the return data
- kwargs -- Pass any arguments needed to execute the function(s)
- test-isbm-2
- **ssh_username**: sles
- **image**: sles12sp2
- **securitygroup**: default
- **size**: 'c3.large'
- **location**: ap-northeast-1
- **delvol_on_destroy**: True

Returns

```python
salt.states.module.wait(name, **kwargs)
```
Run a single module function only if the watch statement calls it

**name**
The module function to execute

**kwargs**
Pass any arguments needed to execute the function

**Note:** Like the `cmd.run` state, this state will return `True` but not actually execute, unless one of the following two things happens:

1. The state has a `watch requisite`, and the state which it is watching changes.
2. Another state has a `watch_in requisite` which references this state, and the state with the `watch_in` changes.

```python
salt.states.module.watch(name, **kwargs)
```
This function is an alias of `wait`.
Run a single module function only if the watch statement calls it

**name**
The module function to execute

**kwargs**
Pass any arguments needed to execute the function

**Note:** Like the `cmd.run` state, this state will return `True` but not actually execute, unless one of the following two things happens:

1. The state has a `watch requisite`, and the state which it is watching changes.
2. Another state has a `watch_in requisite` which references this state, and the state with the `watch_in` changes.

### 25.20.183 `salt.states.mongodb_database`

**Management of MongoDB Databases**

```python
depends
```
- pymongo Python module

Only deletion is supported, creation doesn't make sense and can be done using `mongodb_user.present`.

```python
salt.states.mongodb_database.absent(name, user=None, password=None, host=None, port=None, authdb=None)
```
Ensure that the named database is absent. Note that creation doesn't make sense in MongoDB.
name
  The name of the database to remove
user
  The user to connect as (must be able to create the user)
password
  The password of the user
host
  The host to connect to
port
  The port to connect to
authdb
  The database in which to authenticate

25.20.184 salt.states.mongodb_user

Management of MongoDB Users

depends
  • pymongo Python module
salt.states.mongodb_user.absent(name, user=None, password=None, host=None, port=None, database='admin', authdb=None)
  Ensure that the named user is absent
  name
    The name of the user to remove
  user
    MongoDB user with sufficient privilege to create the user
  password
    Password for the admin user specified by the user parameter
  host
    The hostname/IP address of the MongoDB server
  port
    The port on which MongoDB is listening
  database
    The database from which to remove the user specified by the name parameter
  authdb
    The database in which to authenticate
salt.states.mongodb_user.present(name, passwd, database='admin', user=None, password=None, host='localhost', port=27017, authdb=None, roles=None)
  Ensure that the user is present with the specified properties
  name
    The name of the user to manage
  passwd
    The password of the user to manage
  user
    MongoDB user with sufficient privilege to create the user
  password
    Password for the admin user specified with the user parameter
  host
    The hostname/IP address of the MongoDB server
  port
    The port on which MongoDB is listening
database
The database in which to create the user

Note: If the database doesn't exist, it will be created.

authdb
The database in which to authenticate

roles
The roles assigned to user specified with the name parameter

Example:

`mongouser-myapp:
  mongodb_user.present:
    - name: myapp
    - passwd: password-of-myapp
    - database: admin
  # Connect as admin:sekrit
    - user: admin
    - password: sekrit
    - roles:
      - readWrite
      - userAdmin
      - dbOwner`

25.20.185 salt.states.monit

Monit state

Manage monit states

`monit_enable_service_monitoring:
  monit.monitor:
    - name: service`

`monit_disable_service_monitoring:
  monit.unmonitor:
    - name: service`

Note: Use of these states require that the monit execution module is available.

salt.states.monit.**monitor**(name)
Get the summary from module monit and try to see if service is being monitored. If not then monitor the service.

salt.states.monit.**unmonitor**(name)
Get the summary from module monit and try to see if service is being monitored. If it is then stop monitoring the service.
25.20.186 salt.states.mount

Mounting of filesystems

Mount any type of mountable filesystem with the mounted function:

```
/mnt/sdb:
    mount.mounted:
        - device: /dev/sdb1
        - fstype: ext4
        - mkmnt: True
        - opts: defaults

/srv/bigdata:
    mount.mounted:
        - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
        - fstype: xfs
        - opts: nobootwait, noatime, nodiratime, nobarrier, logbufs=8
        - dump: 0
        - pass_num: 2
        - persist: True
        - mkmnt: True

/var/lib/bigdata:
    mount.mounted:
        - device: /srv/bigdata
        - fstype: none
        - opts: bind
        - dump: 0
        - pass_num: 0
        - persist: True
        - mkmnt: True
```

salt.states.mount.fstab_absent(name, fs_file, mount_by=None, config='/etc/fstab')

Makes sure that a fstab mount point is absent.

name
   The name of block device. Can be any valid fs_spec value.

fs_file
   Mount point (target) for the filesystem.

mount_by
   Select the final value for fs_spec. Can be [None, device, label, uuid, partlabel, partuuid]. If None, the value for fs_spec will be the parameter name, in other case will search the correct value based on the device name. For example, for uuid, the value for fs_spec will be of type 'UUID=xxx' instead of the device name set in name.

config
   Place where the fstab file lives

salt.states.mount.fstab_present(name, fs_file, fs_vfstype, fs_mntops='defaults', fs_freq=0, fs_passno=0, mount_by=None, config='/etc/fstab', mount=True, match_on='auto', not_change=False, fs_mount=True)

Makes sure that a fstab mount point is present.

name
   The name of block device. Can be any valid fs_spec value.
**fs_file**
Mount point (target) for the filesystem.

**fs_vfstype**
The type of the filesystem (e.g. ext4, xfs, btrfs, ...)

**fs_mntops**
The mount options associated with the filesystem. Default is `defaults`.

**fs_freq**
Field is used by `dump` to determine which filesystem need to be dumped. Default is `0`

**fs_passno**
Field is used by `fsck` to determine the order in which filesystem checks are done at boot time. Default is `0`

**fs_mount**
Field is used only in AIX systems to determine if the filesystem will be mounted by `mount all`

**mount_by**
Select the final value for `fs_spec`. Can be `[None, device, label, uuid, partlabel, partuuid]`. If `None`, the value for `fs_spec` will be the parameter `name`, in other case will search the correct value based on the device name. For example, for `uuid`, the value for `fs_spec` will be of type `'UUID=xxx'` instead of the device name set in `name`.

**config**
Place where the `fstab` file lives. Default is `/etc/fstab`

**mount**
Set if the mount should be mounted immediately. Default is `True`

**match_on**
A name or list of `fstab` properties on which this state should be applied. Default is `auto`, a special value indicating to guess based on `fstype`. In general, `auto` matches on name for recognized special devices and device otherwise.

**not_change**
By default, if the entry is found in the `fstab` file but is different from the expected content (like different options), the entry will be replaced with the correct content. If this parameter is set to `True` and the line is found, the original content will be preserved.

### salt.states.mount.mod_watch(name, user=None, **kwargs)

The mounted watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the `watch requisite`. It should not be called directly.

Parameters for this function should be set by the state being triggered.

### name
The name of the mount point

### salt.states.mount.mounted(name, device, fstype, mkmnt=False, opts='defaults', dump=0, passnum=0, config='/etc/fstab', persist=True, mount=True, user=None, match_on='auto', device_name_regex=None, extra_mount_invisible_options=None, extra_mount_invisible_keys=None, extra_mount_ignore_fs_keys=None, extra_mount_translate_options=None, hidden_opts=None, bind_mount_copy_active_opts=True, **kwargs)

Verify that a device is mounted

**name**
The path to the location where the device is to be mounted

**device**
The device name, typically the device node, such as `/dev/sdb1` or `UUID=066e0200-2867-4ebe-b9e6-f30026ca2314` or `LABEL=DATA`
The filesystem type, this will be \texttt{xfs}, \texttt{ext2/3/4} in the case of classic filesystems, \texttt{fuse} in the case of fuse mounts, and \texttt{nfs} in the case of nfs mounts

\texttt{mkmnt}
If the mount point is not present then the state will fail, set \texttt{mkmnt: True} to create the mount point if it is otherwise not present

\texttt{opts}
A list object of options or a comma delimited list

\texttt{dump}
The dump value to be passed into the fstab, Default is 0

\texttt{pass\_num}
The pass value to be passed into the fstab, Default is 0

\texttt{config}
Set an alternative location for the fstab, Default is /etc/fstab

\texttt{persist}
Set if the mount should be saved in the fstab, Default is True

\texttt{mount}
Set if the mount should be mounted immediately, Default is True

\texttt{user}
The account used to execute the mount; this defaults to the user salt is running as on the minion

\texttt{match\_on}
A name or list of fstab properties on which this state should be applied. Default is \texttt{auto}, a special value indicating to guess based on fstype. In general, \texttt{auto} matches on name for recognized special devices and device otherwise.

\texttt{device\_name\_regex}
A list of device exact names or regular expressions which should not force a remount. For example, glusterfs may be mounted with a comma-separated list of servers in fstab, but the /proc/self/mountinfo will show only the first available server.

{\%
\texttt{set glusterfs\_ip\_list = ['10.0.0.1', '10.0.0.2', '10.0.0.3']} \%
}

\texttt{mount glusterfs volume:}
\texttt{mount.mounted:}
\begin{itemize}
  \item name: /mnt/glusterfs\_mount\_point
  \item device: \texttt{{\{ glusterfs\_ip\_list|join(',') \}}:/volume\_name}
  \item fstype: glusterfs
  \item opts: _netdev,rw,defaults,direct-io-mode=disable
  \item mkmnt: True
  \item persist: True
  \item dump: 0
  \item pass\_num: 0
  \item device\_name\_regex:
    \begin{itemize}
      \item ({{ glusterfs\_ip\_list|join('|') }}):/volume\_name
    \end{itemize}
\end{itemize}

New in version 2016.11.0.

\texttt{extra\_mount\_invisible\_options}
A list of extra options that are not visible through the /proc/self/mountinfo interface.

If a option is not visible through this interface it will always remount the device. This option extends the builtin mount\_invisible\_options list.

\texttt{extra\_mount\_invisible\_keys}
A list of extra key options that are not visible through the /proc/self/mountinfo interface.

If a key option is not visible through this interface it will always remount the device. This option extends the builtin mount\_invisible\_keys list.

A good example for a key option is the password option:
```python
password=badsecret
```

**extra.mount.ignore_fs_keys**

A dict of filesystem options which should not force a remount. This will update the internal dictionary. The dict should look like this:

```python
{
    'ramfs': [ 'size' ]
}
```

**extra.mount.translate_options**

A dict of mount options that gets translated when mounted. To prevent a remount add additional options to the default dictionary. This will update the internal dictionary. The dictionary should look like this:

```python
{
    'tcp': 'proto=tcp',
    'udp': 'proto=udp'
}
```

**hidden_opts**

A list of mount options that will be ignored when considering a remount as part of the state application. New in version 2015.8.2.

**bind.mount.copy_active_opts**

If set to `False`, this option disables the default behavior of copying the options from the bind mount if it was found to be active. New in version 3006.0.

**salt.states.mount.swap**(name, persist=True, config='/etc/fstab')

Activates a swap device `/root/swapfile`:

```bash
mount.swap
```

---

**Note:** swap does not currently support LABEL

**salt.states.mount.unmounted**(name, device=None, config='/etc/fstab', persist=False, user=None, **kwargs)

New in version 0.17.0.

Verify that a device is not mounted.

**name**

The path to the location where the device is to be unmounted from.

**device**

The device to be unmounted. This is optional because the device could be mounted in multiple places. New in version 2015.5.0.

**config**

Set an alternative location for the fstab, Default is `/etc/fstab`

**persist**

Set if the mount should be purged from the fstab, Default is `False`

**user**

The user to own the mount; this defaults to the user salt is running as on the minion
25.20.187 salt.states.mssql_database

Management of Microsoft SQLServer Databases

The mssql_database module is used to create and manage SQL Server Databases

```python
yolo:
  mssql_database.present
```

```python
salt.states.mssql_database.absent(name, **kwargs)
    Ensure that the named database is absent
    name
        The name of the database to remove

salt.states.mssql_database.present(name, containment='NONE', options=None, **kwargs)
    Ensure that the named database is present with the specified options
    name
        The name of the database to manage
    containment
        Defaults to NONE
    options
        Can be a list of strings, a dictionary, or a list of dictionaries
```

25.20.188 salt.states.mssql_login

Management of Microsoft SQLServer Logins

The mssql_login module is used to create and manage SQL Server Logins

```python
frank:
  mssql_login.present
    - domain: mydomain
```

```python
salt.states.mssql_login.absent(name, **kwargs)
    Ensure that the named login is absent
    name
        The name of the login to remove

salt.states.mssql_login.present(name, password=None, domain=None, server_roles=None, options=None, **kwargs)
    Checks existence of the named login. If not present, creates the login with the specified roles and options.
    name
        The name of the login to manage
    password
        Creates a SQL Server authentication login. Since hashed passwords are varbinary values, if the
        new_login_password is 'long', it will be considered to be HASHED.
    domain
        Creates a Windows authentication login. Needs to be NetBIOS domain or hostname
    server_roles
        Add this login to all the server roles in the list
    options
        Can be a list of strings, a dictionary, or a list of dictionaries
25.20.189 salt.states.mssql_role

Management of Microsoft SQLServer Databases

The mssql_role module is used to create and manage SQL Server Roles

```
yolo:
  mssql_role.present
```

```
salt.states.mssql_role.absent(name, **kwargs)
  Ensure that the named database is absent
  name
    The name of the database to remove

salt.states.mssql_role.present(name, owner=None, grants=None, **kwargs)
  Ensure that the named database is present with the specified options
  name
    The name of the database to manage
  owner
    Adds owner using AUTHORIZATION option
  Grants
    Can only be a list of strings
```

25.20.190 salt.states.mssql_user

Management of Microsoft SQLServer Users

The mssql_user module is used to create and manage SQL Server Users

```
frank:
  mssql_user.present:
    - database: yolo
```

```
salt.states.mssql_user.absent(name, **kwargs)
  Ensure that the named user is absent
  name
    The username of the user to remove

salt.states.mssql_user.present(name, login=None, domain=None, database=None, roles=None, options=None, **kwargs)
  Checks existence of the named user. If not present, creates the user with the specified roles and options.
  name
    The name of the user to manage
  login
    If not specified, will be created WITHOUT LOGIN
  domain
    Creates a Windows authentication user. Needs to be NetBIOS domain or hostname
  database
    The database of the user (not the login)
  roles
    Add this user to all the roles in the list
  options
    Can be a list of strings, a dictionary, or a list of dictionaries
```
25.20.191 salt.states.msteams

Send a message card to Microsoft Teams

This state is useful for sending messages to Teams during state runs.

New in version 2017.7.0.

```yaml
teams-message:
  msteams.post_card:
    - message: 'This state was executed successfully.'
    - hook_url: https://outlook.office.com/webhook/837
```

The hook_url can be specified in the master or minion configuration like below:

```yaml
msteams:
  hook_url: https://outlook.office.com/webhook/837
```

salt.states.msteams.post_card(name, message, hook_url=None, title=None, theme_color=None)

Send a message to a Microsoft Teams channel

```yaml
send-msteams-message:
  msteams.post_card:
    - message: 'This state was executed successfully.'
    - hook_url: https://outlook.office.com/webhook/837
```

The following parameters are required:

message
  The message that is to be sent to the MS Teams channel.

The following parameters are optional:

hook_url
  The webhook URL given configured in Teams interface, if not specified in the configuration options of master or minion.

title
  The title for the card posted to the channel

theme_color
  A hex code for the desired highlight color

25.20.192 salt.states.mysql_database

Management of MySQL databases (schemas)

depends
  • MySQLdb Python module

configuration
  See salt.modules.mysql for setup instructions.

The mysql_database module is used to create and manage MySQL databases. Databases can be set as either absent or present.

```yaml
frank:
  mysql_database.present
```
**salt.states.mysql_database.absent**

Ensure that the named database is absent

```python
name
```

The name of the database to remove

**salt.states.mysql_database.p resent**

Ensure that the named database is present with the specified properties

```python
name
```

The name of the database to manage

### 25.20.193 salt.states.mysql_grants

**Management of MySQL grants (user permissions)**

```python
depends
```

- MySQLdb Python module

```python
configuration
```

See `salt.modules.mysql` for setup instructions.

The mysql_grants module is used to grant and revoke MySQL permissions.

The `name` you pass in purely symbolic and does not have anything to do with the grant itself.

The `database` parameter needs to specify a 'priv_level' in the same specification as defined in the MySQL documentation:

- `*`
- `**`
- `db_name.*`
- `db_name.tbl_name`
- etc...

This state is not able to set password for the permission from the specified host. See `salt.states.mysql_user` for further instructions.

```yaml
frank_exampledb:
  mysql_grants.present:
    - grant: select,insert,update
    - database: exampledb.*
    - user: frank
    - host: localhost

frank_otherdb:
  mysql_grants.present:
    - grant: all privileges
    - database: otherdb.*
    - user: frank

restricted_single_table:
  mysql_grants.present:
    - grant: select
```

(continues on next page)
- **database**: somedb.sometable
- **user**: joe

salt.states.mysql_grants.absent(name, grant=None, database=None, user=None, host='localhost',
    grant_option=False, escape=True, **connection_args)

Ensure that the grant is absent

- **name**: The name (key) of the grant to add
- **grant**: The grant priv_type (i.e. select,insert,update OR all privileges)
- **database**: The database priv_level (i.e. db.tbl OR db.*)
- **user**: The user to apply the grant to
- **host**: The network/host that the grant should apply to

salt.states.mysql_grants.present(name, grant=None, database=None, user=None, host='localhost',
    grant_option=False, escape=True, revoke_first=False,
    ssl_option=False, **connection_args)

Ensure that the grant is present with the specified properties

- **name**: The name (key) of the grant to add
- **grant**: The grant priv_type (i.e. select,insert,update OR all privileges)
- **database**: The database priv_level (i.e. db.tbl OR db.*)
- **user**: The user to apply the grant to
- **host**: The network/host that the grant should apply to
- **grant_option**: Adds the WITH GRANT OPTION to the defined grant. Default is False
- **escape**: Defines if the database value gets escaped or not. Default is True
- **revoke_first**: By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what’s already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.table/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the `revoke_first` options.

WARNING: This will remove permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

- **Default is False**
- **ssl_option**: Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dicts in the value:
- SSL: True
- X509: True
- SUBJECT: <subject>
- ISSUER: <issuer>
- CIPHER: <cipher>

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified by the MySQL documentation for these options.

Default is False (no ssl options will be used)

### 25.20.194 salt.states.mysql_query

**Execution of MySQL queries**

New in version 2014.7.0.

```
depends
• MySQLdb Python module
```

**configuration**

See `salt.modules.mysql` for setup instructions.

The mysql_query module is used to execute queries on MySQL databases. Its output may be stored in a file or in a grain.

```
query_id:
mysql_query.run
- database: my_database
- query: "SELECT * FROM table;"
- output: "/tmp/query_id.txt"
```

**salt.states.mysql_query.run**(name, database, query, output=None, grain=None, key=None, overwrite=True, check_db_exists=True, client_flags=None, **connection_args)

Execute an arbitrary query on the specified database

**name**

Used only as an ID

**database**

The name of the database to execute the query on

**query**

The query to execute

**output**

grain: output in a grain other: the file to store results None: output to the result comment (default)

grain:

grain to store the output (need output=grain)

**key**

the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.

**overwrite**

The file or grain will be overwritten if it already exists (default)

**check_db_exists**

The state run will check that the specified database exists (default=True) before running any queries
client_flags:

salt.states.mysql_query.run_file(name, database, query_file=None, output=None, grain=None, key=None, overwrite=True, saltenv=None, check_db_exists=True, client_flags=None, **connection_args)

Execute an arbitrary query on the specified database
New in version 2017.7.0.

name
Used only as an ID

database
The name of the database to execute the query_file on

query_file
The file of mysql commands to run

output
grain: output in a grain other: the file to store results None: output to the result comment (default)

grain:
grain to store the output (need output=grain)

key:
the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.

overwrite:
The file or grain will be overwritten if it already exists (default)

saltenv:
The saltenv to pull the query_file from

check_db_exists:
The state run will check that the specified database exists (default=True) before running any queries

client_flags:

25.20.195 salt.states.mysql_user

Management of MySQL users

depends
- MySQLdb Python module

configuration
See salt.modules.mysql for setup instructions.

frank:

mysql_user.present:
- host: localhost
- password: bobcat

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments: connection_host, connection_port, connection_user, connection_pass, connection_db, connection_unix_socket, connection_default_file and connection_charset.
frank:

```
mysql_user.present:
  - host: localhost
  - password: "bob@cat"
  - connection_user: someuser
  - connection_pass: somepass
  - connection_charset: utf8
  - saltenv:
    - LC_ALL: "en_US.utf8"
```

This state is not able to grant permissions for the user. See `salt.states.mysql_grants` for further instructions.

```
salt.states.mysql_user.absent(name, host='localhost', **connection_args)
```

Ensure that the named user is absent.

```
name
```

The name of the user to remove.

```
salt.states.mysql_user.present(name, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, password_column=None, auth_plugin='mysql_native_password', **connection_args)
```

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting `password` and `password_hash`, and setting `allow_passwordless` to True.

```
name
```

The name of the user to manage.

```
host
```

Host for which this user/password combo applies.

```
password
```

The password to use for this user. Will take precedence over the `password_hash` option if both are specified.

```
password_hash
```

The password in hashed form. Be sure to quote the password because YAML doesn't like the *. A password hash can be obtained from the `mysql` command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+----------------------------------+
| PASSWORD('mypass')               |
| +----------------------------------+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
| +----------------------------------+
1 row in set (0.00 sec)
```

```
allow_passwordless
```

If True, then `password` and `password_hash` can be omitted to permit a passwordless login.

New in version 0.16.2.

```
unix_socket
```

If True and `allow_passwordless` is True, the `unix_socket` auth plugin will be used.
25.20.196 salt.states.net_napalm_yang

NAPALM YANG state

Manage the configuration of network devices according to the YANG models (OpenConfig/IETF).

New in version 2017.7.0.

Dependencies

- napalm-yang
- pyangbing > 0.5.11

To be able to load configuration on network devices, it requires NAPALM library to be installed: pip install napalm. Please check Installation for complete details.

```python
salt.states.net_napalm_yang.configured(name, data, **kwargs)
```

Configure the network device, given the input data structured according to the YANG models.

---

**Note:** The main difference between this function and managed is that the later generates and loads the configuration only when there are differences between the existing configuration on the device and the expected configuration. Depending on the platform and hardware capabilities, one could be more optimal than the other. Additionally, the output of the managed is different, in such a way that the pchange field in the output contains structured data, rather than text.

- **data**
  - YANG structured data.
- **models**
  - A list of models to be used when generating the config.
- **profiles:** *None*
  - Use certain profiles to generate the config. If not specified, will use the platform default profile(s).
- **test:** *False*
  - Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
- **commit:** *True*
  - Commit? Default: True.
- **debug:** *False*
  - Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.
- **replace:** *False*
  - Should replace the config with the new generate one?

State SLS example:

```python
{% set expected_config = pillar.get('openconfig_interfaces_cfg') %}
interfaces_config:
  napalm_yang.configured:
  - data: {{ expected_config | json }}
  - models:
    - models.openconfig_interfaces
  - debug: true
```

Pillar example:
salt.states.net_napalm_yang.managed(name, data, **kwargs)

Manage the device configuration given the input data structured according to the YANG models.

data
YANG structured data.

models
A list of models to be used when generating the config.

profiles: None
Use certain profiles to generate the config. If not specified, will use the platform default profile(s).

compliance_report: False
Return the compliance report in the comment.

New in version 2017.7.3.

test: False
Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.

commit: True
Commit? Default: True.

dump: False
Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.

replace: False
Should replace the config with the new generate one?

State SLS example:

```yaml
{% set expected_config = pillar.get('openconfig_interfaces_cfg') -%}

interfaces_config:
  napalm_yang.managed:
    - data: {{ expected_config | json }}
    - models:
      - models.openconfig_interfaces
    - debug: true
```

Pillar example:

```yaml
openconfig_interfaces_cfg:
  _kwargs:
    filter: true
  interfaces:
    interface:
      Et1:
        config:
          mtu: 9000
      Et2:
        config:
          description: "description example"
```

(continues on next page)
25.20.197 salt.states.netacl

Network ACL

Manage the firewall configuration on the network device managed through NAPALM. The firewall configuration is generated by Capirca.

New in version 2017.7.0.

codeauthor Mircea Ulinic <ping@mirceaulinic.net>
maturity new
depends capirca, napalm
platform unix

Dependencies

Capirca

To install Capirca, execute: pip install capirca.

NAPALM

To be able to load configuration on network devices, it requires NAPALM library to be installed: pip install napalm. Please check Installation for complete details.

salt.states.netacl.filter(name, filter_name=None, filter_options=None, terms=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)

Generate and load the configuration of a policy filter.

filter_name
The name of the policy filter.

filter_options
Additional filter options. These options are platform-specific. See the complete list of options.

terms
Dictionary of terms for this policy filter. If not specified or empty, will try to load the configuration from the pillar, unless merge_pillar is set as False.
prepend: **True**
When `merge_pillar` is set as `True`, the final list of terms generated by merging the terms from `terms` with those defined in the pillar (if any): new terms are prepended at the beginning, while existing ones will preserve the position. To add the new terms at the end of the list, set this argument to **False**.

**pillar_key:** `acl`
The key in the pillar containing the default attributes values. Default: `acl`.

**pillarenv**
Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.

**saltenv**
Included only for compatibility with `pillarenv_from_saltenv`, and is otherwise ignored.

**merge_pillar:** **False**
Merge `terms` with the corresponding value from the pillar. Default: `False`.

**Note:** By default this state does not merge, to avoid any unexpected behaviours.
The merge logic depends on the `prepend` argument.
The terms specified through the `terms` argument have higher priority than the pillar.

**only_lower_merge:** **False**
Specify if it should merge only the terms fields. Otherwise it will try to merge also filters fields. Default: `False`. This option requires `merge_pillar`, otherwise it is ignored.

**revision_id**
Add a comment in the filter config having the description for the changes applied.

**revision_no**
The revision count.

**revision_date:** **True**
Boolean flag: display the date when the filter configuration was generated. Default: `True`.

**revision_date_format:** `%Y/%m/%d`
The date format to be used when generating the perforce data. Default: `%Y/%m/%d` (<year>/<month>/<day>).

**test:** **False**
Dry run? If set as `True`, will apply the config, discard and return the changes. Default: `False` and will commit the changes on the device.

**commit:** **True**
Commit? Default: `True`.

**debug:** **False**
Debug mode. Will insert a new key under the output dictionary, as `loaded_config` containing the raw configuration loaded on the device.

CLI Example:
```
salt 'edge01.flw01' state.sls router.acl test=True
```

Output Example:
```
edge01.flw01:
----------
   ID: my-filter
Function: netacl.filter
   Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:24:40.598232
Duration: 2437.139 ms
```

Summary for edge01.flw01

----------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
----------
Total states run: 1
Total run time: 2.437 s

Pillar example:

```
 acl:
  - my-filter:
    options:
      - inet6
    terms:
      - my-term:
        source_port: [1234, 1235]
        protocol:
          - tcp
          - udp
        source_address: 1.2.3.4
        action: reject
      - my-other-term:
        source_port:
          - [5678, 5680]
        protocol: tcp
        action: accept
```
State SLS Example:

```yaml
{%- set filter_name = 'my-filter' -%}
{%- set my_filter_cfg = salt.netacl.get_filter_pillar(filter_name, pillar_ key='firewall') -%}
my_first_filter_state:
  netacl.filter:
    - filter_name: {{ filter_name }}
    - options: {{ my_filter_cfg['options'] | json }}
    - terms: {{ my_filter_cfg['terms'] | json }}
    - revision_date: false
    - revision_no: 5
    - debug: true
```

Or:

```yaml
my_first_filter_state:
  netacl.filter:
    - filter_name: my-filter
    - merge_pillar: true
    - pillar_key: firewall
    - revision_date: false
    - revision_no: 5
    - debug: true
```

In the example above, as inet6 has been specified in the filter_options, the configuration chunk referring to my-term has been ignored as it referred to IPv4 only (from source_address field).

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`` | json``), instead of relying on the default Python serializer.

salt.states.netacl.managed(name, filters=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)

Manage the whole firewall configuration.

**filters**
Dictionary of filters for this policy. If not specified or empty, will try to load the configuration from the pillar, unless merge_pillar is set as False.

**prepend:** True
When merge_pillar is set as True, the final list of filters generated by merging the filters from filters with those defined in the pillar (if any): new filters are prepended at the beginning, while existing ones will preserve the position. To add the new filters at the end of the list, set this argument to False.

**pillar_key:** acl
The key in the pillar containing the default attributes values. Default: acl.

**pillarenv**
Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.

**saltenv**

Included only for compatibility with `pillarenv_from_saltenv`, and is otherwise ignored.

**merge_pillar: False**

Merge the filters will the corresponding values from the pillar. Default: False.

**Note:** By default this state does not merge, to avoid any unexpected behaviours.

The merge logic depends on the `prepend` argument.

The filters specified through the `filters` argument have higher priority than the pillar.

**only_lower_merge: False**

Specify if should merge only the filters and terms fields. Otherwise it will try to merge everything at the policy level. Default: False. This option requires `merge_pillar`, otherwise it is ignored.

**test: False**

Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.

**revision_id**

Add a comment in the policy config having the description for the changes applied.

**revision_no**

The revision count.

**revision_date: True**

Boolean flag: display the date when the policy configuration was generated. Default: True.

**revision_date_format: %Y/%m/%d**

The date format to be used when generating the perforce data. Default: %Y/%m/%d (year/month/day).

**commit: True**

Commit? Default: True.

**debug: False**

Debug mode. Will insert a new key under the output dictionary, as `loaded_config` containing the raw configuration loaded on the device.

CLI Example:

```
salt 'edge01.bjm01' state.sls router.acl test=True
```

Output Example:

```
edge01.bjm01: -------------
ID: netacl_example
Function: netacl.managed
Result: None
Comment: Testing mode: Configuration discarded.

                    reject;
                }
            }
        } Summary for edge01.bjm01
        Succeeded: 1 (unchanged=1, changed=1)
The policy configuration has been loaded from the pillar, having the following structure:

```yaml
firewall:
  - my-filter:
      terms:
        - my-term:
            source_port: [1234, 1235]
            protocol:
              - tcp
              - udp
            source_address: 1.2.3.4
            action: reject
        - my-other-term:
            source_port: [5678, 5680]
            protocol: tcp
            action: accept
  - block-icmp:
      terms:
        - first-term:
            protocol:
              - icmp
            action: reject
```

Example SLS file:

```yaml
{% set fw_filters = pillar.get('firewall', {}) %}
netacl_example:
  netacl.managed:
    - filters: {{ fw_filters | json }}
    - revision_no: 2
    - debug: true
```

Or:

```yaml
netacl_example:
  netacl.managed:
    - pillar_key: firewall
    - merge_pillar: true
    - revision_no: 2
    - debug: true
```

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.
Note: When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`` | json``), instead of relying on the default Python serializer.

salt.states.netacl.term(name, filter_name, term_name, filter_options=None, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False, source_service=None, destination_service=None, **term_fields)

Manage the configuration of a specific policy term.

filter_name
  The name of the policy filter.

term_name
  The name of the term.

filter_options
  Additional filter options. These options are platform-specific. See the complete list of options.

pillar_key: acl
  The key in the pillar containing the default attributes values. Default: acl.

pillarenv
  Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.

saltenv
  Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.

merge_pillar: False
  Merge the CLI variables with the pillar. Default: False.

  The properties specified through the state arguments have higher priority than the pillar.

revision_id
  Add a comment in the term config having the description for the changes applied.

revision_no
  The revision count.

revision_date: True
  Boolean flag: display the date when the term configuration was generated. Default: True.

revision_date_format: %Y/%m/%d
  The date format to be used when generating the perforce data. Default: %Y/%m/%d
  (<year>/<month>/<day>).

test: False
  Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.

commit: True
  Commit? Default: True.

deploy: False
  Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.

source_service
  A special service to choose from. This is a helper so the user is able to select a source just using the name, instead of specifying a source_port and protocol.

  As this module is available on Unix platforms only, it reads the IANA port assignment from /etc/services.

  If the user requires additional shortcuts to be referenced, they can add entries under /etc/services, which can be managed using the file state.

destination_service
  A special service to choose from. This is a helper so the user is able to select a source just using the name, instead of specifying a destination_port and protocol. Allows the same options as source_service.
**term_fields**

Term attributes. To see what fields are supported, please consult the list of supported keywords. Some platforms have few other optional keywords.

**Note:** The following fields are accepted:

- action
- address
- address_exclude
- comment
- counter
- expiration
- destination_address
- destination_address_exclude
- destination_port
- destination_prefix
- forwarding_class
- forwarding_class_except
- logging
- log_name
- loss_priority
- option
- policer
- port
- precedence
- principals
- protocol
- protocol_except
- qos
- pan_application
- routing_instance
- source_address
- source_address_exclude
- source_port
- source_prefix
- verbatim
- packet_length
- fragment_offset
- hop_limit
- icmp_type
- ether_type
- traffic_class_count
- traffic_type
- translated
- dscp_set
- dscp_match
- dscp_except
- next_ip
- flexible_match_range
- source_prefix_except
- destination_prefix_except
- vpn
- source_tag
- destination_tag
- source_interface
• destination_interface
• flattened
• flattened_addr
• flattened_saddr
• flattened_daddr
• priority

Note: The following fields can be also a single value and a list of values:
• action
• address
• address_exclude
• comment
• destination_address
• destination_address_exclude
• destination_port
• destination_prefix
• forwarding_class
• forwarding_class_except
• logging
• option
• port
• precedence
• principals
• protocol
• protocol_except
• pan_application
• source_address
• source_address_exclude
• source_port
• source_prefix
• verbatim
• icmp_type
• ether_type
• traffic_type
• dscp_match
• dscp_except
• flexible_match_range
• source_prefix_except
• destination_prefix_except
• source_tag
• destination_tag
• source_service
• destination_service

Example: destination_address can be either defined as:

| destination_address: | 172.17.17.1/24 |

or as a list of destination IP addresses:

| destination_address: |
| - 172.17.17.1/24 |
| - 172.17.19.1/24 |
or a list of services to be matched:

```
source_service:
    - ntp
    - snmp
    - ldap
    - bgpd
```

Note: The port fields `source_port` and `destination_port` can be used as above to select either a single value, either a list of values, but also they can select port ranges. Example:

```
source_port:
    - [1000, 2000]
    - [3000, 4000]
```

With the configuration above, the user is able to select the 1000-2000 and 3000-4000 source port ranges.

CLI Example:

```
salt 'edge01.bjm01' state.sls router.acl
```

Output Example:

```
edge01.bjm01:
   ---------
   ID: update_icmp_first_term
   Function: netacl.term
   Result: None
   Comment: Testing mode: Configuration discarded.
   Started: 12:49:09.174179
   Duration: 5751.882 ms
   Changes:
       ---------
       diff:
       [edit firewall]
       +  family inet {
       +    /*
       +    ** $Id: update_icmp_first_term $
       +    ** $Date: 2017/02/30 $
       +    **
       +    */
       +    filter block-icmp {
       +       term first-term {
       +           from {
       +               protocol icmp;
       +           }
       +           then {
       +               reject;
       +           }
       +       }
       +   }
       + }
       (continues on next page)
```
Summary for edge01.bjm01
-------------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
-------------
Total states run: 1
Total run time: 5.752 s

Pillar example:

```
firewall:
  - block-icmp:
    terms:
      - first-term:
        protocol:
          - icmp
        action: reject
```

State SLS example:

```
{% set filter_name = 'block-icmp' %}
{% set term_name = 'first-term' %}
{% set my_term_cfg = salt.netacl.get_term_pillar(filter_name, term_name) %}

update_icmp_first_term:
  netacl.term:
    - filter_name: {{ filter_name }}
    - filter_options:
      - not-interface-specific
    - term_name: {{ term_name }}
    - {{ my_term_cfg | json }}
```

Or directly referencing the pillar keys:

```
update_icmp_first_term:
  netacl.term:
    - filter_name: block-icmp
    - filter_options:
      - not-interface-specific
    - term_name: first-term
    - merge_pillar: true
```

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`"| json"`), instead of relying on the default Python serializer.
25.20.198 salt.states.netconfig

Network Config

Manage the configuration on a network device given a specific static config or template.

codeauthor

maturity

new

depends

napalm

platform

unix

Dependencies

- NAPALM proxy minion
- Network-related basic features execution module

New in version 2017.7.0.
salt.states.netconfig.commit_cancelled(name)

New in version 2019.2.0.

Cancel a commit scheduled to be executed via the commit_in and commit_at arguments from the net.load_template or net.load_config execution functions. The commit ID is displayed when the commit is scheduled via the functions named above.

State SLS Example:

```yaml
'20180726083540640360':
  netconfig.commit_cancelled
```

salt.states.netconfig.commit_confirmed(name)

New in version 2019.2.0.

Confirm a commit scheduled to be reverted via the revert_in and revert_at arguments from the net.load_template or net.load_config execution functions. The commit ID is displayed when the commit confirmed is scheduled via the functions named above.

State SLS Example:

```yaml
'20180726083540640360':
  netconfig.commit_confirmed
```

salt.states.netconfig.managed(name, template_name=None, template_source=None, template_hash=None, template_hash_name=None, saltenv='base', template_engine='jinja', skip_verify=False, context=None, defaults=None, test=False, commit=True, debug=False, replace=False, commit_in=None, commit_at=None, revert_in=None, revert_at=None, **template_vars)

Manages the configuration on network devices.
By default this state will commit the changes on the device. If there are no changes required, it does not commit and the field already_configured from the output dictionary will be set as True to notify that.

To avoid committing the configuration, set the argument test to True (or via the CLI argument test=True) and will discard (dry run).

To preserve the changes, set commit to False (either as CLI argument, either as state parameter). However, this is recommended to be used only in exceptional cases when there are applied few consecutive states and/or configuration changes. Otherwise the user might forget that the config DB is locked and the candidate config buffer is not cleared/merged in the running config.

To replace the config, set replace to True. This option is recommended to be used with caution!

**template_name**

Identifies path to the template source. The template can be either stored on the local machine, either remotely. The recommended location is under the file_roots as specified in the master config file. For example, let's suppose the file_roots is configured as:

```yaml
file_roots:
  base:
    - /etc/salt/states
```

Placing the template under /etc/salt/states/templates/example.jinja, it can be used as salt://templates/example.jinja. Alternatively, for local files, the user can specify the absolute path. If remotely, the source can be retrieved via http, https or ftp.

Examples:

- `salt://my_template.jinja`
- `/absolute/path/to/my_template.jinja`
- `http://example.com/template.cheetah`
- `https://example.com/template.mako`
- `ftp://example.com/template.py`

Changed in version 2019.2.0: This argument can now support a list of templates to be rendered. The resulting configuration text is loaded at once, as a single configuration chunk.

**template_source:** None

Inline config template to be rendered and loaded on the device.

**template_hash:** None

Hash of the template file. Format: \{hash_type: 'md5', 'hsum': \<md5sum>\}

**template_hash_name:** None

When template_hash refers to a remote file, this specifies the filename to look for in that file.

**saltenv:** base

Specifies the template environment. This will influence the relative imports inside the templates.

**template_engine:** jinja

The following templates engines are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

**skip_verify:** False

If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

Changed in version 2017.7.1.

**test:** False

Dry run? If set to True, will apply the config, discard and return the changes. Default: False (will commit the changes on the device).
commit: True
Commit? Default: True.

dbuge: False
Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the
raw result after the template was rendered.

**Note:** This argument cannot be used directly on the command line. Instead, it can be passed through
the pillar variable when executing either of the state.sls or state.apply (see below for an
example).

commit_in: None
Commit the changes in a specific number of minutes / hours. Example of accepted formats: 5 (commit in
5 minutes), 2m (commit in 2 minutes), 1h (commit the changes in 1 hour), 5h30m (commit the changes
in 5 hours and 30 minutes).

**Note:** This feature works on any platforms, as it does not rely on the native features of the network
operating system.

**Note:** After the command is executed and the diff is not satisfactory, or for any other reasons you
have to discard the commit, you are able to do so using the net.cancel_commit execution function,
using the commit ID returned by this function.

**Warning:** Using this feature, Salt will load the exact configuration you expect, however the diff
may change in time (i.e., if an user applies a manual configuration change, or a different process or
command changes the configuration in the meanwhile).

New in version 2019.2.0.

commit_at: None
Commit the changes at a specific time. Example of accepted formats: 1am (will commit the changes at
the next 1AM), 13:20 (will commit at 13:20), 1:20am, etc.

**Note:** This feature works on any platforms, as it does not rely on the native features of the network
operating system.

**Note:** After the command is executed and the diff is not satisfactory, or for any other reasons you
have to discard the commit, you are able to do so using the net.cancel_commit execution function,
using the commit ID returned by this function.

**Warning:** Using this feature, Salt will load the exact configuration you expect, however the diff
may change in time (i.e., if an user applies a manual configuration change, or a different process or
command changes the configuration in the meanwhile).

New in version 2019.2.0.

revert_in: None
Commit and revert the changes in a specific number of minutes / hours. Example of accepted formats:
5 (revert in 5 minutes), 2m (revert in 2 minutes), 1h (revert the changes in 1 hour), 5h30m (revert the changes in 5 hours and 30 minutes).

**Note:** To confirm the commit, and prevent reverting the changes, you will have to execute the `net.confirm_commit` function, using the commit ID returned by this function.

**Warning:** This works on any platform, regardless if they have or don’t have native capabilities to confirming a commit. However, please be very cautious when using this feature: on Junos (as it is the only NAPALM core platform supporting this natively) it executes a commit confirmed as you would do from the command line. All the other platforms don’t have this capability natively, therefore the revert is done via Salt. That means, your device needs to be reachable at the moment when Salt will attempt to revert your changes. Be cautious when pushing configuration changes that would prevent you reach the device.

Similarly, if an user or a different process apply other configuration changes in the meanwhile (between the moment you commit and till the changes are reverted), these changes would be equally reverted, as Salt cannot be aware of them.

---

New in version 2019.2.0.

**revert_at:** None
Commit and revert the changes at a specific time. Example of accepted formats: 1am (will commit and revert the changes at the next 1AM), 13:20 (will commit and revert at 13:20), 1:20am, etc.

**Note:** To confirm the commit, and prevent reverting the changes, you will have to execute the `net.confirm_commit` function, using the commit ID returned by this function.

**Warning:** This works on any platform, regardless if they have or don’t have native capabilities to confirming a commit. However, please be very cautious when using this feature: on Junos (as it is the only NAPALM core platform supporting this natively) it executes a commit confirmed as you would do from the command line. All the other platforms don’t have this capability natively, therefore the revert is done via Salt. That means, your device needs to be reachable at the moment when Salt will attempt to revert your changes. Be cautious when pushing configuration changes that would prevent you reach the device.

Similarly, if an user or a different process apply other configuration changes in the meanwhile (between the moment you commit and till the changes are reverted), these changes would be equally reverted, as Salt cannot be aware of them.

---

New in version 2019.2.0.

**replace:** False
Load and replace the configuration. Default: False (will apply load merge).

**context:** None
Overrides default context variables passed to the template.

New in version 2019.2.0.

**defaults:** None
Default variables/context passed to the template.

**template_vars**
Dictionary with the arguments/context to be used when the template is rendered. Do not explicitly specify this argument. This represents any other variable that will be sent to the template render-
Please see an example below! In both ntp_peers_example_using_pillar and ntp_peers_example, peers is sent as template variable.

Note: It is more recommended to use the context argument instead, to avoid any conflicts with other arguments.

SLS Example (e.g.: under salt://router/config.sls):

```
whole_config_example:
  netconfig.managed:
    - template_name: salt://path/to/complete_config.jinja
    - debug: True
    - replace: True
bgp_config_example:
  netconfig.managed:
    - template_name: /absolute/path/to/bgp_neighbors.mako
    - template_engine: mako
prefix_lists_example:
  netconfig.managed:
    - template_name: prefix_lists.cheetah
    - debug: True
    - template_engine: cheetah
ntp_peers_example:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - skip_verify: False
    - debug: True
    - peers:
      - 192.168.0.1
      - 192.168.0.1
ntp_peers_example_using_pillar:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - peers: {{ pillar.get('ntp.peers', []) }}
```

Multi template example:

```
hostname_and_ntp:
  netconfig.managed:
    - template_name:
    - debug: true
    - context:
      hostname: {{ opts.id }}
      servers:
        - 172.17.17.1
        - 172.17.17.2
      peers:
        - 192.168.0.1
        - 192.168.0.2
```

Usage examples:
$ sudo salt 'juniper.device' state.sls router.config test=True

$ sudo salt -N all-routers state.sls router.config pillar="{'debug': True}

router.config depends on the location of the SLS file (see above). Running this command, will be executed all five steps from above. These examples above are not meant to be used in a production environment, their sole purpose is to provide usage examples.

Output example:

```
$ sudo salt 'juniper.device' state.sls router.config test=True

juniper.device:
---------
    ID: ntp_peers_example_using_pillar
    Function: netconfig.managed
    Result: None
    Comment: Testing mode: Configuration discarded.
    Started: 12:01:40.744535
    Duration: 8755.788 ms
    Changes:
    ----------
        diff:
        [edit system ntp]
        peer 192.168.0.1 { ... } + peer 172.17.17.1;
        + peer 172.17.17.3;

Summary for juniper.device
---------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
---------
Total states run: 1
Total run time: 8.756 s
```

Raw output example (useful when the output is reused in other states/execution modules):

```
$ sudo salt --out=pprint 'juniper.device' state.sls router.config test=True
dict
{    'juniper.device': {        'netconfig_|-ntp_peers_example_using_pillar_|-ntp_peers_example_using_pillar_|-managed': {            '__id__': 'ntp_peers_example_using_pillar',            '__run_num__': 0,            'already_configured': False,            'changes': {                'diff': '[edit system ntp] peer 192.168.0.1 { ... }+ peer 172.17.17.1;+ peer 172.17.17.3;',                'comment': 'Testing mode: Configuration discarded.',            },        },    },}
```

(continues on next page)
salt.states.netconfig.replace_pattern(name, pattern, repl, count=0, flags=8, bufsize=1,
append_if_not_found=False, prepend_if_not_found=False,
not_found_content=None, search_only=False, show_changes=True, backslash_literal=False,
source='running', path=None, test=False, replace=True, debug=False, commit=True)

New in version 2019.2.0.

Replace occurrences of a pattern in the configuration source. If show_changes is True, then a diff of what changed will be returned, otherwise a True will be returned when changes are made, and False when no changes are made. This is a pure Python implementation that wraps Python's sub().

**pattern**
A regular expression, to be matched using Python's search().

**repl**
The replacement text.

**count:** 0
Maximum number of pattern occurrences to be replaced. If count is a positive integer n, only n occurrences will be replaced, otherwise all occurrences will be replaced.

**flags (list or int):** 8
A list of flags defined in the re module documentation from the Python standard library. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Optionally, flags may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which supports 'MULTILINE').

**bufsize (int or str):** 1
How much of the configuration to buffer into memory at once. The default value 1 processes one line at a time. The special value file may be specified which will read the entire file into memory before processing.

**append_if_not_found:** False
If set to True, and pattern is not found, then the content will be appended to the file.

**prepend_if_not_found:** False
If set to True and pattern is not found, then the content will be prepended to the file.

**not_found_content**
Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.

**search_only:** False
If set to true, this no changes will be performed on the file, and this function will simply return True if the pattern was matched, and False if not.

**show_changes:** True
If True, return a diff of changes made. Otherwise, return True if changes were made, and False if not.

**backslash_literal:** False
Interpret backslashes as literal backslashes for the repl and not escape characters. This will help when using append/prepend so that the backslashes are not interpreted for the repl on the second run of the
state.

source: **running**
The configuration source. Choose from: running, candidate, or startup. Default: running.

path
Save the temporary configuration to a specific path, then read from there.

test: **False**
Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.

commit: **True**
Commit the configuration changes? Default: True.

debug: **False**
Debug mode. Will insert a new key in the output dictionary, as loaded_config containing the raw configuration loaded on the device.

replace: **True**
Load and replace the configuration. Default: True.

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

State SLS Example:

```
update_policy_name:
netconfig.replace_pattern:
  - pattern: OLD-POLICY-NAME
  - repl: new-policy-name
  - debug: true
```

---

salt.states.netconfig.saved(name, source='running', user=None, group=None, mode=None, attrs=None, makedirs=False, dir_mode=None, replace=True, backup='', show_changes=True, create=True, tmp_dir='', tmp_ext='', encoding=None, encoding_errors='strict', allow_empty=False, follow_symlinks=True, check_cmd=None, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False, **kwargs)

New in version 2019.2.0.

Save the configuration to a file on the local file system.

name
Absolute path to file where to save the configuration. To push the files to the Master, use cp.push Execution function.

source: **running**

user
The user to own the file, this defaults to the user salt is running as on the minion.

group
The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored.

mode
The permissions to set on this file, e.g. 644, 0775, or 4664. The default mode for new files and directories corresponds to the umask of the salt process. The mode of existing files and directories will only be changed if mode is specified.

---

**Note:** This option is **not** supported on Windows.
attrs
The attributes to have on this file, e.g. a, i. The attributes can be any or a combination of the following characters: aAcCdDeijPsStTu.

Note: This option is not supported on Windows.

makedirs: False
If set to True, then the parent directories will be created to facilitate the creation of the named file. If False, and the parent directory of the destination file doesn't exist, the state will fail.

dir_mode
If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

replace: True
If set to False and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

backup
Overrides the default backup mode for this specific file. See backup_mode documentation for more details.

show_changes: True
Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

create: True
If set to False, then the file will only be managed if the file already exists on the system.

encoding
If specified, then the specified encoding will be used. Otherwise, the file will be encoded using the system locale (usually UTF-8). See https://docs.python.org/3/library/codecs.html#standard-encodings for the list of available encodings.

encoding_errors: 'strict'
Error encoding scheme. Default is `'strict'`. See https://docs.python.org/2/library/codecs.html#codec-base-classes for the list of available schemes.

allow_empty: True
If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.

follow_symlinks: True
If the desired path is a symlink follow it and make changes to the file to which the symlink points.

check_cmd
The specified command will be run with an appended argument of a temporary file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

tmp_dir
Directory for temp file created by check_cmd. Useful for checkers dependent on config file location (e.g. daemons restricted to their own config directories by an apparmor profile).

tmp_ext
Suffix for temp file created by check_cmd. Useful for checkers dependent on config file extension (e.g. the init-checkconf upstart config checker).

win_owner: None
The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

win_perms: None
A dictionary containing permissions to grant and their propagation. For example: {
    'Administrators': {'perms': 'full_control'}
} Can be a single basic perm or
a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

**win_deny_perms:** None
A dictionary containing permissions to deny and their propagation. For example:
{'Administrators': {'perms': 'full_control'}} Can be a single basic perm or a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

**win_inheritance:** True
True to inherit permissions from the parent directory, False not to inherit permission.

**win_perms_reset:** False
If True the existing DACL will be cleared and replaced with the settings defined in this function. If False, new entries will be appended to the existing DACL. Default is False.

State SLS Example:

```
/var/backups/{{ opts.id }}/\{ salt.status.time('%s') \}.cfg:
netconfig.saved:
- source: running
- makedirs: true
```

The state SLS above would create a backup config grouping the files by the Minion ID, in chronological files. For example, if the state is executed at on the 3rd of August 2018, at 5:15PM, on the Minion core1.lon01, the configuration would saved in the file: /var/backups/core01.lon01/1533316558.cfg

---

25.20.199 salt.states.netntp

Network NTP

New in version 2016.11.0.

Manage the configuration of NTP peers and servers on the network devices through the NAPALM proxy.

**codeauthor**
Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>

**maturity**
new

**depends**
napalm

**platform**
unix

**Dependencies**

- Requires netaddr to be installed: `pip install netaddr` to check if IP Addresses are correctly specified.
- Requires dnspython to be installed: `pip install dnspython` to resolve the nameserver entities (in case the user does not configure the peers/servers using their IP addresses)
- NAPALM proxy minion
- NTP operational and configuration management module

salt.states.netntp.managed(name, peers=None, servers=None)

Manages the configuration of NTP peers and servers on the device, as specified in the state SLS file. NTP entities not specified in these lists will be removed whilst entities not configured on the device will be set.

SLS Example:
Output example:

```
{
  'edge01.nrt04': {
    'netntp_|-netntp_example_|-netntp_example_|-managed': {
      'comment': 'NTP servers already configured as needed.',
      'name': 'netntp_example',
      'start_time': '12:45:24.056659',
      'duration': 2938.857,
      'changes': {
        'peers': {
          'removed': [
            '192.168.0.2',
            '192.168.0.3'
          ],
          'added': [
            '192.168.0.1',
            '172.17.17.1'
          ]
        }
      },
      'result': None
    }
  }
}
```

### 25.20.200 salt.states.netsnmp

**Network SNMP**

Manage the SNMP configuration on network devices.

**codeauthor**

Mircea Ulinic <ping@mirceaulinic.net>

**maturity**

new

**depends**

napalm

**platform**

unix
Dependencies

- napalm snmp management module (salt.modules.napalm_snmp)

New in version 2016.11.0.

salt.states.netsnmp.managed(name, config=None, defaults=None)

Configures the SNMP on the device as specified in the SLS file.

SLS Example:

```yaml
snmp_example:
  netsnmp.managed:
    - config:
      location: Honolulu, HI, US
    - defaults:
      contact: noc@cloudflare.com
```

Output example (for the SLS above, e.g. called snmp.sls under /router/):

```
$ sudo salt edge01.hnl01 state.sls router.snmp test=True
edge01.hnl01:
--------
ID: snmp_example
Function: snmp.managed
Result: None
Comment: Testing mode: configuration was not changed!
Started: 13:29:06.872363
Duration: 920.466 ms
Changes:
--------
added:
--------
  chassis_id:
    None
  contact:
    noc@cloudflare.com
  location:
    Honolulu, HI, US

Summary for edge01.hnl01
--------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
--------
Total states run: 1
Total run time: 920.466 ms
```
25.20.201 salt.states.netusers

Network Users

Manage the users configuration on network devices via the NAPALM proxy.

codeauthor
Mircea Ulinic <ping@mirceaulinic.net>
maturity
new
depends
napalm
platform
unix

Dependencies

- NAPALM proxy minion
- Users configuration management module

New in version 2016.11.0.

salt.states.netusers.managed(name, users=None, defaults=None)

Manages the configuration of the users on the device, as specified in the state SLS file. Users not defined in that file will be removed whilst users not configured on the device, will be added.

SLS Example:

```
netusers_example:
  netusers.managed:
    - users:
      admin:
        level: 15
        password: $1$knmhgPPv$g8745biu4rb.Zf.I.T.F/U1
        sshkeys: []
      restricted:
        level: 1
        password: $1$j34j5k4b$4d5SVjTiz1l.Zf.I.T.F/K7
      martin:
        level: 15
        password: '
        sshkeys:
          - ssh-dss AAAAB3NzaC1kc3MAAAAABK9dP3KariMlM/
            ⎯ JmFW9rTSm5cXs4nR0+o6fTHP9o+b0LXMbTP8R4vwWHh9w
          - JPjQM3YafAqZTnlgi0srGjyifFwPtODppDWLCgLe2M4Lxnu3OMqknr54w344zPHP3iFwWxHrBrZKtCj08LhbV
          - X528+i87t6r5e4ersdfxgchjbnio87t6r5drcfhgjhbknio8976tycv7t86ftyiu870zlnKsKuNzm2cs0f
          - trmRfpjsOPNookmOz5WG0YxhwDmKeo6fWK+ATk10iP+QT39fn4G77j8o+e4WAwxM570s350f/
          - vV0zoOccj753sXn
```
CLI Example:

```
salt 'edge01.kix01' state.sls router.users
```

Output example (raw python - can be reused in other modules):

```
{
    'netusers_|-netusers_example_|-netusers_example_|-managed': {
        'comment': 'Configuration updated!',
        'name': 'netusers_example',
        'start_time': '10:57:08.678811',
        '__id__': 'netusers_example',
        'duration': 1620.982,
        '__run_num__': 0,
        'changes': {
            'updated': {
                'admin': {
                    'level': 15
                },
                'restricted': {
                    'level': 1
                },
                'martin': {
                    'sshkeys': [
                        'ssh-dss AAAAB3NzaC1kc3MAAACBAK9dP3KariMLM/
                    ]
                }
            }
        }
    }
```

Summary for edge01.kix01
----------------------
Succeeded: 1 (changed=1)
Failed: 0
----------------------
Total states run: 1
Total run time:  1.220 s
25.20.202 salt.states.network

Configuration of network interfaces

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

**Note:** RedHat-based systems (RHEL, CentOS, Scientific, etc.) have been supported since version 2014.1.0.

Debian-based systems (Debian, Ubuntu, etc.) have been supported since version 2017.7.0. The following options are not supported: ipaddr_start, and ipaddr_end.

Other platforms are not yet supported.

**Note:** On Debian-based systems, networking configuration can be specified in /etc/network/interfaces or via included files such as (by default) /etc/network/interfaces.d/*. This can be problematic for configuration management. It is recommended to use either file.managed or network.managed.

If using network.managed, it can be useful to ensure interfaces.d/ is empty. This can be done using the following state

```
/etc/network/interfaces.d:
    file.directory:
        - clean: True
```

Configuring Global Network Settings

Use the network.system state to set global network settings:

```
system:
    network.system:
        - enabled: True
        - hostname: server1.example.com
        - gateway: 192.168.0.1
        - gatewaydev: eth0
        - nozeroconf: True
        - nisdomain: example.com
        - require_reboot: True
        - apply_hostname: True
```

**Note:** The use of apply_hostname above will apply changes to the hostname immediately.

Changed in version 2015.5.0: apply_hostname added
retain_settings

New in version 2016.11.0.

Use retain_settings to retain current network settings that are not otherwise specified in the state. Particularly useful if only setting the hostname. Default behavior is to delete unspecified network settings.

```yaml
system:
  network.system:
    - hostname: server2.example.com
    - apply_hostname: True
    - retain_settings: True
```

Configuring Network Routes

Use the `network.routes` state to set network routes.

```yaml
routes:
  network.routes:
    - name: eth0
    - routes:
      - name: secure_network
        ipaddr: 10.2.0.0
        netmask: 255.255.255.0
        gateway: 10.1.0.3
      - name: HQ_network
        ipaddr: 10.100.0.0
        netmask: 255.255.0.0
        gateway: 10.1.0.10
```

Managing Network Interfaces

The `network.managed` state is used to configure network interfaces. Here are several examples:

Ethernet Interface

```yaml
eth0:
  network.managed:
    - enabled: True
    - type: eth
    - proto: static
    - ipaddr: 10.1.0.7
    - netmask: 255.255.255.0
    - gateway: 10.1.0.1
    - enable_ipv6: true
    - ipv6proto: static
    - ipv6addrs:
      - 2001:db8:dead:beef::3/64
      - 2001:db8:dead:beef::7/64
```

(continues on next page)
- **ipv6gateway**: 2001:db8:dead:beef::1
- **ipv6netmask**: 64
- **dns**: 8.8.8.8, 8.8.4.4
- **channels**: rx: 4, tx: 4, other: 4, combined: 4

Ranged Interfaces (RHEL/CentOS Only)

New in version 2015.8.0.

Ranged interfaces can be created by including the word `range` in the interface name.

**Important**: The interface type must be `eth`.

```
eth0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

bond0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

eth1.0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - vlan: True
    - mtu: 9000

bond0.1-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
```
Bond Interfaces

To configure a bond, you must do the following:

- Configure the bond slaves with a type of slave, and a master option set to the name of the bond interface.
- Configure the bond interface with a type of bond, and a slaves option defining the bond slaves for the bond interface.

```
eth2:
    network.managed:
    - enabled: True
    - type: slave
    - master: bond0

eth3:
    network.managed:
    - enabled: True
    - type: slave
    - master: bond0

bond0:
    network.managed:
    - type: bond
    - ipaddr: 10.1.0.1
    - netmask: 255.255.255.0
    - mode: gre
    - proto: static
    - dns:
        - 8.8.8.8
        - 8.8.4.4
    - enabled: False
    - slaves: [eth2, eth3]
    - require:
        - network: eth2
        - network: eth3
    - miimon: 100
    - arp_interval: 250
    - downdelay: 200
    - lacp_rate: fast
    - max_bonds: 1
    - updelay: 0
    - use_carrier: on
    - hashing-algorithm: layer2
    - mtu: 9000
    - autoneg: on
    - speed: 1000
    - duplex: full
    - rx: on
```
- tx: off
- sg: on
- tso: off
- ufo: off
- gso: off
- gro: off
- lro: off

### VLANs

Set type to `vlan` to configure a VLANs. These VLANs are configured on the bond interface defined above.

```
bond0.2:
  network.managed:
    - type: vlan
    - ipaddr: 10.1.0.2
    - use:
      - network: bond0
    - require:
      - network: bond0

bond0.3:
  network.managed:
    - type: vlan
    - ipaddr: 10.1.0.3
    - use:
      - network: bond0
    - require:
      - network: bond0

bond0.10:
  network.managed:
    - type: vlan
    - ipaddr: 10.1.0.4
    - use:
      - network: bond0
    - require:
      - network: bond0

bond0.12:
  network.managed:
    - type: vlan
    - ipaddr: 10.1.0.5
    - use:
      - network: bond0
    - require:
      - network: bond0
```
Bridge Interfaces

```
eth4:
   network.managed:
   - enabled: True
   - type: eth
   - proto: dhcp
   - bridge: br0

br0:
   network.managed:
   - enabled: True
   - type: bridge
   - proto: dhcp
   - bridge: br0
   - delay: 0
   - ports: eth4
   - bypassfirewall: True
   - use:
     - network: eth4
   - require:
     - network: eth4
```

Note: When managing bridged interfaces on a Debian/Ubuntu based system, the `ports` argument is required. RedHat-based systems will ignore the argument.

Network Teaming (RHEL/CentOS 7 and later)

New in version 3002.

- Configure the members of the team interface with a `type` of `teamport`, and a `team_master` option set to the name of the bond interface.
  - `master` also works, but will be ignored if both `team_master` and `master` are present.
  - If applicable, include a `team_port_config` option. This should be formatted as a dictionary. Keep in mind that due to a quirk of PyYAML, dictionaries nested under a list item must be double-indented (see example below for interface `eth5`).

- Configure the team interface with a `type` of `team`. The team configuration should be passed via the `team_config` option. As with `team_port_config`, the dictionary should be double-indented.

```
eth5:
   network.managed:
   - type: teamport
   - team_master: team0
   - team_port_config:
     prio: 100

eth6:
   network.managed:
   - type: teamport
```

(continues on next page)
- team_master: team0

team0:
  network.managed:
    - type: team
    - ipaddr: 172.24.90.42
    - netmask: 255.255.255.128
    - enable_ipv6: True
    - ipv6addr: 'feef:dead:beef:af43::'
    - team_config:
      runner:
        hwaddr_policy: by_active
        name: activebackup
        link_watch:
          name: ethtool

Note: While teamd must be installed to manage a team interface, it is not required to configure a separate pkg. installed state for it, as it will be silently installed if needed.

Configuring the Loopback Interface

Use network.managed with a type of eth and a proto of loopback.

lo:
  network.managed:
    - name: lo
    - type: eth
    - proto: loopback
    - onboot: yes
    - userctl: no
    - ipv6_autoconf: no
    - enable_ipv6: true

Other Useful Options

noifupdown

The noifupdown option, if set to True, will keep Salt from restart the interface if changes are made, requiring them to be restarted manually. Here are a couple examples:

eth7:
  network.managed:
    - enabled: True
    - type: eth
    # Automatic IP/DNS
    - proto: dhcp
    - noifupdown: True
eth8:
  network.managed:
    - type: eth
    - noifupdown: True

    # IPv4
    - proto: static
    - ipaddr: 192.168.4.9
    - netmask: 255.255.255.0
    - gateway: 192.168.4.1
    - enable_ipv6: True

    # IPv6
    - ipv6proto: static
    - ipv6addr: 2001:db8:dead:c0::3
    - ipv6netmask: 64
    - ipv6gateway: 2001:db8:dead:c0::1
    # override shared; makes those options v4-only
    - ipv6ttl: 15

    # Shared
    - mtu: 1480
    - ttl: 18
    - dns:
      - 8.8.8.8
      - 8.8.4.4

salt.states.network.managed(name, enabled=True, **kwargs)

Ensure that the named interface is configured properly.

  name
  The name of the interface to manage.

  type
  [eth] Type of interface and configuration
  Changed in version 3002.

  enabled
  Designates the state of this interface.

salt.states.network.routes(name, **kwargs)

Manage network interface static routes.

  name
  Interface name to apply the route to.

  kwargs
  Named routes

salt.states.network.system(name, **kwargs)

Ensure that global network settings are configured properly.

  name
  Custom name to represent this configuration change.

  kwargs
  The global parameters for the system.
25.20.203 salt.states.neutron_network

Management of OpenStack Neutron Networks

New in version 2018.3.0.

depends
configuration
see salt.modules.neutronng for setup instructions

Example States

```yaml
create network:
    neutron_network.present:
        - name: network1

delete network:
    neutron_network.absent:
        - name: network1

create network with optional params:
    neutron_network.present:
        - name: network1
        - vlan: 200
        - shared: False
        - external: False
        - project: project1
```

salt.states.neutron_network.absent(name, auth=None, **kwargs)
Ensure a network does not exist
name
    Name of the network

salt.states.neutron_network.present(name, auth=None, **kwargs)
Ensure a network exists and is up-to-date
name
    Name of the network
provider
    A dict of network provider options.
shared
    Set the network as shared.
external
    Whether this network is externally accessible.
admin_state_up
    Set the network administrative state to up.
vlan
    Vlan ID. Alias for provider
    * physical_network: provider
    * network_type: vlan
    * segmentation_id: (vlan id)
25.20.204  salt.states.neutron_secgroup

Management of OpenStack Neutron Security Groups

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.neutronng for setup instructions

Example States

create security group;
  neutron_secgroup.present:
    - name: security_group1
    - description: "Very Secure Security Group"

delete security group:
  neutron_secgroup.absent:
    - name_or_id: security_group1
    - project_name: Project1

create security group with optional params:
  neutron_secgroup.present:
    - name: security_group1
    - description: "Very Secure Security Group"
    - project_id: 1dcac318a83b4610b7a7f7ba01465548

create security group with optional params:
  neutron_secgroup.present:
    - name: security_group1
    - description: "Very Secure Security Group"
    - project_name: Project1

salt.states.neutron_secgroup.absent(name, auth=None, **kwargs)
  Ensure a security group does not exist
  name
    Name of the security group

salt.states.neutron_secgroup.present(name, auth=None, **kwargs)
  Ensure a security group exists.
  You can supply either project_name or project_id.
  Creating a default security group will not show up as a change; it gets created through the lookup process.
  name
    Name of the security group
  description
    Description of the security group
  project_name
    Name of Project
  project_id
    ID of Project
25.20.205  salt.states.neutron_secgroup_rule

Management of OpenStack Neutron Security Group Rules

New in version 2018.3.0.

depends
  shade

configuration
  see salt.modules.neutronng for setup instructions

Example States

create security group rule:
  neutron_secgroup_rule.present:
  - name: security_group1
  - project_name: Project1
  - protocol: icmp

delete security group:
  neutron_secgroup_rule.absent:
  - name_or_id: security_group1

create security group with optional params:
  neutron_secgroup_rule.present:
  - name: security_group1
  - description: "Very Secure Security Group"
  - project_id: 1dcac318a83b4610b7a7f7ba01465548

salt.states.neutron_secgroup_rule.absent(name, auth=None, **kwargs)
  Ensure a security group rule does not exist
  name
    name or id of the security group rule to delete
  rule_id
    uuid of the rule to delete
  project_id
    id of project to delete rule from
	salt.states.neutron_secgroup_rule.present(name, auth=None, **kwargs)
  Ensure a security group rule exists
  defaults: port_range_min=None, port_range_max=None, protocol=None,
    remote_ip_prefix=None, remote_group_id=None, direction='ingress',
    ethertype='IPv4',
  name
    Name of the security group to associate with this rule
  project_name
    Name of the project associated with the security group
  protocol
    The protocol that is matched by the security group rule. Valid values are None, tcp, udp, and icmp.
25.20.206 salt.states.neutron_subnet

Management of OpenStack Neutron Subnets

New in version 2018.3.0.

depends
  shade
configuration
  see salt.modules.neutronng for setup instructions

Example States

create subnet:
  neutron_subnet.present:
    - name: subnet1
    - network_name_or_id: network1
    - cidr: 192.168.199.0/24

delete subnet:
  neutron_subnet.absent:
    - name: subnet2

create subnet with optional params:
  neutron_subnet.present:
    - name: subnet1
    - network_name_or_id: network1
    - enable_dhcp: True
    - cidr: 192.168.199.0/24
    - allocation_pools:
      - start: 192.168.199.5
        end: 192.168.199.250
    - host_routes:
      - destination: 192.168..0.0/24
        nexthop: 192.168.0.1
      - gateway_ip: 192.168.199.1
    - dns_nameservers:
      - 8.8.8.8
      - 8.8.8.7

create ipv6 subnet:
  neutron_subnet.present:
    - name: v6subnet1
    - network_name_or_id: network1
    - ip_version: 6

salt.states.neutron_subnet.absent(name, auth=None)
  Ensure a subnet does not exists
  name
    Name of the subnet

salt.states.neutron_subnet.present(name, auth=None, **kwargs)
  Ensure a subnet exists and is up-to-date
name
   Name of the subnet

network_name_or_id
   The unique name or ID of the attached network. If a non-unique name is supplied, an exception is raised.

allocation_pools
   A list of dictionaries of the start and end addresses for the allocation pools

gateway_ip
   The gateway IP address.

dns_nameservers
   A list of DNS name servers for the subnet.

host_routes
   A list of host route dictionaries for the subnet.

ipv6_ra_mode
   IPv6 Router Advertisement mode. Valid values are: 'dhcpv6-stateful', 'dhcpv6-stateless', or 'slaac'.

ipv6_address_mode
   IPv6 address mode. Valid values are: 'dhcpv6-stateful', 'dhcpv6-stateless', or 'slaac'.

25.20.207 salt.states.nexus

This state downloads artifacts from Nexus 3.x.

New in version 2018.3.0.

salt.states.nexus.downloaded(name, artifact, target_dir='/tmp', target_file=None)

Ensures that the artifact from nexus exists at given location. If it doesn't exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in nexus. If it is different then the step will fail.

artifact
   Details of the artifact to be downloaded from nexus. Various options are:
   - nexus_url: URL of the nexus instance
   - repository: Repository in nexus
   - artifact_id: Artifact ID
   - group_id: Group ID
   - packaging: Packaging
   - classifier: Classifier
   - version: Version
     One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
   - username: nexus username
   - password: nexus password

target_dir
   Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.

target_file
   Target file to download artifact to. By default file name is resolved by nexus.

An example to download an artifact to a specific file:

```
jboss_module_downloaded:
   nexus.downloaded:
     - artifact:
         nexus_url: http://nexus.intranet.example.com/repository
       repository: 'libs-release-local'
       artifact_id: 'module'
       group_id: 'com.company.module'
```
packaging: 'jar'
classifier: 'sources'
version: '1.0'
- target_file: /opt/jboss7/modules/com/company/lib/module.jar

Download artifact to the folder (automatically resolves file name):

maven_artifact_downloaded:
nexus.downloaded:
  - artifact:
      nexus_url: http://nexus.intranet.example.com/repository
      repository: 'maven-releases'
      artifact_id: 'module'
      group_id: 'com.company.module'
      packaging: 'zip'
      classifier: 'dist'
      version: '1.0'
  - target_dir: /opt/maven/modules/com/company/release

25.20.208 salt.states.nfs_export

Management of NFS exports

New in version 2018.3.0.

To ensure an NFS export exists:

add_simple_export:
  nfs_export.present:
    - name: '/srv/nfs'
    - hosts: '10.0.2.0/24'
    - options:
      - 'rw'

This creates the following in /etc/exports:

/srv/nfs 10.0.2.0/24(rw)

For more complex exports with multiple groups of hosts, use 'clients':

add_complex_export:
  nfs_export.present:
    - name: '/srv/nfs'
    - clients:
      # First export, same as simple one above
      - hosts: '10.0.2.0/24'
      options:
        - 'rw'
      # Second export
      - hosts: '*.example.com'
        options:
This creates the following in /etc/exports:

```
//srv/nfs 10.0.2.0/24(rw) 192.168.0.0/24,172.19.0.0/16(ro,subtree_check)
```

Any export of the given path will be modified to match the one specified.

To ensure an NFS export is absent:

```
salt.states.nfs_export.absent:
    - name: '/srv/nfs'
```

salt.states.nfs_export.absent(name, exports='/etc/exports')

Ensure that the named path is not exported

name

The export path to remove

salt.states.nfs_export.present(name, clients=None, hosts=None, options=None, exports='/etc/exports')

Ensure that the named export is present with the given options

name

The export path to configure

clients

A list of hosts and the options applied to them. This option may not be used in combination with the ‘hosts’ or ‘options’ shortcuts.

```
- clients:
  # First export
  - hosts: '10.0.2.0/24'
    options:
      - 'rw'
  # Second export
  - hosts: '*.example.com'
    options:
      - 'ro'
      - 'subtree_check'
```

hosts

A string matching a number of hosts, for example:

```
hosts: '10.0.2.123'
hosts: '10.0.2.0/24'
hosts: 'minion1.example.com'
hosts: '*.example.com'
hosts: '*'
```

options

A list of NFS options, for example:
options:
- 'rw'
- 'subtree_check'

25.20.209 salt.states.nftables

Management of nftables

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

httpd:
```
  nftables.append:
    - table: filter
    - chain: input
    - jump: accept
    - match: state
    - connstate: new
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
```

httpd:
```
  nftables.append:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
```

httpd:
```
  nftables.insert:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
```

httpd:
```
  nftables.insert:
```

(continues on next page)
- position: 1
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

httpd:

    nftables.delete:
        - position: 1
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:

    nftables.delete:
        - position: 1
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:

    nftables.delete:
        - table: filter
        - family: ipv6
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

output:

    nftables.chain_present:
- family: ip
- table: filter

output:
  nftables.chain_absent:
  - family: ip
  - table: filter

salt.states.nftables.append(name, family='ipv4', **kwargs)

New in version 0.17.0.
Append a rule to a chain
name
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
family
Network family, ipv4 or ipv6.
All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

salt.states.nftables.chain_absent(name, table='filter', family='ipv4')

New in version 2014.7.0.
Verify the chain is absent.
family
Networking family, either ipv4 or ipv6

salt.states.nftables.chain_present(name, table='filter', table_type=None, hook=None, priority=None, family='ipv4')

New in version 2014.7.0.
Changed in version 3002.
Verify a chain exists in a table.
name
A user-defined chain name.
table
The table to own the chain.
family
Networking family, either ipv4 or ipv6

salt.states.nftables.delete(name, family='ipv4', **kwargs)

New in version 2014.7.0.
Delete a rule to a chain
name
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
family
Networking family, either ipv4 or ipv6
All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

salt.states.nftables.flush(name, family='ipv4', ignore_absence=False, **kwargs)

New in version 2014.7.0.
Changed in version 3002.
Flush current nftables state

**family**
Networking family, either ipv4 or ipv6

**ignore_absence**
If set to True, attempts to flush a non-existent table will not result in a failed state.
New in version 3002.

`salt.states.nftables.insert(name, family='ipv4', **kwargs)`
New in version 2014.7.0.
Insert a rule into a chain

**name**
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family**
Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

`salt.states.nftables.set_policy(name, table='filter', family='ipv4', **kwargs)`
New in version 3002.
Sets the default policy for nftables chains

**table**
The table that owns the chain that should be modified

**family**
Networking family, either ipv4 or ipv6

**policy**
The requested table policy (accept or drop)

**save**
Boolean to save the in-memory nftables settings to a file.

**save_filename**
The filename to save the nftables settings (default: `/etc/nftables` or `/etc/nftables/salt-all-in-one.nft` if the former is a directory)

`salt.states.nftables.table_absent(name, family='ipv4', **kwargs)`
New in version 3002.
Ensure an nftables table is absent

**name**
Name of the table to ensure is absent

**family**
Networking family, either ipv4 or ipv6

`salt.states.nftables.table_present(name, family='ipv4', **kwargs)`
New in version 3002.
Ensure an nftables table is present

**name**
A user-defined table name.

**family**
Networking family, either ipv4 or ipv6
25.20.210 salt.states.npm

Installation of NPM Packages

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state for the package which provides npm (simply npm in most cases). Example:

```
# Salt State Manifest

# NPM package installation

pkg:
  - require:
    - pkg: npm

# CoffeeScript installation

coffee-script:
  npm.installed:
    - user: someuser

coffee-script@1.0.1:
  npm.installed: []
```

salt.states.npm.bootstrap(name, user=None, silent=True)

Bootstraps a node.js application.

- **name**
  The package to install

- **user**
  The user to run NPM with

New in version 0.17.0.

salt.states.npm.cache_cleaned(name=None, user=None, force=False)

Ensure that the given package is not cached.

- **name**
  The name of the package to remove from the cache, or None for all packages

- **user**
  The user to run NPM with

- **force**
  Force cleaning of cache. Required for npm@5 and greater

New in version 2016.11.6.

salt.states.npm.installed(name, pkgs=None, dir=None, user=None, force_reinstall=False, registry=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

- **name**
  The package to install

- **pkgs**
  A list of packages to install with a single npm invocation; specifying this argument will ignore the name argument

Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.
New in version 2014.7.0.

dir
The target directory in which to install the package, or None for global installation

user
The user to run NPM with

New in version 0.17.0.

registry
The NPM registry from which to install the package

New in version 2014.7.0.

env
A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.

New in version 2014.7.0.

force_reinstall
Install the package even if it is already installed

call: states.npm

removed(name, dir=None, user=None)

Verify that the given package is not installed.

dir
The target directory in which to install the package, or None for global installation

user
The user to run NPM with

New in version 0.17.0.

25.20.211  salt.states.ntp

Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```yaml
win_ntp:
  ntp.managed:
    - servers:
      - pool.ntp.org
      - us.pool.ntp.org

salt.states.ntp.managed(name, servers=None)

Manage NTP servers

servers
A list of NTP servers
```
25.20.212 salt.states.nxos

State module for Cisco NX-OS Switch Proxy and Native minions

New in version 2016.11.0.

For documentation on setting up the nxos proxy minion look in the documentation for `salt.proxy.nxos`.

```
salt.states.nxos.config_absent(name)
```

Ensure a specific configuration line does not exist in the running config

name

cfg line to remove

Examples:

```
add snmp group:
  nxos.config_absent:
    - names:
      - snmp-server community randoSNMPstringHERE group network-operator
      - snmp-server community AnotherRandomSNMPString group network-admin
```

Note: For certain cases extra lines could be removed based on dependencies. In this example, included after the example for `config_present`, the ACLs would be removed because they depend on the existence of the group.

```
salt.states.nxos.config_present(name)
```

Ensure a specific configuration line exists in the running config

name

cfg line to set

Examples:

```
add snmp group:
  nxos.config_present:
    - names:
      - snmp-server community randoSNMPstringHERE group network-operator
      - snmp-server community AnotherRandomSNMPString group network-admin

add acl:
  nxos.config_present:
    - names:
      - snmp-server community randoSNMPstringHERE use-acl snmp-acl-ro
      - snmp-server community AnotherRandomSNMPString use-acl snmp-acl-rw
```

```
salt.states.nxos.replace(name, repl, full_match=False)
```

Replace all instances of a string or full line in the running config

name

String to replace

repl

The replacement text

full_match

Whether name will match the full line or only a subset of the line. Defaults to False. When False, `.` is added around name for matching in the `show run` config.

Examples:
replace snmp string:
```
xos.replace:
    - name: randoSNMPstringHERE
    - repl: NEWrandoSNMPstringHERE
```

replace full snmp string:
```
xos.replace:
    - name: ^snmp-server community randoSNMPstringHERE group network-operat
er$repl: snmp-server community NEWrandoSNMPstringHERE group network-operat
er
    - full_match: True
```

**Note:** The first example will replace the SNMP string on both the group and the ACL, so you will not lose the ACL setting. Because the second is an exact match of the line, when the group is removed, the ACL is removed, but not readded, because it was not matched.

salt.states.nxos.user_absent(name)
Ensure a user is not present

name
username to remove if it exists

Examples:
```
delete:
    nxos.user_absent:
        - name: daniel
```

salt.states.nxos.user_present(name, password=None, roles=None, encrypted=False, crypt_salt=None, algorithm='sha256')
Ensure a user is present with the specified groups

name
Name of user

password
Encrypted or Plain Text password for user

roles
List of roles the user should be assigned. Any roles not in this list will be removed

encrypted
Whether the password is encrypted already or not. Defaults to False

crypt_salt
Salt to use when encrypting the password. Default is None (salt is randomly generated for unhashed passwords)

algorithm
Algorithm to use for hashing password. Defaults to sha256. Accepts md5, blowfish, sha256, sha512

Examples:
```
create:
    nxos.user_present:
        - name: daniel
        - roles:
            - vdc-admin
```
(continues on next page)
set_password:
  nxos.user_present:
    - name: daniel
    - password: admin
    - roles:
      - network-admin

update:
  nxos.user_present:
    - name: daniel
    - password: AiN9jaoP
    - roles:
      - network-admin
      - vdc-admin

25.20.213 salt.states.nxos_upgrade

Manage NX-OS System Image Upgrades.

New in version 3001.

maturity
  new

platform
  nxos

codeauthor
  Michael G Wiebe

For documentation on setting up the nxos proxy minion look in the documentation for salt.proxy.nxos.

salt.states.nxos_upgrade.image_running(name, system_image, kickstart_image=None, issu=True, **kwargs)

Ensure the NX-OS system image is running on the device.

name
  Name of the salt state task

system_image
  Name of the system image file on bootflash:

kickstart_image
  Name of the kickstart image file on bootflash: This is not needed if the system_image is a combined system and kickstart image Default: None

issu
  Ensure the correct system is running on the device using an in service software upgrade, or force a disruptive upgrade by setting the option to False. Default: False

timeout
  Timeout in seconds for long running 'install all' upgrade command. Default: 900

Examples:

upgrade_software_image_n9k:
  nxos.image_running:
    - name: Ensure nxos.7.0.3.I7.5a.bin is running
    - system_image: nxos.7.0.3.I7.5a.bin
- **issu**: True

**upgrade_software_image_n7k**:
- **nxos.image_running**:
  - **name**: Ensure n7000-s2-kickstart.8.0.1.bin is running
  - **kickstart_image**: n7000-s2-kickstart.8.0.1.bin
  - **system_image**: n7000-s2-dk9.8.0.1.bin
  - **issu**: False

---

### 25.20.214 salt.states.openstack_config

Manage OpenStack configuration file settings.

- **maintainer**: Jeffrey C. Ollie <jeff@ocjtech.us>
- **maturity**: new
- **depends**: platform
- **platform**: linux

**salt.states.openstack_config.absent**(name, filename, section, parameter=None)

Ensure a value is not set in an OpenStack configuration file.

- **filename**: The full path to the configuration file
- **section**: The section in which the parameter will be set
- **parameter (optional)**: The parameter to change. If the parameter is not supplied, the name will be used as the parameter.

**salt.states.openstack_config.present**(name, filename, section, value, parameter=None)

Ensure a value is set in an OpenStack configuration file.

- **filename**: The full path to the configuration file
- **section**: The section in which the parameter will be set
- **parameter (optional)**: The parameter to change. If the parameter is not supplied, the name will be used as the parameter.
- **value**: The value to set

---

### 25.20.215 salt.states.openvswitch_bridge

Management of Open vSwitch bridges.

**salt.states.openvswitch_bridge.absent**(name)

Ensures that the named bridge does not exist, eventually deletes it.

- **Parameters**
  - **name**: The name of the bridge.
salt.states.openvswitch_bridge.present(name, parent=None, vlan=None)

Ensures that the named bridge exists, eventually creates it.

Parameters

- **name** -- string name of the bridge
- **parent** -- string name of the parent bridge (if the bridge shall be created as a fake bridge). If specified, vlan must also be specified.
- **versionadded**: (..) -- 3006.0:
- **vlan** -- int VLAN ID of the bridge (if the bridge shall be created as a fake bridge). If specified, parent must also be specified.
- **versionadded**: -- 3006.0:

25.20.216 salt.states.openvswitch_db module

Management of Open vSwitch database records.
New in version 3006.0.

salt.states.openvswitch_db.managed(name, table, data, record=None)

Ensures that the specified columns of the named record have the specified values.

Parameters

- **name** -- string name of the record
- **table** -- string name of the table to which the record belongs.
- **data** -- dict dictionary containing a mapping from column names to the desired values. Columns that exist, but are not specified in this dictionary are not touched.
- **record** -- string name of the record (optional). Replaces name if specified.

25.20.217 salt.states.openvswitch_port

Management of Open vSwitch ports.

salt.states.openvswitch_port.absent(name, bridge=None)

Ensures that the named port exists on bridge, eventually deletes it. If bridge is not set, port is removed from whatever bridge contains it.

Parameters

- **name** -- The name of the port.
- **bridge** -- The name of the bridge.

salt.states.openvswitch_port.present(name, bridge, tunnel_type=None, id=None, remote=None, dst_port=None, internal=False)

Ensures that the named port exists on bridge, eventually creates it.

Parameters

- **name** -- The name of the port.
- **bridge** -- The name of the bridge.
- **tunnel_type** -- Optional type of interface to create, currently supports: vlan, vxlan and gre.
- **id** -- Optional tunnel's key.
- **remote** -- Remote endpoint's IP address.
- **dst_port** -- Port to use when creating tunnelport in the switch.
- **internal** -- Create an internal port if one does not exist
25.20.218 salt.states.opsgenie

Create/Close an alert in OpsGenie

New in version 2018.3.0.

This state is useful for creating or closing alerts in OpsGenie during state runs.

```
used_space:
  disk.status:
    - name: /
    - maximum: 79%
    - minimum: 20%

opsgenie_create_action_sender:
  opsgenie.create_alert:
    - api_key: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
    - reason: 'Disk capacity is out of designated range.'
    - name: disk.status
    - onfail:
      - disk: used_space

opsgenie_close_action_sender:
  opsgenie.close_alert:
    - api_key: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
    - name: disk.status
    - require:
      - disk: used_space
```

salt.states.opsgenie.close_alert(name=None, api_key=None, reason='Conditions are met.', action_type='Close')

Close an alert in OpsGenie. It's a wrapper function for create_alert. Example usage with Salt's requisites and other global state arguments could be found above.

Required Parameters:
name
  It will be used as alert's alias. If you want to use the close functionality you must provide name field for both states like in above case.

Optional Parameters:
api_key
  It's the API Key you've copied while adding integration in OpsGenie.
reason
  It will be used as alert's default message in OpsGenie.
action_type
  OpsGenie supports the default values Create/Close for action_type. You can customize this field with OpsGenie's custom actions for other purposes like adding notes or acknowledging alerts.

salt.states.opsgenie.create_alert(name=None, api_key=None, reason=None, action_type='Create')

Create an alert in OpsGenie. Example usage with Salt's requisites and other global state arguments could be found above.

Required Parameters:
api_key
  It's the API Key you've copied while adding integration in OpsGenie.
reason
  It will be used as alert's default message in OpsGenie.
Optional Parameters:

**name**

It will be used as alert's alias. If you want to use the close functionality you must provide name field for both states like in above case.

**action_type**

OpsGenie supports the default values Create/Close for action_type. You can customize this field with OpsGenie's custom actions for other purposes like adding notes or acknowledging alerts.

### 25.20.219 salt.states.pagerduty

Create an Event in PagerDuty

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.

```python
server-warning-message:
pagerduty.create_event:
    - name: 'This is a server warning message'
    - details: 'This is a much more detailed message'
    - service_key: 9abcd123456789efabcde362783cdbaf
    - profile: my-pagerduty-account
```

salt.states.pagerduty.create_event(name, details, service_key, profile)

Create an event on the PagerDuty service

The following parameters are required:

**name**

This is a short description of the event.

**details**

This can be a more detailed description of the event.

**service_key**

This key can be found by using pagerduty.list_services.

**profile**

This refers to the configuration profile to use to connect to the PagerDuty service.

### 25.20.220 salt.states.pagerduty_escalation_policy

Manage PagerDuty escalation policies.

Schedules and users can be referenced by pagerduty ID, or by name, or by email address.

For example:

```python
ensure test escalation policy:
pagerduty_escalation_policy.present:
```

(continues on next page)
- **name**: bruce test escalation policy
  - **escalation_rules**:
    - **targets**:
      - **type**: schedule
        - **id**: 'bruce test schedule level1'
      - **type**: user
        - **id**: 'Bruce Sherrod'
        - **escalation_delay_in_minutes**: 15
    - **targets**:
      - **type**: schedule
        - **id**: 'bruce test schedule level2'
        - **escalation_delay_in_minutes**: 15
      - **targets**:
        - **type**: user
          - **id**: 'Bruce TestUser1'
        - **type**: user
          - **id**: 'Bruce TestUser2'
        - **type**: user
          - **id**: 'Bruce TestUser3'
        - **type**: user
          - **id**: 'bruce@test4@lyft.com'
        - **escalation_delay_in_minutes**: 15

.. code-block:: python

    salt.states.pagerduty_escalation_policy.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a PagerDuty escalation policy does not exist. Accepts all the arguments that pager-
duty_escalation_policy.present accepts; but ignores all arguments except the name.

Name can be the escalation policy id or the escalation policy name.

.. code-block:: python

    salt.states.pagerduty_escalation_policy.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty escalation policy exists. Will create or update as needed.

This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/
escalation_policies/create. In addition, user and schedule id's will be translated from name (or email address)
into PagerDuty unique ids. For example:

.. code-block:: yaml

    pagerduty_escalation_policy.present:
      - name: bruce test escalation policy
        - escalation_rules:
          - targets:
            - type: schedule
              id: 'bruce test schedule level1'
            - type: user
              id: 'Bruce Sherrod'
              escalation_delay_in_minutes: 15
            - type: user
              id: 'Bruce TestUser1'
              escalation_delay_in_minutes: 15
            - type: user
              id: 'Bruce TestUser2'
              escalation_delay_in_minutes: 15
            - type: user
              id: 'Bruce TestUser3'
              escalation_delay_in_minutes: 15
            - type: user
              id: 'bruce@test4@lyft.com'
              escalation_delay_in_minutes: 15

In this example, 'Bruce Sherrod' will be looked up and replaced with the PagerDuty id (usually a 7 digit all-caps
string, e.g. PX6GQL7)
25.20.221 salt.states.pagerduty_schedule

Manage PagerDuty schedules.

Example:

```py
ensure test schedule:
    pagerduty_schedule.present:
        - name: 'bruce test schedule level1'
        - schedule:
            name: 'bruce test schedule level1'
            time_zone: 'Pacific Time (US & Canada)'
            schedule_layers:
                - name: 'Schedule Layer 1'
                  start: '2015-01-01T00:00:00'
                  users:
                      - user:
                          id: 'Bruce TestUser1'
                          member_order: 1
                      - user:
                          id: 'Bruce TestUser2'
                          member_order: 2
                      - user:
                          id: 'bruce+test3@lyft.com'
                          member_order: 3
                      - user:
                          id: 'bruce+test4@lyft.com'
                          member_order: 4
            rotation_virtual_start: '2015-01-01T00:00:00'
            priority: 1
            rotation_turn_length_seconds: 604800
```

salt.states.pagerduty_schedule.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule does not exist. Name can be pagerduty schedule id or pagerduty schedule name.

salt.states.pagerduty_schedule.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule exists. This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/schedules/create. This means that most arguments are in a dict called "schedule."

User id's can be pagerduty id, or name, or email address.
25.20.222 salt.states.pagerduty_service

Manage PagerDuty services

Escalation policies can be referenced by pagerduty ID or by namea.

For example:

```python
generic_email_service = {'name': 'my email service', 'service': {'description': 'email service controlled by salt', 'escalation_policy_id': 'my escalation policy', 'type': 'generic_email', 'service_key': 'test-email'}}
```

salt.states.pagerduty_service.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure a pagerduty service does not exist. Name can be the service name or pagerduty service id.

salt.states.pagerduty_service.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty service exists. This method accepts as arguments everything defined in https://developer.pagerduty.com/documentation/rest/services/create

Note that many arguments are mutually exclusive, depending on the "type" argument.

Examples:

```python
# create a PagerDuty email service at test-email@DOMAIN.pagerduty.com
ensure generic email service exists:
    pagerduty_service.present:
        - name: my email service
        - service:
            description: "email service controlled by salt"
            escalation_policy_id: "my escalation policy"
            type: "generic_email"
            service_key: "test-email"

# create a pagerduty service using cloudwatch integration
ensure my cloudwatch service exists:
    pagerduty_service.present:
        - name: my cloudwatch service
        - service:
            escalation_policy_id: "my escalation policy"
            type: aws_cloudwatch
            description: "my cloudwatch service controlled by salt"
```
25.20.223 salt.states.pagerduty_user

Manage PagerDuty users.

Example

ensure bruce test user 1:

   pagerduty.user_present:
       - name: 'Bruce TestUser1'
       - email: bruce+test1@lyft.com
       - requester_id: P1GV5NT

salt.states.pagerduty_user.absent(
    profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty user does not exist. Name can be pagerduty id, email address, or user name.

salt.states.pagerduty_user.present(
    profile='pagerduty', subdomain=None, api_key=None, **kwargs)

25.20.224 salt.states.panos

A state module to manage Palo Alto network devices.

codeauthor
   Spencer Ervin <spencer_ervin@hotmail.com>

maturity
   new

depends
   none

platform
   unix

About

This state module was designed to handle connections to a Palo Alto based firewall. This module relies on the Palo Alto proxy module to interface with the devices.

This state module is designed to give extreme flexibility in the control over XPATH values on the PANOS device. It exposes the core XML API commands and allows state modules to chain complex XPATH commands.

Below is an example of how to construct a security rule and move to the top of the policy. This will take a config lock to prevent execution during the operation, then remove the lock. After the XPATH has been deployed, it will commit to the device.

panos/takelock:
   panos.add_config_lock

panos/service_tcp_22:
(continues on next page)
**Version Specific Configurations**

Palo Alto devices running different versions will have different supported features and different command structures. In order to account for this, the proxy module can be leveraged to check if the panos device is at a specific revision level.

The proxy['panos.is_required_version'] method will check if a panos device is currently running a version equal or greater than the passed version. For example, proxy['panos.is_required_version']('7.0.0') would match both 7.1.0 and 8.0.0.

```python
{% if proxy['panos.is_required_version']('8.0.0') %}
panos/deviceconfig/system/motd-and-banner:
  panos.set_config:
    - xpath: /config/devices/entry[@name='localhost.localdomain']/vsys/
      → entry[@name='vsys1']/deviceconfig/system/motd-and-banner
    - value: |
      <banner-header>BANNER TEXT</banner-header>
      <banner-header-color>color2</banner-header-color>
{% endif %}
```
See also:

**Palo Alto Proxy Module**

salt.states.panos.add_config_lock(name)

Prevent other users from changing configuration until the lock is released.

name: The name of the module function to execute.

SLS Example:

```
panos/takelock:
    panos.add_config_lock
```

salt.states.panos.address_exists(name, addressname=None, vsys=1, ipnetmask=None, iprange=None, fqdn=None, description=None, commit=False)

Ensures that an address object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will only process a single address type (ip-netmask, ip-range, or fqdn). It will process the specified value if the following order: ip-netmask, ip-range, fqdn. For proper execution, only specify a single address type.

name: The name of the module function to execute.

addressname(str): The name of the address object. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

ipnetmask(str): The IPv4 or IPv6 address or IP address range using the format ip_address/mask or ip_address where the mask is the number of significant binary digits used for the network portion of the address. Ideally, for IPv6, you specify only the network portion, not the host portion.

iprange(str): A range of addresses using the format ip_address–ip_address where both addresses can be IPv4 or both can be IPv6.

fqdn(str): A fully qualified domain name format. The FQDN initially resolves at commit time. Entries are subsequently refreshed when the firewall performs a check every 30 minutes; all changes in the IP address for the entries are picked up at the refresh cycle.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/address/h-10.10.10.10:
    panos.address_exists:
        - addressname: h-10.10.10.10
        - vsys: 1
        - ipnetmask: 10.10.10.10
        - commit: False
```
panos/address/10.0.0.1-10.0.0.50:
    panos.address_exists:
        - addressname: r-10.0.0.1-10.0.0.50
        - vsys: 1
        - iprange: 10.0.0.1-10.0.0.50
        - commit: False

panos/address/foo.bar.com:
    panos.address_exists:
        - addressname: foo.bar.com
        - vsys: 1
        - fqdn: foo.bar.com
        - description: My fqdn object
        - commit: False

salt.states.panos.address_group_exists(name, groupname=None, vsys=1, members=None, description=None, commit=False)
Ensures that an address group object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will enforce group membership. If a group exists and contains members this state does not include, those members will be removed and replaced with the specified members in the state.

name: The name of the module function to execute.
groupname(str): The name of the address group object. The name is case-sensitive and can have up to 31 characters, which an be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.
vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.
members(str, list): The members of the address group. These must be valid address objects or address groups on the system that already exist prior to the execution of this state.
description(str): A description for the policy (up to 255 characters).
commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

panos/address-group/my-group:
    panos.address_group_exists:
        - groupname: my-group
        - vsys: 1
        - members:
            - my-address-object
            - my-other-address-group
        - description: A group that needs to exist
        - commit: False

salt.states.panos.clone_config(name, xpath=None, newname=None, commit=False)
Clone a specific XPATH and set it to a new name.

name: The name of the module function to execute.
xpath(str): The XPATH of the configuration API tree to clone.
Salt Documentation, Release 3006.3

rename(str): The new name of the XPATH clone.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/clonerule:
  panos.clone_config:
    - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules&from=/config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules/entry[@name='rule1']
    - value: rule2
    - commit: True
```

salt.states.panos.commit_config(name)

Commits the candidate configuration to the running configuration.

name: The name of the module function to execute.

SLS Example:

```yaml
panos/commit:
  panos.commit_config
```

salt.states.panos.delete_config(name, xpath=None, commit=False)

Deletes a Palo Alto XPATH to a specific value.

Use the xpath parameter to specify the location of the object to be deleted.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/deletegroup:
  panos.delete_config:
    - xpath: /config/devices/entry/vsys/entry[@name='vsys1']/address-group/entry[@name='test']
    - commit: True
```

salt.states.panos.download_software(name, version=None, synch=False, check=False)

Ensures that a software version is downloaded.

name: The name of the module function to execute.

version(str): The software version to check. If this version is not already downloaded, it will attempt to download the file from Palo Alto.

synch(bool): If true, after downloading the file it will be synched to its peer.

check(bool): If true, the PANOS device will first attempt to pull the most recent software inventory list from Palo Alto.

SLS Example:
salt.states.panos.edit_config(name, xpath=None, value=None, commit=False)

Edits a Palo Alto XPATH to a specific value. This will always overwrite the existing value, even if it is not changed.

You can replace an existing object hierarchy at a specified location in the configuration with a new value. Use the xpath parameter to specify the location of the object, including the node to be replaced.

This is the recommended state to enforce configurations on a xpath.

name: The name of the module function to execute.
xpath(str): The XPATH of the configuration API tree to control.
value(str): The XML value to edit. This must be a child to the XPATH.
commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/addressgroup:
  panos.edit_config:
    xpath: /config/devices/entry/vsys/entry[@name='vsys1']/addressgroup/entry[@name='test']
    value: <static><entry name='test'><member>abc</member><member>xyz</member></entry></static>
    commit: True
```

salt.states.panos.move_config(name, xpath=None, where=None, dst=None, commit=False)

Moves a XPATH value to a new location.

Use the xpath parameter to specify the location of the object to be moved, the where parameter to specify type of move, and dst parameter to specify the destination path.

name: The name of the module function to execute.
xpath(str): The XPATH of the configuration API tree to move.
where(str): The type of move to execute. Valid options are after, before, top, bottom. The after and before options will require the dst option to specify the destination of the action. The top action will move the XPATH to the top of its structure. The bottom action will move the XPATH to the bottom of its structure.
dst(str): Optional. Specifies the destination to utilize for a move action. This is ignored for the top or bottom action.
commit(bool): If true the firewall will commit the changes, if false do not commit changes. If the operation is not successful, it will not commit.

SLS Example:

```yaml
panos/moveruletop:
  panos.move_config:
    xpath: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules/entry[@name='rule1']
```

(continues on next page)
- **where**: top
- **commit**: True

**panos/moveruleafter**:  
panos.move_config:  
- **xpath**: /config/devices/entry/vsys/entry[@name='vsys1']/rulebase/security/rules/entry[@name='rule1']  
- **where**: after  
- **dst**: rule2  
- **commit**: True

---

**salt.states.panos.remove_config_lock**(name)

Release config lock previously held.

name: The name of the module function to execute.

SLS Example:

**panos/takelock:**  
panos.remove_config_lock

---

**salt.states.panos.rename_config**(name, xpath=None, newname=None, commit=False)

Rename a Palo Alto XPATH to a specific value. This will always rename the value even if a change is not needed.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

newname(str): The new name of the XPATH value.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

**panos/renamegroup:**  
panos.rename_config:  
- **xpath**: /config/devices/entry/vsys/entry[@name='vsys1']/address/entry[@name='old_address']  
- **value**: new_address  
- **commit**: True

---

**salt.states.panos.security_rule_exists**(name, rulename=None, vsys=1, action=None, disabled=None, sourcezone=None, destinationzone=None, source=None, destination=None, application=None, service=None, description=None, logsetting=None, logstart=None, logend=None, negatesource=None, negatedestination=None, profilegroup=None, datafilter=None, fileblock=None, spyware=None, urlfilter=None, virus=None, vulnerability=None, wildfire=None, move=None, movetarget=None, commit=False)

Ensures that a security rule exists on the device. Also, ensure that all configurations are set appropriately.

This method will create the rule if it does not exist. If the rule does exist, it will ensure that the configurations are set appropriately.
If the rule does not exist and is created, any value that is not provided will be provided as the default. The action, to, from, source, destination, application, and service fields are mandatory and must be provided.

This will enforce the exact match of the rule. For example, if the rule is currently configured with the log-end option, but this option is not specified in the state method, it will be removed and reset to the system default.

It is strongly recommended to specify all options to ensure proper operation.

When defining the profile group settings, the device can only support either a profile group or individual settings. If both are specified, the profile group will be preferred and the individual settings are ignored. If neither are specified, the value will be set to system default of none.

name: The name of the module function to execute.

rulename(str): The name of the security rule. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

action(str): The action that the security rule will enforce. Valid options are: allow, deny, drop, reset-client, reset-server, reset-both.

disabled(bool): Controls if the rule is disabled. Set 'True' to disable and 'False' to enable.

sourcezone(str, list): The source zone(s). The value 'any' will match all zones.

destinationzone(str, list): The destination zone(s). The value 'any' will match all zones.

source(str, list): The source address(es). The value 'any' will match all addresses.

destination(str, list): The destination address(es). The value 'any' will match all addresses.

application(str, list): The application(s) matched. The value 'any' will match all applications.

service(str, list): The service(s) matched. The value 'any' will match all services. The value 'application-default' will match based upon the application defined ports.

description(str): A description for the policy (up to 255 characters).

logsetting(str): The name of a valid log forwarding profile.

logstart(bool): Generates a traffic log entry for the start of a session (disabled by default).

logend(bool): Generates a traffic log entry for the end of a session (enabled by default).

negatesource(bool): Match all but the specified source addresses.

negatedestination(bool): Match all but the specified destination addresses.

profilegroup(str): A valid profile group name.

datafilter(str): A valid data filter profile name. Ignored with the profilegroup option set.

fileblock(str): A valid file blocking profile name. Ignored with the profilegroup option set.

spyware(str): A valid spyware profile name. Ignored with the profilegroup option set.

urlfilter(str): A valid URL filtering profile name. Ignored with the profilegroup option set.

virus(str): A valid virus profile name. Ignored with the profilegroup option set.

vulnerability(str): A valid vulnerability profile name. Ignored with the profilegroup option set.

wildfire(str): A valid vulnerability profile name. Ignored with the profilegroup option set.
move(str): An optional argument that ensure the rule is moved to a specific location. Valid options are 'top', 'bottom', 'before', or 'after'. The 'before' and 'after' options require the use of the 'movetarget' argument to define the location of the move request.

movetarget(str): An optional argument that defines the target of the move operation if the move argument is set to 'before' or 'after'.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```yaml
panos/rulebase/security/rule01:
  panos.security_rule_exists:
    - rulename: rule01
    - vsys: 1
    - action: allow
    - disabled: False
    - sourcezone: untrust
    - destinationzone: trust
    - source:
      - 10.10.10.0/24
      - 1.1.1.1
    - destination:
      - 2.2.2.2-2.2.2.4
    - application:
      - any
    - service:
      - tcp-25
    - description: My test security rule
    - logsetting: logprofile
    - logstart: False
    - logend: True
    - negatesource: False
    - negatedestination: False
    - profilegroup: myprofilegroup
    - move: top
    - commit: False

(continues on next page)
```
description: My test security rule
logsetting: logprofile
logstart: False
logend: False
datafilter: foobar
fileblock: foobar
spyware: foobar
urlfilter: foobar
virus: foobar
vulnerability: foobar
wildfire: foobar
move: after
movetarget: rule02
commit: False

Salt Documentation, Release 3006.3
(continued from previous page)

salt.states.panos.service_exists(name, servicename=None, vsys=1, protocol=None, port=None,
description=None, commit=False)

Ensures that a service object exists in the configured state. If it does not exist or is not configured with the
specified attributes, it will be adjusted to match the specified values.

name: The name of the module function to execute.

servicename(str): The name of the security object. The name is case-sensitive and can have up to 31 characters,
which an be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and,
on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

protocol(str): The protocol that is used by the service object. The only valid options are tcp and udp.

port(str): The port number that is used by the service object. This can be specified as a single integer or a valid
range of ports.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/service/tcp-80:
  panos.service_exists:
    - servicename: tcp-80
    - vsys: 1
    - protocol: tcp
    - port: 80
    - description: Hypertext Transfer Protocol
    - commit: False

panos/service/udp-500-550:
  panos.service_exists:
    - servicename: udp-500-550
    - vsys: 3
    - protocol: udp
    - port: 500-550
    - commit: False
```
salt.states.panos.service_group_exists(name, groupname=None, vsys=1, members=None, description=None, commit=False)

Ensures that a service group object exists in the configured state. If it does not exist or is not configured with the specified attributes, it will be adjusted to match the specified values.

This module will enforce group membership. If a group exists and contains members this state does not include, those members will be removed and replaced with the specified members in the state.

name: The name of the module function to execute.

groupname(str): The name of the service group object. The name is case-sensitive and can have up to 31 characters, which can be letters, numbers, spaces, hyphens, and underscores. The name must be unique on a firewall and, on Panorama, unique within its device group and any ancestor or descendant device groups.

vsys(str): The string representation of the VSYS ID. Defaults to VSYS 1.

members(str, list): The members of the service group. These must be valid service objects or service groups on the system that already exist prior to the execution of this state.

description(str): A description for the policy (up to 255 characters).

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/service-group/my-group:
  panos.service_group_exists:
    - groupname: my-group
    - vsys: 1
    - members:
      - tcp-80
      - custom-port-group
    - description: A group that needs to exist
    - commit: False
```

salt.states.panos.set_config(name, xpath=None, value=None, commit=False)

Sets a Palo Alto XPATH to a specific value. This will always overwrite the existing value, even if it is not changed.

You can add or create a new object at a specified location in the configuration hierarchy. Use the xpath parameter to specify the location of the object in the configuration.

name: The name of the module function to execute.

xpath(str): The XPATH of the configuration API tree to control.

value(str): The XML value to set. This must be a child to the XPATH.

commit(bool): If true the firewall will commit the changes, if false do not commit changes.

SLS Example:

```
panos/hostname:
  panos.set_config:
    - xpath: /config/devices/entry[@name='localhost.localdomain']/deviceconfig/system
    - value: <hostname>foobar</hostname>
    - commit: True
```
25.20.225 salt.states.pbm

Manages VMware storage policies (called pbm because the vCenter endpoint is /pbm)

Examples

Storage policy

```json
{
    "name": "salt_storage_policy",
    "description": "Managed by Salt. Random capability values.",
    "resource_type": "STORAGE",

```

### Dependencies

- pyVmomi Python Module

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 <https://github.com/saltstack/salt/issues/29537> for more information.

**salt.states.pbm**

- `default_storage_policy_assigned(name, policy, datastore)`
  Assigns a default storage policy to a datastore
  
  **policy**
  Name of storage policy

  **datastore**
  Name of datastore

- `default_vsan_policy_configured(name, policy)`
  Configures the default VSAN policy on a vCenter. The state assumes there is only one default VSAN policy on a vCenter.

  **policy**
  Dict representation of a policy

- `storage_policies_configured(name, policies)`
  Configures storage policies on a vCenter.

  **policies**
  List of dict representation of the required storage policies
25.20.226  salt.states.pcs

Management of Pacemaker/Corosync clusters with PCS

A state module to manage Pacemaker/Corosync clusters with the Pacemaker/Corosync configuration system (PCS)
New in version 2016.11.0.

    depends
    pcs

Requirements:
    PCS is installed, pcs service is started and the password for the hacluster user is set and known.

Remark on the cibname variable used in the examples:
    The use of the cibname variable is optional. Use it only if you want to deploy your changes into a cibfile first and then push it. This makes only sense if you want to deploy multiple changes (which require each other) at once to the cluster.

At first the cibfile must be created:

    mysql_pcs__cib_present_cib_for_galera:
    pcs.cib_present:
      - cibname: cib_for_galera
      - scope: None
      - extra_args: None

Then the cibfile can be modified by creating resources (creating only 1 resource for demonstration, see also 7):

    mysql_pcs__resource_present_galera:
    pcs.resource_present:
      - resource_id: galera
      - resource_type: "ocf:heartbeat:galera"
      - resource_options:
          - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
          - '--master'
      - cibname: cib_for_galera

After modifying the cibfile, it can be pushed to the live CIB in the cluster:

    mysql_pcs__cib_pushed_cib_for_galera:
    pcs.cib_pushed:
      - cibname: cib_for_galera
      - scope: None
      - extra_args: None

Create a cluster from scratch:

    1. This authorizes nodes to each other. It probably won't work with Ubuntu as it rolls out a default cluster that needs to be destroyed before the new cluster can be created. This is a little complicated so it's best to just run the cluster_setup below in most cases.
2. Do the initial cluster setup:

```yaml
pcs_setup__setup:
  pcs.cluster_setup:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsclustername: pcscluster
    - extra_args:
      - '--start'
      - '--enable'
    - pcsuser: hacluster
    - pcspasswd: hoonetorg
```

3. Optional: Set cluster properties:

```yaml
pcs_properties__prop_has_value_no-quorum-policy:
  pcs.prop_has_value:
    - prop: no-quorum-policy
    - value: ignore
    - cibname: cib_for_cluster_settings
```

4. Optional: Set resource defaults:

```yaml
pcs_properties__resource_defaults_to_resource-stickiness:
  pcs.resource_defaults_to:
    - default: resource-stickiness
    - value: 100
    - cibname: cib_for_cluster_settings
```

5. Optional: Set resource op defaults:

```yaml
pcs_properties__resource_op_defaults_to_monitor-interval:
  pcs.resource_op_defaults_to:
    - op_default: monitor-interval
    - value: 60s
    - cibname: cib_for_cluster_settings
```

6. Configure Fencing (!is often not optional on production ready cluster!):

```yaml
pcs_stonith__created_eps_fence:
  pcs.stonith_present:
    - stonith_id: eps_fence
    - stonith_device_type: fence_eps
    - stonith_device_options:
      - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
```

(continues on next page)
7. Add resources to your cluster:

```yaml
mysql_pcs__resource_present_galera:
  pcs.resource_present:
    - resource_id: galera
    - resource_type: "ocf:heartbeat:galera"
    - resource_options:
      - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
      - '--master'
    - cibname: cib_for_galera
```

8. Optional: Add constraints (locations, colocations, orders):

```yaml
haproxy_pcs__constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
  pcs.constraint_present:
    - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
    - constraint_type: colocation
    - constraint_options:
      - 'add'
      - 'vip_galera'
      - 'with'
      - 'haproxy-clone'
    - cibname: cib_for_haproxy
```

New in version 2016.3.0.

`salt.states.pcs.auth(name, nodes, pcsuser='hacluster', pcspasswd='hacluster', extra_args=None)`

Ensure all nodes are authorized to the cluster

- name: Irrelevant, not used (recommended: pcs_auth__auth)
- nodes: a list of nodes which should be authorized to the cluster
- pcsuser: user for communication with pcs (default: hacluster)
- pcspasswd: password for pcsuser (default: hacluster)
- extra_args: list of extra args for the 'pcs cluster auth' command, there are none so it's here for compatibility.

Example:

```yaml
pcs_auth__auth:
  pcs.auth:
    - nodes:
```

(continues on next page)
- node1.example.com
- node2.example.com
- pcsuser: hacluster
- pcspasswd: hoonetorg
- extra_args: []

```
salt.states.pcs.cib_present(name, cibname, scope=None, extra_args=None)
```

Ensure that a CIB-file with the content of the current live CIB is created

Should be run on one cluster node only (there may be races)

name
Irrelevant, not used (recommended: {{formulaname}}__cib_present_{{cibname}})
cibname
name/path of the file containing the CIB
scope
specific section of the CIB (default: None)
extra_args
additional options for creating the CIB-file

Example:
```
mysql_pcs__cib_present_cib_for_galera:
  pcs.cib_present:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

```
salt.states.pcs.cib_pushed(name, cibname, scope=None, extra_args=None)
```

Ensure that a CIB-file is pushed if it is changed since the creation of it with pcs.cib_present

Should be run on one cluster node only (there may be races)

name
Irrelevant, not used (recommended: {{formulaname}}__cib_pushed_{{cibname}})
cibname
name/path of the file containing the CIB
scope
specific section of the CIB
extra_args
additional options for creating the CIB-file

Example:
```
mysql_pcs__cib_pushed_cib_for_galera:
  pcs.cib_pushed:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

```
salt.states.pcs.cluster_node_present(name, node, extra_args=None)
```

Add a node to the Pacemaker cluster via PCS
Should be run on one cluster node only (there may be races)
Can only be run on a already setup/added node

name
Irrelevant, not used (recommended: pcs_setup__node_add_{{node}})
node
node that should be added
extra_args
list of extra args for the 'pcs cluster node add' command

Example:

```python
cpcs_setup__node_add_node1.example.com:
  pcs.cluster_node_present:
    - node: node1.example.com
    - extra_args:
      - '--start'
      - '--enable'
```

salt.states.pcs.cluster_setup(name, nodes, pcsclustername='pcscluster', extra_args=None, pcsuser='hacluster', pcspasswd='hacluster', pcs_auth_extra_args=None, wipe_default=False)

Setup Pacemaker cluster on nodes. Should be run on one cluster node only to avoid race conditions. This performs auth as well as setup so can be run in place of the auth state. It is recommended not to run auth on Debian/Ubuntu for a new cluster and just to run this because of the initial cluster config that is installed on Ubuntu/Debian by default.

name
Irrelevant, not used (recommended: pcs_setup__setup)

nodes
a list of nodes which should be set up

pcsclustername
Name of the Pacemaker cluster

extra_args
list of extra args for the 'pcs cluster setup' command

pcsuser
The username for authenticating the cluster (default: hacluster)

pcspasswd
The password for authenticating the cluster (default: hacluster)

pcs_auth_extra_args
Extra args to be passed to the auth function in case of reauth.

wipe_default
This removes the files that are installed with Debian based operating systems.

Example:

```python
cpcs_setup__setup:
  pcs.cluster_setup:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsclustername: pcscluster
    - extra_args:
      - '--start'
      - '--enable'
    - pcsuser: hacluster
    - pcspasswd: hoonetorg
```

salt.states.pcs.constraint_present(name, constraint_id, constraint_type, constraint_options=None, cibname=None)

Ensure that a constraint is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync
name
   Irrelevant, not used (recommended: {{formulaname}}__constraint_present_{{constraint_id}})
constraint_id
   name for the constraint (try first to create manually to find out the autocreated name)
constraint_type
   constraint type (location, colocation, order)
constraint_options
   options for creating the constraint
cibname
   use a cached CIB-file named like cibname instead of the live CIB
Example:

```
 haproxy_pcs__constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
   pcs.constraint_present:
      - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
      - constraint_type: colocation
      - constraint_options:
         - 'add'
         - 'vip_galera'
         - 'with'
         - 'haproxy-clone'
      - cibname: cib_for_haproxy
```

salt.states.pcs.prop_has_value(name, prop, value, extra_args=None, cibname=None)
Ensure that a property in the cluster is set to a given value
Should be run on one cluster node only (there may be races)
name
   Irrelevant, not used (recommended: pcs_properties__prop_has_value_{{prop}})
prop
   name of the property
value
   value of the property
extra_args
   additional options for the pcs property command
cibname
   use a cached CIB-file named like cibname instead of the live CIB
Example:

```
 pcs_properties__prop_has_value_no-quorum-policy:
   pcs.prop_has_value:
      - prop: no-quorum-policy
      - value: ignore
      - cibname: cib_for_cluster_settings
```

salt.states.pcs.resource_defaults_to(name, default, value, extra_args=None, cibname=None)
Ensure a resource default in the cluster is set to a given value
Should be run on one cluster node only (there may be races) Can only be run on a node with a functional
pacemaker/corosync
name
   Irrelevant, not used (recommended: pcs_properties__resource_defaults_to_{{default}})
default
   name of the default resource property
value
value of the default resource property
default
additional options for the pcs command
cibname
use a cached CIB-file named like cibname instead of the live CIB
Example:

```plaintext
pcs_properties__resource_defaults_to_resource-stickiness:
    pcs.resource_defaults_to:
        - default: resource-stickiness
        - value: 100
        - cibname: cib_for_cluster_settings
```

salt.states.pcs.resource_op_defaults_to(name, op_default, value, extra_args=None, cibname=None)

Ensure a resource operation default in the cluster is set to a given value

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

default
name
Irrelevant, not used (recommended: pcs_properties__resource_op_defaults_to_{{op_default}})
op_default
name of the operation default resource property
value
value of the operation default resource property
extra_args
additional options for the pcs command
cibname
use a cached CIB-file named like cibname instead of the live CIB
Example:

```plaintext
pcs_properties__resource_op_defaults_to_monitor-interval:
    pcs.resource_op_defaults_to:
        - op_default: monitor-interval
        - value: 60s
        - cibname: cib_for_cluster_settings
```

salt.states.pcs.resource_present(name, resource_id, resource_type, resource_options=None, cibname=None)

Ensure that a resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

name
Irrelevant, not used (recommended: {{formulaname}}__resource_present_{{resource_id}})
resource_id
name for the resource
resource_type
resource type (f.e. ocf:heartbeat:IPaddr2 or VirtualIP)
resource_options
additional options for creating the resource
cibname
use a cached CIB-file named like cibname instead of the live CIB
Example:
**mysql_pcs__resource_present_galera**:
```
pcs.resource_present:
- resource_id: galera
- resource_type: "ocf:heartbeat:galera"
- resource_options:
  - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
  - '--master'
- cibname: cib_for_galera
```

**salt.states.pcs.stonith_present** *(name, stonith_id, stonith_device_type, stonith_device_options=\None, cibname=\None)*

Ensure that a fencing resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

- **name**
  Irrelevant, not used (recommended: pcs_stonith__created_\{\{stonith_id\}\})

- **stonith_id**
  name for the stonith resource

- **stonith_device_type**
  name of the stonith agent fence_eps, fence_xvm f.e.

- **stonith_device_options**
  additional options for creating the stonith resource

- **cibname**
  use a cached CIB-file named like cibname instead of the live CIB

Example:
```
pcs_stonith__created_eps_fence:
pcs.stonith_present:
- stonith_id: eps_fence
- stonith_device_type: fence_eps
- stonith_device_options:
  - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
  - 'ipaddr=myepsdevice.example.org'
  - 'power_wait=5'
  - 'verbose=1'
  - 'debug=/var/log/pcsd/eps_fence.log'
  - 'login=hidden'
  - 'passwd=hoonetorg'
- cibname: cib_for_stonith
```

---

**25.20.227 salt.states.pdbedit**

Manage accounts in Samba's passdb using pdbedit

- **maintainer**
  Jorge Schrauwen <sjorge@blackdot.be>

- **maturity**
  new

- **depends**
  pdbedit
platform
posix

New in version 2017.7.0.

**wash:**
```python
pdbedit.absent
```

**kaylee:**
```python
pdbedit.managed:
- password: A70C708517B5DD0EDB67714FE25336EB
- password_hashed: True
- drive: 'X:'
- homedir: '\\serenity\mechanic\profile'
```

salt.states.pdbedit.absent(name)
Ensure user account is absent
name
[string] username

salt.states.pdbedit.managed(name, **kwargs)
Manage user account
login
[string] login name
password
[string] password
password_hashed
[boolean] set if password is a nt hash instead of plain text
domain
[string] users domain
profile
[string] profile path
script
[string] logon script
drive
[string] home drive
homedir
[string] home directory
fullname
[string] full name
account_desc
[string] account description
machine_sid
[string] specify the machines new primary group SID or rid
user_sid
[string] specify the users new primary group SID or rid
account_control
[string] specify user account control properties

Note: Only the following can be set: - N: No password required - D: Account disabled - H: Home directory required - L: Automatic Locking - X: Password does not expire

reset_login_hours
[boolean] reset the users allowed logon hours
reset_bad_password_count
[boolean] reset the stored bad login counter
salt.states.pdbedit.present(name, **kwargs)
 Alias for pdbedit.managed

25.20.228 salt.states.pecl
Installation of PHP Extensions Using pecl
These states manage the installed pecl extensions. Note that php-pear must be installed for these states to be available, so pecl states should include a requisite to a pkg.installed state for the package which provides pecl (php-pear in most cases). Example:

```
php-pear:
  pkg.installed

mongo:
  pecl.installed:
    - require:
      - pkg: php-pear
```

salt.states.pecl.installed(name, version=None, defaults=False, force=False, preferred_state='stable')
New in version 0.17.0.
Make sure that a pecl extension is installed.
name
The pecl extension name to install
version
The pecl extension version to install. This option may be ignored to install the latest stable version.
defaults
Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.
force
Whether to force the installed version or not
preferred_state
The pecl extension state to install
salt.states.pecl.removed(name)
Make sure that a pecl extension is not installed.
name
The pecl extension name to uninstall

25.20.229 salt.states.pip_state
Installation of Python Packages Using pip
These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a pkg.installed state for the package which provides pip (python-pip in most cases). Example:
python-pip:
  pkg.installed

virtualenvwrapper:
  pip.installed:
    - require:
      - pkg: python-pip

salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=False, proxy=None, timeout=None, repo=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, install_options=None, global_options=None, cwd=None, pre_releases=False, cert=None, allow_all_external=False, allow_external=None, allow_unverified=False, process_dependency_links=False, env_vars=None, use_vt=False, trusted_host=None, no_cache_dir=False, cache_dir=None, no_binary=False, extra_args=None, **kwargs)

Make sure the package is installed

name
The name of the python package to install. You can also specify version numbers here using the standard operators ==, >=, <=. If requirements or pkgs is given, this parameter will be ignored.

Example:

django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
      - pkg: python-pip

Installs the latest Django version greater than 1.6 but less than 1.7.

pkgs
A list of python packages to install. This let you install multiple packages at the same time.

Example:

django-and-psycopg2:
  pip.installed:
    - pkgs:
      - django >= 1.6, <= 1.7
      - psycopg2 >= 2.8.4
    - require:
      - pkg: python-pip

Installs the latest Django version greater than 1.6 but less than 1.7 and the latest psycopg2 greater than 2.8.4 at the same time.

requirements
Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.
user
    The user under which to run pip
use_wheel
    [False] Prefer wheel archives (requires pip>=1.4)
no_use_wheel
    [False] Force to not use wheel archives (requires pip>=1.4)
no_binary
    Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages,
    :none: to empty the set, or a list of one or more packages

Example:

```
django:
    pip.installed:  
    - no_binary: ':all:'

flask:
    pip.installed:  
    - no_binary: 
        - itsdangerous
        - click
```

log
    Log file where a complete (maximum verbosity) record will be kept
proxy
    Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional
    and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then
    you will be prompted for a password.

timeout
    Set the socket timeout (default 15 seconds)
editable
    install something editable (i.e. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)
find_links
    URL to look for packages at
index_url
    Base URL of Python Package Index
extra_index_url
    Extra URLs of package indexes to use in addition to index_url
no_index
    Ignore package index
mirrors
    Specific mirror URL(s) to query (automatically adds --use-mirrors)
build
    Unpack packages into build dir
target
    Install packages into target dir
download
    Download packages into download instead of installing them
download_cache
    Cache downloaded packages in download_cache dir
source
    Check out editable packages into source dir
upgrade
    Upgrade all packages to the newest available version
force_reinstall
When upgrading, reinstall all packages even if they are already up-to-date.

**ignore_installed**
Ignore the installed packages (reinstalling instead)

**exists_action**
Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

**no_deps**
Ignore package dependencies

**no_install**
Download and unpack all packages, but don't actually install them

**no_cache_dir:**
Disable the cache.

**cwd**
Current working directory to run pip from

**pre_releases**
Include pre-releases in the available versions

**cert**
Provide a path to an alternate CA bundle

**allow_all_external**
Allow the installation of all externally hosted files

**allow_external**
Allow the installation of externally hosted files (comma separated list)

**allow_unverified**
Allow the installation of insecure and unverifiable files (comma separated list)

**process_dependency_links**
Enable the processing of dependency links

**env_vars**
Add or modify environment variables. Useful for tweaking build steps, such as specifying INCLUDE or LIBRARY paths in Makefiles, build scripts or compiler calls. This must be in the form of a dictionary or a mapping.

Example:

```yaml
django:
  pip.installed:
    - name: django_app
    - env_vars:
      CUSTOM_PATH: /opt/django_app
      VERBOISE: True
```

**use_vt**
Use VT terminal emulation (see output while installing)

**trusted_host**
Mark this host as trusted, even though it does not have valid or any HTTPS.

**bin_env**
[None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at /foo/.virtualenvs/bar.

Example:

```yaml
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar
    - require:
      - pkg: python-pip
```
Or

Example:

```python
django:
pip.installed:
  - name: django >= 1.6, <= 1.7
  - bin_env: /foo/.virtualenvs/bar/bin/pip
  - require:
    - pkg: python-pip
```

**Attention**

The following arguments are deprecated, do not use.

**pip_bin**

[None] Deprecated, use `bin_env`

Changed in version 0.17.0: `use_wheel` option added.

**install_options**

Extra arguments to be supplied to the setup.py install command. If you are using an option with a directory path, be sure to use absolute path.

Example:

```python
django:
pip.installed:
  - name: django
  - install_options:
    - --prefix=/blah
  - require:
    - pkg: python-pip
```

**global_options**

Extra global options to be supplied to the setup.py call before the install command.

New in version 2014.1.3.

**Attention**

As of Salt 0.17.0 the pip state needs an importable pip module. This usually means having the system's pip package installed or running Salt from an active virtualenv.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements. It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip library. It's functionality duplication and it's more error prone.

**Attention**

Please set `reload_modules: True` to have the salt minion import this module after installation.

Example:
PyOpenSSL:

```yaml
pyopenssl:
  pip.installed:
    - name: pyOpenSSL
    - reload_modules: True
    - exists_action: i
```

**extra_args**

Pip keyword and positional arguments not yet implemented in Salt

Pandas:

```yaml
pandas:
  pip.installed:
    - name: pandas
    - extra_args:
        - --latest-pip-kwarg: param
        - --latest-pip-arg
```

**Warning:** If unsupported options are passed here that are not supported in a minion's version of pip, a *No such option error* will be thrown.

If you are using onedir packages and you need to install python packages into the system python environment, you must provide the `pip_bin` or `bin_env` to the `pip state` module.

```yaml
lib-foo:
  pip.installed:
    - pip_bin: /usr/bin/pip3

lib-bar:
  pip.installed:
    - bin_env: /usr/bin/python3
```

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>salt.states.pip_state.pip_has_exceptions_mod(ver)</code></td>
<td>True when the pip version has the <code>pip.exceptions</code> module</td>
</tr>
<tr>
<td><code>salt.states.pip_state.pip_has_internal_exceptions_mod(ver)</code></td>
<td>True when the pip version has the <code>pip._internal.exceptions</code> module</td>
</tr>
<tr>
<td><code>salt.states.pip_state.purge_pip()</code></td>
<td>Purge pip and its sub-modules</td>
</tr>
<tr>
<td><code>salt.states.pip_state.removed(name, requirements= None, bin_env= None, log= None, proxy= None, timeout= None, user= None, cwd= None, use_vt= False)</code></td>
<td>Make sure that a package is not installed.</td>
</tr>
<tr>
<td><code>salt.states.pip_state.uptodate(name, bin_env= None, user= None, cwd= None, use_vt= False)</code></td>
<td>New in version 2015.5.0.</td>
</tr>
</tbody>
</table>
Verify that the system is completely up to date.

**name**
The name has no functional value and is only used as a tracking reference

**user**
The user under which to run pip

**bin_env**
the pip executable or virtualenv to use

**use_vt**
Use VT terminal emulation (see output while installing)

## 25.20.230 salt.states.pkg

Installation of packages using OS package managers such as yum or apt-get

**Note:** On minions running systemd>=205, as of version 2015.8.12, 2016.3.3, and 2016.11.0, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing the package manager commands spawned by Salt, when Salt updates itself (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.use_scope`, with a value of `False` (no quotes).

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

```
**vim**:
  pkg.installed
```

A more involved example involves pulling from a custom repository.

```
**base**:
  pkgrepo.managed:
    - name: ppa:wolfnet/logstash
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com

**logstash**:
  pkg.installed:
    - fromrepo: ppa:wolfnet/logstash
```

Multiple packages can also be installed with the use of the pkgs state module.

```
**dotdeb.repo**:
  pkgrepo.managed:
    - name: deb http://packages.dotdeb.org wheezy-php55 all
    - dist: wheezy-php55
    - file: /etc/apt/sources.list.d/dotdeb.list
    - keyid: 89DF5277
    - keyserver: keys.gnupg.net
    - refresh_db: true
```

(continues on next page)
**php.packages:**
- **pkg.installed:**
  - **fromrepo:** wheezy-php55
  - **pkgs:**
    - php5-fpm
    - php5-cli
    - php5-curl

**Warning:** Make sure the package name has the correct case for package managers which are case-sensitive (such as pkgng).

salt.states.pkg.downloaded(*name*, *version=None*, *pkgs=None*, *fromrepo=None*, *ignore_epoch=None*, **kwargs)

New in version 2017.7.0.

Ensure that the package is downloaded, and that it is the correct version (if specified).

**Note:** Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like saltenv, or reload_modules, will be passed through to the call to pkg.install to download the package(s). For example, you can include a disablerepo argument on platforms that use yum/dnf to disable that repo:

```python
dpkg:
  pkg.downloaded:
    - disablerepo: base,updates
```

To see what is supported, check [this page](https://docs.saltstack.com) to find the documentation for your platform's pkg module, then look at the documentation for the install function.

Any argument that is passed through to the install function, which is not defined for that function, will be silently ignored.

Currently supported for the following pkg providers: **yum, zypper** and **apt**

**Parameters**

- **name** (*str*) -- The name of the package to be downloaded. This parameter is ignored if either "pkgs" is used. Additionally, please note that this option can only be used to download packages from a software repository.
- **version** (*str*) -- Download a specific version of a package.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon must have the epoch included when specifying the version number. For example:

```python
dvim-enhanced:
  pkg.downloaded:
    - version: 2:7.4.160-1.el7
```

An ignore_epoch argument has been added to which causes the epoch to be disregarded when the state checks to see if the desired version was installed.
You can install a specific version when using the `pkgs` argument by including the version after the package:

```yaml
common_packages:
  pkg.downloaded:
    - pkgs:
        - unzip
        - dos2unix
        - salt-minion: 2015.8.5-1.el6
```

- `resolve_capabilities (bool)`— Turn on resolving capabilities. This allows one to name "provides" or alias names for packages.

  New in version 2018.3.0.

CLI Example:

```zsh
zsh:
pkg.downloaded:
  - version: 5.0.5-4.63
  - fromrepo: "myrepository"
```

`salt.states.pkg.group_installed(name, skip=None, include=None, **kwargs)`

New in version 2015.8.0.

Changed in version 2016.11.0: Added support in `pacman`

Ensure that an entire package group is installed. This state is currently only supported for the `yum` and `pacman` package managers.

- `skip`— Packages that would normally be installed by the package group ("default" packages), which should not be installed.

  ```yaml
  Load Balancer:
  pkg.group_installed:
    - skip:
      - piranha
  ```

- `include`— Packages which are included in a group which would not normally be installed by a `yum` `groupinstall` ("optional" packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed.

  ```yaml
  Load Balancer:
  pkg.group_installed:
    - include:
      - haproxy
  ```

Changed in version 2016.3.0: This option can no longer be passed as a comma-separated list, it must now be passed as a list (as shown in the above example).

**Note:** Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed on to the call to `pkg.install`.

`salt.states.pkg.held(name, version=None, pkgs=None, replace=False, **kwargs)`

New in version 3005.
Set package in 'hold' state, meaning it will not be changed.

Parameters
  - **name** *(str)* -- The name of the package to be held. This parameter is ignored if **pkgs** is used.
  - **version** *(str)* -- Hold a specific version of a package. Full description of this parameter is in *installed* function.

Note: This parameter make sense for Zypper-based systems. Ignored for YUM/DNF and APT

  - **pkgs** *(list)* -- A list of packages to be held. All packages listed under **pkgs** will be held.

```
myPKGS:
  pkg.held:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
```

Note: For Zypper-based systems the package could be held for the version specified. YUM/DNF and APT ignore it.

  - **replace** *(bool)* -- Force replacement of existings holds with specified. By default, this parameter is set to False.

salt.states.pkg.*installed* *(name, version=None, refresh=None, fromrepo=None, skip_verify=False, skip_suggestions=False, pkgs=None, sources=None, allow_updates=False, pkg_verify=False, normalize=True, ignore_epoch=None, reinstall=False, update_holds=False, **kwargs)*

Changed in version 3007.0.

Ensure that the package is installed, and that it is the correct version (if specified).

Note: Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like *saltenv*, or *reload_modules*, will be passed through to the call to *pkg.install* to install the package(s). For example, you can include a *disablerepo* argument on platforms that use yum/dnf to disable that repo:

```
myPKG:
  pkg.installed:
    - disablerepo: base,updates
```

To see what is supported, check this page to find the documentation for your platform's *pkg* module, then look at the documentation for the *install* function.

Any argument that is passed through to the *install* function, which is not defined for that function, will be silently ignored.

Note: In Windows, some packages are installed using the task manager. The Salt minion installer does this. In that case, there is no way to know if the package installs correctly. All that can be reported is that the task
that launches the installer started successfully.

Parameters

- **name (str)** -- The name of the package to be installed. This parameter is ignored if either "pkgs" or "sources" is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the "sources" option detailed below.

- **version (str)** -- Install a specific version of a package. This option is ignored if "sources" is used. Currently, this option is supported for the following pkg providers: apt, ebuild, pacman, pkgin, win_pkg, yum, and zypper. The version number includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the pkg.latest_version function for an uninstalled package will tell you the version available.

```
# salt myminion pkg.latest_version vim-enhanced
myminion:
    2:7.4.160-1.el7
```

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the pkg.latest_version output above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
    pkg.installed:
        - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed, pkg.removed, and pkg.purged states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed.

Also, while this function is not yet implemented for all pkg frontends, pkg.list_repo_pkgs will show all versions available in the various repositories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs bash
myminion:
    ---------
    bash:
        - 4.2.46-21.el7_3
        - 4.2.46-20.el7_2
```

This function was first added for pkg.list_repo_pkgs in 2014.1.0, and was expanded to Debian/Ubuntu and Arch Linux-based distros in the 2017.7.0 release.

The version strings returned by either of these functions can be used as version specifiers in pkg states.

You can install a specific version when using the pkgs argument by including the version after the package:

```
common_packages:
    pkg.installed:
```

(continues on next page)
- pkgs:
  - unzip
  - dos2unix
  - **salt-minion**: 2015.8.5-1.el6

If the version given is the string `latest`, the latest available package version will be installed à la `pkg.latest`.

**WILDCARD VERSIONS**

As of the 2017.7.0 release, this state now supports wildcards in package versions for SUSE SLES/Leap/Tumbleweed, Debian/Ubuntu, RHEL/CentOS, Arch Linux, and their derivatives. Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like `1.2.34-5.el7`. An example of the usage for this would be:

```ini
mypkg:
  pkg.installed:
    - version: '1.2.34*'
```

Keep in mind that using wildcard versions will result in a slower state run since Salt must gather the available versions of the specified packages and figure out which of them match the specified wildcard expression.

- **refresh** *(bool)* -- This parameter controls whether or not the package repo database is updated prior to installing the requested package(s).

  If **True**, the package database will be refreshed (`apt-get update` or equivalent, depending on platform) before installing.

  If **False**, the package database will *not* be refreshed before installing.

  If unset, then Salt treats package database refreshes differently depending on whether or not a `pkg` state has been executed already during the current Salt run. Once a refresh has been performed in a `pkg` state, for the remainder of that Salt run no other refreshes will be performed for `pkg` states which do not explicitly set `refresh` to `True`. This prevents needless additional refreshes from slowing down the Salt run.

- **cache_valid_time** *(str)* -- New in version 2016.11.0.

  This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the `refresh` parameter’s default behavior.

  Example:

```ini
httpd:
  pkg.installed:
    - fromrepo: mycustomrepo
    - skip_verify: True
    - skip_suggestions: True
    - version: 2.0.6~ubuntu3
    - refresh: True
    - cache_valid_time: 300
    - allow_updates: True
    - hold: False
```

In this case, a refresh will not take place for 5 minutes since the last `apt-get update` was executed on the system.
Note: This parameter is available only on Debian based distributions and has no effect on the rest.

- **fromrepo** (*str*) -- Specify a repository from which to install

  Note: Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

  ```
  deb http://ppa.launchpad.net/saltstack/salt/ubuntu
  → precise main
  ```

  The packages provided by this source would be made available via the precise release, therefore `fromrepo` would need to be set to `precise` for Salt to install the package from this source.

  Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the `version` parameter.

  If the `pkgs` parameter is being used to install multiple packages in the same state, then instead of using `version`, use the method of version specification described in the **Multiple Package Installation Options** section below.

  Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:

  ```
  root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policy ffmpeg'
  ubuntu01:
    ffmpeg:
      Installed: (none)
      Candidate: 7:0.10.11-1-precise1
      Version table:
      7:0.10.11-1-precise1  0
      → 500 http://ppa.launchpad.net/jon-severinsson/ffmpeg/ubuntu/precise/main amd64 Packages
      → ffmpeg/ubuntu/ precise/main amd64 Packages
      4:0.8.10-0ubuntu0.12.04.1  0
      → 500 http://us.archive.ubuntu.com/ubuntu/precise-updates/main amd64 Packages
      → precise-updates/main amd64 Packages
      → precise-security/main amd64 Packages
      4:0.8.1-0ubuntu1  0
      → 500 http://security.ubuntu.com/ubuntu/precise/main amd64 Packages
      → precise/main amd64 Packages
  ```

  The release is located directly after the source's URL. The actual release name is the part before the slash, so to install version `4:0.8.10-0ubuntu0.12.04.1` either `precise-updates` or `precise-security` could be used for the `fromrepo` value.

- **skip_verify** (*bool*) -- Skip the GPG verification check for the package to be installed
• **skip_suggestions** *(bool)* -- Force strict package naming. Disables lookup of package alternatives.

New in version 2014.1.1.

• **resolve_capabilities** *(bool)* -- Turn on resolving capabilities. This allow one to name “provides” or alias names for packages.

New in version 2018.3.0.

• **allow_updates** *(bool)* -- Allow the package to be updated outside Salt's control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a reinstallation of the package.

New in version 2014.7.0.

Example:

```sh
httpd:
    pkg.installed:
        fromrepo: mycustomrepo
        skip_verify: True
        skip_suggestions: True
        version: 2.0.6~ubuntu3
        refresh: True
        allow_updates: True
        hold: False
```

• **pkg_verify** *(bool)* -- New in version 2014.7.0.

Use pkg.verify to check if already installed packages require reinstallation. Requested packages that are already installed and not targeted for up- or downgrade are verified with pkg.verify to determine if any file installed by the package have been modified or if package dependencies are not fulfilled. `ignore_types` and `verify_options` can be passed to pkg.verify. See examples below. Currently, this option is supported for the following pkg providers: *yum, zypperpkg*.

Examples:

```sh
httpd:
    pkg.installed:
        version: 2.2.15-30.el6.centos
        pkg_verify: True

mypkgs:
    pkg.installed:
        pkgs:
            foo
            bar: 1.2.3-4
            baz
        pkg_verify:
            ignore_types:
                config
doc

mypkgs:
    pkg.installed:
```

(continues on next page)
pkgs:
- foo
- bar: 1.2.3-4
- baz
pkg_verify:
- ignore_types:
  - config
  - doc
- verify_options:
  - nodeps
  - nofileddigest

ignore_types (list) -- List of types to ignore when verifying the package

New in version 2014.7.0.

verify_options (list) -- List of additional options to pass when verifying the package. These options will be added to the rpm -V command, prepended with -- (for example, when nodeps is passed in this option, rpm -V will be run with --nodeps).

New in version 2016.11.0.

normalize (bool) -- Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2014.7.0.

Example:

gpfs.gplbin-2.6.32-279.31.1.el6.x86_64:
  pkg.installed:
    - normalize: False

ignore_epoch (bool) -- If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to True to explicitly ignore the epoch, and False to strictly enforce it.

New in version 2015.8.9.

Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to True.

MULTIPLE PACKAGE INSTALLATION OPTIONS:

Parameters

pkgs (list) -- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.

mypkgs:
  pkg.installed:
    - pkgs:
NOTE: For `apt`, `ebuild`, `pacman`, `winrepo`, `yum`, and `zypper`, version numbers can be specified in the `pkgs` argument. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
    - foo
    - bar: 1.2.3-4
    - baz
```

Additionally, `ebuild`, `pacman`, `zypper`, `yum/dnf`, and `apt` support the `<`, `<=`, `>=`, and `>` operators for more control over what versions will be installed. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
    - foo
    - bar: '>=1.2.3-4'
    - baz
```

NOTE: When using comparison operators, the expression must be enclosed in quotes to avoid a YAML render error.

With `ebuild` is also possible to specify a use flag list and/or if the given packages should be in `package.accept_keywords` file and/or the overlay from which you want the package to be installed. For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
    - foo: ' ~'
    - bar: ' ~>=1.2:slot::overlay[use,-otheruse]'
    - baz
```

- **sources** *(list)* -- A list of packages to install, along with the source URI or local path from which to install each package. In the example below, `foo`, `bar`, `baz`, etc. refer to the name of the package, as it would appear in the output of the `pkg.version` or `pkg.list_pkgs` salt CLI commands.

```yaml
mypkgs:
  pkg.installed:
    - sources:
      - foo: salt://rpms/foo.rpm
      - bar: http://som esite.org/bar.rpm
      - baz: ftp://someothersite.org/baz.rpm
      - qux: /minion/path/to/qux.rpm
```

**PLATFORM-SPECIFIC ARGUMENTS**

These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.
Parameters

- **hold** *(bool)* -- Force the package to be held at the current installed version.
  Supported on YUM/DNF & APT based systems.
  New in version 2014.7.0.
  Supported on Zypper-based systems.
  New in version 3003.

- **update_holds** *(bool)* -- If True, and this function would update the package version, any packages which are being held will be temporarily unheld so that they can be updated. Otherwise, if this function attempts to update a held package, the held package(s) will be skipped and the state will fail. By default, this parameter is set to False.
  Supported on YUM/DNF & APT based systems.
  New in version 2016.11.0.
  Supported on Zypper-based systems.
  New in version 3003.

- **names** *(list)* -- A list of packages to install from a software repository. Each package will be installed individually by the package manager.

  Warning: Unlike pkgs, the names parameter cannot specify a version. In addition, it makes a separate call to the package management frontend to install each package, whereas pkgs makes just a single call. It is therefore recommended to use pkgs instead of names to install multiple packages, both for the additional features and the performance improvement that it brings.

- **install_recommends** *(bool)* -- Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.
  New in version 2015.5.0.

```
httpd:
  pkg.installed:
    - install_recommends: False
```

- **only_upgrade** *(bool)* -- Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.
  New in version 2015.5.0.

```
httpd:
  pkg.installed:
    - only_upgrade: True
```

Note: If this parameter is set to True and the package is not already installed, the state will fail.

- **report_reboot_exit_codes** *(bool)* -- If the installer exits with a recognized exit code indicating that a reboot is required, the module function
  
  `win_system.set_reboot_required_witnessed`

  will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, 3010 is the only recognized exit code, but
this is subject to future refinement. The value of this param defaults to True. This parameter has no effect on non-Windows systems.

New in version 2016.11.0.

<table>
<thead>
<tr>
<th>ms vcpp installed:</th>
</tr>
</thead>
<tbody>
<tr>
<td>pkg.installed:</td>
</tr>
<tr>
<td>- name: ms-vcpp</td>
</tr>
<tr>
<td>- version: 10.0.40219</td>
</tr>
<tr>
<td>- report_reboot_exit_codes: False</td>
</tr>
</tbody>
</table>

**Returns**

A dictionary containing the state of the software installation

Rtype dict

**Note:** The `pkg.installed` state supports the usage of `reload_modules`. This functionality allows you to force Salt to reload all modules. In many cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require the package which was installed. However, there are some edge cases where this may not be the case, which is what `reload_modules` is meant to resolve.

You should only use `reload_modules` if your `pkg.installed` does some sort of installation where if you do not reload the modules future items in your state which rely on the software being installed will fail. Please see the `Reloading Modules` documentation for more information.

**See also:**

unless and onlyif

If running pkg commands together with `aggregate` isn't an option, you can use the `creates, unless, or onlyif` syntax to skip a full package run. This can be helpful in large environments with multiple states that include requisites for packages to be installed.

```
# Using creates for a simple single-factor check
install_nginx:
  pkg.installed:
    - name: nginx
    - creates: /etc/nginx/nginx.conf

# Using file.file_exists for a single-factor check
install_nginx:
  pkg.installed:
    - name: nginx
    - unless:
      - fun: file.file_exists
        args: - /etc/nginx/nginx.conf

# Using unless with a shell test
install_nginx:
  pkg.installed:
    - name: nginx
    - unless: test -f /etc/nginx/nginx.conf
```
The above examples use different methods to reasonably ensure that a package has already been installed. First, with checking for a file that would be created with the package. Second, by checking for specific text within a file that would be created or managed by salt. With these requisists satisfied, creates/unless will return `True` and the `pkg.installed` state will be skipped.

```
# Using file.search for a two-factor check
install_nginx:
  pkg.installed:
    - name: nginx
    - unless:
      - fun: file.search
        args:
          - /etc/nginx/nginx.conf
          - 'user www-data;'
```

The result is a reduction of almost 3 seconds. In larger environments, small reductions in waiting time can add up.

**Unless Requisite**

```
salt.states.pkg.latest(name, refresh=None, fromrepo=None, skip_verify=False, pkgs=None, watch_flags=True, **kwargs)
```

Changed in version 3007.0.

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the `installed` function to be used, as `latest` will update the package whenever a new package is available.
Note: Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like saltenv, or reload_modules, will be passed through to the call to pkg.install to install the package(s). For example, you can include a disablerepo argument on platforms that use yum/dnf to disable that repo:

```
mypkg:
  pkg.latest:
    - disablerepo: base,updates
```

To see what is supported, check this page to find the documentation for your platform's pkg module, then look at the documentation for the install function.

Any argument that is passed through to the install function, which is not defined for that function, will be silently ignored.

**name**
The name of the package to maintain at the latest available version. This parameter is ignored if "pkgs" is used.

**fromrepo**
Specify a repository from which to install

**skip_verify**
Skip the GPG verification check for the package to be installed

**refresh**
This parameter controls whether or not the package repo database is updated prior to checking for the latest available version of the requested packages.

If True, the package database will be refreshed (apt-get update or equivalent, depending on platform) before checking for the latest available version of the requested packages.

If False, the package database will not be refreshed before checking.

If unset, then Salt treats package database refreshes differently depending on whether or not a pkg state has been executed already during the current Salt run. Once a refresh has been performed in a pkg state, for the remainder of that Salt run no other refreshes will be performed for pkg states which do not explicitly set refresh to True. This prevents needless additional refreshes from slowing down the Salt run.

**Parameters**

- **cache_valid_time** *(str)* -- New in version 2016.11.0.

  This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the refresh parameter's default behavior.

  Example:

```
httpd:
  pkg.latest:
    - refresh: True
    - cache_valid_time: 300
```

In this case, a refresh will not take place for 5 minutes since the last apt-get update was executed on the system.

Note: This parameter is available only on Debian based distributions and has no
\* resolve_capabilities (bool) -- Turn on resolving capabilities. This allow one to name "provides" or alias names for packages.

New in version 2018.3.0.

Multiple Package Installation Options:

(Not yet supported for: FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)

**pkgs**

A list of packages to maintain at the latest available version.

```
mpkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz
```

**install_recommends**

Whether to install the packages marked as recommended. Default is `True`. Currently only works with APT-based systems.

New in version 2015.5.0.

```
httpd:
  pkg.latest:
    - install_recommends: False
```

**only_upgrade**

Only upgrade the packages, if they are already installed. Default is `False`. Currently only works with APT-based systems.

New in version 2015.5.0.

```
httpd:
  pkg.latest:
    - only_upgrade: True
```

**Note:** If this parameter is set to `True` and the package is not already installed, the state will fail.

**report_reboot_exit_codes**

If the installer exits with a recognized exit code indicating that a reboot is required, the module function `win_system.set_reboot_required_witnessed` will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, `3010` is the only recognized exit code, but this is subject to future refinement. The value of this param defaults to `True`. This parameter has no effect on non-Windows systems.

New in version 2016.11.0.

```
ms_vcpp installed:
  pkg.latest:
    - name: ms-vcpp
    - report_reboot_exit_codes: False
```
salt.states.pkg.mod_aggregate(low, chunks, running)

The mod_aggregate function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

salt.states.pkg.mod_beacon(name, **kwargs)

Create a beacon to monitor a package or packages based on a beacon state argument.

**Note:** This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

salt.states.pkg.mod_watch(name, **kwargs)

Install/reinstall a package based on a watch requisite

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.pkg.patch_downloaded(name, advisory_ids=None, **kwargs)

New in version 2017.7.0.

Ensure that packages related to certain advisory ids are downloaded.

Currently supported for the following pkg providers: `yum` and `zypper`

CLI Example:

```yaml
preparing-to-fix-issues:
  pkg.patch_downloaded:
    - advisory_ids:
      - SUSE-SLE-SERVER-12-SP2-2017-185
      - SUSE-SLE-SERVER-12-SP2-2017-150
      - SUSE-SLE-SERVER-12-SP2-2017-120
```

salt.states.pkg.patch_installed(name, advisory_ids=None, downloadonly=None, **kwargs)

New in version 2017.7.0.

Ensure that packages related to certain advisory ids are installed.

**Note:** Any argument which is either a) not explicitly defined for this state, or b) not a global state argument like saltenv, or reload_modules, will be passed through to the call to pkg.install to install the patch(es).

To see what is supported, check this page to find the documentation for your platform's pkg module, then look at the documentation for the install function.

Any argument that is passed through to the install function, which is not defined for that function, will be silently ignored.

Currently supported for the following pkg providers: `yum` and `zypper`

CLI Example:
**issue-foo-fixed:**

**pkg.patch_installed:**
- **advisory_ids:**
  - SUSE-SLE-SERVER-12-SP2-2017-185
  - SUSE-SLE-SERVER-12-SP2-2017-150
  - SUSE-SLE-SERVER-12-SP2-2017-120

```
salt.states.pkg.purged(name, version=None, pkgs=None, normalize=True, ignore_epoch=None, **kwargs)
```

Verify that a package is not installed, calling pkg.purge if necessary to purge the package. All configuration files are also removed.

**name**
The name of the package to be purged.

**version**
The version of the package that should be removed. Don’t do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.purged:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed`, `pkg.removed`, and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If `ignore_epoch` was not set to `True`, and instead of `2:7.4.160-1.el7` a version of `7.4.160-1.el7` were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

**normalize**
[True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

**ignore_epoch**
[None] If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to `True` to explicitly ignore the epoch, and `False` to strictly enforce it.

New in version 2015.8.9.

Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to `True`.

**Multiple Package Options:**

**pkgs**
A list of packages to purge. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

```
salt.states.pkg.removed(name, version=None, pkgs=None, normalize=True, ignore_epoch=None, **kwargs)
```

Verify that a package is not installed, calling pkg.remove if necessary to remove the package.
name

The name of the package to be removed.

version

The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.removed:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed`, `pkg.removed`, and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If `ignore_epoch` was not set to `True`, and instead of `2:7.4.160-1.el7` a version of `7.4.160-1.el7` were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

**normalize**

[True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

**ignore_epoch**

[None] If this option is not explicitly set, and there is no epoch in the desired package version, the epoch will be implicitly ignored. Set this argument to `True` to explicitly ignore the epoch, and `False` to strictly enforce it.

New in version 2015.8.9.

Changed in version 3001: In prior releases, the default behavior was to strictly enforce epochs unless this argument was set to `True`.

Multiple Package Options:

**pkgs**

A list of packages to remove. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

salt.states.pkg.unheld(name, version=None, pkgs=None, all=False, **kwargs)

New in version 3005.

Unset package from 'hold' state, to allow operations with the package.

**Parameters**

- **name** (str) -- The name of the package to be unheld. This parameter is ignored if `pkgs` is used.
- **version** (str) -- Unhold a specific version of a package. Full description of this parameter is in `installed` function.

**Note:** This parameter make sense for Zypper-based systems. Ignored for YUM/DNF and APT
• **pkgs** *(list)* -- A list of packages to be unheld. All packages listed under `pkgs` will be unheld.

```yaml
mypkgs:
  pkg.unheld:
    - pkgs:
      - foo
    - bar: 1.2.3-4
    - baz
```

**Note:** For Zyper-based systems the package could be held for the version specified. YUM/DNF and APT ingore it. For `unheld` there is no need to specify the exact version to be unheld.

• **all** *(bool)* -- Force removing of all existings locks. By default, this parameter is set to `False`.

```python
salt.states.pkg.uptodate(name, refresh=False, pkgs=None, **kwargs)
```

*New in version 2014.7.0.*

*Changed in version 2018.3.0:* Added support for the `pkgin` provider.

Verify that the system is completely up to date.

- **param** `name`  
  The name has no functional value and is only used as a tracking reference

- **param** `refresh`  
  refresh the package database before checking for new upgrades

- **param** `pkgs`  
  list of packages to upgrade

*Parameters*

- **resolve_capabilities** *(bool)* -- Turn on resolving capabilities. This allow one to name “provides” or alias names for packages.

  *New in version 2018.3.0.*

- **param** `kwargs`  
  Any keyword arguments to pass through to the `pkg` module.

  For example, for apt systems: `dist_upgrade, cache_valid_time, force_conf_new`

  *New in version 2015.5.0.*

### 25.20.231 salt.states.pkgbuild

The `pkgbuild` state is the front of Salt package building backend. It automatically builds DEB and RPM packages from specified sources

*New in version 2015.8.0.*

```python
salt_2015.5.2:
  pkgbuild.built:
    - runas: thatch
    - results:
      - salt-2015.5.2-2.el7.centos.noarch.rpm
      - salt-api-2015.5.2-2.el7.centos.noarch.rpm
```

(continues on next page)

  - salt://pkg/salt/sources/saltpkg.sls
  - salt://pkg/salt/sources/salt-syndic
  - salt://pkg/salt/sources/salt-syndic.service
  - salt://pkg/salt/sources/SaltTesting-2015.5.8.tar.gz

/tmp/pkg:
  pkgbuild.repo

salt.states.pkgbuild.built(name, runas, dest_dir, spec, sources, tgt, template=\None, deps=\None, env=\None, results=\None, force=False, saltenv=\base, log_dir=\'/var/log/salt/pkkgbuild\')

Ensure that the named package is built and exists in the named directory.

name
  The name to track the build, the name value is otherwise unused.
runas
  The user to run the build process as.
dest_dir
  The directory on the minion to place the built package(s).
spec
  The location of the spec file (used for rpms).
sources
  The list of package sources.
tgt
  The target platform to run the build on.
template
  Run the spec file through a templating engine.

Changed in version 2015.8.2: This argument is now optional, allowing for no templating engine to be used if none is desired.
deps
  Packages required to ensure that the named package is built can be hosted on either the salt master server or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading...
directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials

env

A dictionary of environment variables to be set prior to execution. Example:

```yaml
env:
    DEB_BUILD_OPTIONS: 'nocheck'
```

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

results

The names of the expected rpms that will be built

force

[False] If True, packages will be built even if they already exist in the dest_dir. This is useful when building a package for continuous or nightly package builds.

New in version 2015.8.2.

saltenv

The saltenv to use for files downloaded from the salt fileserver

log_dir

[/var/log/salt/rpmbuild] Root directory for log files created from the build. Logs will be organized by package name, version, OS release, and CPU architecture under this directory.

New in version 2015.8.2.

salt.states.pkgbuild.repo

```python
make a package repository and optionally sign it and packages present
```

name

The directory to turn into a repo. This state is best used with onchanges linked to your package building states.

keyid

Changed in version 2016.3.0.

Optional Key ID to use in signing packages and repository. Utilizes Public and Private keys associated with keyid which have been loaded into the minion’s Pillar data.

For example, contents from a Pillar data file with named Public and Private keys as follows:

```python
GPG_PKG_PRIV_KEY: |
    -----BEGIN PGP PRIVATE KEY BLOCK-----
    Version: GnuPG v1

    lQO+BFciI9fQBCADAPCtzw7sI5Rl32escCMZsPzaEKe7bIX1em4KCKKbOx47I5G4b
    w82PCE8Y1jF/9Uk2m3RkVWp3YcLlC7Ap3gjV04ysvVz28UbhrPxsIhK0lf2cq8qc
    .
    Ebe+8JCqTtwSXPRTzXmy/b5WXDeM79CklWvuGpXFor76D+EJMRpv/awukEcNpnt
    R50mgHqvydEnO4pWbn83jzQ09YX/Us0SMHVzLC8eIi5ZIopzalvX
    =JvW8
    -----END PGP PRIVATE KEY BLOCK-----
```

(continues on next page)
gpg_pkg_priv_keyname: gpg_pkg_key.pem

gpg_pkg_pub_key: |
------BEGIN PGP PUBLIC KEY BLOCK------
Version: GnuPG v1

=s1CX
------END PGP PUBLIC KEY BLOCK------
gpg_pkg_pub_keyname: gpg_pkg_key.pub

env

Changed in version 2016.3.0.

A dictionary of environment variables to be utilized in creating the repository. Example:

- env:
  OPTIONS: 'ask-passphrase'

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Use of OPTIONS on some platforms, for example: ask-passphrase, will require gpg-agent or similar to cache passphrases.

Note: This parameter is not used for making yum repositories.

use_passphrase

[False] New in version 2016.3.0.

Use a passphrase with the signing key presented in keyid. Passphrase is received from Pillar data which could be passed on the command line with pillar parameter. For example:

gnupghome

[/etc/salt/gpgkeys] New in version 2016.3.0.

Location where GPG related files are stored, used with 'keyid'

runas

[builder] New in version 2016.3.0.

User to create the repository as, and optionally sign packages.
### Note
Ensure the user has correct permissions to any files and directories which are to be utilized.

.timeout
[15.0] New in version 2016.3.4.

Timeout in seconds to wait for the prompt for inputting the passphrase.

#### 25.20.232 salt.states.pkgng

Manage package remote repo using FreeBSD pkgng

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```yaml
pkgng_clients:
  pkgng.update_packaging_site:
    - name: "http://192.168.0.2"
```

salt.states.pkgng.update_packaging_site(name)

#### 25.20.233 salt.states.pkgrepo

Management of APT/DNF/YUM/Zypper package repos

States for managing software package repositories on Linux distros. Supported package managers are APT, DNF, YUM and Zypper. Here is some example SLS:

```yaml
base:
  pkgrepo.managed:
    - humanname: CentOS-$releasever - Base
    - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os
    - comments:
      - 'http://mirror.centos.org/centos/$releasever/os/$basearch/'
    - gpgcheck: 1
    - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6
```

```yaml
base:
  pkgrepo.managed:
    - humanname: Logstash PPA
    - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash

pkg.latest:
    - name: logstash
    - refresh: True
```
base:
  pkgrepo.managed:
    - humanname: deb-multimedia
    - name: deb http://www.deb-multimedia.org stable main
    - file: /etc/apt/sources.list.d/deb-multimedia.list
    - key_url: salt://deb-multimedia/files/marillat.pub

base:
  pkgrepo.managed:
    - humanname: Google Chrome
    - name: deb http://dl.google.com/linux/chrome/deb/ stable main
    - dist: stable
    - file: /etc/apt/sources.list.d/chrome-browser.list
    - require_in:
      - pkg: google-chrome-stable
    - gpgcheck: 1
    - key_url: https://dl-ssl.google.com/linux/linux_signing_key.pub

base:
  pkgrepo.managed:
  - ppa: wolfnet/logstash
  pkg.latest:
    - name: logstash
    - refresh: True

Note: On Ubuntu systems, the python-software-properties package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`.

On Ubuntu & Debian systems, the python-apt package is required to be installed. To check if this package is installed, run `dpkg -l python-apt`. python-apt will need to be manually installed if it is not present.

hello-copr:
  pkgrepo.managed:
    - copr: mymindstorm/hello
  pkg.installed:
    - name: hello

apt-key deprecated

apt-key is deprecated and will be last available in Debian 11 and Ubuntu 22.04. The recommended way to manage repo keys going forward is to download the keys into /etc/apt/keyrings and use signed-by in your repo file pointing to the key. This module was updated in version 3005 to implement the recommended approach. You need to add - aptkey: False to your state and set signed-by in your repo name, to use this recommended approach. If the cli command apt-key is not available it will automatically set aptkey to False.

Using aptkey: False with key_url example:

deb [signed-by=/etc/apt/keyrings/salt-archive-keyring.gpg arch=amd64] https://repo.saltproject.io/py3/ubuntu/18.04/amd64/latest bionic main:
  pkgrepo.managed:
- **file**: `/etc/apt/sources.list.d/salt.list`
- **key_url**: `https://repo.saltproject.io/py3/ubuntu/18.04/amd64/latest/salt-archive-keyring.gpg`
- **aptkey**: False

Using `aptkey`: False with keyserver and keyid:

```
deb [signed-by=/etc/apt/keyrings/salt-archive-keyring.gpg arch=amd64] https://repo.saltproject.io/py3/ubuntu/18.04/amd64/latest bionic main:
  pkgrepo.managed:
  - **file**: `/etc/apt/sources.list.d/salt.list`
  - **keyserver**: keyserver.ubuntu.com
  - **keyid**: 0E08A149DE57BFBE
  - **aptkey**: False
```

salt.states.pkgrepo.absent(name, **kwargs)

This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`

**name**

The name of the package repo, as it would be referred to when running the regular package manager commands.

**FEDORA/REDHAT-SPECIFIC OPTIONS**

- **copr**
  
  Use community packages outside of the main package repository.

  New in version 3002.

```
  **hello-copr:**
  pkgrepo.absent:
  - **copr**: mymindstorm/hello
```

**UBUNTU-SPECIFIC OPTIONS**

- **ppa**
  
  On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

```
  **logstash-ppa:**
  pkgrepo.absent:
  - **ppa**: wolfnet/logstash
```

- **ppa_auth**
  
  For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be specified. This is required for matching if the name format uses the `ppa:` specifier and is private (requires username/password to access, which is encoded in the URI).

```
  **logstash-ppa:**
  pkgrepo.absent:
  - **ppa**: wolfnet/logstash
  - **ppa_auth**: username:password
```

- **keyid**
  
  If passed, then the GPG key corresponding to the passed KeyID will also be removed.

- **keyid_ppa**
  
  [False] If set to `True`, the GPG key’s ID will be looked up from ppa.launchpad.net and removed, and the `keyid` argument will be ignored.
Salt Documentation, Release 3006.3

salt.states.pkgrepo.managed(name, ppa=None, copr=None, aptkey=True, **kwargs)

This state manages software package repositories. Currently, `yum`, `apt`, and `zypper` repositories are supported.

### YUM/DNF/ZYPPE-BASED SYSTEMS

**Note:** One of `baseurl` or `mirrorlist` below is required. Additionally, note that this state is not presently capable of managing more than one repo in a single repo file, so each instance of this state will manage a single repo file containing the configuration for a single repo.

- **name**
  This value will be used in two ways: Firstly, it will be the repo ID, as seen in the entry in square brackets (e.g. `[foo]`) for a given repo. Secondly, it will be the name of the file as stored in `/etc/yum.repos.d` (e.g. `/etc/yum.repos.d/foo.conf`).

- **enabled**
  [True] Whether the repo is enabled or not. Can be specified as True/False or 1/0.

- **disabled**
  [False] Included to reduce confusion due to APT's use of the `disabled` argument. If this is passed for a YUM/DNF/Zypper-based distro, then the reverse will be passed as `enabled`. For example passing `disabled=True` will assume `enabled=False`.

- **copr**
  Fedora and RedHat based distributions only. Use community packages outside of the main package repository.

  New in version 3002.

- **humanname**
  This is used as the `name` value in the repo file in `/etc/yum.repos.d/` (or `/etc/zypp/repos.d` for SUSE distros).

- **baseurl**
  The URL to a yum repository

- **mirrorlist**
  A URL which points to a file containing a collection of baseurls

- **comments**
  Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (#) in front.

- **gpgautoimport**
  Only valid for Zypper package manager. If set to True, automatically trust and import the new repository signing key. The key should be specified with `gpgkey` parameter. See details below.

Additional configuration values seen in YUM/DNF/Zypper repo files, such as `gpgkey` or `gpgcheck`, will be used directly as key-value pairs. For example:

```
foo:
  pkgrepo.managed:
    - humanname: Personal repo for foo
    - baseurl: https://mydomain.tld/repo/foo/$releasever/$basearch
    - gpgkey: file:///etc/pki/rpm-gpg/foo-signing-key
    - gpgcheck: 1
```

### APT-BASED SYSTEMS
ppa
On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set automatically. You can override any of the below settings by simply setting them as you would normally. For example:

```
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
```

ppa_auth
For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.

```
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
  - ppa_auth: username:password
```

name
On apt-based systems this must be the complete entry as it would be seen in the `sources.list` file. This can have a limited subset of components (e.g. `main`) which can be added/modified with the `comps` option.

```
precise-repo:
pkgrepo.managed:
  - name: deb http://us.archive.ubuntu.com/ubuntu precise main
```

Note: The above example is intended as a more readable way of configuring the SLS, it is equivalent to the following:

```
'deb http://us.archive.ubuntu.com/ubuntu precise main':
pkgrepo.managed
```

disabled
[False] Toggles whether or not the repo is used for resolving dependencies and/or installing packages.

enabled
[True] Included to reduce confusion due to YUM/DNF/Zypper's use of the `enabled` argument. If this is passed for an APT-based distro, then the reverse will be passed as `disabled`. For example, passing `enabled=False` will assume `disabled=False`.

architectures
On apt-based systems, `architectures` can restrict the available architectures that the repository provides (e.g. only `amd64`). `architectures` should be a comma-separated list.

comps
On apt-based systems, `comps` dictate the types of packages to be installed from the repository (e.g. `main`, `nonfree`, ...). For purposes of this, `comps` should be a comma-separated list.

file
The filename for the `*.list` that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages.

dist
This dictates the release of the distro the packages should be built for (e.g. `unstable`). This option is rarely needed.

keyid
The KeyID or a list of KeyIDs of the GPG key to install. This option also requires the `keyserver` option
to be set.

**keyserver**
This is the name of the keyserver to retrieve GPG keys from. The `keyid` option must also be set for this option to work.

**key_url**
URL to retrieve a GPG key from. Allows the usage of `https://` as well as `salt://`. If `allow_insecure_key` is True, this also allows `http://`.

---

**Note:** Use either `keyid/keyserver` or `key_url`, but not both.

**key_text**
The string representation of the GPG key to install.
New in version 2018.3.0.

---

**Note:** Use either `keyid/keyserver`, `key_url`, or `key_text` but not more than one method.

**consolidate**
[False] If set to `True`, this will consolidate all sources definitions to the `sources.list` file, cleanup the now unused files, consolidate components (e.g. `main`) for the same URL, type, and architecture to a single line, and finally remove comments from the `sources.list` file. The consolidation will run every time the state is processed. The option only needs to be set on one repo managed by Salt to take effect.

**clean_file**
[False] If set to `True`, empty the file before configuring the defined repository

---

**Note:** Use with care. This can be dangerous if multiple sources are configured in the same file.

New in version 2015.8.0.

**refresh**
[True] If set to `False` this will skip refreshing the apt package database on Debian based systems.

**refresh_db**
[True] Deprecated since version 2018.3.0: Use `refresh` instead.

**require_in**
Set this to a list of `pkg.installed` or `pkg.latest` to trigger the running of `apt-get update` prior to attempting to install these packages. Setting a require in the pkg state will not work for this.

**aptkey:**
Use the binary `apt-key`. If the command `apt-key` is not found in the path, `aptkey` will be `False`, regardless of what is passed into this argument.

**allow_insecure_key**
[True] Whether to allow an insecure (e.g. `http` vs. `https`) `key_url`.
New in version 3006.0.
25.20.234 salt.states.portage_config

Management of Portage package configuration on Gentoo

A state module to manage Portage configuration on Gentoo

```python
salt:
    portage_config.flags:
        - use:
            - openssl
```

**salt.states.portage_config.flags** *(name, use=None, accept_keywords=None, env=None, license=None, properties=None, unmask=False, mask=False)*

Enforce the given flags on the given package or DEPEND atom.

**Warning:** In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

**name**
- The name of the package or its DEPEND atom

**use**
- A list of USE flags

**accept_keywords**
- A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords

**env**
- A list of environment files

**license**
- A list of accepted licenses

**properties**
- A list of additional properties

**unmask**
- A boolean to unmask the package

**mask**
- A boolean to mask the package

25.20.235 salt.states.ports

Manage software from FreeBSD ports

New in version 2014.1.0.

**Note:** It may be helpful to use a higher timeout when running a `ports.installed` state, since compiling the port may exceed Salt’s timeout.

```bash
salt -t 1200 '*.' state.highstate
```

**salt.states.ports.installed** *(name, options=None)*

Verify that the desired port is installed, and that it was compiled with the desired options.

**options**
- Make sure that the desired non-default options are set
Warning: Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous `make config`.

Example usage:

```markdown
security/nmap:
  ports.installed:
    - options:
    - IPV6: off
```

### 25.20.236 salt.states.postgres_cluster

Management of PostgreSQL clusters

The `postgres_cluster` state module is used to manage PostgreSQL clusters. Clusters can be set as either absent or present.

```
create cluster 9.3 main:
  postgres_cluster.present:
    - name: 'main'
    - version: '9.3'
```

**`salt.states.postgres_cluster.absent(version, name)`**

Ensure that the named cluster is absent

- **version**
  - Version of the postgresql server of the cluster to remove
- **name**
  - The name of the cluster to remove

New in version 2016.3.0.

**`salt.states.postgres_cluster.present(version, name, port=None, encoding=None, locale=None, datadir=None, allow_group_access=None, data_checksums=None, wal_segsize=None)`**

Ensure that the named cluster is present with the specified properties. For more information about all of these options see man `pg_createcluster(1)`

- **version**
  - Version of the postgresql cluster
- **name**
  - The name of the cluster
- **port**
  - Cluster port
- **encoding**
  - The character encoding scheme to be used in this database
- **locale**
  - Locale with which to create cluster
- **datadir**
  - Where the cluster is stored
- **allow_group_access**
  - Allows users in the same group as the cluster owner to read all cluster files created by initdb
- **data_checksums**
  - Use checksums on data pages
wal_segsize
Set the WAL segment size, in megabytes
New in version 2016.3.0.

25.20.237 salt.states.postgres_database

Management of PostgreSQL databases

The postgres_database module is used to create and manage Postgres databases. Databases can be set as either absent or present

```python
frank:
    postgres_database.present
```

salt.states.postgres_database.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is absent
name
The name of the database to remove
db_user
database username if different from config or default
db_password
user password if any password for a specified user
db_host
Database host if different from config or default
db_port
Database port if different from config or default
user
System user all operations should be performed on behalf of
New in version 0.17.0.

salt.states.postgres_database.present(name, tablespace=None, encoding=None, lc_collate=None, lc_ctype=None, owner=None, owner_recurse=False, template=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is present with the specified properties. For more information about all of these options see man createdb(1)
name
The name of the database to manage	tablespace
Default tablespace for the database	encoding
The character encoding scheme to be used in this database	lc_collate
The LC_COLLATE setting to be used in this database	lc_ctype
The LC_CTYPE setting to be used in this database	owner
The username of the database owner	owner_recurse
Recurse owner change to all relations in the database
The template database from which to build this database

System user all operations should be performed on behalf of

Database username if different from config or default

User password if any password for a specified user

Database host if different from config or default

Database port if different from config or default

New in version 0.17.0.

25.20.238 salt.states.postgres_extension

Management of PostgreSQL extensions

A module used to install and manage PostgreSQL extensions.

**adminpack:**

    postgres_extension.present

New in version 2014.7.0.

salt.states.postgres_extension.absent(name, if_exists=None, restrict=None, cascade=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named extension is absent.

name
    Extension name of the extension to remove

if_exists
    Add if exist slug

restrict
    Add restrict slug

cascade
    Drop on cascade

user
    System user all operations should be performed on behalf of

maintenance_db
    Database to act on

db_user
    Database username if different from config or default

db_password
    User password if any password for a specified user

db_host
    Database host if different from config or default

db_port
    Database port if different from config or default

salt.states.postgres_extension.present(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)
Ensure that the named extension is present.

**Note:** Before you can use the state to load an extension into a database, the extension's supporting files must be already installed.

For more information about all of these options see CREATE EXTENSION SQL command reference in the PostgreSQL documentation.

```python
name
    The name of the extension to be installed
if_not_exists
    Add an IF NOT EXISTS parameter to the DDL statement
schema
    Schema to install the extension into
ext_version
    Version to install
from_version
    Old extension version if already installed
user
    System user all operations should be performed on behalf of
maintenance_db
    Database to act on
db_user
    Database username if different from config or default
db_password
    User password if any password for a specified user
db_host
    Database host if different from config or default
db_port
    Database port if different from config or default
```

### 25.20.239 salt.states.postgres_group

**Management of PostgreSQL groups (roles)**

The postgres_group module is used to create and manage Postgres groups.

```bash
frank:
    postgres_group.present

salt.states.postgres_group.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Ensure that the named group is absent

```python
name
    The groupname of the group to remove
user
    System user all operations should be performed on behalf of
    New in version 0.17.0.
db_user
    database username if different from config or default
```
**db_password**
user password if any password for a specified user

**db_host**
Database host if different from config or default

**db_port**
Database port if different from config or default

salt.states.postgres_group.present(name, createdb=None, createroles=None, encrypted=None, superuser=None, inherit=None, login=None, replication=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is present with the specified privileges. Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

**name**
The name of the group to manage

**createdb**
Is the group allowed to create databases?

**createroles**
Is the group allowed to create other roles/users

**encrypted**
How the password should be stored.
If encrypted is None, True, or md5, it will use PostgreSQL's MD5 algorithm.
If encrypted is False, it will be stored in plaintext.
If encrypted is scram-sha-256, it will use the algorithm described in RFC 7677.

Changed in version 3003: Prior versions only supported True and False

**login**
Should the group have login perm

**inherit**
Should the group inherit permissions

**superuser**
Should the new group be a "superuser"

**replication**
Should the new group be allowed to initiate streaming replication

**password**
The group's password. It can be either a plain string or a pre-hashed password:

- `{md5}{MD5OF(password){role}}`
- `{SCRAM-SHA-256}{iterations}:{salt}${stored_key}:{server_key}`

If encrypted is not False, then the password will be converted to the appropriate format above, if not already. As a consequence, passwords that start with "md5" or "SCRAM-SHA-256" cannot be used.

**refresh_password**
Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.
groups
A string of comma separated groups the group should be in

user
System user all operations should be performed on behalf of

New in version 0.17.0.

New in version 0.17.0.

db_user
database username if different from config or default
db_password
user password if any password for a specified user
db_host
Database host if different from config or default
db_port
Database port if different from config or default

25.20.240 salt.states.postgres_initdb

Initialization of PostgreSQL data directory

The postgres_initdb module is used to initialize the postgresql data directory.

New in version 2016.3.0.

```
pgsql-data-dir:
  postgres_initdb.present:
    - name: /var/lib/pgsql/data
    - auth: password
    - user: postgres
    - password: strong_password
    - encoding: UTF8
    - locale: C
    - runas: postgres
    - checksums: True
    - waldir: /var/postgresql/wal
```

salt.states.postgres_initdb.present(name, user=None, password=None, auth='password',
                      encoding='UTF8', locale=None, runas=None, waldir=None,
                      checksums=False)

Initialize the PostgreSQL data directory
name
The name of the directory to initialize
user
The database superuser name
password
The password to set for the postgres user
auth
The default authentication method for local connections
encoding
The default encoding for new databases
locale
The default locale for new databases
waldir
The transaction log (WAL) directory (default is to keep WAL inside the data directory)
New in version 2019.2.0.

**checksums**
If True, the cluster will be created with data page checksums.

---

**Note:** Data page checksums are supported since PostgreSQL 9.3.

New in version 2019.2.0.

**runas**
The system user the operation should be performed on behalf of

### 25.20.241 salt.states.postgres_language

Management of PostgreSQL languages

The postgres_language module is used to create and manage Postgres languages. Languages can be set as either absent or present

New in version 2016.3.0.

```
plpgsql:
  postgres_language.present:
    - maintenance_db: testdb
```

```
plpgsql:
  postgres_language.absent:
    - maintenance_db: testdb
```

**salt.states.postgres_language.absent**(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is absent in the specified database.

- **name**
  The name of the language to remove

- **maintenance_db**
  The name of the database in which the language is to be installed

- **user**
  System user all operations should be performed on behalf of

- **db_user**
  Database username if different from config or default

- **db_password**
  User password if any password for a specified user

- **db_host**
  Database host if different from config or default

- **db_port**
  Database port if different from config or default

**salt.states.postgres_language.present**(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is present in the specified database.

- **name**
  The name of the language to install

- **maintenance_db**
  The name of the database in which the language is to be installed
System user all operations should be performed on behalf of

**db_user**
- database username if different from config or default

**db_password**
- user password if any password for a specified user

**db_host**
- Database host if different from config or default

**db_port**
- Database port if different from config or default

### 25.20.242 salt.states.postgres_privileges

**Management of PostgreSQL Privileges**

The postgres_privileges module is used to manage Postgres privileges. Privileges can be set as either absent or present.

Privileges can be set on the following database object types:

- database
- schema
- tablespace
- table
- sequence
- language
- group

Setting the grant option is supported as well.

New in version 2016.3.0.

```yaml
baruwa:
  postgres_privileges.present:
    - object_name: awl
    - object_type: table
    - privileges:
      - SELECT
      - INSERT
      - DELETE
    - grant_option: False
    - prepend: public
    - maintenance_db: testdb

andrew:
  postgres_privileges.present:
    - object_name: admins
    - object_type: group
    - grant_option: False
    - maintenance_db: testdb
```
Revoke the requested privilege(s) on the specified object(s)

**name**
Name of the role whose privileges should be revoked

**object_name**
Name of the object on which the revoke is to be performed

**object_type**
The object type, which can be one of the following:
- table
- sequence
- schema
- tablespace
- language
- database
- group
- function

View permissions should specify **object_type**: table.

**privileges**
Comma separated list of privileges to revoke, from the list below:
- INSERT
- CREATE
- TRUNCATE
- CONNECT
- TRIGGER
- SELECT
- USAGE
- TEMPORARY
- UPDATE
- EXECUTE
- REFERENCES
- DELETE
- ALL
Note

Privileges should not be set when revoking group membership.

Prepend

Table and Sequence object types live under a schema so this should be provided if the object is not under the default public schema.

Maintenance_db

The name of the database in which the language is to be installed.

User

System user all operations should be performed on behalf of.

db_user

Database username if different from config or default.

db_password

User password if any password for a specified user.

db_host

Database host if different from config or default.

db_port

Database port if different from config or default.

salt.states.postgres_privileges.present(name, object_name, object_type, privileges=None, grant_option=None, prepend='public', maintenance_db=None, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Grant the requested privilege(s) on the specified object to a role.

Name

Name of the role to which privileges should be granted.

Object_name

Name of the object on which the grant is to be performed. 'ALL' may be used for objects of type 'table' or 'sequence'.

Object_type

The object type, which can be one of the following:

- table
- sequence
- schema
- tablespace
- language
- database
- group
- function

View permissions should specify object_type: table.

Privileges

List of privileges to grant, from the list below:

- INSERT
- CREATE
- TRUNCATE
- CONNECT
- TRIGGER
- SELECT
- USAGE
- TEMPORARY
- UPDATE
- EXECUTE
- REFERENCES
- DELETE
- ALL
privileges should not be set when granting group membership

grant_option
If grant_option is set to True, the recipient of the privilege can in turn grant it to others

prepend
Table and Sequence object types live under a schema so this should be provided if the object is not under the default public schema

maintenance_db
The name of the database in which the language is to be installed

user
System user all operations should be performed on behalf of

db_user
database username if different from config or default

db_password
user password if any password for a specified user

db_host
Database host if different from config or default

db_port
Database port if different from config or default

25.20.243 salt.states.postgres_schema

Management of PostgreSQL schemas

The postgres_schemas module is used to create and manage Postgres schemas.

```python
public:
postgres_schema.present 'dbname' 'name'
```

salt.states.postgres_schema.absent(dname, name, user=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is absent.

dbname
The database's name will work on

name
The name of the schema to remove

user
system user all operations should be performed on behalf of

db_user
database username if different from config or default

db_password
user password if any password for a specified user

db_host
Database host if different from config or default

db_port
Database port if different from config or default

salt.states.postgres_schema.present(dname, name, owner=None, user=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is present in the database.

dbname
The database's name will work on
name

The name of the schema to manage

user

system user all operations should be performed on behalf of

db_user

database username if different from config or default

db_password

user password if any password for a specified user

$db_host$

Database host if different from config or default

db_port

Database port if different from config or default

25.20.244 salt.states.postgres_tablespace

Management of PostgreSQL tablespace

A module used to create and manage PostgreSQL tablespaces.

```yaml
ssd-tablespace:
  postgres_tablespace.present:
    - name: indexes
    - directory: /mnt/ssd-data
```

New in version 2015.8.0.

salt.states.postgres_tablespace.absent(name, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named tablespace is absent.

name

The name of the tablespace to remove

user

System user all operations should be performed on behalf of

maintenance_db

Database to act on

db_user

Database username if different from config or default

db_password

User password if any password for a specified user

$db_host$

Database host if different from config or default

db_port

Database port if different from config or default

salt.states.postgres_tablespace.present(name, directory, options=None, owner=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named tablespace is present with the specified properties. For more information about all of these options run man 7 create_tablespace.

name

The name of the tablespace to create/manage.

directory

The directory where the tablespace will be located, must already exist
options
A dictionary of options to specify for the tablespace. Currently, the only tablespace options supported
are `seq_page_cost` and `random_page_cost`. Default values are shown in the example below:

```yaml
my_space:
  postgres_tablespace.present:
    - directory: /srv/my_tablespace
    - options:
      seq_page_cost: 1.0
      random_page_cost: 4.0
```

owner
The database user that will be the owner of the tablespace. Defaults to the user executing the command
(i.e. the `user` option)

user
System user all operations should be performed on behalf of

maintenance_db
Database to act on
db_user
Database username if different from config or default
db_password
User password if any password for a specified user
db_host
Database host if different from config or default
db_port
Database port if different from config or default

25.20.245 salt.states.postgres_user

Management of PostgreSQL users (roles)

The postgres_users module is used to create and manage Postgres users.

```yaml
frank:
  postgres_user.present

salt.states.postgres_user.absent(name, user=None, maintenance_db=None, db_password=None,
  db_host=None, db_port=None, db_user=None)
```

Ensure that the named user is absent

name
The username of the user to remove

user
System user all operations should be performed on behalf of

New in version 0.17.0.

db_user
database username if different from config or default
db_password
user password if any password for a specified user
db_host
Database host if different from config or default
db_port
Database port if different from config or default
salt.states.postgres_user.present(name, createdb=None, createroles=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, default_password=None, refresh_password=None, valid_until=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None)

Ensure that the named user is present with the specified privileges. Please note that the user/group notion in PostgreSQL is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

**name**
The name of the system user to manage.

**createdb**
Is the user allowed to create databases?

**createroles**
Is the user allowed to create other users?

**encrypted**
How the password should be stored.

- If encrypted is None, True, or md5, it will use PostgreSQL's MD5 algorithm.
- If encrypted is False, it will be stored in plaintext.
- If encrypted is scram-sha-256, it will use the algorithm described in RFC 7677.

**login**
Should the group have login perm

**inherit**
Should the group inherit permissions

**superuser**
Should the new user be a "superuser"

**replication**
Should the new user be allowed to initiate streaming replication

**password**
The user's password. It can be either a plain string or a pre-hashed password:

```
'md5{MD5OF({password}{role})}'
'SCRAM-SHA-256{iterations}:{salt}${stored_key}:${server_key}'
```

If encrypted is not False, then the password will be converted to the appropriate format above, if not already. As a consequence, passwords that start with "md5" or "SCRAM-SHA-256" cannot be used.

**default_password**
The password used only when creating the user, unless password is set.

New in version 2016.3.0.

**refresh_password**
Password refresh flag

- Boolean attribute to specify whether to password comparison check should be performed.

- If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.

**valid_until**
A date and time after which the role's password is no longer valid.
groups  
A string of comma separated groups the user should be in  

user  
System user all operations should be performed on behalf of  
New in version 0.17.0.  

db_user  
Postgres database username, if different from config or default.  

db_password  
Postgres user's password, if any password, for a specified db_user.  

db_host  
Postgres database host, if different from config or default.  

db_port  
Postgres database port, if different from config or default.  

25.20.246 salt.states.powerpath  
Powerpath configuration support  
Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.  

key:  

| powerpath.license_present: [] |  

salt.states.powerpath.license_absent(name)  
Ensures that the specified PowerPath license key is absent on the host.  
name  
The license key to ensure is absent  

salt.states.powerpath.license_present(name)  
Ensures that the specified PowerPath license key is present on the host.  
name  
The license key to ensure is present  

25.20.247 salt.states.probes  
Network Probes  
Configure RPM (JunOS)/SLA (Cisco) probes on the device via NAPALM proxy.  

codeauthor  
Mircea Ulinic <ping@mirceaulinic.net> & Jerome Fleury <jf@cloudflare.com>  
maturity  
new

platform  
unix  

25.20. state modules
Dependencies

• napalm probes management module

New in version 2016.11.0.

salt.states.probes.managed (name, probes, defaults=None)

Ensure the networks device is configured as specified in the state SLS file. Probes not specified will be removed, while probes not configured as expected will trigger config updates.

Parameters

• probes -- Defines the probes as expected to be configured on the device. In order to ease the configuration and avoid repeating the same parameters for each probe, the next parameter (defaults) can be used, providing common characteristics.

• defaults -- Specifies common parameters for the probes.

SLS Example:

```yaml
rpmprobes:
  probes.managed:
    - probes:
      probe_name1:
        probe1_test1:
          source: 192.168.0.2
          target: 192.168.0.1
        probe1_test2:
          target: 172.17.17.1
        probe1_test3:
          target: 8.8.8.8
          probe_type: http-ping
      probe_name2:
        probe2_test1:
          test_interval: 100
    - defaults:
      target: 10.10.10.10
      probe_count: 15
      test_interval: 3
      probe_type: icmp-ping
```

In the probes configuration, the only mandatory attribute is target (specified either in probes configuration, either in the defaults dictionary). All the other parameters will use the operating system defaults, if not provided:

• source - Specifies the source IP Address to be used during the tests. If not specified will use the IP Address of the logical interface loopback0.

• target - Destination IP Address.

• probe_count - Total number of probes per test (1..15). System defaults: 1 on both JunOS & Cisco.

• probe_interval - Delay between tests (0..86400 seconds). System defaults: 3 on JunOS, 5 on Cisco.

• probe_type - Probe request type. Available options:
  - icmp-ping
  - tcp-ping
  - udp-ping

Using the example configuration above, after running the state, on the device will be configured 4 probes, with the following properties:

```yaml
probe_name1:
  probe1_test1:
```
source: 192.168.0.2
target: 192.168.0.1
probe_count: 15
test_interval: 3
probe_type: icmp-ping
probe1_test2:
    target: 172.17.17.1
    probe_count: 15
    test_interval: 3
    probe_type: icmp-ping
probe1_test3:
    target: 8.8.8.8
    probe_count: 15
    test_interval: 3
    probe_type: icmp-ping
probe_name2:
    probe2_test1:
        target: 10.10.10.10
        probe_count: 15
        test_interval: 3
        probe_type: icmp-ping

25.20.248  salt.states.process

Process Management

Ensure a process matching a given pattern is absent.

```python
httpd-absent:
    process.absent:
        - name: apache2
```

salt.states.process.absent(name, user=None, signal=None)

Ensures that the named command is not running.

- **name**
  The pattern to match.
- **user**
  The user to which the process belongs
- **signal**
  Signal to send to the process(es).
25.20.249  salt.states.proxy

Allows you to manage proxy settings on minions

Setup proxy settings on minions

```
192.168.1.4:
  proxy.managed:
    - port: 3128
    - bypass_domains: localhost 127.0.0.1
```

salt.states.proxy.managed(name, port, services=None, user=None, password=None, bypass_domains=None, network_service='Ethernet')

Manages proxy settings for this mininon

**name**
   The proxy server to use

**port**
   The port used by the proxy server

**services**
   A list of the services that should use the given proxy settings, valid services include http, https and ftp.
   If no service is given all of the valid services will be used.

**user**
   The username to use for the proxy server if required

**password**
   The password to use for the proxy server if required

**bypass_domains**
   An array of the domains that should bypass the proxy

**network_service**
   The network service to apply the changes to, this only necessary on macOS

25.20.250  salt.states.pushover

Send a message to PushOver

This state is useful for sending messages to PushOver during state runs.

New in version 2015.5.0.

```
pusher-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
    - message: 'This state was executed successfully.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml
pushover:
   token: peWcBiMOS9HrzG15peWcBiMOS9HrzG15

salt.states.pushover.post_message(name, user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

Send a message to a PushOver channel.

```
pushover-message:
pushover.post_message:
   - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
   - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
   - title: Salt Returner
   - device: phone
   - priority: -1
   - expire: 3600
   - retry: 5
```

The following parameters are required:

- **name**
  The unique name for this event.

- **user**
  The user or group of users to send the message to. Must be ID of user, not name or email address.

- **message**
  The message that is to be sent to the PushOver channel.

The following parameters are optional:

- **title**
  The title to use for the message.

- **device**
  The device for the user to send the message to.

- **priority**
  The priority for the message.

- **expire**
  The message should expire after specified amount of seconds.

- **retry**
  The message should be resent this many times.

- **token**
  The token for PushOver to use for authentication, if not specified in the configuration options of master or minion.

## 25.20.251 salt.states.pyenv

Managing python installations with pyenv

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will *not* automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to /usr/local/pyenv, otherwise it will be installed to the users ~/.pyenv directory. To make pyenv available in the shell you may need to add the pyenv/shims and pyenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access pyenv then you will need to add pyenv_ROOT to their environment.

This is how a state configuration could look like:
pyenv-deps:
   pkg.installed:
     - pkgs:
       - make
       - build-essential
       - libssl-dev
       - zlib1g-dev
       - libbz2-dev
       - libreadline-dev
       - libsqlite3-dev
       - wget
       - curl
       - llvm

python-2.6:
   pyenv.absent:
     - require:
       - pkg: pyenv-deps

python-2.7.6:
   pyenv.installed:
     - default: True
     - require:
       - pkg: pyenv-deps

---

**Note:** Git needs to be installed and available via PATH if pyenv is to be installed automatically by the module.

salt.states.pyenv.absent(name, user=None)

Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.

name
   The version of python to uninstall

user: None
   The user to run pyenv as.

   New in version 0.17.0.

salt.states.pyenv.install_pyenv(name, user=None)

Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.

Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.

user: None
   The user to run pyenv as.

salt.states.pyenv.installed(name, default=False, user=None)

Verify that the specified python is installed with pyenv. pyenv is installed if necessary.

name
   The version of python to install

default
   [False] Whether to make this python the default.
user: None
  The user to run pyenv as.
  New in version 0.17.0.
  New in version 0.16.0.

25.20.252 salt.states.pyrax_queues

Manage Rackspace Queues

New in version 2015.5.0.

Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.

This module uses pyrax, which can be installed via package, or pip. This module is greatly inspired by boto_* modules from SaltStack code source.

```
myqueue:
  pyrax_queues.present:
    - provider: my-pyrax

myqueue:
  pyrax_queues.absent:
    - provider: my-pyrax
```

salt.states.pyrax_queues.absent(name, provider)
  Ensure the named Rackspace queue is deleted.
  name
    Name of the Rackspace queue.
  provider
    Salt Cloud provider

salt.states.pyrax_queues.present(name, provider)
  Ensure the RackSpace queue exists.
  name
    Name of the Rackspace queue.
  provider
    Salt Cloud Provider

25.20.253 salt.states.quota

Management of POSIX Quotas

The quota can be managed for the system:

```
/: 
  quota.mode:
    mode: off
  quotatypes: user
```

salt.states.quota.mode(name, mode, quotatypetype)
  Set the quota for the system
name
   The filesystem to set the quota mode on
mode
   Whether the quota system is on or off
quotatype
   Must be user or group

25.20.254  salt.states.rabbitmq_cluster

Manage RabbitMQ Clusters

Example:

```
rabbit@rabbit.example.com:
rabbitmq_cluster.join:
   - user: rabbit
   - host: rabbit.example.com
```

```
salt.states.rabbitmq_cluster.join(name, host, user='rabbit', ram_node=None, runas='root')
```

This function is an alias of joined.

```
salt.states.rabbitmq_cluster.joined(name, host, user='rabbit', ram_node=None, runas='root')
```

Ensure the current node joined to a cluster with node user@host

name
   Irrelevant, not used (recommended: user@host)
user
   The user of node to join to (default: rabbit)
host
   The host of node to join to
ram_node
   Join node as a RAM node
runas
   The user to run the rabbitmq command as
25.20.255  salt.states.rabbitmq_plugin

Manage RabbitMQ Plugins

New in version 2014.1.0.

Example:

```python
some_plugin:
  rabbitmq_plugin.enabled: []
```

```python
salt.states.rabbitmq_plugin.disabled(name, runas=None)
    Ensure the RabbitMQ plugin is disabled.
    name
        The name of the plugin
    runas
        The user to run the rabbitmq-plugin command as
```

```python
salt.states.rabbitmq_plugin.enabled(name, runas=None)
    Ensure the RabbitMQ plugin is enabled.
    name
        The name of the plugin
    runas
        The user to run the rabbitmq-plugin command as
```

25.20.256  salt.states.rabbitmq_policy

Manage RabbitMQ Policies

maintainer
Benn Eichhorn <benn@getlocalmeasure.com>

maturity
new

platform
all

Example:

```python
rabbit_policy:
  rabbitmq_policy.present:
    - name: HA
    - pattern: '.*'
    - definition: '{"ha-mode": "all"}'
```

```python
salt.states.rabbitmq_policy.absent(name, vhost='/', runas=None)
    Ensure the named policy is absent
    Reference: http://www.rabbitmq.com/ha.html
    name
        The name of the policy to remove
    runas
        Name of the user to run the command as
```
salt.states.rabbitmq_policy.present(name, pattern, definition, priority=0, vhost='/', runas=None, apply_to=None)

Ensure the RabbitMQ policy exists.

Reference: https://rabbitmq.com/parameters.html#policies

- **name** -- Policy name
- **pattern** -- A regex of queues to apply the policy to
- **definition** -- A json dict describing the policy
- **priority** -- Priority (defaults to 0)
- **vhost** -- Virtual host to apply to (defaults to '/')
- **runas** -- Name of the user to run the command as
- **apply_to** -- Apply policy to 'queues', 'exchanges' or 'all' (default to 'all')

25.20.257 salt.states.rabbitmq_upstream

Manage RabbitMQ Upstreams

Example:

```yaml
rabbit_upstream:
  rabbitmq_upstream.present:
    - name: upstream_1
    - uri: amqp://my_user:my_password@rabbitmq_host
    - trust_user_id: True
    - ack_mode: on-confirm
    - max_hops: 1
```

New in version 3000.

salt.states.rabbitmq_upstream.absent(name, runas=None)

Ensure the named upstream is absent.

Parameters

- **name** (str) -- The name of the upstream to remove
- **runas** (str) -- User to run the command

New in version 3000.

salt.states.rabbitmq_upstream.present(name, uri, prefetch_count=None, reconnect_delay=None, ack_mode=None, trust_user_id=None, exchange=None, max_hops=None, expires=None, message_ttl=None, ha_policy=None, queue=None, runas=None)

Ensure the RabbitMQ upstream exists.

Parameters

- **name** (str) -- The name of the upstream connection
- **uri** (str) -- The URI to connect to. If upstream is a cluster and can have several URIs, you can enter them here separated by spaces. Examples: - amqp://user:password@server_name - amqp://user:password@server_name/vhost
When connecting with SSL, several URI-parameters need also be specified:
- `cacert-file = /path/to/cacert.pem`
- `certfile = /path/to/cert.pem`
- `keyfile = /path/to/key.pem`
- `verify = verify_peer`
- `fail_if_no_peer_cert = true | false`
- `auth_mechanism = external`

Example:
- `amqp://user:password@server_name?cacertfile=/path/to/cacert.pem&certfile=/path/to/cert.pem&keyfile=/path/to/key.pem&verify=verify_peer`
- `amqp://server-name?cacertfile=/path/to/cacert.pem&certfile=/path/to/cert.pem&keyfile=/path/to/key.pem&verify=verify_peer&fail_if_no_peer_cert=true&auth_mechanism=external`

- **prefetch_count (int)** -- Maximum number of unacknowledged messages that may be in flight over a federation link at one time. Default: 1000
- **reconnect_delay (int)** -- Time in seconds to wait after a network link goes down before attempting reconnection. Default: 5
- **ack_mode (str)** -- The following values are allowed:
  - `on-confirm`: Messages are acknowledged to the upstream broker after they have been confirmed downstream. Handles network errors and broker failures without losing messages. The slowest option, and the default.
  - `on-publish`: Messages are acknowledged to the upstream broker after they have been published downstream. Handles network errors without losing messages, but may lose messages in the event of broker failures.
  - `no-ack`: Message acknowledgements are not used. The fastest option, but you may lose messages in the event of network or broker failures.
- **trust_user_id (bool)** -- Set `True` to preserve the "user-id" field across a federation link, even if the user-id does not match that used to republish the message. Set to `False` to clear the "user-id" field when messages are federated. Only set this to `True` if you trust the upstream broker not to forge user-ids.
- **exchange (str)** -- The name of the upstream exchange. Default is to use the same name as the federated exchange.
- **max_hops (int)** -- Maximum number of federation links that messages can traverse before being dropped. Defaults to 1 if not set.
- **expires (int)** -- Time in milliseconds that the upstream should remember about this node for. After this time all upstream state will be removed. Set to `None` (Default) to mean "forever".
- **message_ttl (int)** -- Time in milliseconds that undelivered messages should be held upstream when there is a network outage or backlog. Set to `None` (default) to mean "forever".
- **ha_policy (str)** -- Determines the "x-ha-policy"-argument for the upstream queue for a federated exchange. Default is "none" meaning the queue is not HA.
- **queue (str)** -- The name of the upstream queue. Default is to use the same name as the federated queue.

New in version 3000.

### 25.20.258 `salt.states.rabbitmq_user`

**Manage RabbitMQ Users**

Example:

```
rabbit_user:
  rabbitmq_user.present:
    - password: password
    - force: True
    - tags:
      - monitoring
      - user
```

(continues on next page)
perms:
- '/*':
  - '.*'
  - '.*'
  - '.*'
- runas: rabbitmq

```
salt.states.rabbitmq_user.absent(name, runas=None)
```

Ensure the named user is absent

- **name**: The name of the user to remove
- **runas**: User to run the command

```
salt.states.rabbitmq_user.present(name, password=None, force=False, tags=None, perms=(), runas=None)
```

Ensure the RabbitMQ user exists.

- **name**: User name
- **password**: The user's password
- **force**: If force is True, the password will be automatically updated without extra password change check.
- **tags**: Optional list of tags for the user
- **perms**: A list of dicts with vhost keys and 3-tuple values
- **runas**: Name of the user to run the command

25.20.259 salt.states.rabbitmq_vhost

Manage RabbitMQ Virtual Hosts

Example:

```
virtual_host:
  rabbitmq_vhost.present:
    - user: rabbit_user
    - conf: .*
    - write: .*
    - read: .*
```

```
salt.states.rabbitmq_vhost.absent(name)
```

Ensure the RabbitMQ Virtual Host is absent

- **name**: Name of the Virtual Host to remove
- **runas**: User to run the command

Deprecated since version 2015.8.0.
salt.states.rabbitmq_vhost.present(name)
    Ensure the RabbitMQ VHost exists.
    name
        VHost name
    user
        Initial user permission to set on the VHost, if present
        Deprecated since version 2015.8.0.
    owner
        Initial owner permission to set on the VHost, if present
        Deprecated since version 2015.8.0.
    conf
        Initial conf string to apply to the VHost and user. Defaults to .*  
        Deprecated since version 2015.8.0.
    write
        Initial write permissions to apply to the VHost and user. Defaults to .*  
        Deprecated since version 2015.8.0.
    read
        Initial read permissions to apply to the VHost and user. Defaults to .*  
        Deprecated since version 2015.8.0.
    runas
        Name of the user to run the command
        Deprecated since version 2015.8.0.

25.20.260 salt.states.rbac_solaris

Management of Solaris RBAC

    maintainer
        Jorge Schrauwen <sjorge@blackdot.be>
    maturity
        new
    depends
        rbac_solaris,solaris_user
    platform
        solaris,illumos

New in version 2016.11.0.

sjorge:
    rbac.managed:
        - roles:
              - netcfg
        - profiles:
              - System Power
        - authorizations:
              - solaris.audit.*

salt.states.rbac_solaris.managed(name, roles=Name, profiles=Name, authorizations=Name)
    Manage RBAC properties for user
name
  [string] username
roles
  [list] list of roles for user
profiles
  [list] list of profiles for user
authorizations
  [list] list of authorizations for user

Warning: All existing roles, profiles and authorizations will be replaced! An empty list will remove everything.
Set the property to None to not manage it.

25.20.261 salt.states.rbenv

Managing Ruby installations with rbenv

This module is used to install and manage ruby installations with rbenv and the ruby-build plugin. Different versions of ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which rbenv will need to compile the versions of ruby. If your version of ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: https://github.com/rbenv/ruby-build/wiki

If rbenv is run as the root user then it will be installed to /usr/local/rbenv, otherwise it will be installed to the user’s ~/.rbenv directory. To make rbenv available in the shell you may need to add the rbenv/shims and rbenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access rbenv then you will need to add RBENV_ROOT to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

rbenv-deps:
  pkg.installed:
    - names:
      - bash
      - git
      - openssl
      - libssl-dev
      - make
      - curl
      - autoconf
      - bison
      - build-essential
      - libffi-dev
      - libyaml-dev
      - libreadline6-dev
      - zlib1g-dev
      - libncurses5-dev

ruby-1.9.3-p429:
  rbenv.absent:
    - require:
      - pkg: rbenv-deps

(continues on next page)
ruby-2.0.0-p598:
  rbenv.installed:
    - default: True
    - require:
      - pkg: rbenv-deps

salt.states.rbenv.absent(name, user=None)
Verify that the specified ruby is not installed with rbenv. Rbenv is installed if necessary.
  name
    The version of ruby to uninstall
  user: None
    The user to run rbenv as.
New in version 0.17.0.
New in version 0.16.0.

salt.states.rbenv.install_rbenv(name, user=None)
Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any rubies.
  user: None
    The user to run rbenv as.

salt.states.rbenv.installed(name, default=False, user=None)
Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.
  name
    The version of ruby to install
  default
    [False] Whether to make this ruby the default.
  user: None
    The user to run rbenv as.
New in version 0.17.0.
New in version 0.16.0.

25.20.262  salt.states.rdp
Manage RDP Service on Windows servers

salt.states.rdp.disabled(name)
Disable the RDP service

salt.states.rdp.enabled(name)
Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration
25.20.263 salt.states.redismod

Management of Redis server

New in version 2014.7.0.

depends

• redis Python module

configuration

See salt.modules.redis for setup instructions.

```
key_in_redis:
  redis.string:
    - value: string data
```

The redis server information specified in the minion config file can be overridden in states using the following arguments: host, post, db, password.

```
key_in_redis:
  redis.string:
    - value: string data
    - host: localhost
    - port: 6379
    - db: 0
    - password: somuchkittycat
```

salt.states.redismod.absent(name, keys=None, **connection_args)

Ensure key absent from redis

name

Key to ensure absent from redis

keys

list of keys to ensure absent, name will be ignored if this is used

salt.states.redismod.slaveof(name, sentinel_host=None, sentinel_port=None, sentinel_password=None, **connection_args)

Set this redis instance as a slave.

New in version 2016.3.0.

name

Master to make this a slave of

sentinel_host

Ip of the sentinel to check for the master

sentinel_port

Port of the sentinel to check for the master

salt.states.redismod.string(name, value, expire=None, expireat=None, **connection_args)

Ensure that the key exists in redis with the value specified

name

Redis key to manage

value

Data to persist in key

expire

Sets time to live for key in seconds

expireat

Sets expiration time for key via UNIX timestamp, overrides expire
25.20.264 salt.states.reg

Manage the Windows registry

Many python developers think of registry keys as if they were python keys in a dictionary which is not the case. The windows registry is broken down into the following components:

Hives

This is the top level of the registry. They all begin with HKEY.

- HKEY_CLASSES_ROOT (HKCR)
- HKEY_CURRENT_USER (HKCU)
- HKEY_LOCAL_MACHINE (HKLM)
- HKEY_USER (HKU)
- HKEY_CURRENT_CONFIG

Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

When passing the hivekey values they must be quoted correctly depending on the backslashes being used (\ vs \\). The way backslashes are handled in the state file is different from the way they are handled when working on the CLI. The following are valid methods of passing the hivekey:

Using single backslashes:

HKLM\SOFTWARE\Python 'HKLM\SOFTWARE\Python'

Using double backslashes:

"HKLM\SOFTWARE\Python"

Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. The name is (Default) with a displayed value of (value not set). The actual value is Null.

Example

The following example is taken from the windows startup portion of the registry:

[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run]
"RTHDVCPL"=""C:\\Program Files\\Realtek\\Audio\\HDA\\RtkNGUI64.exe" -s"
"NvBackend"=""C:\\Program Files (x86)\\NVIDIA Corporation\\Update Core\\...
...NvBackend.exe"
"BTMTrayAgent"="rundll32.exe "C:\\Program Files (x86)\\Intel\\Bluetooth\\...
...btmshelflex.dll","TrayApp"

In this example these are the values for each:

Hive: HKEY_LOCAL_MACHINE
Key and subkeys:
SOFTWARE\Microsoft\Windows\CurrentVersion\Run

Value:
- There are 3 value names: RTHDVCPL, NvBackend, and BTMTrayAgent
- Each value name has a corresponding value

class salt.states.reg.absent(name, vname=None, use_32bit_registry=False)

Ensure a registry value is removed. To remove a key use key_absent.

Parameters
- **name** (str) -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include:
  - HKEY_CURRENT_USER or HKCU
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_USERS or HKU

- **vname** (str) -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

- **use_32bit_registry** (bool) -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

Returns
A dictionary showing the results of the registry operation.

Return type
dict

CLI Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':
reg.absent
  - vname: version
```

In the above example the value named version will be removed from the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive. If vname was not passed, the (Default) value would be deleted.

class salt.states.reg.key_absent(name, use_32bit_registry=False)

New in version 2015.5.4.

Ensure a registry key is removed. This will remove the key, subkeys, and all value entries.

Parameters
- **name** (str) -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following:
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USERS or HKU

- **use_32bit_registry** (bool) -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

Returns
A dictionary showing the results of the registry operation.

Return type
dict

CLI Example:
The following example will delete the SOFTWARE\DeleteMe key in the HKEY_LOCAL_MACHINE hive including all its subkeys and value pairs.
```yaml
remove_key_demo:
  reg.key_absent:
    - name: HKEY_CURRENT_USER\SOFTWARE\DeleteMe
```

In the above example the path is interpreted as follows:
- HKEY_CURRENT_USER is the hive
- SOFTWARE\DeleteMe is the key

```python
salt.states.reg.present(name, vname=None, vdata=None, vtype='REG_SZ', use_32bit_registry=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, win_perms_reset=False)
```

Ensure a registry key or value is present.

**Parameters**
- **name (str)** -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:
  
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include:
  - HKEY_CURRENT_USER or HKCU
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_USERS or HKU
- **vname (str)** -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value
- **vdata (str, int, list, bytes)** -- The value you'd like to set. If a value name (vname) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

The type of data this parameter expects is determined by the value type specified in vtype. The correspondence is as follows:
- REG_BINARY: Binary data
- REG_DWORD: int
- REG_EXPAND_SZ: str
- REG_MULTI_SZ: list of str
- REG_QWORD: int
- REG_SZ: str

**Note:** When setting REG_BINARY, string data will be converted to binary automatically. To pass binary data, use the built-in yaml tag `!!binary` to denote the actual binary characters. For example, the following lines will both set the same data in the registry:

- vdata: Salty Test
- vdata: !!binary U2FsdHkgVGVzdA==

For more information about the `!!binary` tag see [here](#)

**Note:** The type for the (Default) value is always REG_SZ and cannot be changed. This parameter is optional. If not passed, the Key will be created with no associated item/value pairs.

- **vtype (str)** -- The value type for the data you wish to store in the registry. Valid values are:
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
- REG_MULTI_SZ
- REG_QWORD
- REG_SZ (Default)

- **use_32bit_registry (bool)** — Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False.

- **win_owner (str)** — The owner of the registry key. If this is not passed, the account under which Salt is running will be used.

  **Note:** Owner is set for the key that contains the value/data pair. You cannot set ownership on value/data pairs themselves.

**New in version 2019.2.0.**

- **win_perms (dict)** — A dictionary containing permissions to grant and their propagation. If not passed the 'Grant' permissions will not be modified.

  **Note:** Permissions are set for the key that contains the value/data pair. You cannot set permissions on value/data pairs themselves.

For each user specify the account name, with a sub dict for the permissions to grant and the 'Applies to' setting. For example: 

```
{ 'Administrators': { 'perms': 'full_control', 'applies_to': 'this_key_subkeys' } }
```

perms must be specified.

Registry permissions are specified using the perms key. You can specify a single basic permission or a list of advanced perms. The following are valid perms:

**Basic (passed as a string):**
- full_control
- read
- write

**Advanced (passed as a list):**
- delete
- query_value
- set_value
- create_subkey
- enum_subkeys
- notify
- create_link
- read_control
- write_dac
- write_owner

The 'Applies to' setting is optional. It is specified using the applies_to key. If not specified this_key_subkeys is used. Valid options are:

**Applies to settings:**
- this_key_only
- this_key_subkeys
- subkeys_only

**New in version 2019.2.0.**

- **win_deny_perms (dict)** — A dictionary containing permissions to deny and their propagation. If not passed the Deny permissions will not be modified.

  **Note:** Permissions are set for the key that contains the value/data pair. You cannot
set permissions on value/data pairs themselves.

Valid options are the same as those specified in \texttt{win_perms}

\textbf{Note:} \textquote{Deny} permissions always take precedence over \textquote{grant} permissions.

New in version 2019.2.0.
- \texttt{win_inheritance (bool)} -- \texttt{True} to inherit permissions from the parent key. \texttt{False} to disable inheritance. Default is \texttt{True}.

\textbf{Note:} Inheritance is set for the key that contains the value/data pair. You cannot set inheritance on value/data pairs themselves.

New in version 2019.2.0.
- \texttt{win_perms_reset (bool)} -- If \texttt{True} the existing DACL will be cleared and replaced with the settings defined in this function. If \texttt{False}, new entries will be appended to the existing DACL. Default is \texttt{False}.

\textbf{Note:} Perms are reset for the key that contains the value/data pair. You cannot set permissions on value/data pairs themselves.

\textbf{Returns}
- A dictionary showing the results of the registry operation.

\textbf{Return type}
- \texttt{dict}

\textbf{Example:}
The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1:

\begin{verbatim}
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vdata: 2016.3.1
\end{verbatim}

\textbf{Example:}
The following example will set the value for the version entry under the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1. The value will be reflected in Wow6432Node:

\begin{verbatim}
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vname: version
    - vdata: 2016.3.1
\end{verbatim}

In the above example the path is interpreted as follows:
- HKEY_CURRENT_USER is the hive
- SOFTWARE\Salt is the key
- vname is the value name ('version') that will be created under the key
- vdata is the data that will be assigned to 'version'
Example:

Binary data can be set in two ways. The following two examples will set a binary value of **Salty Test**

```plaintext
no_conversion:
reg.present:
  - name: HKLM\SOFTWARE\SaltTesting
  - vname: test_reg_binary_state
  - vdata: Salty Test
  - vtype: REG_BINARY

conversion:
reg.present:
  - name: HKLM\SOFTWARE\SaltTesting
  - vname: test_reg_binary_state_with_tag
  - vdata: !!binary U2FsdHkgVGVzdA==
  - vtype: REG_BINARY
```

Example:

To set a **REG_MULTI_SZ** value:

```plaintext
reg_multi_sz:
reg.present:
  - name: HKLM\SOFTWARE\Salt
  - vname: reg_multi_sz
  - vdata:
    - list item 1
    - list item 2
```

Example:

To ensure a key is present and has permissions:

```plaintext
set_key_permissions:
reg.present:
  - name: HKLM\SOFTWARE\Salt
  - vname: version
  - vdata: 2016.3.1
  - win_owner: Administrators
  - win_perms:
    jsnuffy:
      perms: full_control
    sjones:
      perms:
        - read_control
        - enum_subkeys
        - query_value
      applies_to:
        - this_key_only
    win_denied_perms:
      bsimpson:
        perms: full_control
        applies_to: this_key_subkeys
    win_inheritance: True
    win_perms_reset: True
```
25.20.265 salt.states.restconf

RESTCONF State module for Proxy minions

**codeauthor**
Jamie (Bear) Murphy <jamiemurphyit@gmail.com>

**maturity**
new

**platform**
any

**About**

This state module was designed to manage RESTCONF states. This module relies on the RESTCONF proxy module to interface with the devices.

```python
salt.states.restconf.config_manage(name, path, method, config, init_path=None, init_method='PATCH', init_config=None)
```

Ensure a specific value exists at a given path

- **name**: (str) The name for this rule
- **path**: (str) The RESTCONF path to set / get config
- **method**: (str) rest method to use eg GET, PUT, POST, PATCH, DELETE
- **config**: (dict) The new value at the given path
- **init_path**: (optional)
  - (str) Alternative path incase the path doesn't exist on first pass
- **init_method**: (optional)
  - (str) Method to use on alternative path when setting config, default: PATCH
- **init_config**: (optional)
  - (dict) The new value at the given init path. This is only needed if you need to supply a different style of data to an init path.

**Examples:**

```python
do_configure_restconf_endpoint:
    restconf.config_manage:
        - name: random_name_here
        - path: restconf/data/Cisco-IOS-XE-native:native/interface/
            GigabitEthernet=1%2F0%2F3
        - config:
            Cisco-IOS-XE-native:GigabitEthernet:
                description: interfaceDescription
                name: "1/0/3"
```

25.20. state modules
25.20.266  salt.states.rsync

State to synchronize files and directories with rsync.

New in version 2016.3.0.

```
[opts user-backups:
rsync.synchronized:  
  - source: /home
  - force: True

salt.states.rsync.synchronized(name, source, delete=False, force=False, update=False,  
passwordfile=None, exclude=None, excludefrom=None, prepare=False,  
dryrun=False, additional_opts=None)
```

Guarantees that the source directory is always copied to the target.

- **name**: Name of the target directory.
- **source**: Source directory.
- **prepare**: Create destination directory if it does not exists.
- **delete**: Delete extraneous files from the destination dirs (True or False)
- **force**: Force deletion of dirs even if not empty
- **update**: Skip files that are newer on the receiver (True or False)
- **passwordfile**: Read daemon-access password from the file (path)
- **exclude**: Exclude files, that matches pattern.
- **excludefrom**: Read exclude patterns from the file (path)
- **dryrun**: Perform a trial run with no changes made. Is the same as doing test=True

New in version 2016.3.1.

- **additional_opts**: Pass additional options to rsync, should be included as a list.

New in version 2018.3.0.

25.20.267  salt.states.rvm

Managing Ruby installations and gemsets with Ruby Version Manager (RVM)

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it’s not present. This module will not automatically install packages that RVM depends on or ones that are needed to build ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself. This is how a state configuration could look like:

```
rvm:
   group.present: []
```

(continues on next page)
user.present:
  - gid: rvm
  - home: /home/rvm
  - require:
    - group: rvm

rvm-deps:
  pkg.installed:
    - pkgs:
      - bash
      - coreutils
      - gzip
      - bzip2
      - gawk
      - sed
      - curl
      - git-core
      - subversion

mri-deps:
  pkg.installed:
    - pkgs:
      - build-essential
      - openssl
      - libreadline6
      - libreadline6-dev
      - curl
      - git-core
      - zlib1g
      - zlib1g-dev
      - libssl-dev
      - libyaml-dev
      - libsqlite3-0
      - libsqlite3-dev
      - sqlite3
      - libxml2-dev
      - libxslt1-dev
      - autoconf
      - libc6-dev
      - libncurses5-dev
      - automake
      - libtool
      - bison
      - subversion
      - ruby

jruby-deps:
  pkg.installed:
    - pkgs:
      - curl
      - g++
      - openjdk-6-jre-headless

(continued on next page)
ruby-1.9.2:
  rvm.installed:
    - default: True
    - user: rvm
    - require:
      - pkg: rvm-deps
      - pkg: mri-deps
      - user: rvm

jruby:
  rvm.installed:
    - user: rvm
    - require:
      - pkg: rvm-deps
      - pkg: jruby-deps
      - user: rvm

jgemset:
  rvm.gemset_present:
    - ruby: jruby
    - user: rvm
    - require:
      - rvm: jruby

mygemset:
  rvm.gemset_present:
    - ruby: ruby-1.9.2
    - user: rvm
    - require:
      - rvm: ruby-1.9.2

salt.states.rvm.gemset_present(name, ruby='default', user=None)

  Verify that the gemset is present.

  name
    The name of the gemset.
  ruby: default
    The ruby version this gemset belongs to.
  user: None
    The user to run rvm as.

  New in version 0.17.0.

salt.states.rvm.installed(name, default=False, user=None, opts=None, env=None)

  Verify that the specified ruby is installed with RVM. RVM is installed when necessary.

  name
    The version of ruby to install
  default
    [False] Whether to make this ruby the default.
  user: None
    The user to run rvm as.
  env: None
    A list of environment variables to set (ie, RUBY_CONFIGURE_OPTS)
opts: None  
A list of option flags to pass to RVM (ie -C, --patch)  
New in version 0.17.0.

25.20.268 salt.states.salt_proxy

Salt proxy state  
New in version 2015.8.2.  
State to deploy and run salt-proxy processes on a minion.  
Set up pillar data for your proxies per the documentation.  
Run the state as below

```bash
salt-proxy-configure:  
salt_proxy.configure_proxy:  
  - proxynname: p8000  
  - start: True
```

This state will configure the salt proxy settings within /etc/salt/proxy (if /etc/salt/proxy doesn't exists) and start the salt-proxy process (default true), if it isn't already running.

```bash
salt.states.salt_proxy.configure_proxy(name, proxynname='p8000', start=True)
```

Create the salt proxy file and start the proxy process if required

Parameters

- name -- The name of this state  
- proxynname -- Name to be used for this proxy (should match entries in pillar)  
- start -- Boolean indicating if the process should be started

Example:

```bash
salt-proxy-configure:  
salt_proxy.configure_proxy:  
  - proxynname: p8000  
  - start: True
```

25.20.269 salt.states.saltmod

Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt’s Python API.  

New in version 2016.11.0.  
Support for masterless minions was added to the salt.state function, so they can run orchestration sls files. This is particularly useful when the rendering of a state is dependent on the execution of another state. Orchestration will render and execute each orchestration block independently, while honoring requisites to ensure the states are applied in the correct order.

See also:

More Orchestrate documentation

- Full Orchestrate Tutorial
- **The Orchestrate runner**

```python
salt.states.saltmod.function(name, tgt, ssh=False, tgt_type='glob', ret='', ret_config=None, ret_kwargs=None, expect_minions=False, fail_minions=None, fail_function=None, arg=None, kwarg=None, timeout=None, batch=None, subset=None, failhard=None, **kwargs)
```

Execute a single module function on a remote minion via salt or salt-ssh

- **name**
  The name of the function to run, aka cmd.run or pkg.install

- **tgt**
  The target specification, aka "*" for all minions

- **tgt_type**
  The target type, defaults to `glob`

- **arg**
  The list of arguments to pass into the function

- **kwarg**
  The dict (not a list) of keyword arguments to pass into the function

- **ret**
  Optionally set a single or a list of returners to use

- **ret_config**
  Use an alternative returner configuration

- **ret_kwargs**
  Override individual returner configuration items

- **expect_minions**
  An optional boolean for failing if some minions do not respond

- **fail_minions**
  An optional list of targeted minions where failure is an option

- **fail_function**
  An optional string that points to a salt module that returns True or False based on the returned data dict for individual minions

- **ssh**
  Set to `True` to use the ssh client instead of the standard salt client

- **roster**
  In the event of using salt-ssh, a roster system can be set
  New in version 3005.

- **batch**
  Execute the command in batches. E.g.: `10%`

- **subset**
  Number of minions from the targeted set to randomly use
  New in version 2017.7.0.

- **failhard**
  pass failhard down to the executing state
  New in version 2019.2.2.

```python
salt.states.saltmod.parallel_runners(name, runners, **kwargs)
```

Executes multiple runner modules on the master in parallel.

New in version 2018.3.0.

A separate thread is spawned for each runner. This state is intended to be used with the orchestrate runner in place of the `saltmod.runner` state when different tasks should be run in parallel. In general, Salt states are not safe when used concurrently, so ensure that they are used in a safe way (e.g. by only targeting separate minions in parallel tasks).
name:
name identifying this state. The name is provided as part of the output, but not used for anything else.

runners:
list of runners that should be run in parallel. Each element of the list has to be a dictionary. This
dictionary’s name entry stores the name of the runner function that shall be invoked. The optional
kwarg entry stores a dictionary of named arguments that are passed to the runner function.

```
parallel-state:
salt.parallel_runners:
  - runners:
    my_runner_1:
      - name: state.orchestrate
      - kwarg:
        mods: orchestrate_state_1
    my_runner_2:
      - name: state.orchestrate
      - kwarg:
        mods: orchestrate_state_2
```

salt.states.saltmod.runner(name, **kwargs)
Execute a runner module on the master

New in version 2014.7.0.

name
The name of the function to run

kwargs
Any keyword arguments to pass to the runner function

```
run-manage-up:
salt.runner:
  - name: manage.up
```

salt.states.saltmod.state(name, tgt, ssh=False, tgt_type='glob', ret='*', ret_config=None, ret_kwargs=None,
highstate=None, sls=None, top=None, saltenv=None, test=None, pillar=None,
pillarenv=None, expect_minions=True, exclude=None, fail_minions=None,
allow_fail=0, concurrent=False, timeout=None, batch=None, queue=False,
subset=None, orchestration_jid=None, failhard=None, **kwargs)
Invoke a state run on a given target

name
An arbitrary name used to track the state execution

tgt
The target specification for the state run.

New in version 2016.11.0.

Masterless support: When running on a masterless minion, the tgt is ignored and will always be the
local minion.

tgt_type
The target type to resolve, defaults to glob

ret
Optionally set a single or a list of returners to use

ret_config
Use an alternative returner configuration

ret_kwargs
Override individual returner configuration items
highstate
Defaults to None, if set to True the target systems will ignore any sls references specified in the sls option and call state.highstate on the targeted minions

top
Should be the name of a top file. If set state.top is called with this top file instead of state.sls.

sls
A group of sls files to execute. This can be defined as a single string containing a single sls file, or a list of sls files

test
Pass test=true or test=false through to the state function. This can be used to override a test mode set in the minion's config file. If left as the default of None and the 'test' mode is supplied on the command line, that value is passed instead.
pillar
Pass the pillar kwarg through to the state function
pillarenv
The pillar environment to grab pillars from
New in version 2017.7.0.
saltenv
The default salt environment to pull sls files from
ssh
Set to True to use the ssh client instead of the standard salt client
roster
In the event of using salt-ssh, a roster system can be set
expect_minions
An optional boolean for failing if some minions do not respond
fail_minions
An optional list of targeted minions where failure is an option
allow_fail
Pass in the number of minions to allow for failure before setting the result of the execution to False
exclude
Pass exclude kwarg to state
concurrent
Allow multiple state runs to occur at once.
WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same Do not use this flag for performance optimization.
queue
Pass queue=true through to the state function
batch
Execute the command in batches. E.g.: 10%.
New in version 2016.3.0.
subset
Number of minions from the targeted set to randomly use
New in version 2017.7.0.
failhard
pass failhard down to the executing state
New in version 2019.2.2.
Examples:
Run a list of sls files via state.sls on target minions:

**webservers:**
Run sls file via state.sls on target minions with exclude:

```yaml
docker:
salt.state:
  - tgt: 'docker*'
  - sls: docker
  - exclude: docker.swarm
  - saltenv: prod
```

Run a full state.highstate on target minions.

```yaml
databases:
salt.state:
  - tgt: role:database
  - tgt_type: grain
  - highstate: True
```

`salt.states.saltmod.wait_for_event(name, id_list, event_id='id', timeout=300, node='master')`

Watch Salt’s event bus and block until a condition is met

New in version 2014.7.0.

`name`
An event tag to watch for; supports Reactor-style globbing.

`id_list`
A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched the event data is inspected for event_id, if found it is removed from id_list. When id_list is empty this function returns success.

`event_id`
[id] The name of a key in the event data. Default is id for the minion ID, another common value is name for use with orchestrating salt-cloud events.

`timeout`
[300] The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

```yaml
reboot_all_minions:
salt.function:
  - name: system.reboot
    - tgt: '*'

wait_for_reboots:
salt.wait_for_event:
  - name: salt/minion/*/start
    - id_list:
      - jerry
      - stuart
```

(continues on next page)
- dave
- phil
- kevin
- mike
- **require**: 
  - **salt**: reboot_all_minions

salt.states.saltmod.wheel(name, **kwargs)

Execute a wheel module on the master

New in version 2014.7.0.

name
The name of the function to run

kwargs
Any keyword arguments to pass to the wheel function

25.20.270 salt.states.saltutil

Saltutil State

This state wraps the saltutil execution modules to make them easier to run from a states. Rather than needing to use module.run this state allows for improved change detection.

New in version 3000.

salt.states.saltutil.sync_all(name, **kwargs)

Performs the same task as saltutil.sync_all module See saltutil module for full list of options

sync_everything:
  saltutil.sync_all:
    - refresh: True

salt.states.saltutil.sync_beacons(name, **kwargs)

Performs the same task as saltutil.sync_beacons module See saltutil module for full list of options

sync_everything:
  saltutil.sync_beacons:
    - refresh: True

salt.states.saltutil.sync_clouds(name, **kwargs)

Performs the same task as saltutil.sync_clouds module See saltutil module for full list of options
salt.states.saltutil.sync_clouds()
salt.states.saltutil.sync_engines(name, **kwargs)
  Performs the same task as saltutil.sync_engines module See saltutil module for full list of options
salt.states.saltutil.sync_executors(name, **kwargs)
  Performs the same task as saltutil.sync_executors module See saltutil module for full list of options

salt.states.saltutil.sync_wrapper(name, **kwargs)
New in version 3007.0.
Performs the same task as saltutil.sync_wrapper module See saltutil module for full list of options

sync_everything:
saltutil.sync_wrapper:
  - refresh: True
```
Management of the Salt scheduler

**job3:**
```yaml
  schedule.present:
    - function: test.ping
    - seconds: 3600
    - splay: 10
```

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 0 and 10 seconds

**job2:**
```yaml
  schedule.present:
    - function: test.ping
    - seconds: 15
    - splay:
      start: 10
      end: 20
```

This will schedule the command: test.ping every 15 seconds splaying the time between 10 and 20 seconds

**job1:**
```yaml
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that python-dateutil is installed on the minion.

**job1:**
```yaml
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - cron: '*/5 * * * *'
```

Scheduled jobs can also be specified using the format used by cron. This will schedule the command: state.sls httpd test=True to run every 5 minutes. Requires that python-croniter is installed on the minion.

(continues on next page)
This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the xmpp returner to return the results of the scheduled job, with the alternative configuration options found in the xmpp_state_run section.

```
job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      - test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
    - returner: xmpp
    - return_config: xmpp_state_run
    - return_kwargs:
      - recipient: user@domain.com
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that python-dateutil is installed on the minion.

`salt.states.schedule.absent(name, **kwargs)`

Ensure a job is absent from the schedule

- **name**
  The unique name that is given to the scheduled job.
- **persist**
  Whether changes to the scheduled job should be saved, defaults to True.
  When used with absent this will decide whether the scheduled job will be removed from the saved scheduled jobs and not be available when the Salt minion is restarted.

`salt.states.schedule.disabled(name, **kwargs)`

Ensure a job is disabled in the schedule

- **name**
  The unique name that is given to the scheduled job.
- **persist**
  Whether changes to the scheduled job should be saved, defaults to True.
salt.states.schedule.enabled(name, **kwargs)

Ensure a job is enabled in the schedule

name
The unique name that is given to the scheduled job.
persist
Whether changes to the scheduled job should be saved, defaults to True.

salt.states.schedule.present(name, **kwargs)

Ensure a job is present in the schedule

name
The unique name that is given to the scheduled job.
seconds
The scheduled job will be executed after the specified number of seconds have passed.
minutes
The scheduled job will be executed after the specified number of minutes have passed.
hours
The scheduled job will be executed after the specified number of hours have passed.
days
The scheduled job will be executed after the specified number of days have passed.
when
This will schedule the job at the specified time(s). The when parameter must be a single value or a
dictionary with the date string(s) using the dateutil format. Requires python-dateutil.
cron
This will schedule the job at the specified time(s) using the crontab format. Requires python-croniter.
run_on_start
Whether the scheduled job will run when Salt minion starts, or the job will be skipped once and run at
the next scheduled run. Value should be a boolean.
function
The function that should be executed by the scheduled job.
job_args
The arguments that will be used by the scheduled job.
job_kwargs
The keyword arguments that will be used by the scheduled job.
maxrunning
Ensure that there are no more than N copies of a particular job running.
jid_include
Include the job into the job cache.
splay
The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds or
as a dictionary range with 'start' and 'end' values.
range
This will schedule the command within the range specified. The range parameter must be a dictionary
with the date strings using the dateutil format. Requires python-dateutil.
once
This will schedule a job to run once on the specified date.
once_fmt
The default date format is ISO 8601 but can be overridden by also specifying the once_fmt option.
enabled
Whether the scheduled job should be enabled or disabled. Value should be a boolean.
return_job
Whether to return information to the Salt master upon job completion.
metadata
Using the metadata parameter special values can be associated with a scheduled job. These values are
not used in the execution of the job, but can be used to search for specific jobs later if combined with
the return_job parameter. The metadata parameter must be specified as a dictionary, otherwise it will be ignored.

**returner**

The returner to use to return the results of the scheduled job.

**return_config**

The alternative configuration to use for returner configuration options.

**return_kwargs**

Any individual returner configuration items to override. Should be passed as a dictionary.

**persist**

Whether changes to the scheduled job should be saved, defaults to True.

**skip_during_range**

This will ensure that the scheduled command does not run within the range specified. The range parameter must be a dictionary with the date strings using the dateutil format. Requires python-dateutil.

**run_after_skip_range**

Whether the scheduled job should run immediately after the skip_during_range time period ends.

### 25.20.272 salt.states.selinux

**Management of SELinux rules**

If SELinux is available for the running system, the mode can be managed and booleans can be set.

```python
enforcing:
    selinux.mode

samba_create_home_dirs:
    selinux.boolean:
        - value: True
        - persist: True

nginx:
    selinux.module:
        - enabled: False
```

**Note:** Use of these states require that the selinux execution module is available.

```python
salt.states.selinux.boolean(name, value, persist=False)
```

Set up an SELinux boolean

- **name**
  The name of the boolean to set

- **value**
  The value to set on the boolean

- **persist**
  Defaults to False, set persist to true to make the boolean apply on a reboot

```python
salt.states.selinux.fcontext_policy_absent(name, filetype='a', sel_type=None, sel_user=None, sel_level=None)
```

New in version 2017.7.0.

Makes sure an SELinux file context policy for a given filespec (name), filetype and SELinux context type is absent.
name
   filespec of the file or directory. Regex syntax is allowed.

filetype
   The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
   Defaults to ‘a’ (all files).

sel_type
   The SELinux context type. There are many.

sel_user
   The SELinux user.

sel_level
   The SELinux MLS range.

salt.states.selinux.fcontext_policy_applied(name, recursive=False)
   New in version 2017.7.0.
   Checks and makes sure the SELinux policies for a given filespec are applied.

salt.states.selinux.fcontext_policy_present(name, sel_type, filetype='a', sel_user=None, sel_level=None)
   New in version 2017.7.0.
   Makes sure a SELinux policy for a given filespec (name), filetype and SELinux context type is present.

name
   filespec of the file or directory. Regex syntax is allowed.

sel_type
   SELinux context type. There are many.

filetype
   The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
   Defaults to ‘a’ (all files).

sel_user
   The SELinux user.

sel_level
   The SELinux MLS range.

salt.states.selinux.mode(name)
   Verifies the mode SELinux is running in, can be set to enforcing, permissive, or disabled

Note: A change to or from disabled mode requires a system reboot. You will need to perform this yourself.

name
   The mode to run SELinux in, permissive, enforcing, or disabled.

salt.states.selinux.module(name, module_state='Enabled', version='any', **opts)
   Enable/Disable and optionally force a specific version for an SELinux module

name
   The name of the module to control

module_state
   Should the module be enabled or disabled?

version
   Defaults to no preference, set to a specified value if required. Currently can only alert if the version is incorrect.

install
   Setting to True installs module

source
   Points to module source file, used only when install is True
remove
  Setting to True removes module
  New in version 2016.3.0.

`salt.states.selinux.module_install(name)`
  Installs custom SELinux module from given file
  name
    Path to file with module to install
  New in version 2016.11.6.

`salt.states.selinux.module_remove(name)`
  Removes SELinux module
  name
    The name of the module to remove
  New in version 2016.11.6.

`salt.states.selinux.port_policy_absent(name, sel_type=None, protocol=None, port=None)`
  New in version 2019.2.0.
  Makes sure an SELinux port policy for a given port, protocol and SELinux context type is absent.
  name
    The protocol and port spec. Can be formatted as (tcp|udp)/(port|port-range).
  sel_type
    The SELinux Type. Optional; can be used in determining if policy is present, ignored by `semanage port --delete`.
  protocol
    The protocol for the port, tcp or udp. Required if name is not formatted.
  port
    The port or port range. Required if name is not formatted.

`salt.states.selinux.port_policy_present(name, sel_type, protocol=None, port=None, sel_range=None)`
  New in version 2019.2.0.
  Makes sure an SELinux port policy for a given port, protocol and SELinux context type is present.
  name
    The protocol and port spec. Can be formatted as (tcp|udp)/(port|port-range).
  sel_type
    The SELinux Type.
  protocol
    The protocol for the port, tcp or udp. Required if name is not formatted.
  port
    The port or port range. Required if name is not formatted.
  sel_range
    The SELinux MLS/MCS Security Range.
25.20.273 salt.states.serverdensity_device

Monitor Server with Server Density

New in version 2014.7.0.

Server Density is a hosted monitoring service.

**Warning:** This state module is beta. It might be changed later to include more or less automation.

**Note:** This state module requires a pillar for authentication with Server Density To install a v1 agent:

```yaml
serverdensity:
  api_token: "b97da80a41c4f61bff05975ee51eb1aa"
  account_url: "https://your-account.serverdensity.io"
```

To install a v2 agent:

```yaml
serverdensity:
  api_token: "b97da80a41c4f61bff05975ee51eb1aa"
  account_name: "your-account"
```

**Note:** Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```yaml
'server_name':
  serverdensity_device.monitored
```

**salt.states.serverdensity_device.monitored**(name, group=None, salt_name=True, salt_params=True, agent_version=1, **params)

Device is monitored with Server Density.

- **name**
  Device name in Server Density.

- **salt_name**
  If True (default), takes the name from the id grain. If False, the provided name is used.

- **group**
  Group name under with device will appear in Server Density dashboard. Default - None.

- **agent_version**
  The agent version you want to use. Valid values are 1 or 2. Default - 1.

- **salt_params**
  If True (default), needed config parameters will be sourced from grains and from status.all_status.

- **params**
  Add parameters that you want to appear in the Server Density dashboard. Will overwrite the salt_params parameters. For more info, see the API docs.

Usage example:
25.20.274  salt.states.service

Starting or restarting of services and daemons

Services are defined as system daemons and are typically launched using system init or rc scripts. This service state uses whichever service module is loaded on the minion with the virtualname of service. Services can be defined as either running or dead.

If you need to know if your init system is supported, see the list of supported service modules for your desired init system (systemd, sysvinit, launchctl, etc.).

Note that Salt’s service execution module, and therefore this service state, uses OS grains to ascertain which service module should be loaded and used to execute service functions. As existing distributions change init systems or new distributions are created, OS detection can sometimes be incomplete. If your service states are running into trouble with init system detection, please see the Overriding Virtual Module Providers section of Salt’s module documentation to work around possible errors.

For services managed by systemd, the systemd_service module includes a built-in feature to reload the daemon when unit files are changed or extended. This feature is used automatically by the service state and the systemd_service module when running on a systemd minion, so there is no need to set up your own methods of reloading the daemon. If you need to manually reload the daemon for some reason, you can use the systemd_service. systemctl_reload function provided by Salt.

Note: The current status of a service is determined by the return code of the init/rc script status command. A status return code of 0 it is considered running. Any other return code is considered dead.

httpd:
  service.running: []

The service can also be set to start at runtime via the enable option:

openvpn:
  service.running:
    - enable: True

By default if a service is triggered to refresh due to a watch statement the service is restarted. If the desired behavior is to reload the service, then set the reload value to True:
### redis:

```yaml
- service.running:
  - enable: True
  - reload: True
  - watch:
    - pkg: redis
```

**Note:** More details regarding `watch` can be found in the *Requisites* documentation.

```python
salt.states.service.dead(name, enable=None, sig=None, init_delay=None, **kwargs)
```

Ensure that the named service is dead by stopping the service if it is running.

- **name**
  The name of the init or rc script used to manage the service.

- **enable**
  Set the service to be enabled at boot time, `True` sets the service to be enabled, `False` sets the named service to be disabled. The default is `None`, which does not enable or disable anything.

- **sig**
  The string to search for when looking for the service process with `ps`.

- **init_delay**
  Add a sleep command (in seconds) before the check to make sure service is killed.

  New in version 2017.7.0.

- **no_block**
  `[False]` For *systemd* minions only. Stops the service using `--no-block`.

  New in version 2017.7.0.

- **timeout**
  For Windows minions only.

  The time in seconds to wait for the service to stop before returning. Default is the default for `win_service.stop`.

  New in version 2017.8.9, 2018.3.4.

```python
salt.states.service.disabled(name, **kwargs)
```

Ensure that the service is disabled on boot, only use this state if you don't want to manage the running process, remember that if you want to disable a service to use the enable: `False` option for the running or dead function.

- **name**
  The name of the init or rc script used to manage the service.

```python
salt.states.service.enabled(name, **kwargs)
```

Ensure that the service is enabled on boot, only use this state if you don't want to manage the running process, remember that if you want to enable a running service to use the enable: `True` option for the running or dead function.

- **name**
  The name of the init or rc script used to manage the service.

```python
salt.states.service.masked(name, runtime=False)
```

New in version 2017.7.0.

**Note:** This state is only available on minions which use *systemd*.

Ensures that the named service is masked (i.e. prevented from being started).
name
   Name of the service to mask
runtime
   [False] By default, this state will manage an indefinite mask for the named service. Set this argument to True to runtime mask the service.

Note: It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will manage a runtime or indefinite mask independently of each other. This means that if the service is already indefinitely masked, running this state with runtime set to True will _not_ remove the indefinite mask before setting a runtime mask. In these cases, if it is desirable to ensure that the service is runtime masked and not indefinitely masked, pair this state with a service.unmasked state, like so:

```yaml
mask_runtime_foo:
   service.masked:
      - name: foo
      - runtime: True

unmask_indefinite_foo:
   service.unmasked:
      - name: foo
      - runtime: False
```

salt.states.service.mod_beacon(name, **kwargs)
Create a beacon to monitor a service based on a beacon state argument.

Note: This state exists to support special handling of the beacon state argument for supported state functions. It should not be called directly.

salt.states.service.mod_watch(name, sfun=None, sig=None, reload=False, full_restart=False, init_delay=None, force=False, **kwargs)
The service watcher, called to invoke the watch command. When called, it will restart or reload the named service.

Note: This state exists to support special handling of the watch requisite. It should not be called directly.

Parameters for this function should be set by the watching service (e.g. service.running).

name
   The name of the service to control.
sfun
   The original function which triggered the mod_watch call (service.running, for example).
sig
   The string to search for when looking for the service process with ps.
reload
   When set, reload the service instead of restarting it (e.g. service nginx reload).
full_restart
   Perform a full stop/start of a service by passing --full-restart. This option is ignored if reload is set and is supported by only a few service modules.
force
   Use service.force_reload instead of reload (needs reload to be set to True).
**init_delay**
Add a sleep command (in seconds) before the service is restarted/reloaded.

salt.states.service.running(name, enable=None, sig=None, init_delay=None, **kwargs)
Ensure that the service is running

* name
  The name of the init or rc script used to manage the service

* enable
  Set the service to be enabled at boot time, `True` sets the service to be enabled, `False` sets the named service to be disabled. The default is `None`, which does not enable or disable anything.

* sig
  The string to search for when looking for the service process with `ps`

* init_delay
  Some services may not be truly available for a short period after their startup script indicates to the system that they are. Provide an 'init_delay' to specify that this state should wait an additional given number of seconds after a service has started before returning. Useful for requisite states wherein a dependent state might assume a service has started but is not yet fully initialized.

* no_block
  `[False]` For systemd minions only. Starts the service using `--no-block`.
  New in version 2017.7.0.

* timeout
  For Windows minions only.
  The time in seconds to wait for the service to start before returning. Default is the default for `win_service.start`.
  New in version 2017.7.9, 2018.3.4.

* unmask
  `[False]` For systemd minions only. Set to `True` to remove an indefinite mask before attempting to start the service.
  New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any changes. This behavior is no longer the default.

* unmask_runtime
  `[False]` For systemd minions only. Set to `True` to remove a runtime mask before attempting to start the service.
  New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any changes. This behavior is no longer the default.

* wait
  `[3]` For systemd minions only. Passed through when using `service.status` to determine whether the service is running or not.
  New in version 2019.2.3.

---

**Note:**
*watch* can be used with `service.running` to restart a service when another state changes (example: a file.managed state that creates the service's config file). More details regarding `watch` can be found in the `Requisites` documentation.

salt.states.service.unmasked(name, runtime=False)
New in version 2017.7.0.

---

**Note:** This state is only available on minions which use `systemd`. 
Ensures that the named service is unmasked

name
Name of the service to unmask

runtime
[False] By default, this state will manage an indefinite mask for the named service. Set this argument to True to ensure that the service is runtime masked.

Note: It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will manage a runtime or indefinite mask independently of each other. This means that if the service is indefinitely masked, running this state with runtime set to True will _not_ remove the indefinite mask.

25.20.275 salt.states.slack

Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

```yaml
slack-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The api key can be specified in the master or minion configuration like below:

```yaml
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.states.slack.post_message(name, **kwargs)

Send a message to a Slack channel.

```yaml
slack-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The following parameters are required:

api_key parameters:

- name
  The unique name for this event.
- channel
  The channel to send the message to. Can either be the ID or the name.
- from_name
  The name of that is to be shown in the "from" field.
- message
  The message that is to be sent to the Slack channel.

The following parameters are optional:
api_key
The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.

icon
URL to an image to use as the icon for this message

webhook parameters:
name
The unique name for this event.
message
The message that is to be sent to the Slack channel.
color
The color of border of left side
short
An optional flag indicating whether the value is short enough to be displayed side-by-side with other values.
webhook
The identifier of WebHook (URL or token).
channel
The channel to use instead of the WebHook default.
username
Username to use instead of WebHook default.
icon_emoji
Icon to use instead of WebHook default.

25.20.276 salt.states.smartos

Management of SmartOS Standalone Compute Nodes

maintainer
Jorge Schrauwen <sjorge@blackdot.be>
maturity
new
depends
vmadm, imgadm
platform
smartos

New in version 2016.3.0.

```yaml
vmtest.example.org:
  smartos.vm_present:
    - config:
        reprovision: true
    - vmconfig:

  - **resolvers**:
    - 172.16.1.1
  - **nics**:
    - "82:1b:8e:49:e9:18":
      - **nic_tag**: trunk
      - **mtu**: 1500
    - **ips**:
      - 172.16.1.118/24
    - **vlan_id**: 10
  - **filesystems**:
    - "/config:
      - **source**: "/vmdata/emby_config"
      - **type**: lofs
      - **options**:
        - nodevices

**cleanup_images**:
  - smartos.image_vacuum

**Note:** Keep in mind that when removing properties from vmconfig they will not get removed from the vm's current configuration, except for nics, disk, tags, ... they get removed via add_*, set_*, update_*, and remove_. Properties must be manually reset to their default value. The same behavior as when using 'vmadm update'.

**Warning:** For HVM (bhyve and KVM) brands the **image_uuid** field should go on the boot disks, this disk should NOT have a size specified. (See man vmadm)

salt.states.smartos.config_absent(name)

Ensure configuration property is absent in /usbkey/config

name [string] name of property

salt.states.smartos.config_present(name, value)

Ensure configuration property is set to value in /usbkey/config

name [string] name of property

value [string] value of property

salt.states.smartos.image_absent(name)

Ensure image is absent on the computenode
name

[string] uuid of image

**Note:** computenode.image_absent will only remove the image if it is not used by a vm.

salt.states.smartos.image_present(name)

Ensure image is present on the computenode

name

[string] uuid of image

salt.states.smartos.image_vacuum(name)

Delete images not in use or installed via image_present

**Warning:** Only image_present states that are included via the top file will be detected.

salt.states.smartos.source_absent(name)

Ensure an image source is absent on the computenode

name

[string] source url

salt.states.smartos.source_present(name, source_type='imgapi')

Ensure an image source is present on the computenode

name

[string] source url

source_type

[string] source type (imgapi or docker)

salt.states.smartos.vm_absent(name, archive=False)

Ensure vm is absent on the computenode

name

[string] hostname of vm

archive

[boolean] toggle archiving of vm on removal

**Note:** State ID is used as hostname. Hostnames must be unique.

salt.states.smartos.vm_present(name, vmconfig, config=None)

Ensure vm is present on the computenode

name

[string] hostname of vm

vmconfig

[dict] options to set for the vm

config

[dict] fine grain control over vm_present

**Note:**

The following configuration properties can be toggled in the config parameter.

- kvm_reboot (true) - reboots of kvm zones if needed for a config update
- auto_import (false) - automatic importing of missing images
- auto_lx_vars (true) - copy kernel_version and docker:* variables from image
- reprovision (false) - reprovision on image_uuid changes
- enforce_tags (true) - false = add tags only, true = add, update, and remove tags
- enforce_routes (true) - false = add tags only, true = add, update, and remove routes
- enforce_internal_metadata (true) - false = add metadata only, true = add, update, and remove metadata
- enforce_customer_metadata (true) - false = add metadata only, true = add, update, and remove metadata

Note: State ID is used as hostname. Hostnames must be unique.

Note: If hostname is provided in vmconfig this will take president over the State ID. This allows multiple states to be applied to the same vm.

Note:
The following instances should have a unique ID.
- nic: mac
- filesystem: target
- disk: path or diskN for zvols
  e.g. disk0 will be the first disk added, disk1 the 2nd,...

Changed in version 2019.2.0: Added support for docker image uuids, added auto_lx_vars configuration, documented some missing configuration options.

call.states.smartos.vm_running(name)
Ensure vm is in the running state on the computenode
name
  [string] hostname of vm

Note: State ID is used as hostname. Hostnames must be unique.

call.states.smartos.vm_stopped(name)
Ensure vm is in the stopped state on the computenode
name
  [string] hostname of vm

Note: State ID is used as hostname. Hostnames must be unique.

25.20.277 call.states.smtp

Sending Messages via SMTP

New in version 2014.7.0.
This state is useful for firing messages during state runs, using the SMTP protocol

server-warning-message:
  smtp.send_msg:
    name: 'This is a server warning message'
salt.states.smtp.send_msg(name, recipient, subject, sender=None, profile=None, use_ssl='True', attachments=None)

Send a message via SMTP

server-warning-message:
smtplib.send_msg:
  - name: 'This is a server warning message'
  - profile: my-smtp-account
  - subject: 'Message from Salt'
  - recipient: admin@example.com
  - sender: admin@example.com
  - use_ssl: True
  - attachments:
    - /var/log/syslog
    - /var/log/messages

name
The message to send via SMTP

25.20.278 salt.states.snapper

Managing implicit state and baselines using snapshots

New in version 2016.11.0.
Salt can manage state against explicitly defined state, for example if your minion state is defined by:

/etc/config_file:
file.managed:
  - source: salt://configs/myconfig

If someone modifies this file, the next application of the highstate will allow the admin to correct this deviation and the file will be corrected.

Now, what happens if somebody creates a file /etc/new_config_file and deletes /etc/important_config_file? Unless you have a explicit rule, this change will go unnoticed.

The snapper state module allows you to manage state implicitly, in addition to explicit rules, in order to define a baseline and iterate with explicit rules as they show that they work in production.

The workflow is: once you have a working and audited system, you would create your baseline snapshot (eg. with salt tgt snapper.create_snapshot) and define in your state this baseline using the identifier of the snapshot (in this case: 20):

my_baseline:
  snapper.baseline_snapshot:
    - number: 20
    - include_diff: False
    - ignore:
      - /var/log
      - /var/cache
Baseline snapshots can be also referenced by tag. Most recent baseline snapshot is used in case of multiple snapshots with the same tag:

```
my_baseline_external_storage:
  snapper.baseline_snapshot:
    - tag: my_custom_baseline_tag
    - config: external
    - ignore: - /mnt/tmp_files/
```

If you have this state, and you haven’t done changes to the system since the snapshot, and you add a user, the state will show you the changes (including full diffs) to `/etc/passwd`, `/etc/shadow`, etc if you call it with `test=True` and will undo all changes if you call it without.

This allows you to add more explicit state knowing that you are starting from a very well defined state, and that you can audit any change that is not part of your explicit configuration.

So after you made this your state, you decided to introduce a change in your configuration:

```
my_baseline:
  snapper.baseline_snapshot:
    - number: 20
    - ignore:
      - /var/log
      - /var/cache

hosts_entry:
  file.blockreplace:
    - name: /etc/hosts
    - content: 'First line of content'
    - append_if_not_found: True
```

The change in `/etc/hosts` will be done after any other change that deviates from the specified snapshot are reverted. This could be for example, modifications to the `/etc/passwd` file or changes in the `/etc/hosts` that could render your the `hosts_entry` rule void or dangerous.

Once you take a new snapshot and you update the baseline snapshot number to include the change in `/etc/hosts` the `hosts_entry` rule will basically do nothing. You are free to leave it there for documentation, to ensure that the change is made in case the snapshot is wrong, but if you remove anything that comes after the `snapper.baseline_snapshot` as it will have no effect; by the moment the state is evaluated, the baseline state was already applied and include this change.

**Warning:** Make sure you specify the baseline state before other rules, otherwise the baseline state will revert all changes if they are not present in the snapshot.

**Warning:** Do not specify more than one baseline rule as only the last one will affect the result.

Duncan Mac-Vicar P. `<dmacvicar@suse.de>`

**codeauthor**

Pablo Suárez Hernández `<psuarezhernandez@suse.de>`
**maturity**
new

**platform**
Linux

`salt.states.snapper.baseline_snapshot(name, number=None, tag=None, include_diff=True, config='root', ignore=None)`

Enforces that no file is modified comparing against a previously defined snapshot identified by number.

- **number**
  Number of selected baseline snapshot.

- **tag**
  Tag of the selected baseline snapshot. Most recent baseline snapshot is used in case of multiple snapshots with the same tag. (*tag* and *number* cannot be used at the same time)

- **include_diff**
  Include a diff in the response (Default: True)

- **config**
  Snapper config name (Default: root)

- **ignore**
  List of files to ignore. (Default: None)

---

**25.20.279 salt.states.solrcloud**

States for solrcloud alias and collection configuration

New in version 2017.7.0.

`salt.states.solrcloud.alias(name, collections, **kwargs)`

Create alias and enforce collection list.

Use the solrcloud module to get alias members and set them.

You can pass additional arguments that will be forwarded to http.query

- **name**
  The collection name

- **collections**
  list of collections to include in the alias

`salt.states.solrcloud.collection(name, options=None, **kwargs)`

Create collection and enforce options.

Use the solrcloud module to get collection parameters.

You can pass additional arguments that will be forwarded to http.query

- **name**
  The collection name

- **options**
  [{} options to ensure

---

**25.20. state modules**

4483
25.20.280 salt.states.splunk

Splunk User State Module
New in version 2016.3.0.
This state is used to ensure presence of users in splunk.

```python
ensure example test user 1:
splunk.present:
    - name: 'Example TestUser1'
    - email: example@domain.com
```

```
salt.states.splunk.absent(email, profile='splunk', **kwargs)
Ensure a splunk user is absent

ensure example test user 1:
splunk.absent:
    - email: 'example@domain.com'
    - name: 'exampleuser'
```

The following parameters are required:

- **email**
  This is the email of the user in splunk

- **name**
  This is the splunk username used to identify the user.

```
salt.states.splunk.present(email, profile='splunk', **kwargs)
Ensure a user is present

ensure example test user 1:
splunk.user_present:
    - realname: 'Example TestUser1'
    - name: 'exampleuser'
    - email: 'example@domain.com'
    - roles: ['user']
```

The following parameters are required:

- **email**
  This is the email of the user in splunk

25.20.281 salt.states.splunk_search

Splunk Search State Module
New in version 2015.5.0.
This state is used to ensure presence of splunk searches.

```
server-warning-message:
splunk_search.present:
    - name: This is the splunk search name
    - search: index=main sourcetype=
```
salt.states.splunk_search.absent(name, profile='splunk')

Ensure a search is absent

**API Error Search:**
splunk_search.absent

The following parameters are required:
- name
  - This is the name of the search in splunk

salt.states.splunk_search.present(name, profile='splunk', **kwargs)

Ensure a search is present

**API Error Search:**
splunk_search.present:
  - search: index=main sourcetype=blah
  - template: alert_5min

The following parameters are required:
- name
  - This is the name of the search in splunk

### 25.20.282 salt.states.sqlite3

**Management of SQLite3 databases**

New in version 2016.3.0.

- **depends**
  - SQLite3 Python Module

- **configuration**
  - See `salt.modules.sqlite3` for setup instructions

The sqlite3 module is used to create and manage sqlite3 databases and execute queries

Here is an example of creating a table using sql statements:

```
salt.states.sqlite3.table_present:
  - db: /var/www/data/app.sqlite
  - schema: CREATE TABLE `users` (`username` TEXT COLLATE NOCASE UNIQUE NOT NULL, `password` BLOB NOT NULL, `salt` BLOB NOT NULL, `last_login` INT)
```

Here is an example of creating a table using yaml/jinja instead of sql:

```
salt.states.sqlite3.table_present:
  - db: /var/www/app.sqlite
  - schema:
    - email TEXT COLLATE NOCASE UNIQUE NOT NULL
    - firstname TEXT NOT NULL
    - lastname TEXT NOT NULL
    - company TEXT NOT NULL
```

(continues on next page)
Here is an example of making sure a table is absent:

```
badservers:
  sqlite3.table_absent:
    - db: /var/www/data/users.sqlite
```

Sometimes you would to have specific data in tables to be used by other services Here is an example of making sure rows with specific data exist:

```
user_john_doe_xyz:
  sqlite3.row_present:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email='john.doe@companyxyz.com'
    - data:
      email: john.doe@companyxyz.com
      lastname: doe
      firstname: john
      company: companyxyz.com
      password: abcdef012934125
      salt: abcdef012934125
    - require:
      - sqlite3: users
```

Here is an example of removing a row from a table:

```
user_john_doe_abc:
  sqlite3.row_absent:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email="john.doe@companyabc.com"
    - require:
      - sqlite3: users
```

Note that there is no explicit state to perform random queries, however, this can be approximated with sqlite3's module functions and module.run:

```
zone-delete:
  module.run:
    - name: sqlite3.modify
    - db: {{ db }}
    - sql: "DELETE FROM records WHERE id > {{ count[0] }} AND domain_id = {{ domain_id }}"
    - watch:
      - sqlite3: zone-insert-12
```

salt.states.sqlite3.row_absent(name, db, table, where_sql, where_args=None)

Makes sure the specified row is absent in db. If multiple rows match where_sql, then the state will fail.

name

Only used as the unique ID
The database file name
The table name to check
The sql to select the row to check
The list parameters to substitute in where_sql

salt.states.sqlite3.row_present(name, db, table, data, where_sql, where_args=None, update=False)
Checks to make sure the given row exists. If row exists and update is True then row will be updated with data. Otherwise it will leave existing row unmodified and check it against data. If the existing data doesn't match data_check the state will fail. If the row doesn't exist then it will insert data into the table. If more than one row matches, then the state will fail.

name
   Only used as the unique ID
db
   The database file name
table
   The table name to check the data
data
   The dictionary of key/value pairs to check against if row exists, insert into the table if it doesn't
where_sql
   The sql to select the row to check
where_args
   The list parameters to substitute in where_sql
update
   True will replace the existing row with data When False and the row exists and data does not equal the row data then the state will fail

salt.states.sqlite3.table_absent(name, db)
Make sure the specified table does not exist
name
   The name of the table
db
   The name of the database file

salt.states.sqlite3.table_present(name, db, schema, force=False)
Make sure the specified table exists with the specified schema
name
   The name of the table
db
   The name of the database file
schema
   The dictionary containing the schema information
force
   If the name of the table exists and force is set to False, the state will fail. If force is set to True, the existing table will be replaced with the new table
25.20.283 salt.states.ssh_auth

Control of entries in SSH authorized_key files

The information stored in a user’s SSH authorized key file can be easily controlled via the ssh_auth state. Defaults can be set by the enc, options, and comment keys. These defaults can be overridden by including them in the name.

Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML 'explicit key', as demonstrated in the second example below.

```
AAAAB3NzaC1kc3MAAAACBAL0sQ9fJ5bYTEyY==:
  ssh_auth.present:
    - user: root
    - enc: ssh-dss

thatch:
  ssh_auth.present:
    - user: root
    - source: salt://ssh_keys/thatch.id_rsa.pub
    - config: '/%h/.ssh/authorized_keys'

sshkeys:
  ssh_auth.present:
    - user: root
    - enc: ssh-rsa
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: myuser
    - names:
      - AAAAB3NzaC1kc3MAAAACBAL0sQ9fJ5bYTEyY==
      - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
      - option3="value3" ssh-dss AAAAB3NzaC1kcQ9J5bYTEyY== other@testdomain
      - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

sshkeys:
  ssh_auth.manage:
    - user: root
    - enc: ssh-rsa
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: myuser
    - ssh_keys:
      - AAAAB3NzaC1kc3MAAAACBAL0sQ9fJ5bYTEyY==
      - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
      - option3="value3" ssh-dss AAAAB3NzaC1kcQ9J5bYTEyY== other@testdomain
      - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment
```
salt.states.ssh_auth.absent(name, user, enc='ssh-rsa', comment='', source='', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None)

Verifies that the specified SSH key is absent

name
  The SSH key to manage

user
  The user who owns the SSH authorized keys file to modify

enc
  Defines what type of key is being used, can be ed25519, ecdsa, ssh-rsa, ssh-dss or any other type as of openssh server version 8.7.

comment
  The comment to be placed with the SSH public key

options
  The options passed to the key, pass a list object

source
  The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment, enc and options will be ignored.

New in version 2015.8.0.

config
  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

fingerprint_hash_type
  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

New in version 2016.11.7.

salt.states.ssh_auth.manage(name, ssh_keys, user, enc='ssh-rsa', comment='', source='', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None, **kwargs)

New in version 3000.

Ensures that only the specified ssh_keys are present for the specified user

ssh_keys
  The SSH key to manage

user
  The user who owns the SSH authorized keys file to modify

enc
  Defines what type of key is being used, can be ed25519, ecdsa, ssh-rsa, ssh-dss or any other type as of openssh server version 8.7.

comment
  The comment to be placed with the SSH public key

source
  The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment and enc will be ignored.

**kwargs

Note: The source file must contain keys in the format <enc> <key> <comment>. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

options
The options passed to the keys, pass a list object

**config**
The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

**fingerprint_hash_type**
The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

salt.states.ssh_auth.present(name, user, enc='ssh-rsa', comment='', source='', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None, **kwargs)

Verifies that the specified SSH key is present for the specified user

**name**
The SSH key to manage

**user**
The user who owns the SSH authorized keys file to modify

**enc**
Defines what type of key is being used, can be ed25519, ecdsa, ssh-rsa, ssh-dss or any other type as of openssh server version 8.7.

**comment**
The comment to be placed with the SSH public key

**source**
The source file for the key(s). Can contain any number of public keys, in standard "authorized_keys" format. If this is set, comment and enc will be ignored.

**Note:** The source file must contain keys in the format `<enc> <key> <comment>`. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

**options**
The options passed to the key, pass a list object

**config**
The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

**fingerprint_hash_type**
The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

25.20.284 salt.states.ssh_known_hosts

Control of SSH known_hosts entries

Manage the information stored in the known_hosts files.

```
github.com:
  ssh_known_hosts:
  - present
  - user: root
```

(continues on next page)
salt.states.ssh_known_hosts.absent(name, user=None, config=None)

Verifies that the specified host is not known by the given user

- **name**: The host name Note that only single host names are supported. If foo.example.com and bar.example.com are the same machine and you need to exclude both, you will need one Salt state for each.
- **user**: The user who owns the ssh authorized keys file to modify

salt.states.ssh_known_hosts.present(name, user=None, fingerprint=None, key=None, port=None, enc=None, config=None, hash_known_hosts=True, timeout=5, fingerprint_hash_type=None)

Verifies that the specified host is known by the specified user

On many systems, specifically those running with openssh 4 or older, the **enc** option must be set, only openssh 5 and above can detect the key type.

- **name**: The name of the remote host (e.g. "github.com") Note that only a single hostname is supported, if foo.example.com and bar.example.com have the same host you will need two separate Salt States to represent them.
- **user**: The user who owns the ssh authorized keys file to modify
- **fingerprint**: The fingerprint of the key which must be present in the known_hosts file (optional if key specified)
- **key**: The public key which must be present in the known_hosts file (optional if fingerprint specified)
- **port**: optional parameter, port which will be used to when requesting the public key from the remote host, defaults to port 22.
- **enc**: Defines what type of key is being used, can be ed25519, ecdsa, ssh-rsa, ssh-dss or any other type as of openssh server version 8.7.
- **config**: The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to "/etc/ssh/ssh_known_hosts". If present, must be an absolute path when a user is not specified.
- **hash_known_hosts**
  - [True] Hash all hostnames and addresses in the known hosts file.
- **timeout**
  - [int] Set the timeout for connection attempts. If **timeout** seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, then the connection is closed and the host in question considered unavailable. Default is 5 seconds.

New in version 2016.3.0.
fp

fingerprint_hash_type
The public key fingerprint hash type that the public key fingerprint was originally hashed with. This
defaults to sha256 if not specified.

New in version 2016.11.4.
Changed in version 2017.7.0: default changed from md5 to sha256

25.20.285 salt.states.stateconf

Stateconf System

The stateconf system is intended for use only with the stateconf renderer. This State module presents the set function. This function does not execute any functionality, but is used to interact with the stateconf renderer.
salt.states.stateconf.context(name, **kwargs)
   No-op state to support state config via the stateconf renderer.
salt.states.stateconf.set(name, **kwargs)
   No-op state to support state config via the stateconf renderer.

25.20.286 salt.states.status

Minion status monitoring
Maps to the status execution module.
salt.states.status.loadavg(name, maximum=None, minimum=None)
   Return the current load average for the specified minion. Available values for name are 1-min, 5-min and
   15-min. minimum and maximum values should be passed in as strings.
salt.states.status.process(name)
   Return whether the specified signature is found in the process tree. This differs slightly from the services
   states, in that it may refer to a process that is not managed via the init system.

25.20.287 salt.states.statuspage

StatusPage

Manage the StatusPage configuration.

In the minion configuration file, the following block is required:

```
salt.states.statuspage:
   api_key: <API_KEY>
   page_id: <PAGE_ID>
```

New in version 2017.7.0.
salt.states.statuspage.create(name, endpoint='incidents', api_url=None, page_id=None, api_key=None,
   api_version=None, **kwargs)
   Insert a new entry under a specific endpoint.
   endpoint: incidents
      Insert under this specific endpoint.
page_id
Page ID. Can also be specified in the config file.

api_key
API key. Can also be specified in the config file.

api_version: 1
API version. Can also be specified in the config file.

api_url
Custom API URL in case the user has a StatusPage service running in a custom environment.

kwargs
Other params.

SLS Example:

```yaml
create-my-component:
  statuspage.create:
    - endpoint: components
    - name: my component
    - group_id: 993vgplshj12
```

salt.states.statuspage.delete(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None)

Remove an entry from an endpoint.

deploy_id: incidents
Request a specific endpoint.

page_id
Page ID. Can also be specified in the config file.

api_key
API key. Can also be specified in the config file.

api_version: 1
API version. Can also be specified in the config file.

api_url
Custom API URL in case the user has a StatusPage service running in a custom environment.

SLS Example:

```yaml
delete-my-component:
  statuspage.delete:
    - endpoint: components
    - id: ftgks51sfs2d
```

salt.states.statuspage.managed(name, config, api_url=None, page_id=None, api_key=None, api_version=None, pace=1, allow_empty=False)

Manage the StatusPage configuration.

cfg
Dictionary with the expected configuration of the StatusPage. The main level keys of this dictionary represent the endpoint name. If a certain endpoint does not exist in this structure, it will be ignored / not configured.

page_id
Page ID. Can also be specified in the config file.

api_key
API key. Can also be specified in the config file.

api_version: 1
API version. Can also be specified in the config file.

api_url
Custom API URL in case the user has a StatusPage service running in a custom environment.

pace: 1
Max requests per second allowed by the API.

allow_empty: False
Allow empty config.

SLS example:

```yaml
my-statuspage-config:
  statuspage.managed:
    config:
      components:
        - name: component1
          group_id: uy4g37rf
        - name: component2
          group_id: 3n4uyu4gf
      incidents:
        - name: incident1
          status: resolved
          impact: major
          backfilled: false
        - name: incident2
          status: investigating
          impact: minor
```

salt.states.statuspage.update(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)

Update attribute(s) of a specific endpoint.

id
The unique ID of the endpoint entry.

endpoint: incidents
Endpoint name.

page_id
Page ID. Can also be specified in the config file.

api_key
API key. Can also be specified in the config file.

api_version: 1
API version. Can also be specified in the config file.

api_url
Custom API URL in case the user has a StatusPage service running in a custom environment.

SLS Example:

```yaml
update-my-incident:
  statuspage.update:
    - id: dz959yz2nd4l
    - status: resolved
```
25.20.288  salt.states.supervisord

Interaction with the Supervisor daemon

```yaml
wsgi_server:
    supervisord.running:
        - require:
          - pkg: supervisor
        - watch:
          - file: /etc/nginx/sites-enabled/wsgi_server.conf
```

salt.states.supervisord.dead(name=None, user=None, conf_file=None, bin_env=None, **kwargs)

Ensure the named service is dead (not running).

- **name**
  Service name as defined in the supervisor configuration file
- **user**
  Name of the user to run the supervisorctl command
- **conf_file**
  path to supervisorctl config file
- **bin_env**
  path to supervisorctl bin or path to virtualenv with supervisor installed

salt.states.supervisord.mod_watch(name=None, restart=True, update=False, user=None, conf_file=None, bin_env=None, **kwargs)

The supervisord watcher, called to invoke the watch command. Always restart on watch

**Note:** This state exists to support special handling of the `watch` requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.supervisord.running(name=None, restart=False, update=False, user=None, conf_file=None, bin_env=None, **kwargs)

Ensure the named service is running.

- **name**
  Service name as defined in the supervisor configuration file
- **restart**
  Whether to force a restart
- **update**
  Whether to update the supervisor configuration.
- **user**
  Name of the user to run the supervisorctl command
- **conf_file**
  path to supervisorctl config file
- **bin_env**
  path to supervisorctl bin or path to virtualenv with supervisor installed
### 25.20.289 salt.states.svn

**Manage SVN repositories**

Manage repository checkouts via the `svn` vcs system. Note that subversion must be installed for these states to be available, so `svn` states should include a requisite to a `pkg.installed` state for the package which provides subversion (`subversion` in most cases). Example:

```python
subversion:
  pkg.installed

http://unladen-swallow.googlecode.com/svn/trunk/:
svn.latest:
  - target: /tmp/swallow

salt.states.svn.dirty(name, target=None, user=None, username=None, password=None, ignore_unversioned=False)

Determine if the working directory has been changed.

salt.states.svn.export(name, target=None, rev=None, user=None, username=None, password=None, force=False, overwrite=False, externals=True, trust=False, trust_failures=None)

Export a file or directory from an SVN repository

  name
    Address and path to the file or directory to be exported.

  target
    Name of the target directory where the checkout will put the working directory

  rev
    [None] The name revision number to checkout. Enable "force" if the directory already exists.

  user
    [None] Name of the user performing repository management operations

  username
    [None] The user to access the name repository with. The `svn` default is the current user

  password
    Connect to the Subversion server with this password

    New in version 0.17.0.

  force
    [False] Continue if conflicts are encountered

  overwrite
    [False] Overwrite existing target

  externals
    [True] Change to False to not checkout or update externals

  trust
    [False] Automatically trust the remote server. SVN's --trust-server-cert

  trust_failures
    [None] Comma-separated list of certificate trust failures, that shall be ignored. This can be used if trust=True is not sufficient. The specified string is passed to SVN's --trust-server-cert-failures option as-is.

    New in version 2019.2.0.

salt.states.svn.latest(name, target=None, rev=None, user=None, username=None, password=None, force=False, externals=True, trust=False, trust_failures=None)

Checkout or update the working directory to the latest revision from the remote repository.
name
Address of the name repository as passed to "svn checkout"

target
Name of the target directory where the checkout will put the working directory

rev
[None] The name revision number to checkout. Enable "force" if the directory already exists.

user
[None] Name of the user performing repository management operations

username
[None] The user to access the name repository with. The svn default is the current user

password
Connect to the Subversion server with this password

New in version 0.17.0.

force
[False] Continue if conflicts are encountered

externals
[True] Change to False to not checkout or update externals

trust
[False] Automatically trust the remote server. SVN's --trust-server-cert

trust_failures
[None] Comma-separated list of certificate trust failures, that shall be ignored. This can be used if
trust=True is not sufficient. The specified string is passed to SVN's --trust-server-cert-failures option
as-is.

New in version 2019.2.0.

25.20.290  salt.states.sysctl

Configuration of the kernel using sysctl

Control the kernel sysctl system.

```
25.20.290  salt.states.sysctl

Configuration of the kernel using sysctl

vm.swappiness:

  sysctl.present:
    name: servers
    value: 20

salt.states.sysctl.present(name, value, config=None)

Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default
sysctl configuration file is /etc/sysctl.conf

name
The name of the sysctl value to edit

value
The sysctl value to apply. Make sure to set the value to the correct expected output for sysctl or reading
the respective /proc/sys file. For example, instead of adding the value 1,2,3 you might need to write 1-3.
If you do not set the correct value, Salt will continue to return with changes.

config
The location of the sysctl configuration file. If not specified, the proper location will be detected based
on platform.
```

25.20. state modules 4497
25.20.291 salt.states.sysfs

Configuration of the kernel using sysfs

Control the kernel object attributes exported by sysfs

```
kernell/mm/transparent_hugepage/enabled
  sysfs.present:
    - value: never
```

New in version 3006.0.

```
salt.states.sysfs.present(name, value, config=None)
```

Ensure that the named sysfs attribute is set with the defined value

- **name**: The name of the sysfs attribute to edit
- **value**: The sysfs value to apply

25.20.292 salt.states.syslog_ng

State module for syslog_ng

- **maintainer**: Tibor Benke <btibi@sch.bme.hu>
- **maturity**: new
- **depends**: cmd, ps, syslog_ng
- **platform**: all

Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

**Details**

The service module is not available on all system, so this module includes `syslog_ng.reloaded, syslog_ng.stopped,` and `syslog_ng.started` functions. If the service module is available on the computers, users should use that.

Users can generate syslog-ng configuration with `syslog_ng.config` function. For more information see `syslog-ng state usage`.
Syslog-ng configuration file format

The syntax of a configuration snippet in syslog-ng.conf:

```
object_type object_id {<options>};
```

These constructions are also called statements. There are options inside of them:

```
option(parameter1, parameter2); option2(parameter1, parameter2);
```

```python
salt.states.syslog_ng.config(name, config, write=True)
```

Builds syslog-ng configuration.

- `name`: the id of the Salt document
- `config`: the parsed YAML code
- `write`: if True, it writes the config into the configuration file, otherwise just returns it

```python
salt.states.syslog_ng.reloaded(name)
```

Reloads syslog-ng.

```python
salt.states.syslog_ng.started(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None, **args, **kwargs)
```

Ensures, that syslog-ng is started via the given parameters.

Users shouldn't use this function, if the service module is available on their system.

```python
salt.states.syslog_ng.stopped(name=None)
```

Kills syslog-ng.

25.20.293 salt.states.sysrc

State to work with sysrc

```python
salt.states.sysrc.absent(name, **kwargs)
```

Ensure a sysrc variable is absent.

- `name`: The variable name to set
- `file`: (optional) The rc file to add the variable to.
- `jail`: (option) the name or JID of the jail to set the value in.

```python
salt.states.sysrc.managed(name, value, **kwargs)
```

Ensure a sysrc variable is set to a specific value.

- `name`: The variable name to set
- `value`: Value to set the variable to
- `file`: (optional) The rc file to add the variable to.
jail
  (option) the name or JID of the jail to set the value in.
Example:

```yaml
syslogd:
  sysrc.managed:
    - name: syslogd_flags
    - value: -ss
```

### 25.20.294 `salt.states.telemetry_alert`

Manage Telemetry alert configurations

New in version 2016.3.0.

Create, Update and destroy Mongo Telemetry alert configurations.

This module uses requests, which can be installed via package, or pip.

This module accepts explicit credential (telemetry api key) or can also read api key credentials from a pillar. Example:

```yaml
ensure telemetry alert X is defined on deployment Y:
  telemetry_alert.present:
    - deployment_id: "rs-XXXXXX"
    - metric_name: "testMetric"
    - alert_config:
      max: 1
      filter: SERVER_ROLE_MONGOD_PRIMARY
      escalate_to: "example@pagerduty.com"
      - name: "**MANAGED BY ORCA DO NOT EDIT BY HAND** manages alarm on
        testMetric"

salt.states.telemetry_alert.absent(name, deployment_id, metric_name, api_key=None, profile='telemetry')

Ensure the telemetry alert config is deleted

name
  An optional description of the alarm (not currently supported by telemetry API)
deployment_id
  Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached
metric_name
  Specifies the unique ID of the metric to whose values these thresholds will be applied
api_key
  Telemetry api key for the user
profile
  A dict with telemetry config data. If present, will be used instead of api_key.

salt.states.telemetry_alert.present(name, deployment_id, metric_name, alert_config, api_key=None, profile='telemetry')

Ensure the telemetry alert exists.

name
  An optional description of the alarm (not currently supported by telemetry API)
deployment_id
Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached

metric_name
Specifies the unique ID of the metric to whose values these thresholds will be applied

alert_config: Is a list of dictionaries where each dict contains the following fields:
  filter
    By default the alert will apply to the deployment and all its constituent resources. If the alert only applies to a subset of those resources, a filter may be specified to narrow this scope.
  min
    the smallest "ok" value the metric may take on; if missing or null, no minimum is enforced.
  max
    the largest "ok" value the metric may take on; if missing or null, no maximum is enforced.
  notify_all
    Used to indicate if you want to alert both onCallEngineer and apiNotifications

api_key
  Telemetry api key for the user

profile
  A dict of telemetry config information. If present, will be used instead of api_key.

25.20.295 salt.states.test

Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

always-passes-with-any-kwarg:
  test.nop:
    - name: foo
    - something: else
    - foo: bar

always-passes:
  test.succeed_without_changes:
    - name: foo

always-fails:
  test.fail_without_changes:
    - name: foo

always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo

always-changes-and-fails:
  test.fail_with_changes:
    - name: foo

my-custom-combo:
  test.configurable_test_state:
    - name: foo

(continues on next page)
You may also use these states for controlled failure in state definitions, for example if certain conditions in pillar or grains do not apply. The following state definition will fail with a message "OS not supported!" when `grains['os']` is neither Ubuntu nor CentOS:

```python
{% if grains['os'] in ['Ubuntu', 'CentOS'] %}
# Your state definitions go here
{% else %}
failure:
  test.fail_without_changes:
    - name: "OS not supported!"
    - failhard: True
{% endif %}
```

`salt.states.test.check_pillar(name, present=None, boolean=None, integer=None, string=None, listing=None, dictionary=None, verbose=False)`

Checks the presence and, optionally, the type of given keys in Pillar

Supported kwargs for types are: - boolean (bool) - integer (int) - string (str) - listing (list) - dictionary (dict)

Checking for None type pillars is not implemented yet.

`salt.states.test.configurable_test_state(name, changes=True, result=True, comment='', 
                                           warnings=None, allow_test_mode_failure=False)`

New in version 2014.7.0.

A configurable test state which allows for more control over the return data

**name**

A unique string to serve as the state’s ID

**changes**

[True] Controls whether or not the state reports that there were changes. There are three supported values for this argument:

- If True, the state will report changes
- If False, the state will report no changes
If "Random", the state will randomly report either changes or no changes.

**result**

[True] Controls the result for the state. Like changes, there are three supported values for this argument:
- If True, the state will report a True result
- If False, the state will report a False result
- If "Random", the state will randomly report either True or None

**Note:** The result will be reported as None if all of the following are true:
1. The state is being run in test mode (i.e. test=True on the CLI)
2. result is True (either explicitly, or via being set to "Random")
3. changes is True (either explicitly, or via being set to "Random")

**comment**

["""""] Comment field for the state. By default, this is an empty string.

**warnings**

A string (or a list of strings) to fill the warnings field with. Default is None

New in version 3000.

**allow_test_mode_failure**

When False, running this state in test mode can only return a True or None result. When set to True and result is set to False, the test mode result will be False. Default is False

New in version 3007.0.

salt.states.test.fail_with_changes

New in version 2014.7.0.

Returns False with a non-empty changes dictionary. Useful for testing requisites.

**name**

A unique string to serve as the state's ID

salt.states.test.fail_without_changes

New in version 2014.7.0.

Returns failure

**name**

A unique string to serve as the state's ID

salt.states.test.mod_watch

Call this function via a watch statement

New in version 2014.7.0.

Any parameters in the state return dictionary can be customized by adding the keywords result, comment, and changes.

```
this_state_will_return_changes:
    test.succeed_with_changes

this_state_will_NOT_return_changes:
    test.succeed_without_changes

this_state_is_watching_another_state:
    test.succeed_without_changes:
    - comment: 'This is a custom comment'
    - watch:
```

(continues on next page)
- test: this_state_will_return_changes
- test: this_state_will_NOT_return_changes

test.

test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
  test.succeed_without_changes:
    - watch:
      - test: this_state_will_NOT_return_changes

salt.states.test.nop(name, **kwargs)

A no-op state that does nothing. Useful in conjunction with the use requisite, or in templates which could otherwise be empty due to jinja rendering.

name
  A unique string to serve as the state's ID

salt.states.test.show_notification(name, text=None, **kwargs)

New in version 2015.8.0.

Simple notification using text argument.

name
  A unique string to serve as the state's ID
text
  Text to return in the comment field

salt.states.test.succeed_with_changes(name, **kwargs)

New in version 2014.7.0.

Returns True with an non-empty changes dictionary. Useful for testing requisites.

name
  A unique string to serve as the state's ID

salt.states.test.succeed_without_changes(name, **kwargs)

New in version 2014.7.0.

Returns successful

name
  A unique string to serve as the state's ID

25.20.296 salt.states.testinfra

salt.states.testinfra.camel_to_snake_case(camel_input)

Converts camelCase (or CamelCase) to snake_case. From https://codereview.stackexchange.com/questions/185966/functions-to-convert-camelcase-strings-to-snake-case

Parameters

  camel_input (str) -- The camelcase or CamelCase string to convert to snake_case

:return str
25.20.297  salt.states.timezone

Management of timezones

The timezone can be managed for the system:

```
America/Denver:
    timezone.system
```

The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to
localtime, meaning it is set to the same time as the system clock. If `utc` is set to True, then the hardware clock will
be set to UTC, and the system clock will be an offset of that.

```
America/Denver:
    timezone.system:
        - utc: True
```

The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot
with Windows. This is explained in greater detail here.

```
salt.states.timezone.system(name, utc=True)
```

Set the timezone for the system.

- `name`: The name of the timezone to use (e.g.: America/Denver)
- `utc`: Whether or not to set the hardware clock to UTC (default is True)

25.20.298  salt.states.tls

Enforce state for SSL/TLS

```
salt.states.tls.valid_certificate(name, weeks=0, days=0, hours=0, minutes=0, seconds=0)
```

Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks,
days, hours, minutes, and seconds.

25.20.299  salt.states.tomcat

Manage Apache Tomcat web applications

Note: This state requires the Tomcat Manager webapp to be installed and running.

The following grains/pillars must be set for communication with Tomcat Manager to work:

```
tomcat-manager:
    user: 'tomcat-manager'
    passwd: 'Passw0rd'
```
Configuring Tomcat Manager

To manage webapps via the Tomcat Manager, you'll need to configure a valid user in the file conf/tomcat-users.xml.

Listing 1: conf/tomcat-users.xml

```xml
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
  <role rolename="manager-script"/>
  <user username="tomcat-manager" password="Passw0rd" roles="manager-script"/>
</tomcat-users>
```

Notes

- Using multiple versions (aka. parallel deployments) on the same context path is not supported.
- If you use only this module for deployments you might want to restrict access to the manager so it's only accessible via localhost. For more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)
- Last tested on:

  - **Tomcat Version:**
    - Apache Tomcat/7.0.54
  - **JVM Vendor:**
    - Oracle Corporation
  - **JVM Version:**
    - 1.8.0_101-b13
  - **OS Architecture:**
    - amd64
  - **OS Name:**
    - Linux
  - **OS Version:**
    - 3.10.0-327.22.2.el7.x86_64

**salt.states.tomcat.mod_watch**(name, url='http://localhost:8080/manager', timeout=180)

The tomcat watcher, called to invoke the watch command. When called, it will reload the webapp in question

**Note:** This state exists to support special handling of the watch **requisite**. It should not be called directly.

Parameters for this function should be set by the state being triggered.

**salt.states.tomcat.undeployed**(name, url='http://localhost:8080/manager', timeout=180)

Enforce that the WAR will be undeployed from the server

**name**

The context path to undeploy.

**url**

timeout

| [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```yaml
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```

salt.states.tomcat.wait(name, url='http://localhost:8080/manager', timeout=180)

Wait for the Tomcat Manager to load.

Notice that if tomcat is not running we won’t wait for it start and the state will fail. This state can be required in the tomcat.war_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment.

- **timeout**: [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```yaml
tomcat-service:
  service.running:
    - name: tomcat
    - enable: True

wait-for-tomcatmanager:
  tomcat.wait:
    - timeout: 300
    - require:
      - service: tomcat-service

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager
```

salt.states.tomcat.war_deployed(name, war, force=False, url='http://localhost:8080/manager', timeout=180, temp_war_location=None, version=True)

Enforce that the WAR will be deployed and started in the context path, while making use of WAR versions in the filename.

**Note:** For more info about Tomcats file paths and context naming, please see [http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming](http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming)

- **name**: The context path to deploy (incl. forward slash) the WAR to.
- **war**: Absolute path to WAR file (should be accessible by the user running Tomcat) or a path supported by the salt.modules.cp.get_url function.
force

[False] Force deployment even if the version strings are the same. Disabled by default.

url

timeout

[180] Timeout for HTTP requests to the Tomcat Manager.

temp_war_location

[None] Use another location to temporarily copy the WAR file to. By default the system's temp directory is used.

version

["""] Specify the WAR version. If this argument is provided, it overrides the version encoded in the WAR file name, if one is present.

Use False or blank value to prevent guessing the version and keeping it blank.

New in version 2016.11.0.

Example:

```yaml
class jenkins:
    class tomcat.war_deployed:
        name: /salt-powered-jenkins
        war: salt://jenkins-1.2.4.war
        require:
            service: application-service
```

Note: Be aware that in the above example the WAR jenkins-1.2.4.war will be deployed to the context path salt-powered-jenkins##1.2.4. To avoid this either specify a version yourself, or set version to False.

25.20.300 salt.states.trafficserver

Control Apache Traffic Server

New in version 2015.8.0.

salt.states.trafficserver.bounce_cluster(name)

```yaml
bounce_ats_cluster:
    trafficserver.bounce_cluster
```

salt.states.trafficserver.bounce_local(name, drain=False)

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.
salt.states.trafficserver.clear_cluster(name)

Clears accumulated statistics on all nodes in the cluster.

salt.states.trafficserver.clear_node(name)

Clears accumulated statistics on the local node.

salt.states.trafficserver.config(name, value)

Set Traffic Server configuration variable values.

proxy.config.proxy_name:

trafficserver.config:
  - value: cdn.site.domain.tld

OR

traffic_server_setting:

trafficserver.config:
  - name: proxy.config.proxy_name
  - value: cdn.site.domain.tld

salt.states.trafficserver.offline(name, path)

Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

offline_ats_path:

trafficserver.offline:
  - path: /path/to/cache

salt.states.trafficserver.refresh(name)

Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

refresh_ats:

trafficserver.refresh
salt.states.trafficserver.restart_cluster(name)
   Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.
   
   restart_ats_cluster:
      trafficserver.restart_cluster

salt.states.trafficserver.restart_local(name, drain=False)
   Restart the traffic_manager and traffic_server processes on the local node.
   
   This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is
   not shut down until the number of active client connections drops to the number given by the
   proxy.config.restart.active_client_threshold configuration variable.
   
   restart_ats_local:
      trafficserver.restart_local
   restart_ats_local_drain:
      trafficserver.restart_local
      - drain: True

salt.states.trafficserver.shutdown(name)
   Shut down Traffic Server on the local node.
   
   shutdown_ats:
      trafficserver.shutdown

salt.states.trafficserver.startup(name)
   Start Traffic Server on the local node.
   
   startup_ats:
      trafficserver.startup

salt.states.trafficserver.zero_cluster(name)
   Reset performance statistics to zero across the cluster.
   
   zero_ats_cluster:
      trafficserver.zero_cluster

salt.states.trafficserver.zero_node(name)
   Reset performance statistics to zero on the local node.
   
   zero_ats_node:
      trafficserver.zero_node

25.20.301 salt.states.tuned

Interface to Red Hat tuned-adm module

maintainer
   Syed Ali <alicsyed@gmail.com>

maturity
   new
depends
  cmd.run
platform
  Linux

salt.states.tuned.off(name=None)
  Turns `tuned` off. Example tuned.sls file for turning tuned off:
  tuned:
    tuned.off: []
  To see a valid list of states call execution module:
    tuned.list

salt.states.tuned.profile(name)
  This state module allows you to modify system tuned parameters
  Example tuned.sls file to set profile to virtual-guest
  tuned:
    profile
    name: virtual-guest
  name
tuned profile name to set the system to
  To see a valid list of states call execution module:
    tuned.list

25.20.302 salt.states.uptime

Monitor Web Server with Uptime

Uptime is an open source remote monitoring application using Node.js, MongoDB, and Twitter Bootstrap.

Warning: This state module is beta. It might be changed later to include more or less automation.

Note: This state module requires a pillar to specify the location of your uptime install

| uptime: |
| application_url: "http://uptime-url.example.org"

Example:

| url: |
| uptime.monitored 
url/sitemap.xml: |
| uptime.monitored: |
| polling: 600 # every hour |

salt.states.uptime.monitored(name, **params)
  Makes sure an URL is monitored by uptime. Checks if URL is already monitored, and if not, adds it.
25.20.303 salt.states.user

Management of user accounts.

The user module is used to create and manage user settings, users can be set as either absent or present.

```yaml
fred:
  user.present:
    - fullname: Fred Jones
    - shell: /bin/zsh
    - home: /home/fred
    - uid: 4000
    - gid: 4000
    - groups:
      - wheel
      - storage
      - games

testuser:
  user.absent
```

salt.states.user.absent(name, purge=False, force=False, local=False)

Ensure that the named user is absent

- **name**
  The name of the user to remove

- **purge**
  Set purge to True to delete all of the user's files as well as the user, Default is False.

- **force**
  If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if they are logged in. Not supported in FreeBSD and Solaris, Default is False.

- **local** (Only on systems with luserdel available):
  Ensure the user account is removed locally ignoring global account management (default is False).

  New in version 3007.0.

salt.states.user.present(name, uid=None, gid=None, usergroup=None, groups=None, optional_groups=None, remove_groups=True, home=None, createhome=True, password=None, hash_password=False, enforce_password=True, empty_password=False, shell=None, unique=True, system=False, fullname=None, roomnumber=None, workphone=None, other=None, loginclass=None, date=None, mindays=None, maxdays=None, inactdays=None, warndays=None, expire=None, win_homedrive=None, win_profile=None, win_logonscript=None, win_description=None, nologinit=False, allow_uid_change=False, allow_gid_change=False, password_lock=None, local=False)

Ensure that the named user is present with the specified properties

- **name**
  The name of the user to manage

- **uid**
  The user id to assign. If not specified, and the user does not exist, then the next available uid will be assigned.

- **gid**
  The id of the default group to assign to the user. Either a group name or gid can be used. If not specified, and the user does not exist, then the next available gid will be assigned.
allow_uid_change
[False] Set to True to allow the state to update the uid.
New in version 2018.3.1.

allow_gid_change
[False] Set to True to allow the state to update the gid.
New in version 2018.3.1.

usergroup
If True, a group with the same name as the user will be created. If False, a group with the same name as
the user will not be created. The default is distribution-specific. See the USERGROUPS_ENAB section
of the login.defs(5) man page.

Note: Only supported on GNU/Linux distributions
New in version 3001.

groups
A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the
minion, the state will fail. If set to the empty list, the user will be removed from all groups except the
default group. If unset, salt will assume current groups are still wanted, and will make no changes to
them.

optional_groups
A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the
minion, the state will silently ignore it.
NOTE: If the same group is specified in both "groups" and "optional_groups", then it will be assumed to be
required and not optional.

remove_groups
Remove groups that the user is a member of that weren't specified in the state, Default is True.

home
The custom login directory of user. Uses default value of underlying system if not set. Notice that this
directory does not have to exist. This also the location of the home directory to create if createhome is
set to True.

createhome
[True] If set to False, the home directory will not be created if it doesn't already exist.

Warning: Not supported on Windows or Mac OS.
Additionally, parent directories will not be created. The parent directory for home must already exist.

nologinit
[False] If set to True, it will not add the user to lastlog and faillog databases.

Note: Not supported on Windows.

password
A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD, OpenBSD,
and Solaris. If the empty_password argument is set to True then password is ignored. For
Windows this is the plain text password. For Linux, the hash can be generated with mkpasswd -m
sha-256.
Changed in version 0.16.0: BSD support added.
hash_password
Set to True to hash the clear text password. Default is False.
enforce_password
Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the "password" field. This option will be ignored if "password" is not specified. Default is True.

empty_password
Set to True to enable password-less login for user, Default is False.

password_lock
Set to False to unlock a user's password (or Windows account). On non-Windows systems ONLY, this parameter can be set to True to lock a user's password. Default is None, which does not take action on the password (or Windows account).

New in version 3006.0.

shell
The login shell, defaults to the system default shell

unique
Require a unique UID, Default is True.

system
Choose UID in the range of FIRST_SYSTEM_UID and LAST_SYSTEM_UID, Default is False.

loginclass
The login class, defaults to empty (BSD only)

User comment field (GECOS) support (currently Linux, BSD, and MacOS only):
The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

fullname
The user's full name

roomnumber
The user's room number (not supported in MacOS)

workphone
The user's work phone number (not supported in MacOS)

homephone
The user's home phone number (not supported in MacOS)

other
The user's other attribute (not supported in MacOS) If GECOS field contains more than 4 commas, this field will have the rest of 'em

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):
The below values should be specified as integers.

date
Date of last change of password, represented in days since epoch (January 1, 1970).

mindays
The minimum number of days between password changes.

maxdays
The maximum number of days between password changes.

inactdays
The number of days after a password expires before an account is locked.

warndays
Number of days prior to maxdays to warn users.

expire
Date that account expires, represented in days since epoch (January 1, 1970).

local (Only on systems with luseradd available):
Create the user account locally ignoring global account management (default is False).

New in version 3007.0.
The below parameters apply to windows only:

**win_homedrive (Windows Only)**
The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie:  
\[ \text{win_homedrive: 'U:'} \]

Changed in version 2015.8.0.

**win_profile (Windows Only)**
The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.8.0.

**win_logonscript (Windows Only)**
The full path to the logon script to run when the user logs in.

Changed in version 2015.8.0.

**win_description (Windows Only)**
A brief description of the purpose of the users account.

Changed in version 2015.8.0.

---

**25.20.304 salt.states.vagrant**

Manage Vagrant VMs

Manage execution of Vagrant virtual machines on Salt minions.

Vagrant is a tool for building and managing virtual machine environments. It can use various providers, such as VirtualBox, Docker, or VMware, to run its VMs. Vagrant provides some of the functionality of a light-weight hypervisor. The combination of Salt modules, Vagrant running on the host, and a virtual machine provider, gives hypervisor-like functionality for developers who use Vagrant to quickly define their virtual environments.

New in version 2018.3.0.

The configuration of each virtual machine is defined in a file named Vagrantfile which must exist on the VM host machine. The essential parameters which must be defined to start a Vagrant VM are the directory where the Vagrantfile is located (argument `cwd:`), and the username which will own the Vagrant box created for the VM (argument `vagrant_runas:`).

A single Vagrantfile may define one or more virtual machines. Use the `machine` argument to chose among them. The default (blank) value will select the primary (or only) machine in the Vagrantfile.

[NOTE:] Each virtual machine host must have the following:

- a working salt-minion
- a Salt sdb database configured for `vagrant_sdb_data`.
- Vagrant installed and the `vagrant` command working
- a suitable VM provider

```bash
# EXAMPLE:
# file /etc/salt/minion.d/vagrant_sdb.conf on the host computer
# -- this sdb database is required by the Vagrant module --
vagrant_sdb_data:  # The sdb database must have this name.
    driver: sqlite3  # Let's use SQLite to store the data ...
    database: /var/cache/salt/vagrant.sqlite  # ... in this file ...
    table: sdb  # ... using this table name.
    create_table: True  # if not present
```
salt.states.vagrant.**destroyed**(name)

Stops a VM (or VMs) and removes all references to it (them). (Runs `vagrant destroy`.)

Subsequent re-use of the same machine will require another operation of `vagrant.running` or a call to the `vagrant.init` execution module.

**Parameters**

- `name` -- May be a Salt_id node or a POSIX-style wildcard string.

```python
node_name: vagrant.destroyed
```

salt.states.vagrant.**initialized**(name, **kwargs)

Defines a new VM with specified arguments, but does not start it.

**Parameters**

- `name` -- the Salt_id node name you wish your VM to have.

Each machine must be initialized individually using this function or the "vagrant.running" function, or the `vagrant.init` execution module call.

This command will not change the state of a running or paused machine.

Possible keyword arguments:

- `cwd`: The directory (path) containing the Vagrantfile
- `machine`: ("") the name of the machine (in the Vagrantfile) if not default
- `vagrant_runas`: ("root") the username who owns the vagrantbox file
- `vagrant_provider`: the provider to run the VM (usually 'virtualbox')
- `vm`: (()) a dictionary containing these or other keyword arguments

```python
node_name1:
    vagrant-initialized
    - cwd: /projects/my_project
    - vagrant_runas: my_username
    - machine: machine1

node_name2:
    vagrant-initialized
    - cwd: /projects/my_project
    - vagrant_runas: my_username
    - machine: machine2

start_nodes:
    vagrant.start:
    - name: node_name?
```

salt.states.vagrant.**paused**(name)

Stores the state of a VM (or VMs) for fast restart. (Runs `vagrant suspend`.)

**Parameters**

- `name` -- May be a Salt_id node or a POSIX-style wildcard string.

```python
node_name: vagrant.paused
```

salt.states.vagrant.**powered_off**(name)

Stops a VM (or VMs) by power off. (Runs `vagrant halt`.)

This method is provided for compatibility with other VM-control state modules. For Vagrant, the action is identical with `stopped`. 
Parameters

**name** -- May be a Salt_id node or a POSIX-style wildcard string.

```yaml
node_name:
  vagrant.unpowered
```

**salt.states.vagrant.rebooted(name)**

Reboots a running, paused, or stopped VM (or VMs). (Runs `vagrant reload`.)

The will re-run the provisioning

**Parameters**

**name** -- May be a Salt_id node or a POSIX-style wildcard string.

```yaml
node_name:
  vagrant.reloaded
```

**salt.states.vagrant.running(name, **kwargs)**

Defines and starts a new VM with specified arguments, or restart a VM (or group of VMs). (Runs `vagrant up`.)

**Parameters**

**name** -- the Salt_id node name you wish your VM to have.

If **name** contains a "?" or "*" then it will re-start a group of VMs which have been paused or stopped.

Each machine must be initially started individually using this function or the vagrant.init execution module call.

[NOTE:] Keyword arguments are silently ignored when re-starting an existing VM.

Possible keyword arguments:

- **cwd**: The directory (path) containing the Vagrantfile
- **machine**: ("") the name of the machine (in the Vagrantfile) if not default
- **vagrant_runas**: ("root") the username who owns the vagrantbox file
- **vagrant_provider**: the provider to run the VM (usually 'virtualbox')
- **vm**: ({} a dictionary containing these or other keyword arguments

```yaml
node_name:
  vagrant.running
```

```yaml
node_name:
  vagrant.running:
    - **cwd**: /projects/my_project
    - **vagrant_runas**: my_username
    - **machine**: machine1
```

**salt.states.vagrant.stopped(name)**

Stops a VM (or VMs) by shutting it (them) down nicely. (Runs `vagrant halt`)

**Parameters**

**name** -- May be a Salt_id node, or a POSIX-style wildcard string.

```yaml
node_name:
  vagrant.stopped
```
25.20.305 salt.states.vault

States for managing Hashicorp Vault. Currently handles policies. Configuration instructions are documented in the execution module docs.

maintainer
SaltStack

maturity
new

platform
all

New in version 2017.7.0.

salt.states.vault.policy_present(name, rules)
Ensure a Vault policy with the given name and rules is present.

name
The name of the policy

rules
Rules formatted as in-line HCL

demo-policy:
vault.policy_present:
- name: foo/bar
- rules:
  path "secret/top-secret/*" {
    policy = "deny"
  }
  path "secret/not-very-secret/*" {
    policy = "write"
  }

25.20.306 salt.states.vbox_guest

VirtualBox Guest Additions installer state

salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)
Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

name
The name has no functional value and is only used as a tracking reference.

reboot
[False] Restart OS to complete installation.

upgrade_os
[False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).

salt.states.vbox_guest.additions_removed(name, force=False)
Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press ‘Host+D’ (‘Host’ is usually ‘Right Ctrl’).

name
The name has no functional value and is only used as a tracking reference.

force
Force VirtualBox Guest Additions removing.
salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)

Grant access to auto-mounted shared folders to the users.

User is specified by its name. To grant access for several users use argument users.

name
Name of the user to grant access to auto-mounted shared folders to.

users
List of names of users to grant access to auto-mounted shared folders to. If specified, name will not be taken into account.

25.20.307 salt.states.victorops

Create an Event in VictorOps

New in version 2015.8.0.

This state is useful for creating events on the VictorOps service during state runs.

```
webserver-warning-message:
    victorops.create_event:
        - message_type: 'CRITICAL'
        - entity_id: 'webserver/diskspace'
        - state_message: 'Webserver diskspace is low.'
```

salt.states.victorops.create_event(name, message_type, routing_key='everyone', **kwargs)

Create an event on the VictorOps service

```
webserver-warning-message:
    victorops.create_event:
        - message_type: 'CRITICAL'
        - entity_id: 'webserver/diskspace'
        - state_message: 'Webserver diskspace is low.'

database-server-warning-message:
    victorops.create_event:
        - message_type: 'WARNING'
        - entity_id: 'db_server/load'
        - state_message: 'Database Server load is high.'
        - entity_is_host: True
        - entity_display_name: 'dbdserver.example.com'
```

The following parameters are required:

name
This is a short description of the event.

message_type
One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

routing_key
The key for where messages should be routed. By default, sent to 'everyone' route.

entity_id
The name of alerting entity. If not provided, a random name will be assigned.

timestamp
Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.
timestamp_fmt
The date format for the timestamp parameter. Defaults to '%Y-%m-%dT%H:%M:%S'.

state_start_time
The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.

state_start_time_fmt
The date format for the timestamp parameter. Defaults to '%Y-%m-%dT%H:%M:%S'.

state_message
Any additional status information from the alert item.

entity_is_host
Used within VictorOps to select the appropriate display format for the incident.

entity_display_name
Used within VictorOps to display a human-readable name for the entity.

ack_message
A user entered comment for the acknowledgment.

ack_author
The user that acknowledged the incident.

25.20.308 salt.states.virt

Manage virt

For the key certificate this state uses the external pillar in the master to call for the generation and signing of certificates for systems running libvirt:

libvirt_keys:
  virt.keys

salt.states.virt.defined(name=None, cpu=None, mem=None, vm_type=None, disk_profile=None, disks=None, nic_profile=None, interfaces=None, graphics=None, seed=True, install=True, pub_key=None, priv_key=None, connection=None, username=None, password=None, os_type=None, arch=None, boot=None, numatune=None, boot_dev=None, hypervisor_features=None, clock=None, serials=None, consoles=None, stop_on_reboot=False, live=True, host_devices=None, autostart=False)

Starts an existing guest, or defines and starts a new VM with specified arguments.

New in version 3001.

Parameters

- name -- name of the virtual machine to run
- cpu -- Number of virtual CPUs to assign to the virtual machine or a dictionary with detailed information to configure cpu model and topology, numa node tuning, cpu tuning and iot threads allocation. The structure of the dictionary is documented in cpu parameters definition.

```
cpu:
  placement: static
  cpuset: 0-11
  current: 5
  maximum: 12
  vcpus:
    0:
      enabled: 'yes'
```

(continues on next page)
hotpluggable: 'no'
order: 1

1:
   enabled: 'no'
   hotpluggable: 'yes'
match: minimum
mode: custom
check: full
vendor: Intel
model:
   name: core2duo
   fallback: allow
   vendor_id: GenuineIntel
topology:
   sockets: 1

New in version 3003.

- **mem** -- Amount of memory to allocate to the virtual machine in MiB. Since 3002, a dictionary can be used to contain detailed configuration which support memory allocation or tuning. Supported parameters are boot, current, max, slots, hard_limit, soft_limit, swap_hard_limit, min Guarantee, hugepages, nosharepages, locked, source, access, and allocation.
discard. The structure of the dictionary is documented in Memory parameter definition. Both decimal and binary base are supported. Detail unit specification is documented in Units specification. Please note that the value for slots must be an integer.

```yaml
boot: 1g
current: 1g
max: 1g
slots: 10
hard_limit: 1024
soft_limit: 512m
swap_hard_limit: 1g
min Guarantee: 512mib
hugepages:
  - size: 2m
  - nodeset: 0-2
    size: 1g
  - nodeset: 3
    size: 2g
noSharePages: True
locked: True
source: file
allocation: immediate
discard: True
```

Changed in version 3002.

- **vm_type** -- force virtual machine type for the new VM. The default value is taken from the host capabilities. This could be useful for example to use 'qemu' type instead of the 'kvm' one.
- **disk_profile** -- Name of the disk profile to use for the new virtual machine
- **disks** -- List of disk to create for the new virtual machine. See Disks Definitions for more details on the items on this list.
- **nic_profile** -- Name of the network interfaces profile to use for the new virtual machine
- **interfaces** -- List of network interfaces to create for the new virtual machine. See Network Interfaces Definitions for more details on the items on this list.
- **graphics** -- Graphics device to create for the new virtual machine. See Graphics Definition for more details on this dictionary
- **saltenv** -- Fileserver environment (Default: 'base'). See cp module for more details
- **seed** -- True to seed the disk image. Only used when the image parameter is provided. (Default: True)
- **install** -- install salt minion if absent (Default: True)
- **pub_key** -- public key to seed with (Default: None)
- **priv_key** -- public key to seed with (Default: None)
- **seed_cmd** -- Salt command to execute to seed the image. (Default: 'seed.apply')
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults
- **os_type** -- type of virtualization as found in the //os/type element of the libvirt definition. The default value is taken from the host capabilities, with a preference for hvm. Only used when creating a new virtual machine.
- **arch** -- architecture of the virtual machine. The default value is taken from the host
capabilities, but x86_64 is preferred over i686. Only used when creating a new virtual machine.

- **boot** -- Specifies kernel, initial ramdisk and kernel command line parameters for the virtual machine. This is an optional parameter, all of the keys are optional within the dictionary.

Refer to Boot parameters definition for the complete boot parameters description.

To update any boot parameters, specify the new path for each. To remove any boot parameters, pass a None object, for instance: 'kernel': None.

New in version 3000.

- **boot_dev** -- Space separated list of devices to boot from sorted by decreasing priority. Values can be hd, fd, cdrom or network.

By default, the value will "hd".

New in version 3002.

- **numatune** -- The optional numatune element provides details of how to tune the performance of a NUMA host via controlling NUMA policy for domain process. The optional memory element specifies how to allocate memory for the domain process on a NUMA host. memnode elements can specify memory allocation policies per each guest NUMA node. The definition used in the dictionary can be found at cpu parameters definition.

New in version 3003.

```
{
    'memory': {'mode': 'strict', 'nodeset': '0-11'},
    'memnodes': {0: {'mode': 'strict', 'nodeset': 1}, 1: {'mode': 'preferred', 'nodeset': 2}}
}
```

- **hypervisor_features** -- Enable or disable hypervisor-specific features on the virtual machine.

New in version 3003.

```
hypervisor_features:
    kvm-hint-dedicated: True
```

- **clock** -- Configure the guest clock. The value is a dictionary with the following keys:

  - **adjustment**
    - time adjustment in seconds or reset
  - **utc**
    - set to False to use the host local time as the guest clock. Defaults to True.
  - **timezone**
    - synchronize the guest to the corresponding timezone
  - **timers**
    - a dictionary associating the timer name with its configuration. This configuration is a dictionary with the properties track, tickpolicy, catchup, frequency, mode, present, slew, threshold and limit. See libvirt time keeping documentation for the possible values.

New in version 3003.

Set the clock to local time using an offset in seconds .. code-block:: yaml

clock:
    adjustment: 3600 utc: False
Set the clock to a specific time zone:

```yaml
clock:
  timezone: CEST
```

- **serials** -- Dictionary providing details on the serials connection to create. (Default: `None`) See *Serials and Consoles Definitions* for more details on the possible values. New in version 3003.

- **consoles** -- Dictionary providing details on the consoles device to create. (Default: `None`) See *Serials and Consoles Definitions* for more details on the possible values. New in version 3003.

- **stop_on_reboot** -- If set to `True` the guest will stop instead of rebooting. This is specially useful when creating a virtual machine with an installation cdrom or an autoinstallation needing a special first boot configuration. Defaults to `False`. New in version 3003.

- **live** -- If set to `False` the changes will not be applied live to the running instance, but will only apply at the next start. Note that reboot will not take those changes. New in version 3003.

- **host_devices** -- List of host devices to passthrough to the guest. The value is a list of device names as provided by the `node_devices()` function. (Default: `None`) New in version 3003.

- **autostart** -- If set to `True` the host will start the guest after boot. (Default: `False`)

### Example States

Make sure a virtual machine called `domain_name` is defined:

```yaml
domain_name:
  virt.defined:
    - cpu: 2
    - mem: 2048
    - boot_dev: network hd
    - disk_profile: prod
    - disks:
      - name: system
        size: 8192
        overlay_image: True
        pool: default
        image: /path/to/image.qcow2
      - name: data
        size: 16834
    - nic_profile: prod
    - interfaces:
      - name: eth0
        mac: 01:23:45:67:89:AB
      - name: eth1
        type: network
        source: admin
    - graphics:
      type: spice
```

(continues on next page)
listen:
  type: address
  address: 192.168.0.125

salt.states.virt.keys(name, basepath='/etc/pki', **kwargs)
Manage libvirt keys.

name
  The name variable used to track the execution

basepath
  Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor
  The following parameters are optional:
  country
    The country that the certificate should use. Defaults to US.
    New in version 2018.3.0.
  state
    The state that the certificate should use. Defaults to Utah.
    New in version 2018.3.0.
  locality
    The locality that the certificate should use. Defaults to Salt Lake City.
    New in version 2018.3.0.
  organization
    The organization that the certificate should use. Defaults to Salted.
    New in version 2018.3.0.
  expiration_days
    The number of days that the certificate should be valid for. Defaults to 365 days (1 year)
    New in version 2018.3.0.

salt.states.virt.network_defined(name, bridge, forward, vport=None, tag=None, ipv4_config=None, ipv6_config=None, autostart=True, connection=None, username=None, password=None, mtu=None, domain=None, nat=None, interfaces=None, addresses=None, physical_function=None, dns=None)
Defines a new network with specified arguments.

Parameters
  • name -- Network name
  • bridge -- Bridge name
  • forward -- Forward mode(bridge, router, nat)
    Changed in version 3003: a None value creates an isolated network with no forwarding at all
  • vport -- Virtualport type (Default: 'None') The value can also be a dictionary with type and parameters keys. The parameters value is a dictionary of virtual port parameters.

- vport:
  type: openvswitch
  parameters:
    interfaceid: 09b11c53-8b5c-4eeb-8f00-d84eaa0aa4f

  Changed in version 3003: possible dictionary value

  • tag -- Vlan tag (Default: 'None') The value can also be a dictionary with the tags and optional trunk keys. trunk is a boolean value indicating whether to
use VLAN trunking. tags is a list of dictionaries with keys id and nativeMode. The nativeMode value can be one of tagged or untagged.

```yaml
- tag:
  trunk: True
  tags:
    - id: 42
      nativeMode: untagged
    - id: 47
```

Changed in version 3003: possible dictionary value

- **ipv4_config** -- IPv4 network configuration. See the `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).
- **ipv6_config** -- IPv6 network configuration. See the `virt.network_define` function corresponding parameter documentation for more details on this dictionary. (Default: None).
- **autostart** -- Network autostart (default 'True')
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults
- **mtu** -- size of the Maximum Transmission Unit (MTU) of the network. (default None)

New in version 3003.

- **domain** -- DNS domain name of the DHCP server. The value is a dictionary with a mandatory `name` property and an optional `localOnly` boolean one. (default None)

```yaml
- domain:
  name: lab.acme.org
  localOnly: True
```

New in version 3003.

- **nat** -- addresses and ports to route in NAT forward mode. The value is a dictionary with optional keys address and port. Both values are a dictionary with start and end values. (default None)

```yaml
- forward: nat
- nat:
  address:
    start: 1.2.3.4
    end: 1.2.3.10
  port:
    start: 500
    end: 1000
```

New in version 3003.

- **interfaces** -- whitespace separated list of network interfaces devices that can be used for this network. (default None)

```yaml
- forward: passthrough
- interfaces: "eth10 eth11 eth12"
```

New in version 3003.

- **addresses** -- whitespace separated list of addresses of PCI devices that can be used for this network in `hostdev` forward mode. (default None)
- **forward**: hostdev
- **interfaces**: "0000:04:00.1 0000:e3:01.2"

New in version 3003.

- **physical_function** -- device name of the physical interface to use in hostdev forward mode. (default None)

- **forward**: hostdev
- **physical_function**: "eth0"

New in version 3003.

- **dns** -- virtual network DNS configuration The value is a dictionary described in DNS configuration definition. (default None)

```yaml
- **dns**:
  - **forwarders**:
    - **domain**: example.com
      - **addr**: 192.168.1.1
    - **addr**: 8.8.8.8
    - **domain**: www.example.com
  - **txt**:
    - **example.com**: "v=spf1 a -all"
    - **_http.tcp.example.com**: "name=value,paper=A4"
  - **hosts**:
    - **192.168.1.2**:
      - **mirror.acme.lab**
      - **test.acme.lab**
  - **srvs**:
    - **name**: ldap
      - **protocol**: tcp
      - **domain**: ldapserver.example.com
      - **target**:
      - **port**: 389
      - **priority**: 1
      - **weight**: 10
```

New in version 3003.

```
network_name: virt.network_defined
```

```
network_name:
  virt.network_defined:
    - **bridge**: main
    - **forward**: bridge
    - **vport**: openvswitch
    - **tag**: 180
    - **autostart**: True
```

```
network_name:
  virt.network_defined:
    - **bridge**: natted
```

(continues on next page)
- **forward**: nat
- **ipv4_config**:
  - **cidr**: 192.168.42.0/24
  - **dhcp_ranges**:
    - **start**: 192.168.42.10
    - **end**: 192.168.42.25
    - **start**: 192.168.42.100
    - **end**: 192.168.42.150
  - **autostart**: True

**salt.states.virt.network_running**(name, bridge, forward, vport=None, tag=None, ipv4_config=None, ipv6_config=None, autostart=True, connection=None, username=None, password=None, mtu=None, domain=None, nat=None, interfaces=None, addresses=None, physical_function=None, dns=None)

Defines and starts a new network with specified arguments.

**Parameters**

- **name** -- Network name
- **bridge** -- Bridge name
- **forward** -- Forward mode(bridge, router, nat)

  Changed in version 3003: a None value creates an isolated network with no forwarding at all

- **vport** -- Virtualport type (Default: 'None') The value can also be a dictionary with type and parameters keys. The parameters value is a dictionary of virtual port parameters.

  - **vport**:
    - **type**: openvswitch
    - **parameters**:
      - **interfaceid**: 09b11c53-8b5c-4eeb-8f00-d84eeaa9aaa4f

  Changed in version 3003: possible dictionary value

- **tag** -- Vlan tag (Default: 'None') The value can also be a dictionary with the tags and optional trunk keys. trunk is a boolean value indicating whether to use VLAN trunking. tags is a list of dictionaries with keys `id` and `nativeMode`. The nativeMode value can be one of tagged or untagged.

  - **tag**:
    - **trunk**: True
    - **tags**:
      - **id**: 42
        - **nativeMode**: untagged
      - **id**: 47

  Changed in version 3003: possible dictionary value

- **ipv4_config** -- IPv4 network configuration. See the `py:func`virt.network_define<salt.modules.virt.network_define>` function corresponding parameter documentation for more details on this dictionary. (Default: None).

  New in version 3000.

- **ipv6_config** -- IPv6 network configuration. See the `py:func`virt.network_define<salt.modules.virt.network_define>` function corresponding parameter documentation for more details on this dictionary. (Default: None).
New in version 3000.

- **autostart** -- Network autostart (default 'True')
- **connection** -- libvirt connection URI, overriding defaults

New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults

New in version 2019.2.0.

- **mtu** -- size of the Maximum Transmission Unit (MTU) of the network. (default None)

New in version 3003.

- **domain** -- DNS domain name of the DHCP server. The value is a dictionary with a mandatory `name` property and an optional `localOnly` boolean one. (default None)

```yaml
- domain:
    name: lab.acme.org
    localOnly: True
```

New in version 3003.

- **nat** -- addresses and ports to route in NAT forward mode. The value is a dictionary with optional keys `address` and `port`. Both values are a dictionary with `start` and `end` values. (default None)

```yaml
- forward: nat
  - nat:
    address:
      start: 1.2.3.4
      end: 1.2.3.10
    port:
      start: 500
      end: 1000
```

New in version 3003.

- **interfaces** -- whitespace separated list of network interfaces devices that can be used for this network. (default None)

```yaml
- forward: passthrough
  - interfaces: "eth10 eth11 eth12"
```

New in version 3003.

- **addresses** -- whitespace separated list of addresses of PCI devices that can be used for this network in `hostdev` forward mode. (default None)

```yaml
- forward: hostdev
  - interfaces: "0000:04:00.1 0000:e3:01.2"
```

New in version 3003.

- **physical_function** -- device name of the physical interface to use in `hostdev` forward mode. (default None)

```yaml
- forward: hostdev
  - physical_function: "eth0"
```

New in version 3003.
- **dns** -- virtual network DNS configuration The value is a dictionary described in DNS configuration definition. (default None)

```python
-dns:
    forwarders:
        - domain: example.com
          addr: 192.168.1.1
        - addr: 8.8.8.8
        - domain: www.example.com
    txt:
        host.widgets.com.: "printer=lp5"
        example.com.: "This domain name is reserved for use in documentation"
    hosts:
        192.168.1.2:
            - mirror.acme.lab
            - test.acme.lab
    srvs:
        - name: ldap
          protocol: tcp
          domain: ldapserver.example.com
          target: .
          port: 389
          priority: 1
          weight: 10
```

New in version 3003.

```
salt.states.virt.pool_defined(name, ptype=None, target=None, permissions=None, source=None, transient=False, autostart=True, connection=None, username=None, password=None)
```

25.20. state modules 4531
Defines a new pool with specified arguments.

New in version 3001.

Parameters

- **ptype** -- libvirt pool type
- **target** -- full path to the target device or folder. (Default: None)
- **permissions** -- target permissions. See Permissions definition for more details on this structure.
- **source** -- dictionary containing keys matching the source_* parameters in function salt.modules.virt.pool_define().
- **transient** -- when set to True, the pool will be automatically undefined after being stopped. (Default: False)
- **autostart** -- Whether to start the pool when booting the host. (Default: True)
- **start** -- When True, define and start the pool, otherwise the pool will be left stopped.
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults

```python
pool_name:
  virt.pool_defined:
    - ptype: netfs
    - target: /mnt/cifs
    - permissions:
      - mode: 0770
      - owner: 1000
      - group: 100
    - source:
      dir: samba_share
      hosts:
      - one.example.com
      - two.example.com
    - format: cifs
    - autostart: True
```

salt.states.virt.pool_deleted(name, purge=False, connection=None, username=None, password=None)

Deletes a virtual storage pool.

Parameters

- **name** -- the name of the pool to delete.
- **purge** -- if True, the volumes contained in the pool will be deleted as well as the pool itself. Note that these will be lost for ever. If False the pool will simply be undefined. (Default: False)
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults

In order to be purged a storage pool needs to be running to get the list of volumes to delete.

Some libvirt storage drivers may not implement deleting, those actions are implemented on a best effort idea. In any case check the result's comment property to see if any of the action was unsupported.

```python
pool_name:
  uyuni_virt.pool_deleted:
    - purge: True
```
New in version 3000.

```python
salt.states.virt.pool_running(name, ptype=None, target=None, permissions=None, source=None, transient=False, autostart=True, connection=None, username=None, password=None)
```

Defines and starts a new pool with specified arguments.

New in version 2019.2.0.

**Parameters**
- `ptype` -- libvirt pool type
- `target` -- full path to the target device or folder. (Default: `None`)
- `permissions` -- target permissions. See *Permissions definition* for more details on this structure.
- `source` -- dictionary containing keys matching the `source_*` parameters in function `salt.modules.virt.pool_define()`.
- `transient` -- when set to `True`, the pool will be automatically undefined after being stopped. (Default: `False`)
- `autostart` -- Whether to start the pool when booting the host. (Default: `True`)
- `connection` -- libvirt connection URI, overriding defaults
- `username` -- username to connect with, overriding defaults
- `password` -- password to connect with, overriding defaults

```python
pool_name:
  virt.pool_running
```

```python
pool_name:
  virt.pool_running:
    - ptype: netfs
    - target: /mnt/cifs
    - permissions:
      - mode: 0770
      - owner: 1000
      - group: 100
    - source:
      dir: samba_share
      hosts:
      - one.example.com
      - two.example.com
    format: cifs
    autostart: True
```

```python
salt.states.virt.powered_off(name, connection=None, username=None, password=None)
```

Stops a VM by power off.

New in version 2016.3.0.

**Parameters**
- `connection` -- libvirt connection URI, overriding defaults
  New in version 2019.2.0.
- `username` -- username to connect with, overriding defaults
  New in version 2019.2.0.
- `password` -- password to connect with, overriding defaults
  New in version 2019.2.0.
salt.states.virt.rebooted(name, connection=None, username=None, password=None)
  Reboots VMs
  New in version 2016.3.0.
  Parameters
  - name --
  - connection -- libvirt connection URI, overriding defaults
    New in version 2019.2.0.
  - username -- username to connect with, overriding defaults
    New in version 2019.2.0.
  - password -- password to connect with, overriding defaults
    New in version 2019.2.0.

salt.states.virt.reverted(name, snapshot=None, cleanup=False)
  Deprecated since version 2016.3.0.
  Reverts to the particular snapshot.
  New in version 2016.3.0.

domain_name:
  virt.reverted:
    - cleanup: True

  domain_name_1:
    virt.reverted:
      - snapshot: snapshot_name
        - cleanup: False

domain_name:
  virt.stopped

salt.states.virt.running(name, cpu=None, mem=None, vm_type=None, disk_profile=None, disks=None, nic_profile=None, interfaces=None, graphics=None, seed=True, install=True, pub_key=None, priv_key=None, connection=None, username=None, password=None, os_type=None, arch=None, boot=None, boot_dev=None, numatune=None, hypervisor_features=None, clock=None, serials=None, consoles=None, stop_on_reboot=False, host_devices=None, autostart=False)
  Starts an existing guest, or defines and starts a new VM with specified arguments.
  New in version 2016.3.0.
  Parameters
  - name -- name of the virtual machine to run
  - cpu -- Number of virtual CPUs to assign to the virtual machine or a dictionary with
detailed information to configure cpu model and topology, numa node tuning, cpu
tuning and iothreads allocation. The structure of the dictionary is documented in cpu
parameters definition.

  To update any cpu parameters specify the new values to the corresponding tag. To
remove any element or attribute, specify None object. Please note that None object
is mapped to null in yaml, use null in sls file instead.

  - mem -- Amount of memory to allocate to the virtual machine in MiB. Since
3002, a dictionary can be used to contain detailed configuration which support
memory allocation or tuning. Supported parameters are boot, current, max,
slots, hard_limit, soft_limit, swap_hard_limit, min_guarantee, hugepages, nosharepages, locked, source, access, allocation and discard. The structure of the dictionary is documented in Memory parameter definition. Both decimal and binary base are supported. Detail unit specification is documented in Units specification. Please note that the value for slots must be an integer.

To remove any parameters, pass a None object, for instance: 'soft_limit': None. Please note that None is mapped to null in sls file, pass null in sls file instead.

```python
mem:
    hard_limit: null
    soft_limit: null
```

Changed in version 3002.

- **vm_type** -- force virtual machine type for the new VM. The default value is taken from the host capabilities. This could be useful for example to use 'qemu' type instead of the 'kvm' one.

  New in version 2019.2.0.

- **disk_profile** -- Name of the disk profile to use for the new virtual machine

  New in version 2019.2.0.

- **disks** -- List of disk to create for the new virtual machine. See Disks Definitions for more details on the items on this list.

  New in version 2019.2.0.

- **nic_profile** -- Name of the network interfaces profile to use for the new virtual machine

  New in version 2019.2.0.

- **interfaces** -- List of network interfaces to create for the new virtual machine. See Network Interfaces Definitions for more details on the items on this list.

  New in version 2019.2.0.

- **graphics** -- Graphics device to create for the new virtual machine. See Graphics Definition for more details on this dictionary

  New in version 2019.2.0.

- **saltenv** -- Fileserver environment (Default: 'base'). See cp module for more details

  New in version 2019.2.0.

- **seed** --

  True to seed the disk image. Only used when the image parameter is provided.

  (Default: True)

  New in version 2019.2.0.

- **install** -- install salt minion if absent (Default: True)

  New in version 2019.2.0.

- **pub_key** -- public key to seed with (Default: None)

  New in version 2019.2.0.

- **priv_key** -- public key to seed with (Default: None)

  New in version 2019.2.0.

- **seed_cmd** -- Salt command to execute to seed the image. (Default: 'seed.apply')

  New in version 2019.2.0.
- **connection** -- libvirt connection URI, overriding defaults
  New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults
  New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults
  New in version 2019.2.0.

- **os_type** -- type of virtualization as found in the //os/type element of the libvirt definition. The default value is taken from the host capabilities, with a preference for hvm. Only used when creating a new virtual machine.
  New in version 3000.

- **arch** -- architecture of the virtual machine. The default value is taken from the host capabilities, but x86_64 is prefed over i686. Only used when creating a new virtual machine.
  New in version 3000.

- **boot** -- Specifies kernel, initial ramdisk and kernel command line parameters for the virtual machine. This is an optional parameter, all of the keys are optional within the dictionary.

  Refer to [Boot parameters definition](#) for the complete boot parameters description.

  To update any boot parameters, specify the new path for each. To remove any boot parameters, pass a None object, for instance: 'kernel': None.

  New in version 3000.

- **serials** -- Dictionary providing details on the serials connection to create. (Default: None) See [Serials and Consoles Definitions](#) for more details on the possible values.
  New in version 3003.

- **consoles** -- Dictionary providing details on the consoles device to create. (Default: None) See [Serials and Consoles Definitions](#) for more details on the possible values.
  New in version 3003.

- **boot_dev** -- Space separated list of devices to boot from sorted by decreasing priority. Values can be hd, fd, cdrom or network.

  By default, the value will "hd".

  New in version 3002.

- **numatune** -- The optional numatune element provides details of how to tune the performance of a NUMA host via controlling NUMA policy for domain process. The optional memory element specifies how to allocate memory for the domain process on a NUMA host. memnode elements can specify memory allocation policies per each guest NUMA node. The definition used in the dictionary can be found at [cpu parameters definition](#).

  To update any numatune parameters, specify the new value. To remove any numatune parameters, pass a None object, for instance: 'numatune': None. Please note that None is mapped to null in sls file, pass null in sls file instead.

  New in version 3003.

- **stop_on_reboot** -- If set to True the guest will stop instead of rebooting. This is specially useful when creating a virtual machine with an installation cdrom or an autoinstallation needing a special first boot configuration. Defaults to False

  New in version 3003.
- **hypervisor_features** -- Enable or disable hypervisor-specific features on the virtual machine.

  New in version 3003.

  ```yaml
  hypervisor_features:
    kvm-hint-dedicated: True
  ```

- **clock** -- Configure the guest clock. The value is a dictionary with the following keys:

  - adjustment
    - time adjustment in seconds or reset
  - utc
    - set to False to use the host local time as the guest clock. Defaults to True.
  - timezone
    - synchronize the guest to the corresponding timezone
  - timers
    - a dictionary associating the timer name with its configuration. This configuration is a dictionary with the properties track, tickpolicy, catchup, frequency, mode, present, slew, threshold and limit. See `libvirt time keeping documentation` for the possible values.

  New in version 3003.

  Set the clock to local time using an offset in seconds.

  ```yaml
clock:
  adjustment: 3600 utc: False
```

Set the clock to a specific time zone:

```yaml
clock:
  timezone: CEST
```

- **host_devices** -- List of host devices to passthrough to the guest. The value is a list of device names as provided by the `node_devices()` function. (Default: None)

  New in version 3003.

- **autostart** -- If set to True the host will start the guest after boot. (Default: False)

**Example States**

Make sure an already-defined virtual machine called `domain_name` is running:

```yaml
domain_name:
  virt.running
```

Do the same, but define the virtual machine if needed:

```yaml
domain_name:
  virt.running:
    - cpu: 2
    - mem: 2048
    - disk_profile: prod
    - boot_dev: network hd
    - disks:
      - name: system
        size: 8192
```

(continues on next page)
overlay_image: True
pool: default
image: /path/to/image.qcow2
  name: data
  size: 16834
  nic_profile: prod
  interfaces:
    name: eth0
    mac: 01:23:45:67:89:AB
    name: eth1
    type: network
    source: admin
  graphics:
    type: spice
    listen:
      type: address
      address: 192.168.0.125

```yaml
salt.states.virt.saved(name, suffix=None)
```

Deprecated since version 2016.3.0: Use `snapshot()` instead.

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

```yaml
domain_name:
  virt.saved:
    - suffix: periodic
domain*:
  virt.saved:
    - suffix: periodic
```

```yaml
salt.states.virt.snapshot(name, suffix=None, connection=None, username=None, password=None)
```

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

Parameters
• **connection** -- libvirt connection URI, overriding defaults
  New in version 2019.2.0.
• **username** -- username to connect with, overriding defaults
  New in version 2019.2.0.
• **password** -- password to connect with, overriding defaults
  New in version 2019.2.0.

```yaml
domain_name:
  virt.snapshot:
    - suffix: periodic
domain*:
  virt.snapshot:
    - suffix: periodic
```
salt.states.virt.stopped(name, connection=None, username=None, password=None)

Stops a VM by shutting it down nicely.

New in version 2016.3.0.

Parameters

- **connection** -- libvirt connection URI, overriding defaults
  
  New in version 2019.2.0.

- **username** -- username to connect with, overriding defaults
  
  New in version 2019.2.0.

- **password** -- password to connect with, overriding defaults
  
  New in version 2019.2.0.

```python
domain_name:
  virt.stopped
```

salt.states.virt.unpowered(name)

Deprecated since version 2016.3.0: Use powered_off() instead.

Stops a VM by power off.

New in version 2016.3.0.

```python
domain_name:
  virt.stopped
```

salt.states.virt.volume_defined(pool, name, size, allocation=0, format=None, type=None, permissions=None, backing_store=None, nocow=False, connection=None, username=None, password=None)

Ensure a disk volume is existing.

Parameters

- **pool** -- name of the pool containing the volume
- **name** -- name of the volume
- **size** -- capacity of the volume to define in MiB
- **allocation** -- allocated size of the volume in MiB. Defaults to 0.
- **format** -- volume format. The allowed values are depending on the pool type. Check the virt.pool_capabilities output for the possible values and the default.
- **type** -- type of the volume. One of file, block, dir, network, netdiri, ploop or None. By default, the type is guessed by libvirt from the pool type.
- **permissions** -- Permissions to set on the target folder. This is mostly used for filesystem-based pool types. See Permissions definition for more details on this structure.
- **backing_store** -- dictionary describing a backing file for the volume. It must contain a path property pointing to the base volume and a format property defining the format of the base volume.

The base volume format will not be guessed for security reasons and is thus mandatory.

- **nocow** -- disable COW for the volume.
- **connection** -- libvirt connection URI, overriding defaults
- **username** -- username to connect with, overriding defaults
- **password** -- password to connect with, overriding defaults
CLI Example:

Volume on ESX:

```yaml
esx_volume:
  virt.volume_defined:
    - pool: "[local-storage]"
    - name: myvm/myvm.vmdk
    - size: 8192
```

Qcow2 volume with backing file:

```yaml
myvolume:
  virt.volume_defined:
    - pool: default
    - name: myvm.qcow2
    - format: qcow2
    - size: 8192
    - permissions:
      mode: '0775'
      owner: '123'
      group: '345'
    - backing_store:
      path: /path/to/base.img
      format: raw
    - nocow: True
```

New in version 3001.

25.20.309 salt.states.virtualenv

Setup of Python virtualenv sandboxes.

New in version 0.17.0.

```python
salt.states.virtualenv_mod.manage(name, venv_bin=None, requirements=None,
   system_site_packages=False, distribute=False, use_wheel=False,
   clear=False, python=None, extra_search_dir=None,
   never_download=False, prompt=None, user=None, cwd=None,
   index_url=None, extra_index_url=None, pre_releases=False,
   no_deps=False, pip_download=None, pip_download_cache=None,
   pip_exists_action=None, pip_ignore_installed=False, proxy=None,
   use_vt=False, env_vars=None, no_use_wheel=False,
   pip_upgrade=False, pip_pkgs=None, pip_no_cache_dir=False,
   pip_cache_dir=None, process_dependency_links=False,
   no_binary=None, **kwargs)
```

This function is an alias of managed.

Create a virtualenv and optionally manage it with pip

```python
ame
    Path to the virtualenv.
venv_bin: virtualenv
    The name (and optionally path) of the virtualenv command. This can also be set globally in
    the minion config file as virtualenv.venv_bin.
```
requirements: None
Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

use_wheel: False
Prefer wheel archives (requires pip >= 1.4).

python: None
Python executable used to build the virtualenv

user: None
The user under which to run virtualenv and pip.

cwd: None
Path to the working directory where pip install is executed.

no_deps: False
Pass --no-deps to pip install.

pip_exists_action: None
Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup.

proxy: None
Proxy address which is passed to pip install.

env_vars: None
Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling.

no_use_wheel: False
Force to not use wheel archives (requires pip>=1.4)

no_binary
Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages, none: to empty the set, or a list of one or more packages

pip_upgrade: False
Pass --upgrade to pip install.

pip_pkgs: None
As an alternative to requirements, pass a list of pip packages that should be installed.

process_dependency_links: False
Run pip install with the --process_dependency_links flag.

New in version 2017.7.0.
Also accepts any kwargs that the virtualenv module will. However, some kwargs, such as the pip option, require -- distribute: True.

```
/var/www/myvirtualenv.com:
  virtualenv.managed:
    - system_site_packages: False
    - requirements: salt://REQUIREMENTS.txt
    - env_vars:
      PATH_VAR: '/usr/local/bin/
```

salt.states.virtualenv_mod.managed(name, venv_bin=None, requirements=None,
  system_site_packages=False, distribute=False, use_wheel=False,
  clear=False, python=None, extra_search_dir=None,
  never_download=None, prompt=None, user=None, cwd=None,
  index_url=None, extra_index_url=None, pre_releases=False,
  no_deps=False, pip_download=None, pip_download_cache=None,
  pip_exists_action=None, pip_ignore_installed=False, proxy=None,
  use_vt=False, env_vars=None, no_use_wheel=False,
  pip_upgrade=False, pip_pkgs=None, pip_no_cache_dir=False,
  pip_cache_dir=None, process_dependency_links=False,
  no_binary=None, **kwargs)
Create a virtualenv and optionally manage it with pip

**name**
Path to the virtualenv.

**venv_bin:** virtualenv
The name (and optionally path) of the virtualenv command. This can also be set globally in the minion config file as `virtualenv.venv_bin`.

**requirements:** None
Path to a pip requirements file. If the path begins with `salt://` the file will be transferred from the master file server.

**use_wheel:** False
Prefer wheel archives (requires pip >= 1.4).

**python:** None
Python executable used to build the virtualenv

**user:** None
The user under which to run virtualenv and pip.

**cwd:** None
Path to the working directory where `pip install` is executed.

**no_deps:** False
Pass `--no-deps` to `pip install`.

**pip_exists_action:** None
Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup.

**proxy:** None
Proxy address which is passed to `pip install`.

**env_vars:** None
Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling.

**no_use_wheel:** False
Force to not use wheel archives (requires pip>=1.4)

**no_binary**
Force to not use binary packages (requires pip >= 7.0.0) Accepts either: all: to disable all binary packages, none: to empty the set, or a list of one or more packages

**pip_upgrade:** False
Pass `--upgrade` to `pip install`.

**pip_pkgs:** None
As an alternative to `requirements`, pass a list of pip packages that should be installed.

**process_dependency_links:** False
Run pip install with the `--process_dependency_links` flag.

New in version 2017.7.0.

Also accepts any kwargs that the virtualenv module will. However, some kwargs, such as the `pip` option, require `- distribute: True.

```
/var/www/myvirtualenv.com:
virtualenv.managed:
  - system_site_packages: False
  - requirements: salt://REQUIREMENTS.txt
  - env_vars:
    PATH_VAR: '/usr/local/bin/
```
25.20.310 salt.states.webutil

Support for htpasswd module. Requires the apache2-utils package for Debian-based distros.
New in version 2014.7.0.

```
username:
  webutil.user_exists:
    - password: secr3t
    - htpasswd_file: /etc/nginx/htpasswd
    - options: d
    - force: true
```

salt.states.webutil.user_absent(name, htpasswd_file=None, runas=None)

Make sure the user is not in the specified htpasswd file

- **name**
  - User name

- **htpasswd_file**
  - Path to the htpasswd file

- **runas**
  - The system user to run htpasswd command with

salt.states.webutil.user_exists(name, password=None, htpasswd_file=None, options='', force=False, runas=None, update=False)

Make sure the user is inside the specified htpasswd file

- **name**
  - User name

- **password**
  - User password

- **htpasswd_file**
  - Path to the htpasswd file

- **options**
  - See salt.modules.htpasswd.useradd

- **force**
  - Touch the file even if user already created

- **runas**
  - The system user to run htpasswd command with

- **update**
  - Update an existing user’s password if it’s different from what’s in the htpasswd file (unlike force, which updates regardless)

25.20.311 salt.states.win_appx

Manage Microsoft Store apps on Windows. Removing an app with this modules will deprovision the app from the online Windows image.
New in version 3007.0.

salt.states.win_appx.absent(name, query, include_store=False, frameworks=False, deprovision_only=False)

Removes Microsoft Store packages from the system. If the package is part of a bundle, the entire bundle will be removed.

This function removes the package for all users on the system. It also deprovisions the package so that it isn’t re-installed by later system updates. To only deprovision a package and not remove it for all users, set
deprovision_only=True.

Parameters

• **query** *(str)* -- The query string to use to select the packages to be removed. If the string matches multiple packages, they will all be removed. Here are some example strings:

```
string | description |
-------|-------------|
*teams* | Remove Microsoft Teams |
*zune* | Remove Windows Media Player and Zune Video |
*zuneMusic* | Only remove Windows Media Player |
*xbox* | Remove all xBox packages, there are 5 by default |
* | Remove everything but the Microsoft Store, unless include_store=True |
```

**Note:** Use the `appx.list` function to make sure your query is returning what you expect. Then use the same query to remove those packages.

• **include_store** *(bool)* -- Include the Microsoft Store in the results of the query to be removed. Use this with caution. It is difficult to reinstall the Microsoft Store once it has been removed with this function. Default is `False`.

• **frameworks** *(bool)* -- Include frameworks in the results of the query to be removed. Default is `False`.

• **deprovision_only** *(bool)* -- Only deprovision the package. The package will be removed from the current user and added to the list of deprovisioned packages. The package will not be re-installed in future system updates. New users of the system will not have the package installed. However, the package will still be installed for existing users. Default is `False`.

Returns

`True` if successful, `None` if no packages found.

Return type

`bool`

Raises

* `CommandExecutionError` -- On errors encountered removing the package

**CLI Example:**

```bash
remove_candy_crush:
appx.absent:
  - query: "*candy*"
```

### 25.20.312 salt.states.win_certutil

**Installing of certificates to the Windows Certificate Manager**

Install certificates to the Windows Certificate Manager

```bash
salt://certs/cert.cer:
certutil.add_store:
  - store: TrustedPublisher
```
salt.states.win_certutil.add_store(name, store, saltenv='base')

Store a certificate to the given certificate store

Parameters
- **name** (*str*) -- The path to the certificate to add to the store. This is either the path to a local file or a file from the file server in the form of salt://path/to/file
- **store** (*str*) -- The certificate store to add the certificate to
- **saltenv** (*str*) -- The salt environment to use. This is ignored if the path is local

Returns
A dictionary containing the results

Return type
``dict``

CLI Example:
```
add_certificate:
certutil.add_store:
  name: salt://web_cert.cer
  store: TrustedPublisher
```

salt.states.win_certutil.del_store(name, store, saltenv='base')

Remove a certificate from the given certificate store

Parameters
- **name** (*str*) -- The path to the certificate to remove from the store. This is either the path to a local file or a file from the file server in the form of salt://path/to/file
- **store** (*str*) -- The certificate store to remove the certificate from
- **saltenv** (*str*) -- The salt environment to use. This is ignored if the path is local

Returns
A dictionary containing the results

Return type
``dict``

CLI Example:
```
remove_certificate:
certutil.del_store:
  name: salt://web_cert.cer
  store: TrustedPublisher
```

25.20.313 salt.states.win_dacl

Windows Object Access Control Lists

Ensure an ACL is present

parameters:
- **name** - the path of the object
- **objectType** - Registry/File/Directory
- **user** - user account or SID for the ace
- **permission** - permission for the ace (see module win_acl for available permissions for each objectType)
- **acetype** - Allow/Deny
- **propagation** - how the ACL should apply to child objects (see module win_acl for available propagation types)

```
addAcl:
  win_dacl.present:
  - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
  - objectType: Registry
```

(continues on next page)
Ensure an ACL does not exist

parameters:
- name - the path of the object
- objectType - Registry/File/Directory
- user - user account or SID for the ace
- permission - permission for the ace (see module win_acl for available permissions for each objectType)
- acetype - Allow/Deny
- propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

```python
removeAcl:
    win_dacl.absent:
        - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
        - objectType: Registry
        - user: FakeUser
        - permission: FullControl
        - acetype: ALLOW
        - propagation: KEY&SUBKEYS
```

Ensure an object is inheriting permissions

parameters:
- name - the path of the object
- objectType - Registry/File/Directory
- clear_existing_acl - True/False - when inheritance is enabled, should the existing ACL be kept or cleared out

```python
eInherit:
    win_dacl.enableinheritance:
        - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
        - objectType: Registry

    - clear_existing_acl: True
```

Ensure an object is not inheriting permissions

parameters:
- name - the path of the object
- objectType - Registry/File/Directory
- copy_inherited_acl - True/False - if inheritance is enabled, should the inherited permissions be copied to the ACL when inheritance is disabled

```python
dInherit:
    win_dacl.disableinheritance:
        - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
        - objectType: Registry

        - copy_inherited_acl: False
```

salt.states.win_dacl.absent(name, objectType, user, permission, acetype, propagation)

Ensure an ACL does not exist

salt.states.win_dacl.disinherit(name, objectType, copy_inherited_acl=True)

Ensure an object is not inheriting ACLs from its parent

salt.states.win_dacl.inherit(name, objectType, clear_existing_acl=False)

Ensure an object is inheriting ACLs from its parent
salt.states.win_dacl.present(name, objectType, user, permission, acetype, propagation)
   Ensure an ACE is present

25.20.314 salt.states.win_dism

Installing of Windows features using DISM

Install Windows features, capabilities, and packages with DISM

Language.Basic~~~en-US~0.0.1.0:
   dism.capability_installed
NetFx3:
   dism.feature_installed

salt.states.win_dism.capability_installed(name, source=None, limit_access=False, image=None, restart=False)
   Install a DISM capability
   Parameters
     • name (str) -- The capability to install
     • source (str) -- The optional source of the capability
     • limit_access (bool) -- Prevent DISM from contacting Windows Update for on-line images
     • image (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
     • restart (Optional[bool]) -- Reboot the machine if required by the install

Example

Run dism.available_capabilities to get a list of available capabilities. This will help you get the proper name to use

install_dotnet35:
   dism.capability_installed:
     - name: NetFX3~~~~

salt.states.win_dism.capability_removed(name, image=None, restart=False)
   Uninstall a DISM capability
   Parameters
     • name (str) -- The capability to uninstall
     • image (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
     • restart (Optional[bool]) -- Reboot the machine if required by the uninstall
Example

Run `dism.installed_capabilities` to get a list of installed capabilities. This will help you get the proper name to use

```
remove_dotnet35:
    dism.capability_removed:
    - name: NetFX3~~~~
```

```
salt.states.win_dism.feature_installed(name, package=None, source=None, limit_access=False, enable_parent=False, image=None, restart=False)
```

Install a DISM feature

Parameters
- `name` (str) -- The feature in which to install
- `package` (Optional[str]) -- The parent package for the feature. You do not have to specify the package if it is the Windows Foundation Package. Otherwise, use package to specify the parent package of the feature
- `source` (str) -- The optional source of the feature
- `limit_access` (bool) -- Prevent DISM from contacting Windows Update for online images
- `enable_parent` (Optional[bool]) -- True will enable all parent features of the specified feature
- `image` (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- `restart` (Optional[bool]) -- Reboot the machine if required by the install

Example

Run `dism.available_features` to get a list of available features. This will help you get the proper name to use

```
install_telnet_client:
    dism.feature_installed:
    - name: TelnetClient
```

```
salt.states.win_dism.feature_removed(name, remove_payload=False, image=None, restart=False)
```

Disables a feature.

Parameters
- `name` (str) -- The feature to disable
- `remove_payload` (Optional[bool]) -- Remove the feature's payload. Must supply source when enabling in the future.
- `image` (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- `restart` (Optional[bool]) -- Reboot the machine if required by the uninstall
Example

Run `dism.installed_features` to get a list of installed features. This will help you get the proper name to use

```yaml
remove_telnet_client:
  dism.feature_removed:
  - name: TelnetClient
  - remove_payload: True
```

salt.states.win_dism.kb_removed(name, image=None, restart=False)

Uninstall a KB package

New in version 3006.0.

Parameters

- `name` (str) -- The name of the KB. Can be with or without the KB at the beginning
- `image` (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- `restart` (Optional[bool]) -- Reboot the machine if required by the uninstall

Example

```yaml
# Example using full KB name
remove_KB1231231:
  dism.package_installed:
  - name: KB1231231

# Example using just the KB number
remove_KB1231231:
  dism.package_installed:
  - name: 1231231
```

salt.states.win_dism.package_installed(name, ignore_check=False, prevent_pending=False, image=None, restart=False)

Install a package.

Parameters

- `name` (str) -- The package to install. Can be a .cab file, a .msu file, or a folder
- `ignore_check` (Optional[bool]) -- Skip installation of the package if the applicability checks fail
- `prevent_pending` (Optional[bool]) -- Skip the installation of the package if there are pending online actions
- `image` (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- `restart` (Optional[bool]) -- Reboot the machine if required by the install
Example

```python
install_KB123123123:
  dism.package_installed:
    - name: C:\Packages\KB123123123.cab
```

salt.states.win_dism.package_removed(name, image=None, restart=False)

Uninstall a package

Parameters

- **name** *(str)* -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. This can also be the name of a package as listed in `dism.installed_packages`
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the uninstall

Example

```python
# Example using source
remove_KB1231231:
  dism.package_installed:
    - name: C:\Packages\KB1231231.cab

# Example using name from `dism.installed_packages`
remove_KB1231231:
  dism.package_installed:
    - name: Package_for_KB1231231~31bf3856ad364e35~amd64~~10.0.1.3
```

salt.states.win_dism.provisioned_package_installed(name, image=None, restart=False)

Provision a package on a Windows image.

New in version 3007.0.

Parameters

- **name** *(str)* -- The package to install. Can be one of the following:
  - .appx or .appxbundle
  - .msix or .msixbundle
  - .ppkg

  The name of the file before the file extension must match the name of the package after it is installed. This name can be found by running `dism.provisioned_packages`
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the installation. Default is False
Example

```python
install_windows_media_player:
  dism.provisioned_package_installed:
    - name: C:\Packages\Microsoft.ZuneVideo_2019.22091.10036.0_neutral-_8wekyb3d8bbwe.Msixbundle
```

25.20.315 salt.states.win_dns_client

Module for configuring DNS Client on Windows systems

```python
salt.states.win_dns_client.dns_dhcp(name, interface='Local Area Connection')
```

Configure the DNS server list from DHCP Server

```python
salt.states.win_dns_client.dns_exists(name, servers=None, interface='Local Area Connection', replace=False)
```

Configure the DNS server list in the specified interface

Example:

```python
config_dns_servers:
  win_dns_client.dns_exists:
    
    replace: True  # remove any servers not in the "servers" list, default is False
    
    servers:
      - 8.8.8.8
      - 8.8.8.9
```

```python
salt.states.win_dns_client.primary_suffix(name, suffix=None, updates=False)
```

New in version 2014.7.0.

Configure the global primary DNS suffix of a DHCP client.

`suffix`

[None] The suffix which is advertised for this client when acquiring a DHCP lease. When none is set, the explicitly configured DNS suffix will be removed.

`updates`

[False] Allow syncing the DNS suffix with the AD domain when the client's AD domain membership changes

```python
primary_dns_suffix:
  win_dns_client.primary_suffix:
    
    suffix: sub.domain.tld
    
    updates: True
```
25.20.316 salt.states.win_firewall

State for configuring Windows Firewall

salt.states.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in', remoteip='any')

Add a new inbound or outbound rule to the firewall policy

Parameters

- **name** *(str)* -- The name of the rule. Must be unique and cannot be "all". Required.
- **localport** *(int)* -- The port the rule applies to. Must be a number between 0 and 65535. Can be a range. Can specify multiple ports separated by commas. Required.
- **protocol** *(Optional[str]*) -- The protocol. Can be any of the following:
  - A number between 0 and 255
  - icmpv4
  - icmpv6
  - tcp
  - udp
  - any
- **action** *(Optional[str]*) -- The action the rule performs. Can be any of the following:
  - allow
  - block
  - bypass
- **dir** *(Optional[str]*) -- The direction. Can be in or out.
- **remoteip** *(Optional [str]*) -- The remote IP. Can be any of the following:
  - any
  - localsubnet
  - dns
  - dhcp
  - wins
  - defaultgateway
  - Any valid IPv4 address (192.168.0.12)
  - Any valid subnet (192.168.1.0/24)
  - Any valid range of IP addresses (192.168.0.1-192.168.0.12)
  - A list of valid IP addresses

Can be combinations of the above separated by commas.

New in version 2016.11.6.

Example:

```yaml
open_smb_port:
  win_firewall.add_rule:
    - name: SMB (445)
    - localport: 445
    - protocol: tcp
    - action: allow
```

salt.states.win_firewall.disabled(name='allprofiles')

Disable all the firewall profiles (Windows only)

Parameters

- **profile** *(Optional[str]*) -- The name of the profile to disable. Default is allprofiles. Valid options are:
  - allprofiles
  - domainprofile

salt.states.win_firewall.disabled(name='allprofiles')

Disable all the firewall profiles (Windows only)

Parameters

- **profile** *(Optional[str]*) -- The name of the profile to disable. Default is allprofiles. Valid options are:
  - allprofiles
  - domainprofile
- privateprofile
- publicprofile

Example:

```yaml
# To disable the domain profile
disable_domain:
  win_firewall.disabled:
    - name: domainprofile

# To disable all profiles
disable_all:
  win_firewall.disabled:
    - name: allprofiles
```

`salt.states.win_firewall.enabled(name='allprofiles')`

Enable all the firewall profiles (Windows only)

Parameters

- **profile** (Optional[str]) -- The name of the profile to enable. Default is allprofiles. Valid options are:
  - allprofiles
  - domainprofile
  - privateprofile
  - publicprofile

Example:

```yaml
# To enable the domain profile
enable_domain:
  win_firewall.enabled:
    - name: domainprofile

# To enable all profiles
enable_all:
  win_firewall.enabled:
    - name: allprofiles
```

25.20.317 `salt.states.win_iis`

Microsoft IIS site management

This module provides the ability to add/remove websites and application pools from Microsoft IIS.

New in version 2016.3.0.

`salt.states.win_iis.container_setting(name, container, settings=None)`

Set the value of the setting for an IIS container.

Parameters

- **name** (str) -- The name of the IIS container.
- **container** (str) -- The type of IIS container. The container types are: AppPools, Sites, SslBindings
- **settings** (str) -- A dictionary of the setting names and their values. Example of usage for the AppPools container:
### site0-apppool-setting:
```
- name: site0
- container: AppPools
- settings:
  managedPipelineMode: Integrated
  processModel.maxProcesses: 1
  processModel.userName: TestUser
  processModel.password: TestPassword
  processModel.identityType: SpecificUser
```

Example of usage for the Sites container:
```
site0-site-setting:
  win_iis.container_setting:
  - name: site0
  - container: Sites
  - settings:
    logFile.logFormat: W3C
    logFile.period: Daily
    limits.maxUrlSegments: 32
```

call states.win_iis.create_app(name, site, sourcepath, apppool=None)

Create an IIS application.

**Parameters**

- **name** *(str)* -- The IIS application.
- **site** *(str)* -- The IIS site name.
- **sourcepath** *(str)* -- The physical path.
- **apppool** *(str)* -- The name of the IIS application pool.

Example of usage with only the required arguments:
```
site0-v1-app:
  win_iis.create_app:
  - name: v1
  - site: site0
  - sourcepath: C:\inetpub\site0\v1
```

Example of usage specifying all available arguments:
```
site0-v1-app:
  win_iis.create_app:
  - name: v1
  - site: site0
  - sourcepath: C:\inetpub\site0\v1
  - apppool: site0
```

call states.win_iis.create_apppool(name)

Create an IIS application pool.

**Parameters**

- **name** *(str)* -- The name of the IIS application pool.

**Usage:**
salt.states.win_iis.create_apppool:

- name: site0

salt.states.win_iis.create_binding:

Create an IIS binding.

Parameters

- site (str) -- The IIS site name.
- hostheader (str) -- The host header of the binding.
- ipaddress (str) -- The IP address of the binding.
- port (str) -- The TCP port of the binding.
- protocol (str) -- The application protocol of the binding.
- sslflags (str) -- The flags representing certificate type and certificate storage of the binding.

Example of usage with only the required arguments:

site0-https-binding:

- site: site0

Example of usage specifying all available arguments:

site0-https-binding:

- site: site0
  - hostheader: site0.local
  - ipaddress: '*'
  - port: 443
  - protocol: https
  - sslflags: 0

salt.states.win_iis.create_cert_binding:

Assign a certificate to an IIS binding.

Parameters

- name (str) -- The thumbprint of the certificate.
- site (str) -- The IIS site name.
- hostheader (str) -- The host header of the binding.
- ipaddress (str) -- The IP address of the binding.
- port (str) -- The TCP port of the binding.
- sslflags (str) -- Flags representing certificate type and certificate storage of the binding.

Example of usage with only the required arguments:

site0-cert-binding:

- name: 9988776655443322111000AAABBBCCCDDDEEEFFF
  - site: site0

Example of usage specifying all available arguments:

site0-cert-binding:

(continues on next page)
- name: 99887766554433221100AAABBBCCCDDDEEEFFF
  site: site0
  hostheader: site0.local
  ipaddress: 192.168.1.199
  port: 443
  sslflags: 1

New in version 2016.11.0.

salt.states.win_iis.create_vdir(name, site, sourcepath, app='/')

Create an IIS virtual directory.

Parameters

- name (str) -- The virtual directory name.
- site (str) -- The IIS site name.
- sourcepath (str) -- The physical path.
- app (str) -- The IIS application.

Example of usage with only the required arguments:

site0-foo-vdir:
  win_iis.create_vdir:
  - name: foo
  - site: site0
  - sourcepath: C:\inetpub\vdirs\foo

Example of usage specifying all available arguments:

site0-foo-vdir:
  win_iis.create_vdir:
  - name: foo
  - site: site0
  - sourcepath: C:\inetpub\vdirs\foo
  - app: v1

salt.states.win_iis.deployed(name, sourcepath, apppool='', hostheader='', ipaddress='', port=80, protocol='http')

Ensure the website has been deployed.

Parameters

- name (str) -- The IIS site name.
- sourcepath (str) -- The physical path of the IIS site.
- apppool (str) -- The name of the IIS application pool.
- hostheader (str) -- The host header of the binding.
- ipaddress (str) -- The IP address of the binding.
- port (str) -- The TCP port of the binding.
- protocol (str) -- The application protocol of the binding.

Example of usage with only the required arguments. This will default to using the default application pool assigned by IIS:

site0-deployed:
  win_iis.deployed:
  - name: site0
  - sourcepath: C:\inetpub\site0

Example of usage specifying all available arguments:
salt.states.win_iis.remove_app(name, site)
Remove an IIS application.
Parameters
• name (str) -- The application name.
• site (str) -- The IIS site name.
Usage:

```
site0-v1-app-remove:
    win_iis.remove_app:
    - name: v1
    - site: site0
```

salt.states.win_iis.remove_apppool(name)
Remove an IIS application pool.
Parameters
name (str) -- The name of the IIS application pool.
Usage:

```
defaultapppool-remove:
    win_iis.remove_apppool:
    - name: DefaultAppPool
```

salt.states.win_iis.remove_binding(name, site, hostheader='', ipaddress='*', port=80)
Remove an IIS binding.
Parameters
• site (str) -- The IIS site name.
• hostheader (str) -- The host header of the binding.
• ipaddress (str) -- The IP address of the binding.
• port (str) -- The TCP port of the binding.
Example of usage with only the required arguments:

```
site0-https-binding-remove:
    win_iis.remove_binding:
    - site: site0
```

Example of usage specifying all available arguments:

```
site0-https-binding-remove:
    win_iis.remove_binding:
    - site: site0
    - hostheader: site0.local
    - ipaddress: '*'
    - port: 443
```
salt.states.win_iis.remove_cert_binding(name, site, hostheader='', ipaddress='', port=443)

Remove a certificate from an IIS binding.

Parameters

- **name** *(str)* -- The thumbprint of the certificate.
- **site** *(str)* -- The IIS site name.
- **hostheader** *(str)* -- The host header of the binding.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(str)* -- The TCP port of the binding.

Example of usage with only the required arguments:

```
site0-cert-binding-remove:
    win_iis.remove_cert_binding:
        - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
        - site: site0
```

Example of usage specifying all available arguments:

```
site0-cert-binding-remove:
    win_iis.remove_cert_binding:
        - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
        - site: site0
        - hostheader: site0.local
        - ipaddress: 192.168.1.199
        - port: 443
```

New in version 2016.11.0.

salt.states.win_iis.remove_site(name)

Delete a website from IIS.

Parameters

- **name** *(str)* -- The IIS site name.

Usage:

```
defaultwebsite-remove:
    win_iis.remove_site:
        - name: Default Web Site
```

salt.states.win_iis.remove_vdir(name, site, app='/')

Remove an IIS virtual directory.

Parameters

- **name** *(str)* -- The virtual directory name.
- **site** *(str)* -- The IIS site name.
- **app** *(str)* -- The IIS application.

Example of usage with only the required arguments:

```
site0-foo-vdir-remove:
    win_iis.remove_vdir:
        - name: foo
        - site: site0
```

Example of usage specifying all available arguments:

```
site0-foo-vdir-remove:
    win_iis.remove_vdir:
```

(continues on next page)
salt.states.win_iis.set_app(name, site, settings=None)

New in version 2017.7.0.

Set the value of the setting for an IIS web application.

**Note:** This function only configures existing app. Params are case sensitive.

**Parameters**

- **name**(str) -- The IIS application.
- **site**(str) -- The IIS site name.
- **settings**(str) -- A dictionary of the setting names and their values.

**Available settings:**

- **physicalPath** - The physical path of the webapp
- **applicationPool** - The application pool for the webapp
- **userName** "connectAs" user
- **password** "connectAs" password for user

**Return type**

bool

Example of usage:

```python
site0-webapp-setting:
    win_iis.set_app:
      - name: app0
      - site: Default Web Site
      - settings:
          userName: domain\user
          password: pass
          physicalPath: c:\inetpub\wwwroot
          applicationPool: appPool0
```

salt.states.win_iis.webconfiguration_settings(name, settings=None)

Set the value of webconfiguration settings.

**Parameters**

- **name**(str) -- The name of the IIS PSPath containing the settings. Possible PSPaths are : MACHINE, MACHINE/WEBROOT, IIS:, IIS:Sitessitename, ...
- **settings**(dict) -- Dictionaries of dictionaries. You can match a specific item in a collection with this syntax inside a key: 'Collection[[name: site0]].logFile.directory'

**Example of usage for the MACHINE/WEBROOT PSPath:**

```python
MACHINE-WEBROOT-level-security:
    win_iis.webconfiguration_settings:
      - name: 'MACHINE/WEBROOT'
      - settings:
          system.web/authentication/forms:
            requireSSL: True
            protection: "All"
```

(continues on next page)
credentials.passwordFormat: "SHA1"

system.web/httpCookies:
  httpOnlyCookies: True

Example of usage for the IIS: \Sites\site0 PSPath:

```yaml
site0-IIS-Sites-level-security:
  win_iis.webconfiguration_settings:
    - name: 'IIS:\Sites\site0'
      settings:
        system.webServer/httpErrors:
          errorMode: "DetailedLocalOnly"
        system.webServer/security/requestFiltering:
          allowDoubleEscaping: False
        verbs.Collection:
          - verb: TRACE
            allowed: False
        fileExtensions.allowUnlisted: False
```

Example of usage for the IIS: \ PSPath with a collection matching:

```yaml
site0-IIS-level-security:
  win_iis.webconfiguration_settings:
    - name: 'IIS:\'
      settings:
        system.applicationHost/sites:
          'Collection[{name: site0}].logFile.directory': 'C:\logs\iis\site0'

25.20.318 salt.states.win_lgpo

Manage Windows Local Group Policy

New in version 2016.11.0.

This state module allows you to configure local Group Policy on Windows. You can ensure the setting of a single policy or multiple policies in one pass.

Single policies must specify the policy name, the setting, and the policy class (Machine/User/Both). Here are some examples for setting a single policy setting.

Example single policy configuration:

```yaml
Ensure Account Lockout Duration:
  lgpo.set:
    - name: Account lockout duration
    - setting: 90
    - policy_class: Machine
```

Example using abbreviated form:

```yaml
Account lockout duration:
  lgpo.set:
```

(continues on next page)
It is also possible to set multiple policies in a single state. This is done by setting the settings under either `computer_policy` or `user_policy`. Here are some examples for setting multiple policy settings in a single state.

Multiple policy configuration

**Company Local Group Policy:**

```bash
lgpo.set:
- computer_policy:
  Deny log on locally:
    - Guest
  Account lockout duration: 120
  Account lockout threshold: 10
  Reset account lockout counter after: 120
  Enforce password history: 24
  Maximum password age: 60
  Minimum password age: 1
  Minimum password length: 14
  Password must meet complexity requirements: Enabled
  Store passwords using reversible encryption: Disabled
  Configure Automatic Updates:
    Configure automatic updating: 4 - Auto download and schedule

  Scheduled install day: 7 - Every Saturday
  Scheduled install time: 17:00
  Specify intranet Microsoft update service location:
    Set the intranet update service for detecting updates: http://
  Specify intranet statistics server: http://mywsus

- user_policy:
  Do not process the legacy run list: Enabled
```

**Server Policy:**

```bash
lgpo.set:
- computer_policy:
  Maximum password age: 60
  Minimum password age: 1
  Minimum password length: 14
  Account lockout duration: 120
  Account lockout threshold: 10
  Reset account lockout counter after: 120
  Manage auditing and security log:
    - "BUILTIN\Administrators"
  Replace a process level token:
    - "NT AUTHORITY\NETWORK SERVICE"
    - "NT AUTHORITY\LOCAL SERVICE"
  "Accounts: Guest account status": Disabled
  "Accounts: Rename guest account": Not_4_U
  "Audit: Audit the use of Backup and Restore privilege": Enabled
  "Interactive logon: Do not display last user name": Enabled
```

(continues on next page)
"Network\DNS Client\Dynamic update": Disabled
"System\Logon\Do not display the Getting Started welcome screen at logon": Enabled
"Windows Components\Remote Desktop Services\Remote Desktop Session Host\Connections\Select RDP transport protocols": "Select Transport Type": "Use both UDP and TCP"
"Windows Components\Windows Update\Allow Automatic Updates immediate installation": Enabled
"Windows Components\Windows Update\Allow non-administrators to receive update notifications": Disabled
"Windows Components\Windows Update\Always automatically restart at the scheduled time": "The restart timer will give users this much time to save their work (minutes)": 15
"Windows Components\Windows Update\Automatic Updates detection frequency": "Check for updates at the following interval (hours)": 1
"Windows Components\Windows Update\Configure Automatic Updates": "Configure automatic updating": 4 - Auto download and schedule the install
"Install during automatic maintenance": False
"Scheduled install day": 7 - Every Saturday
"Scheduled install time": "17:00"
"Windows Components\Windows Update\Delay Restart for scheduled installations": "Wait the following period before proceeding with a scheduled restart (minutes)": 1
"Windows Components\Windows Update\No auto-restart with logged on users for scheduled automatic updates installations": Disabled
"Windows Components\Windows Update\Re-prompt for restart with scheduled installations": "Wait the following period before prompting again with a scheduled restart (minutes)": 30
"Windows Components\Windows Update\Reschedule Automatic Updates scheduled installations": Disabled
"Windows Components\Windows Update\Specify intranet Microsoft update service location": Set the intranet update service for detecting updates": http://mywsus
"Set the intranet statistics server": http://mywsus
- cumulative_rights_assignments: True

Some policy settings can't be set on their own and require that other policy settings are set at the same time. It can be difficult to figure out what additional settings need to be applied. The easiest way to do this is to modify the setting manually using the Group Policy Editor (`gpedit.msc`) on the machine. Then `get` the policy settings configured on that machine. Use the following command:

```
.. code-block:: bash

    salt-call --local lgpo.get machine
```
For example, if I want to set the Windows Update settings for a Windows Server 2016 machine I would go into the Group Policy Editor (`gpedit.msc`) and configure the group policy. That policy can be found at: Computer Configuration -> Administrative Templates -> Windows Components -> Windows Update -> Configure Automatic Updates. You have the option to "Enable" the policy and set some configuration options. In this example, just click "Enable" and accept the default configuration options. Click "OK" to apply the setting.

Now run the `get` command as shown above. You will find the following in the minion return:

```
.. code-block:: bash

    Windows Components\Windows Update\Configure Automatic Updates:
    
        Configure automatic updating:
        3 - Auto download and notify for install
        Install during automatic maintenance:
        False
        Install updates for other Microsoft products:
        False
        Scheduled install day:
        0 - Every day
        Scheduled install time:
        03:00
```

This shows you that to enable the "Configure Automatic Updates" policy you also have to configure the following settings:

- Configure automatic updating
- Install during automatic maintenance
- Install updates for other Microsoft products
- Scheduled install day
- Scheduled install time

So, if you were writing a state for the above policy, it would look like this:

```
.. code-block:: bash

    configure_windows_update_settings:
    lgpo.set:
        - computer_policy:
            Configure Automatic Updates:
            Configure automatic updating: 3 - Auto download and notify for install
            Install during automatic maintenance: False
            Install updates for other Microsoft products: False
            Scheduled install day: 0 - Every day
            Scheduled install time: 03:00
```
.. note::

   It is important that you put names of policies and settings exactly as they are displayed in the return. That includes capitalization and punctuation such as periods, dashes, etc. This rule applies to both the setting name and the setting value.

.. warning::

   From time to time Microsoft updates the Administrative templates on the machine. This can cause the policy name to change or the list of settings that must be applied at the same time. These settings often change between versions of Windows as well. For example, Windows Server 2019 allows you to also specify a specific week of the month to apply the update.

Another thing note is the long policy name returned by the `get` function:

.. code-block:: bash

   Windows Components\Windows Update\Configure Automatic Updates:

When we wrote the state for this policy we only used the final portion of the policy name, `Configure Automatic Updates`. This usually works fine, but if you are having problems, you may try the long policy name.

When writing the long name in a state file either wrap the name in single quotes to make yaml see it as raw data, or escape the back slashes.

.. code-block:: bash

   'Windows Components\Windows Update\Configure Automatic Updates:'

or

    Windows Components\Windows Update\Configure Automatic Updates:

salt.states.win_lgpo.set(name, setting=None, policy_class=None, computer_policy=None, user_policy=None, cumulative_rights_assignments=True, admil_language='en-US')

Ensure the specified policy is set.

**Warning:** The **setting** argument cannot be used in conjunction with the **computer_policy** or **user_policy** arguments

**Parameters**

- **name** *(str)* -- The name of a single policy to configure
- **setting** *(str, dict, list)* -- The configuration setting for the single named policy. If this argument is used the **computer_policy** / **user_policy** arguments will be ignored
- **policy_class** *(str)* -- The policy class of the single named policy to configure. This can be machine, user, or both
- **computer_policy** *(dict)* -- A dictionary of containing the policy name and key/value pairs of a set of computer policies to configure. If this argument is used, the name / policy_class arguments will be ignored
- **user_policy** *(dict)* -- A dictionary of containing the policy name and key/value pairs of a set of user policies to configure. If this argument is used, the name / policy_class arguments will be ignored
- **cumulative_rights_assignments** *(bool)* -- If user rights assignments are being configured, determines if any user right assignment policies specified will be cumulative or explicit
- **adml_language** *(str)* -- The adml language to use for AMDX policy data/display conversions. Default is `en-US`
Working with LGPO Reg

The easiest way to figure out the values needed for this module is to set the policy using the Group Policy Editor (gpedit.msc) and then run the lgpo_reg.read_reg_pol function. This function will display a dictionary of all registry-based policies in the Registry.pol file. From its return you can get the key, v_name, v_type, and v_data required to configure that policy.

Note: Not all policies in the Group Policy Editor (gpedit.msc) that write to the registry make that change in the Registry.pol file. Those policies could still be enforced via the Registry.pol file... theoretically. But you will have to find the values needed to set them with this module using a different method.

salt.states.win_lgpo_reg.value_absent(name, key, policy_class='Machine')
Ensure a registry setting is not present in the Registry.pol file.

Parameters

• key (str) -- The registry key path
• name (str) -- The registry value name within the key
• policy_class (str) -- The registry class to write to. Can be one of the following:
  – Computer
  – Machine
  – User
  Default is Machine

CLI Example:

# Using the name parameter in the definition
set_reg_pol_value:
lgpo_reg.value_absent:
- key: SOFTWARE\MyKey
- name: MyValue
- policy_class: Machine

# Using the name as the parameter and modifying the User policy
MyValue:
lgpo_reg.value_absent:
- key: SOFTWARE\MyKey
- policy_class: User

salt.states.win_lgpo_reg.value_disabled(name, key, policy_class='Machine')
Ensure a registry setting is disabled in the Registry.pol file.

Parameters

• key (str) -- The registry key path
• name (str) -- The registry value name within the key
• policy_class (str) -- The registry class to write to. Can be one of the following:
  – Computer
  – Machine
  – User
  Default is Machine

CLI Example:

# Using the name parameter in the definition
set_reg_pol_value:
lgpo_reg.value_disabled:

(continues on next page)
- **key**: SOFTWARE\MyKey
- **name**: MyValue
- **policy_class**: Machine

# Using the name as the parameter and modifying the User policy

**MyValue:**
- **key**: SOFTWARE\MyKey
- **policy_class**: User

salt.states.win_lgpo_reg.value_present(name, key, v_data, v_type='REG_DWORD', policy_class='Machine')

Ensure a registry setting is present in the Registry.pol file.

**Parameters**
- **name**(str) -- The registry value name within the key
- **key**(str) -- The registry key path
- **v_data**(str) -- The registry value
- **v_type**(str) -- The registry value type. Must be one of the following:
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
  - REG_MULTI_SZ
  - REG_QWORD
  - REG_SZ
  Default is REG_DWORD
- **policy_class**(str) -- The registry class to write to. Can be one of the following:
  - Computer
  - Machine
  - User
  Default is Machine

**CLI Example:**

```
# Using the name parameter in the definition
set_reg_pol_value:
  lgpo_reg.value_present:
    - key: SOFTWARE\MyKey
    - name: MyValue
    - v_type: REG_SZ
    - v_data: "some string data"
    - policy_class: Machine

# Using the name as the parameter and modifying the User policy
MyValue:
  lgpo_reg.value_present:
    - key: SOFTWARE\MyKey
    - v_type: REG_SZ
    - v_data: "some string data"
    - policy_class: User
```
25.20.320 salt.states.win_license

Installation and activation of windows licenses

Install and activate windows licenses

```
XXXXX-XXXXX-XXXXX-XXXXX-XXXXX:
license.activate
```

salt.states.win_license.activate(name)

Install and activate the given product key

name

The 5x5 product key given to you by Microsoft

25.20.321 salt.states.win_network

Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the network state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed.

Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: dhcp
        - ip_proto: dhcp
```

**Note:** Both the dns_proto and ip_proto arguments are required.

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: static
        - dns_servers:
            - 8.8.8.8
            - 8.8.4.4
        - ip_proto: static
        - ip_addrs:
            - 10.2.3.4/24
```

**Note:** IP addresses are specified using the format `<ip-address>/<subnet-length>`. Salt provides a convenience function called `ip.get_subnet_length` to calculate the subnet length from a netmask.

Optionally, if you are setting a static IP address, you can also specify the default gateway using the gateway parameter:
Local Area Connection #2:

```yaml
network.managed:
  - dns_proto: static
  - dns_servers:
    - 8.8.8.8
    - 8.8.4.4
  - ip_proto: static
  - ip_addrs:
    - 10.2.3.4/24
  - gateway: 10.2.3.1
```

`salt.states.win_network.managed(name, dns_proto=None, dns_servers=None, ip_proto=None, ip_addrs=None, gateway=None, enabled=True, **kwargs)`

Ensure that the named interface is configured properly.

**Parameters**

- **name** *(str)* -- The name of the interface to manage
- **dns_proto** *(str)* -- None Set to `static` and use the `dns_servers` parameter to provide a list of DNS nameservers. Set to `dhcp` to use DHCP to get the DNS servers.
- **dns_servers** *(list)* -- None A list of static DNS servers. To clear the list of DNS servers pass an empty list (`[]`). None will make no changes.
- **ip_proto** *(str)* -- None Set to `static` and use the `ip_addrs` and (optionally) `gateway` parameters to provide a list of static IP addresses and the default gateway. Set to `dhcp` to use DHCP.
- **ip_addrs** *(list)* -- None A list of static IP addresses with netmask flag, ie: `192.168.0.100/24`
- **gateway** *(str)* -- None The gateway to set for the interface
- **enabled** *(bool)* -- True Set to `False` to ensure that this interface is disabled.

**Returns**

A dictionary of old and new settings

**Return type**

dict

**Example:**

```yaml
Ethernet1:
  network.managed:
    - dns_proto: static
    - dns_servers:
      - 8.8.8.8
      - 8.8.4.4
    - ip_proto: static
    - ip_addrs:
      - 192.168.0.100/24
```

Clear DNS entries example:

```yaml
Ethernet1:
  network.managed:
    - dns_proto: static
    - dns_servers: []
    - ip_proto: dhcp
```
25.20.322 salt.states.win_path

Manage the Windows System PATH

salt.states.win_path.absent(name)
Remove the directory from the SYSTEM path

Example:

'C:\sysinternals':
    win_path.absent

salt.states.win_path.exists(name, index=None)
Add the directory to the system PATH at index location

Position where the directory should be placed in the PATH. This is 0-indexed, so 0 means to prepend at
the very start of the PATH.

Note: If the index is not specified, and the directory needs to be added to the PATH, then the directory
will be appended to the PATH, and this state will not enforce its location within the PATH.

Examples:

'C:\python27':
    win_path.exists

'C:\sysinternals':
    win_path.exists:
        - index: 0

'C:\mystuff':
    win_path.exists:
        - index: -1

25.20.323 salt.states.win_pki

Microsoft certificate management via the Pki PowerShell module.

platform
Windows
New in version 2016.11.0.

salt.states.win_pki.import_cert(name, cert_format='cer', context='LocalMachine', store='My',
                              exportable=True, password='', saltenv='base')

Import the certificate file into the given certificate store.

Parameters
- name (str) -- The path of the certificate file to import.
- cert_format (str) -- The certificate format. Specify 'cer' for X.509, or 'pfx' for
  PKCS #12.
- context (str) -- The name of the certificate store location context.
- store (str) -- The name of the certificate store.
- exportable (bool) -- Mark the certificate as exportable. Only applicable to pfx
  format.
• **password** *(str)* -- The password of the certificate. Only applicable to pfx format.
• **saltenv** *(str)* -- The environment the file resides in.

Example of usage with only the required arguments:

```python
site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.cer
```

Example of usage specifying all available arguments:

```python
site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.pfx
        - cert_format: pfx
        - context: LocalMachine
        - store: My
        - exportable: True
        - password: TestPassword
        - saltenv: base
```

```
salt.states.win_pki.remove_cert(name, thumbprint, context='LocalMachine', store='My')
```

Remove the certificate from the given certificate store.

Parameters

- **thumbprint** *(str)* -- The thumbprint value of the target certificate.
- **context** *(str)* -- The name of the certificate store location context.
- **store** *(str)* -- The name of the certificate store.

Example of usage with only the required arguments:

```python
site0-cert-removed:
    win_pki.remove_cert:
        - thumbprint: 9988776655443322111000AAABBBCCCDDDEEEFFF
```

Example of usage specifying all available arguments:

```python
site0-cert-removed:
    win_pki.remove_cert:
        - thumbprint: 9988776655443322111000AAABBBCCCDDDEEEFFF
        - context: LocalMachine
        - store: My
```

**25.20.324 salt.states.win_powercfg**

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```python
# Set timeout to 30 minutes on battery power
monitor:
    powercfg.set_timeout:
        - value: 30
        - power: dc
```

```
salt.states.win_powercfg.set_timeout(name, value, power='ac', scheme=None)
```

Set the sleep timeouts of specific items such as disk, monitor, etc.
Parameters

- **name (str)** -- The setting to change, can be one of the following:
  - monitor
  - disk
  - standby
  - hibernate
- **value (int)** -- The amount of time in minutes before the item will timeout
- **power (str)** -- Set the value for AC or DC power. Default is ac. Valid options are:
  - ac (AC Power)
  - dc (Battery)
- **scheme (str)** -- The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

CLI Example:

```yaml
# Set monitor timeout to 30 minutes on Battery
monitor:
  powercfg.set_timeout:
    - value: 30
    - power: dc

# Set disk timeout to 10 minutes on AC Power
disk:
  powercfg.set_timeout:
    - value: 10
    - power: ac
```

25.20.325 salt.states.win_servermanager

Manage Windows features via the ServerManager powershell module. Can install and remove roles/features.

- **maintainer**
  Shane Lee <slee@saltstack.com>
- **platform**
  Windows Server 2008R2 or greater
- **depends**
  win_servermanager.install
- **depends**
  win_servermanager.remove

```python
salt.states.win_servermanager.installed(name, features=None, recurse=False, restart=False, source=None, exclude=None, **kwargs)
```

Install the windows feature. To install a single feature, use the name parameter. To install multiple features, use the features parameter.

**Note:** Some features require reboot after un/installation. If so, until the server is restarted other features can not be installed!
- **name** (*str*) -- Short name of the feature (the right column in `win_servermanager.list_available`). This can be a single feature or a string of features in a comma delimited list (no spaces)

Note: A list is not allowed in the name parameter of any state. Use the `features` parameter if you want to pass the features as a list

- **features** *(Optional[list]*) -- A list of features to install. If this is passed it will be used instead of the `name` parameter.

  New in version 2018.3.0.

- **recurse** *(Optional[bool]*) -- Install all sub-features as well. If the feature is installed but one of its sub-features are not installed set this will install additional sub-features. This argument was previously renamed from `force`. To ensure backwards compatibility `force` will continue to work but please update your states to use the preferred `recurse` arg.

- **source** *(Optional[str]*) -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None

- **restart** *(Optional[bool]*) -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is False

- **exclude** *(Optional[str]*) -- The name of the feature to exclude when installing the named feature. This can be a single feature, a string of features in a comma-delimited list (no spaces), or a list of features.

  Warning: As there is no exclude option for the `Add-WindowsFeature` or `Install-WindowsFeature` PowerShell commands the features named in `exclude` will be installed with other sub-features and will then be removed. If the feature named in “exclude” is not a sub-feature of one of the installed items it will still be removed.

**Example**

Do not use the role or feature names mentioned in the PKGMGR documentation. To get a list of available roles and features run the following command:

```
salt <minion_name> win_servermanager.list_available
```

Use the name in the right column of the results.

```
# Installs the IIS Web Server Role (Web-Server)
IIS-WebServerRole:
  win_servermanager.installed:
    - recurse: True
    - name: Web-Server

# Install multiple features, exclude the Web-Service
install_multiple_features:
  win_servermanager.installed:
    - recurse: True
    - features:
      - RemoteAccess
```

(continues on next page)
salt.states.win_servermanager.removed(name, features=None, remove_payload=False, restart=False)

Remove the windows feature. To remove a single feature, use the name parameter. To remove multiple features, use the features parameter.

Parameters

- **name** *(str)* -- Short name of the feature (the right column in win_servermanager.list_available). This can be a single feature or a string of features in a comma-delimited list (no spaces)

  Note: A list is not allowed in the name parameter of any state. Use the features parameter if you want to pass the features as a list

- **features** *(Optional[list]*) -- A list of features to remove. If this is passed it will be used instead of the name parameter.

  New in version 2018.3.0.

- **remove_payload** *(Optional[bool]*) -- True will cause the feature to be removed from the side-by-side store. To install the feature in the future you will need to specify the source

- **restart** *(Optional[bool]*) -- Restarts the computer when uninstall is complete if required by the role/feature uninstall. Default is False

  Note: Some features require a reboot after uninstall. If so the feature will not be completely uninstalled until the server is restarted.

Example

Do not use the role or feature names mentioned in the PKGMGR documentation. To get a list of available roles and features run the following command:

```
salt <minion_name> win_servermanager.list_available
```

Use the name in the right column of the results.

```yaml
# Uninstall the IIS Web Server Role (Web-Server)
IIS-WebserverRole:
  win_servermanager.removed:
    - name: Web-Server

# Uninstall multiple features, reboot if required
uninstall_multiple_features:
  win_servermanager.removed:
    - features:
      - RemoteAccess
      - XPS-Viewer
      - SNMP-Service
    - restart: True
```
25.20.326 salt.states.win_shortcut

State module for creating shortcuts on Windows. Handles file shortcuts (.lnk) and url shortcuts (.url). Allows for the configuration of icons and hot keys on file shortcuts. Changing the icon and hot keys are unsupported for url shortcuts.

New in version 3005.

salt.states.win_shortcut.present(name, arguments='', description='', hot_key='', icon_location='', icon_index=0, target='', window_style='Normal', working_dir='', backup=False, force=False, make_dirs=False, user=None)

Create a new shortcut. This can be a file shortcut (.lnk) or a url shortcut (.url).

Parameters
- **name** (str) -- The full path to the shortcut
- **target** (str) -- The full path to the target
- **arguments** (str, optional) -- Any arguments to be passed to the target
- **description** (str, optional) -- The description for the shortcut. This is shown in the Comment field of the dialog box. Default is an empty string
- **hot_key** (str, optional) -- A combination of hot Keys to trigger this shortcut. This is something like Ctrl+Alt+D. This is shown in the Shortcut key field in the dialog box. Default is an empty string. Available options are:
  - Ctrl
  - Alt
  - Shift
  - Ext
- **icon_index** (int, optional) -- The index for the icon to use in files that contain multiple icons. Default is 0
- **icon_location** (str, optional) -- The full path to a file containing icons. This is shown in the Change Icon dialog box by clicking the Change Icon button. If no file is specified and a binary is passed as the target, Windows will attempt to get the icon from the binary file. Default is an empty string
- **window_style** (str, optional) -- The window style the program should start in. This is shown in the Run field of the dialog box. Default is Normal. Valid options are:
  - Normal
  - Minimized
  - Maximized
- **working_dir** (str, optional) -- The full path to the working directory for the program to run in. This is shown in the Start in field of the dialog box.
- **backup** (bool, optional) -- If there is already a shortcut with the same name, set this value to True to backup the existing shortcut and continue creating the new shortcut. Default is False
- **force** (bool, optional) -- If there is already a shortcut with the same name and you aren't backing up the shortcut, set this value to True to remove the existing shortcut and create a new with these settings. Default is False
- **make_dirs** (bool, optional) -- If the parent directory structure does not exist for the new shortcut, create it. Default is False
- **user** (str, optional) -- The user to be the owner of any directories created by setting make_dirs to True. If no value is passed Salt will use the user account that it is running under. Default is an empty string.

Returns
A dictionary containing the changes, comments, and result of the state

Return type
dict
Example:

```yaml
KB123456:
  wusa.installed:
    - source: salt://kb123456.msu

# Create a shortcut and set the `Shortcut key` (`hot_key`) in the shortcut
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - hot_key: Ctrl+Alt+N

# Create a shortcut and change the icon to the 3rd one in the icon file
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - icon_location: C:\path\to\icon.ico
    - icon_index: 2

# Create a shortcut and change the startup mode to full screen
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - window_style: Maximized

# Create a shortcut and change the icon
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - icon_location: C:\path\to\icon.ico

# Create a shortcut and force it to overwrite an existing shortcut
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - force: True

# Create a shortcut and create any parent directories if they are missing
newShortcut:
  shortcut.present:
    - name: C:\path\to\shortcut.lnk
    - target: C:\Windows\notepad.exe
    - make_dirs: True
```
25.20.327  

`salt.states.win_smtp_server`

Module for managing IIS SMTP server configuration on Windows servers.

`salt.states.win_smtp_server.active_log_format(name, log_format, server='SmtpSvc/1')`

Manage the active log format for the SMTP server.

Parameters

- `log_format (str)` -- The log format name.
- `server (str)` -- The SMTP server name.

Example of usage:

```yaml
smtp-log-format:
  win_smtp_server.active_log_format:
    - log_format: Microsoft IIS Log File Format
```

`salt.states.win_smtp_server.connection_ip_list(name, addresses=None, grant_by_default=False, server='SmtpSvc/1')`

Manage IP list for SMTP connections.

Parameters

- `addresses (str)` -- A dictionary of IP + subnet pairs.
- `grant_by_default (bool)` -- Whether the addresses should be a blacklist or whitelist.
- `server (str)` -- The SMTP server name.

Example of usage for creating a whitelist:

```yaml
smtp-connection-whitelist:
  win_smtp_server.connection_ip_list:
    - addresses:
      127.0.0.1: 255.255.255.255
      172.16.1.98: 255.255.255.255
      172.16.1.99: 255.255.255.255
    - grant_by_default: False
```

Example of usage for creating a blacklist:

```yaml
smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses:
      172.16.1.100: 255.255.255.255
      172.16.1.101: 255.255.255.255
    - grant_by_default: True
```

Example of usage for allowing any source to connect:

```yaml
smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses: {}
    - grant_by_default: True
```

`salt.states.win_smtp_server.relay_ip_list(name, addresses=None, server='SmtpSvc/1')`

Manage IP list for SMTP relay connections.

Due to the unusual way that Windows stores the relay IPs, it is advisable to retrieve the existing list you wish to set from a pre-configured server.
For example, setting '127.0.0.1' as an allowed relay IP through the GUI would generate an actual relay IP list similar to the following:

```
[ '24.0.0.128', '32.0.0.128', '60.0.0.128', '68.0.0.128', '1.0.0.0', '76.0.0.0',
  '0.0.0.0', '0.0.0.0', '1.0.0.0', '1.0.0.0', '2.0.0.0', '2.0.0.0', '4.0.0.0',
  '0.0.0.0', '76.0.0.128', '0.0.0.0', '0.0.0.0', '0.0.0.0', '0.0.0.0',
  '255.255.255.255', '127.0.0.1']
```

**Note:** Setting the list to None corresponds to the restrictive ‘Only the list below’ GUI parameter with an empty access list configured, and setting an empty list/tuple corresponds to the more permissive ‘All except the list below’ GUI parameter.

**Parameters**

- `addresses (str)` -- A list of the relay IPs. The order of the list is important.
- `server (str)` -- The SMTP server name.

**Example of usage:**

```
smtplib-list:
  win_smtp_server.relay_ip_list:
    - addresses:
      - 24.0.0.128
      - 32.0.0.128
      - 60.0.0.128
      - 1.0.0.0
      - 76.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 1.0.0.0
      - 1.0.0.0
      - 2.0.0.0
      - 2.0.0.0
      - 4.0.0.0
      - 0.0.0.0
      - 76.0.0.128
      - 0.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 255.255.255.255
      - 127.0.0.1
```

**Example of usage for disabling relaying:**

```
smtplib-list:
  win_smtp_server.relay_ip_list:
    - addresses: None
```

**Example of usage for allowing relaying from any source:**
```bash
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    - addresses: []
```

`salt.states.win_smtp_server.server_setting(name, settings=None, server='SmtpSvc/1')`

Ensure the value is set for the specified setting.

**Note:** The setting names are case-sensitive.

**Parameters**

- `settings (str)` -- A dictionary of the setting names and their values.
- `server (str)` -- The SMTP server name.

**Example of usage:**

```bash
smtp-settings:
  win_smtp_server.server_setting:
    - settings:
      LogType: 1
      LogFilePeriod: 1
      MaxMessageSize: 16777216
      MaxRecipients: 10000
      MaxSessionSize: 16777216
```

---

### 25.20.328 salt.states.win_snmp

Module for managing SNMP service settings on Windows servers.

`salt.states.win_snmp.agent_settings(name, contact, location, services=None)`

Manage the SNMP sysContact, sysLocation, and sysServices settings.

**Parameters**

- `contact (str)` -- The SNMP contact.
- `location (str)` -- The SNMP location.
- `services (str)` -- A list of selected services.

**Example of usage:**

```bash
snmp-agent-settings:
  win_snmp.agent_settings:
    - contact: Test Contact
    - location: Test Location
    - services:
      - Physical
      - Internet
```

`salt.states.win_snmp.auth_traps_enabled(name, status=True)`

Manage the sending of authentication traps.

**Parameters**

- `status (bool)` -- The enabled status.

**Example of usage:**

---

25.20. state modules
salt.states.win_snmp.community_names(name, communities=None)

Manage the SNMP accepted community names and their permissions.

Parameters

- **communities**(str) -- A dictionary of SNMP communities and permissions.

Example of usage:

```yaml
snmp-community-names:
  win_snmp.community_names:
    - communities:
        TestCommunity: Read Only
        OtherCommunity: Read Write
```

### 25.20.329 salt.states.win_system

Management of Windows system information

New in version 2014.1.0.

This state is used to manage system information such as the computer name and description.

**ERIK-WORKSTATION:**

```yaml
system.computer_name: []
```

This is Erik's computer, don't touch!:

```yaml
system.computer_desc: []
```

salt.states.win_system.computer_desc(name)

Manage the computer's description field

name

The desired computer description

salt.states.win_system.computer_description(name)

This function is an alias of computer_desc.

Manage the computer's description field

name

The desired computer description

salt.states.win_system.computer_name(name)

Manage the computer's name

name

The desired computer name

salt.states.win_system.hostname(name)

New in version 2016.3.0.

Manage the hostname of the computer

name

The hostname to set
salt.states.win_system.join_domain(name, username=None, password=None, account_ou=None, account_exists=False, restart=False)

Checks if a computer is joined to the Domain. If the computer is not in the Domain, it will be joined.

Parameters

- **name**(str) -- The name of the Domain.
- **username**(str) -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user.
- **password**(str) -- Password of the account to add the computer to the Domain.
- **account_ou**(str) -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=departm_432,dc=my-company,dc=com.
- **account_exists**(bool) -- Needs to be set to True to allow re-using an existing computer account.
- **restart**(bool) -- Needs to be set to True to restart the computer after a successful join.

Example:

```python
join_to_domain:
    system.join_domain:
        - name: mydomain.local.com
        - username: myaccount@mydomain.local.com
        - password: mysecretpassword
        - restart: True
```

salt.states.win_system.reboot(name, message=None, timeout=5, force_close=True, in_seconds=False, only_on_pending_reboot=True)

Reboot the computer

Parameters

- **message**(str) -- An optional message to display to users. It will also be used as a comment in the event log entry.

  The default value is None.

- **timeout**(int) -- The number of minutes or seconds before a reboot will occur. Whether this number represents minutes or seconds depends on the value of **in_seconds**.

  The default value is 5.

- **in_seconds**(bool) -- If this is True, the value of timeout will be treated as a number of seconds. If this is False, the value of timeout will be treated as a number of minutes.

  The default value is False.

- **force_close**(bool) -- If this is True, running applications will be forced to close without warning. If this is False, running applications will not get the opportunity to prompt users about unsaved data.

  The default value is True.

- **only_on_pending_reboot**(bool) -- If this is True, the reboot will only occur if the system reports a pending reboot. If this is False, the reboot will always occur.

  The default value is True.

salt.states.win_system.shutdown(name, message=None, timeout=5, force_close=True, reboot=False, in_seconds=False, only_on_pending_reboot=False)

Shutdown the computer
Parameters

- **message** *(str)* -- An optional message to display to users. It will also be used as a comment in the event log entry.
  
The default value is None.

- **timeout** *(int)* -- The number of minutes or seconds before a shutdown will occur. Whether this number represents minutes or seconds depends on the value of in_seconds.
  
The default value is 5.

- **in_seconds** *(bool)* -- If this is True, the value of timeout will be treated as a number of seconds. If this is False, the value of timeout will be treated as a number of minutes.
  
The default value is False.

- **force_close** *(bool)* -- If this is True, running applications will be forced to close without warning. If this is False, running applications will not get the opportunity to prompt users about unsaved data.
  
The default value is True.

- **reboot** *(bool)* -- If this is True, the computer will restart immediately after shutting down. If False the system flushes all caches to disk and safely powers down the system.
  
The default value is False.

- **only_on_pending_reboot** *(bool)* -- If this is True, the shutdown will only occur if the system reports a pending reboot. If this is False, the shutdown will always occur.
  
The default value is False.

`salt.states.win_system.workgroup(name)`

New in version 3001.

Manage the workgroup of the computer.

Parameters

- **name** *(str)* -- The workgroup to set

Example:

```
set workgroup:
  system.workgroup:
    - name: local
```
# Install a single update using the name parameter

```python
install_update:
    wua.installed:
        - name: KB3194343
```

# Install multiple updates using the updates parameter and a combination of
# KB number and GUID

```python
install_updates:
    wua.installed:
        - updates:
            - KB3194343
            - bb1dbb26-3fb6-45fd-bb05-e3c8e379195c
```

For removal:

```python
# Remove a single update using the KB
KB3194343:
    wua.removed

# Remove a single update using the name parameter
remove_update:
    wua.removed:
        - name: KB3194343

# Remove multiple updates using the updates parameter and a combination of
# KB number and GUID
remove_updates:
    wua.removed:
        - updates:
            - KB3194343
            - bb1dbb26-3fb6-45fd-bb05-e3c8e379195c
```

salt.states.win_wua.installed(name, updates=None)
Ensure Microsoft Updates are installed. Updates will be downloaded if needed.

Parameters
- `name` (str) -- The identifier of a single update to install.
- `updates` (list) -- A list of identifiers for updates to be installed. Overrides `name`.
  Default is None.

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you’re installing the correct update.

Warning: Using a partial KB number or a partial Title could result in more than one update being installed.

Returns
- A dictionary containing the results of the update. There are three keys under changes. `installed` is a list of updates that were successfully installed. `failed` is a list of updates that failed to install. `superseded` is a list of updates that were not installed because they were superseded by another update.
Return type
dict

CLI Example:

```python
# using a GUID
install_update:
  wua.installed:
    - name: 28cf1b09-2b1a-458c-9bd1-971d1b26b211

# using a KB
install_update:
  wua.installed:
    - name: KB3194343

# using the full Title
install_update:
  wua.installed:
    - name: Security Update for Adobe Flash Player for Windows 10 Version\x1607 (for x64-based Systems) (KB3194343)

# Install multiple updates
install_updates:
  wua.installed:
    - updates:
      - KB3194343
      - 28cf1b09-2b1a-458c-9bd1-971d1b26b211
```

salt.states.win_wua.removed(name, updates=None)
Ensure Microsoft Updates are uninstalled.

Parameters
- **name**(str) -- The identifier of a single update to uninstall.
- **updates**(list) -- A list of identifiers for updates to be removed. Overrides name.
  Default is None.

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you're uninstalling the correct update.

Warning: Using a partial KB number or a partial Title could result in more than one update being removed.

Returns
A dictionary containing the results of the removal. There are three keys under changes. `removed` is a list of updates that were successfully removed. `failed` is a list of updates that failed to be removed.

Return type
dict

CLI Example:

```python
# using a GUID
uninstall_update:
  wua.removed:
```
(continues on next page)
# using a KB
uninstall_update:
  wua.remove:
    - name: KB3194343

# using the full Title
uninstall_update:
  wua.remove:
    - name: Security Update for Adobe Flash Player for Windows 10 Version 1607 (for x64-based Systems) (KB3194343)

# Install multiple updates
uninstall_updates:
  wua.remove:
    - updates:
      - KB3194343
      - 28cf1b09-2b1a-458c-9bd1-971d1b26b211

salt.states.win_wua.uptodate(name, software=True, drivers=False, skip_hidden=False, skip_mandatory=False, skip_reboot=True, categories=None, severities=None)

Ensure Microsoft Updates that match the passed criteria are installed. Updates will be downloaded if needed.

This state allows you to update a system without specifying a specific update to apply. All matching updates will be installed.

Parameters

- **name** *(str)* -- The name has no functional value and is only used as a tracking reference
- **software** *(bool)* -- Include software updates in the results (default is True)
- **drivers** *(bool)* -- Include driver updates in the results (default is False)
- **skip_hidden** *(bool)* -- Skip updates that have been hidden. Default is False.
- **skip_mandatory** *(bool)* -- Skip mandatory updates. Default is False.
- **skip_reboot** *(bool)* -- Skip updates that require a reboot. Default is True.
- **categories** *(list)* -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:
- Critical Updates
- Definition Updates
- Drivers (make sure you set drivers=True)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender
- **severities** *(list)* -- Specify the severities to include. Must be passed as a list.
All severities returned by default.

Severities include the following:
– Critical
– Important

Returns
A dictionary containing the results of the update. There are three keys under changes. installed is a list of updates that were successfully installed. failed is a list of updates that failed to install. superseded is a list of updates that were not installed because they were superseded by another update.

Return type
dict

CLI Example:

```sh
# Update the system using the state defaults
update_system:
  wua.uptodate

# Update the drivers
update_drivers:
  wua.uptodate:
    - software: False
    - drivers: True
    - skip_reboot: False

# Apply all critical updates
update_critical:
  wua.uptodate:
    - severities:
      - Critical
```

25.20.331 salt.states.win_wusa

Microsoft Updates (KB) Management

This module provides the ability to enforce KB installations from files (.msu), without WSUS or Windows Update

New in version 2018.3.4.

salt.states.win_wusa.installed(name, source)

Ensure an update is installed on the minion

Parameters
– name (str) -- Name of the Windows KB ("KB123456")
– source (str) -- Source of .msu file corresponding to the KB

Example:

```sh
KB123456:
  wusa.installed:
    - source: salt://kb123456.msu
```

salt.states.win_wusa.uninstalled(name)

Ensure an update is uninstalled from the minion

Parameters
– name (str) -- Name of the Windows KB ("KB123456")

Example:
25.20.332 salt.states.winrepo

Manage Windows Package Repository

\texttt{salt.states.winrepo.genrepo}(name, force=False, allow_empty=False)

Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)

If \textit{force} is \texttt{True} no checks will be made and the repository will be generated if \textit{allow_empty} is \texttt{True} then the state will not return an error if there are 0 packages.

\textbf{Note:} This state only loads on minions that have the roles: \texttt{salt-master} grain set.

Example:

\begin{verbatim}
winrepo:
  winrepo.genrepo
\end{verbatim}

25.20.333 salt.states.wordpress

This state module is used to manage Wordpress installations

\texttt{depends}

\texttt{wp} binary from \url{http://wp-cli.org/}

\texttt{salt.states.wordpress.activated}(name, path, user)

Activate wordpress plugins

\texttt{name}

name of plugin to activate

\texttt{path}

path to wordpress installation

\texttt{user}

user who should own the files in the wordpress installation

\begin{verbatim}
HyperDB:
  wordpress.activated:
    - path: /var/www/html
    - user: apache
\end{verbatim}

\texttt{salt.states.wordpress.deactivated}(name, path, user)

Deactivate wordpress plugins

\texttt{name}

name of plugin to deactivate

\texttt{path}

path to wordpress installation

\texttt{user}

user who should own the files in the wordpress installation
salt.states.wordpress.

```python
wordpress.deactivated:
    - path: /var/www/html
    - user: apache
```

salt.states.wordpress.

```python
installed(name, user, admin_user, admin_password, admin_email, title, url)
    Run the initial setup of wordpress
    name
        path to the wordpress installation
    user
        user that owns the files for the wordpress installation
    admin_user
        username for wordpress website administrator user
    admin_password
        password for wordpress website administrator user
    admin_email
        email for wordpress website administrator user
    title
        title for the wordpress website
    url
        url for the wordpress website
```

```python
/path/to/wordpress:
    wordpress.installed:
        - title: Daniel's Awesome Blog
        - user: apache
        - admin_user: dwallace
        - admin_email: dwallace@example.com
        - admin_password: password123
        - url: https://blog.dwallace.com
```

25.20.334 salt.states.x509

Manage X509 Certificates

New in version 2015.8.0.

```
depends
    M2Crypto
```

Deprecated since version 3006.0.

**Warning:** This module has been deprecated and will be removed in Salt 3009 (Potassium). Please migrate to the replacement modules. For breaking changes between both versions, you can refer to the `x509_v2 execution module docs`.

They will become the default `x509` modules in Salt 3008 (Argon). You can explicitly switch to the new modules before that release by setting `features: {x509_v2: true}` in your minion configuration.

This module can enable managing a complete PKI infrastructure including creating private keys, CAs, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.
Here is a simple example scenario. In this example, `ca` is the ca server, and `www` is a web server that needs a certificate signed by `ca`.

For remote signing, peers must be permitted to remotely call the `sign_remote_certificate` function.

```
/etc/salt/master.d/peer.conf
```

```
peer:
  .*:
    - x509.sign_remote_certificate
```

```
/srv/salt/top.sls
```

```
base:
  '*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine where it can be easily retrieved by other minions.

```
/srv/salt/ca.sls
```

```
/etc/salt/minion.d/x509.conf:
  file.managed:
    - source: salt://x509.conf

restart-salt-minion:
  cmd.run:
    - name: 'salt-call service.restart salt-minion'
    - bg: True
    - onchanges:
      - file: /etc/salt/minion.d/x509.conf

/etc/pki:
  file.directory

/etc/pki/issued_certs:
  file.directory

/etc/pki/ca.key:
  x509.private_key Managed:
    - bits: 4096
    - backup: True

/etc/pki/ca.crt:
  x509.certificate Managed:
    - signing_private_key: /etc/pki/ca.key
    - CN: ca.example.com
    - C: US
    - ST: Utah
    - L: Salt Lake City
```

(continues on next page)
- basicConstraints: "critical CA:true"
- keyUsage: "critical cRLSign, keyCertSign"
- subjectKeyIdentifier: hash
- authorityKeyIdentifier: keyid,issuer:always
- days_valid: 3650
- days_remaining: 0
- backup: True
- require:
  - file: /etc/pki

The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.

/srv/salt/x509.conf

mine_functions:
  x509.get_pem_entries: [/etc/pki/ca.crt]

x509_signing_policies:
  www:
    - minions: 'www'
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical keyEncipherment"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/

This state will instruct all minions to trust certificates signed by our new CA. Using Jinja to strip newlines from the text avoids dealing with newlines in the rendered YAML, and the sign_remote_certificate state will handle properly formatting the text before writing the output.

/srv/salt/cert.sls

/usr/local/share/ca-certificates:
  file.directory

/usr/local/share/ca-certificates/intca.crt:
  x509.pem_managed:
    text: {{ salt['mine.get']('ca', 'x509.get_pem_entries')['ca']['/etc/pki/ca.crt']|replace('
', '') }}

This state creates a private key then requests a certificate signed by ca according to the www policy.

/srv/salt/www.sls

/etc/pki/www.crt:
  x509.private_key Managed:
    - name: /etc/pki/www.key

(continues on next page)
- **bits**: 4096
- **backup**: True

/etc/pki/www.crt:
  ```
  x509.certificate_managed:
  - **ca_server**: ca
  - **signing_policy**: www
  - **public_key**: /etc/pki/www.key
  - **CN**: www.example.com
  - **days_remaining**: 30
  - **backup**: True
  ```

This other state creates a private key then requests a certificate signed by ca according to the www policy but adds a strict date range for the certificate to be considered valid.

/srv/salt/www-time-limited.sls

/etc/pki/www-time-limited.crt:
  ```
  x509.certificate_managed:
  - **ca_server**: ca
  - **signing_policy**: www
  - **public_key**: /etc/pki/www-time-limited.key
  - **CN**: www.example.com
  - **not_before**: 2019-05-05 00:00:00
  - **not_after**: 2020-05-05 14:30:00
  - **backup**: True
  ```

salt.states.x509.certificate_managed(name, days_remaining=90, append_certs=None, **kwargs)

Manage a Certificate

**name**
Path to the certificate

**days_remaining**
[90] Recreate the certificate if the number of days remaining on it are less than this number. The value should be less than days_valid, otherwise the certificate will be recreated every time the state is run. A value of 0 disables automatic renewal.

**append_certs**:
A list of certificates to be appended to the managed file. They must be valid PEM files, otherwise an error will be thrown.

**kwargs**:
Any arguments supported by x509.create_certificate or file.managed are supported.

**not_before**:
Initial validity date for the certificate. This date must be specified in the format '%Y-%m-%d %H:%M:%S'. New in version 3001.

**not_after**:
Final validity date for the certificate. This date must be specified in the format '%Y-%m-%d %H:%M:%S'. New in version 3001.

Examples:

/etc/pki/ca.crt:
  ```
  x509.certificate_managed:
  - **signing_private_key**: /etc/pki/ca.key
  - **CN**: ca.example.com
  ```

(continues on next page)
salt.states.x509.crl_managed(name, signing_private_key, signing_private_key_passphrase=None, signing_cert=None, revoked=None, days_valid=100, digest='', days_remaining=30, include_expired=False, **kwargs)

Manage a Certificate Revocation List

name
    Path to the certificate

signing_private_key
    The private key that will be used to sign the CRL. This is usually your CA’s private key.

signing_private_key_passphrase
    Passphrase to decrypt the private key.

signing_cert
    The certificate of the authority that will be used to sign the CRL. This is usually your CA’s certificate.

revoked
    A list of certificates to revoke. Must include either a serial number or a the certificate itself. Can optionally include the revocation date and notAfter date from the certificate. See example below for details.

days_valid
    [100] The number of days the certificate should be valid for.

digest
    The digest to use for signing the CRL. This has no effect on versions of pyOpenSSL less than 0.14.

days_remaining
    [30] The CRL should be automatically recreated if there are less than days_remaining days until the CRL expires. Set to 0 to disable automatic renewal.

include_expired
    [False] If True, include expired certificates in the CRL.

kwargs
    Any arguments supported by file.managed are supported.

Example:
- **signing_cert**: /etc/pki/myca.crt
- **revoked**:
  - **compromised_web_key**:
    - **certificate**: /etc/pki/certs/badweb.crt
    - **revocation_date**: 2015-03-01 00:00:00
    - **reason**: keyCompromise
  - **terminated_vpn_user**:
    - **serial_number**: D6:D2:DC:D8:4D:5C:C0:F4
    - **not_after**: 2016-01-01 00:00:00
    - **revocation_date**: 2015-02-25 00:00:00
    - **reason**: cessationOfOperation

salt.states.x509.csr_managed(name, **kwargs)

Manage a Certificate Signing Request

**name**: Path to the CSR
**properties**: The properties to be added to the certificate request, including items like subject, extensions and public key. See above for valid properties.
**kwargs**: Any arguments supported by file.managed are supported.

Example:

```
/etc/pki/mycert.csr:
x509.csr_managed:
  - **private_key**: /etc/pki/mycert.key
  - **CN**: www.example.com
  - **C**: US
  - **ST**: Utah
  - **L**: Salt Lake City
  - **keyUsage**: 'critical dataEncipherment'
```

salt.states.x509.pem_managed(name, text, backup=False, **kwargs)

Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.

**name**: The path to the file to manage
**text**: The PEM formatted text to write.
**kwargs**: Any arguments supported by file.managed are supported.

salt.states.x509.private_key_managed(name, bits=2048, passphrase=None, cipher='aes_128_cbc', new=False, overwrite=False, verbose=True, **kwargs)

Manage a private key's existence.

**name**: Path to the private key
**bits**: Key length in bits. Default 2048.
**passphrase**: Passphrase for encrypting the private key.
**cipher**: Cipher for encrypting the private key.
new:
Always create a new key. Defaults to False. Combining new with prereq can allow key rotation whenever a new certificate is generated.

overwrite:
Overwrite an existing private key if the provided passphrase cannot decrypt it.

verbose:
Provide visual feedback on stdout, dots while key is generated. Default is True.

New in version 2016.11.0.

kwargs:
Any kwargs supported by file.managed are supported.

Example:
The JINJA templating in this example ensures a private key is generated if the file doesn’t exist and that a new private key is generated whenever the certificate that uses it is to be renewed.

```
/etc/pki/www.key:
x509.private_key_managed:
  - bits: 4096
  - new: True
  {% if salt['file.file_exists']('/etc/pki/www.key') -%}
  - prereq:
    - x509: /etc/pki/www.crt
  {%- endif %}
```

25.20.335 salt.states.x509_v2

Manage X.509 certificates

New in version 3006.0: This module represents a complete rewrite of the original x509 modules and is named x509_v2 since it introduces breaking changes.

depends
cryptography

Note: All parameters that take a public key, private key, certificate, CSR or CRL can be specified either as a PEM/hex/base64 string or a path to a local file encoded in all supported formats for the type.

Configuration instructions and general remarks are documented in the execution module docs.

For the list of breaking changes versus the previous x509 modules, please also refer to the execution module docs.

About

This module can enable managing a complete PKI infrastructure, including creating private keys, CAs, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.
Example

Here is a simple example scenario. In this example ca is the ca server, and www is a web server that needs a certificate signed by ca.

Note: Remote signing requires the setup of Peer Communication and signing policies. Please see the execution module docs.

/srv/salt/top.sls

```yaml
base:
  '*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine, where it can be easily retrieved by other minions.

# /srv/salt/ca.sls

**Configure the x509 module:**

```yaml
file.managed:
  - name: /etc/salt/minion.d/x509.conf
  - source: salt://x509.conf
```

**Restart Salt minion:**

```yaml
cmd.run:
  - name: 'salt-call service.restart salt-minion'
  - bg: true
  - onchanges:
    - file: /etc/salt/minion.d/x509.conf
```

**Ensure PKI directories exist:**

```yaml
file.directory:
  - name: /etc/pki/issued_certs
  - makedirs: true
```

**Create CA private key:**

```yaml
x509.private_key_managed:
  - name: /etc/pki/ca.key
  - keysize: 4096
  - backup: true
  - require:
    - file: /etc/pki
```

**Create self-signed CA certificate:**

```yaml
x509.certificate_managed:
  - name: /etc/pki/ca.crt
  - signing_private_key: /etc/pki/ca.key
  - CN: ca.example.com
```

(continues on next page)
This example state will instruct all minions to trust certificates signed by our new CA. Mind that this example works for Debian-based OS only. Also note the Jinja call to encode the string to JSON, which will avoid YAML issues with newline characters.

# /srv/salt/cert.sls

Ensure the CA trust bundle exists:
```yaml
file.directory:
  - name: /usr/local/share/ca-certificates
```

Ensure our self-signed CA certificate is included:
```yaml
x509.pem_managed:
  - name: /usr/local/share/ca-certificates/myca.crt
```

(continues on next page)
This state creates a private key, then requests a certificate signed by our CA according to the www policy.

```yaml
# /srv/salt/www.sls

Ensure PKI directory exists:
  file.directory:
    - name: /etc/pki

Create private key for the certificate:
  x509.private_key_managed:
    - name: /etc/pki/www.key
    - keysize: 4096
    - backup: true
    - require:
      - file: /etc/pki

Request certificate:
  x509.certificate_managed:
    - name: /etc/pki/www.crt
    - ca_server: ca
    - signing_policy: www
    - private_key: /etc/pki/www.key
    - CN: www.example.com
    - days_remaining: 7
    - backup: true
    - require:
      - x509: /etc/pki/www.key

salt.states.x509_v2.certificate_managed(name, days_remaining=None, ca_server=None, signing_policy=None, encoding='pem', append_certs=None, copypath=None, prepend cn=False, digest='sha256', signing_private_key=None, signing_private_key_passphrase=None, signing_cert=None, public_key=None, private_key=None, private_key_passphrase=None, csr=None, subject=None, serial_number=None, not_before=None, not_after=None, days_valid=None, pkcs12 passphrase=None, pkcs12_encryption_compat=False, pkcs12_friendlyname=None, **kwargs)
```

Ensure an X.509 certificate is present as specified.

This function accepts the same arguments as `x509.create_certificate`, as well as most ones for :py:func:`file.managed <salt.states.file.managed>.

- **name**: The path the certificate should be present at.
- **days_remaining**: The certificate will be recreated once the remaining certificate validity period is less than this number of days. Defaults to 90 (until v3009) or 7 (from v3009 onwards).
- **ca_server**: Request a remotely signed certificate from ca_server. For this to work, a `signing_policy` must be
specified, and that same policy must be configured on the ca_server. Also, the Salt master must permit peers to call the x509.sign_remote_certificate function. See the execution module docs for details.

**signing_policy**
The name of a configured signing policy. Parameters specified in there are hardcoded and cannot be overridden. This is required for remote signing, otherwise optional.

**encoding**
Specify the encoding of the resulting certificate. It can be serialized as a pem (or pkcs7_pem) text file or in several binary formats (der, pkcs7_der, pkcs12). Defaults to pem.

**append_certs**
A list of additional certificates to append to the new one, e.g. to create a CA chain.

---

**Note:** Mind that when der encoding is in use, appending certificates is prohibited.

**copypath**
Create a copy of the issued certificate in PEM format in this directory. The file will be named <serial_number>.crt if prepend_cn is false.

**prepend_cn**
When copypath is set, prepend the common name of the certificate to the file name like so: <CN>-<serial_number>.crt. Defaults to false.

**digest**
The hashing algorithm to use for the signature. Valid values are: sha1, sha224, sha256, sha384, sha512, sha512_224, sha512_256, sha3_224, sha3_256, sha3_384, sha3_512. Defaults to sha256. This will be ignored for ed25519 and ed448 key types.

**signing_private_key**
The private key corresponding to the public key in signing_cert. Required.

**signing_private_key_passphrase**
If signing_private_key is encrypted, the passphrase to decrypt it.

**signing_cert**
The CA certificate to be used for signing the issued certificate.

**public_key**
The public key the certificate should be issued for. Other ways of passing the required information are private_key and csr. If neither are set, the public key of the signing_private_key will be included, i.e. a self-signed certificate is generated.

**private_key**
The private key corresponding to the public key the certificate should be issued for. This is one way of specifying the public key that will be included in the certificate, the other ones being public_key and csr.

**private_key_passphrase**
If private_key is specified and encrypted, the passphrase to decrypt it.

**csr**
A certificate signing request to use as a base for generating the certificate. The following information will be respected, depending on configuration:
- public key
- extensions, if not otherwise specified (arguments, signing_policy)

**subject**
The subject's distinguished name embedded in the certificate. This is one way of passing this information (see kwargs below for the other). This argument will be preferred and allows to control the order of RDNs in the DN as well as to embed RDNs with multiple attributes. This can be specified as a RFC4514-encoded string (CN=example.com,O=Example Inc,C=US, mind that the rendered order is reversed from what is embedded), a list of RDNs encoded as in RFC4514 ("["C=US", "O=Example Inc", "CN=example.com"]) or a dictionary ({"CN": "example.com", "C": "US", "O": "Example Inc"}, default ordering). Multiple name at-
tributes per RDN are concatenated with a +.

---

**Note:** Parsing of RFC4514 strings requires at least cryptography release 37.

---

### serial_number

A serial number to be embedded in the certificate. If unspecified, will autogenerate one. This should be an integer, either in decimal or hexadecimal notation.

### not_before

Set a specific date the certificate should not be valid before. The format should follow `%Y-%m-%d %H:%M:%S` and will be interpreted as GMT/UTC. Defaults to the time of issuance.

### not_after

Set a specific date the certificate should not be valid after. The format should follow `%Y-%m-%d %H:%M:%S` and will be interpreted as GMT/UTC. If unspecified, defaults to the current time plus `days_valid` days.

### days_valid

If `not_after` is unspecified, the number of days from the time of issuance the certificate should be valid for. Defaults to 365 (until v3009) or 30 (from v3009 onwards).

### pkcs12_passphrase

When encoding a certificate as `pkcs12`, encrypt it with this passphrase.

---

**Note:** PKCS12 encryption is very weak and should not be relied on for security.

---

### pkcs12EncryptionCompat

OpenSSL 3 and cryptography v37 switched to a much more secure default encryption for PKCS12, which might be incompatible with some systems. This forces the legacy encryption. Defaults to False.

### pkcs12_friendlyname

When encoding a certificate as `pkcs12`, a name for the certificate can be included.

### kwargs

Embedded X.509v3 extensions and the subject's distinguished name can be controlled via supplemental keyword arguments. See `x509.create_certificate` for an overview.

---

salt.states.x509_v2.crl_managed(name, signing_private_key, revoked, days_remaining=None, signing_cert=None, signing_private_key_passphrase=None, include_expired=False, days_valid=None, digest='sha256', encoding='pem', extensions=None, **kwargs)

Ensure a certificate revocation list is present as specified.

This function accepts the same arguments as `x509.create_crl`, as well as most ones for :py:func:`file.managed <salt.states.file.managed>`.

**name**

The path the certificate revocation list should be present at.

**signing_private_key**

Your certificate authority's private key. It will be used to sign the CRL. Required.

**revoked**

A list of dicts containing all the certificates to revoke. Each dict represents one certificate. A dict must contain either the key `serial_number` with the value of the serial number to revoke, or `certificate` with some reference to the certificate to revoke.

The dict can optionally contain the `revocation_date` key. If this key is omitted, the revocation date will be set to now. It should be a string in the format `%Y-%m-%d %H:%M:%S`.

The dict can also optionally contain the `not_after` key. This is redundant if the `certificate` key is included. If the `certificate` key is not included, this can be used for the logic behind the `include_expired` parameter. It should be a string in the format `%Y-%m-%d %H:%M:%S`.

---

25.20. state modules

4599
The dict can also optionally contain the `extensions` key, which allows to set CRL entry-specific extensions. The following extensions are supported:

**certificateIssuer**

Identifies the certificate issuer associated with an entry in an indirect CRL. The format is the same as for subjectAltName.

**CRLReason**

Identifies the reason for certificate revocation. Available choices are unspecified, keyCompromise, CACompromise, affiliationChanged, superseded, cessationOfOperation, certificateHold, privilegeWithdrawn, aACompromise and removeFromCRL.

**invalidityDate**

Provides the date on which the certificate became invalid. The value should be a string in the same format as `revocation_date`.

**days_remaining**

The certificate revocation list will be recreated once the remaining CRL validity period is less than this number of days. Defaults to 30 (until v3009) or 3 (from v3009 onwards). Set to 0 to disable automatic renewal without anything changing.

**signing_cert**

The CA certificate to be used for signing the issued certificate.

**signing_private_key_passphrase**

If `signing_private_key` is encrypted, the passphrase to decrypt it.

**include_expired**

Also include already expired certificates in the CRL. Defaults to false.

**days_valid**

The number of days that the CRL should be valid for. This sets the Next Update field in the CRL. Defaults to 100 (until v3009) or 7 (from v3009 onwards).

**digest**

The hashing algorithm to use for the signature. Valid values are: sha1, sha224, sha256, sha384, sha512, sha512_224, sha512_256, sha3_224, sha3_256, sha3_384, sha3_512. Defaults to sha256. This will be ignored for ed25519 and ed448 key types.

**encoding**

Specify the encoding of the resulting certificate revocation list. It can be serialized as a pem text or binary der file. Defaults to pem.

**extensions**

Add CRL extensions. See `x509.create_crl` for details.

---

**Note:** For `cRLNumber`, in addition the value `auto` is supported, which automatically increases the counter every time a new CRL is issued.

---

**Example:**

Manage CRL:

```yaml
x509.crlManaged:
  - name: /etc/pki/ca.crl
  - signing_private_key: /etc/pki/myca.key
  - signing_cert: /etc/pki/myca.crt
  - revoked:
    - certificate: /etc/pki/certs/badweb.crt
      revocation_date: 2022-11-01 00:00:00
      extensions:
        CRLReason: keyCompromise
    - serial_number: D6:D2:DC:D8:4D:5C:C0:F4
      not_after: 2023-03-14 00:00:00
```

(continues on next page)
salt.states.x509_v2.pem_managed(name, text, **kwargs)

Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.

name
The path to the file to manage.

text
The PEM-formatted text to write.

kwargs
Most arguments supported by file.managed are passed through.

salt.states.x509_v2.private_key_managed(name, algo='rsa', keysize=None, passphrase=None, encoding='pem', new=False, overwrite=False, pkcs12_encryption_compat=False, **kwargs)

Ensure a private key is present as specified.

This function accepts the same arguments as x509.create_private_key, as well as most ones for file.managed.

Note: If mode is unspecified, it will default to 0400.

name
The path the private key should be present at.
algo
The digital signature scheme the private key should be based on. Available: rsa, ec, ed25519, ed448. Defaults to rsa.

keysize
For rsa, specifies the bitlength of the private key (2048, 3072, 4096). For ec, specifies the NIST curve to use (256, 384, 521). Irrelevant for Edwards-curve schemes (ed25519, ed448). Defaults to 2048 for RSA and 256 for EC.

passphrase
If this is specified, the private key will be encrypted using this passphrase. The encryption algorithm cannot be selected, it will be determined automatically as the best available one.

encoding
Specify the encoding of the resulting private key. It can be serialized as a pem text, binary der or pkcs12 file. Defaults to pem.

new
Always create a new key. Defaults to false. Combining new with prereq can allow key rotation whenever a new certificate is generated.

overwrite
Overwrite an existing private key if the provided passphrase cannot decrypt it. Defaults to false.

pkcs12_encryption_compat
Some operating systems are incompatible with the encryption defaults for PKCS12 used since OpenSSL v3. This switch triggers a fallback to PBESv1SHA1And3KeyTripleDESCBC. Please consider the notes on PKCS12 encryption.

Example:
The Jinja templating in this example ensures a new private key is generated if the file does not exist and whenever the associated certificate is to be renewed.

 Manage www private key:
  x509.private_key_managed:
    - name: /etc/pki/www.key
    - keysize: 4096
    - new: true
    {%- if salt['file.file_exists']('/etc/pki/www.key') %}
    - prereq:
      - x509: /etc/pki/www.crt
    {%- endif %}

25.20.336 salt.states.xml

XML Manager
State management of XML files

salt.states.xml.value_present(name, xpath, value, **kwargs)
New in version 3000.

Manages a given XML file
name
  [string] The location of the XML file to manage, as an absolute path.
xpath
  [string] xpath location to manage
value
  [string] value to ensure present
### 25.20.337 salt.states.xmpp

#### Sending Messages over XMPP

This state is useful for firing messages during state runs, using the XMPP protocol.

**server-warning-message:**

```python
xmpp.send_msg:
- name: 'This is a server warning message'
- profile: my-xmpp-account
- recipient: admins@xmpp.example.com/salt
```

#### salt.states.xmpp.send_msg(name, recipient, profile)

Send a message to an XMPP user

**server-warning-message:**

```python
xmpp.send_msg:
- name: 'This is a server warning message'
- profile: my-xmpp-account
- recipient: admins@xmpp.example.com/salt
```

#### salt.states.xmpp.send_msg_multi(name, profile, recipients=None, rooms=None)

Send a message to an list of recipients or rooms

**server-warning-message:**

```python
xmpp.send_msg:
- name: 'This is a server warning message'
- profile: my-xmpp-account
- recipients:
  - admins@xmpp.example.com/salt
- rooms:
  - qa@conference.xmpp.example.com
```

**name**

The message to send to the XMPP user
25.20.338 salt.states.zabbix_action

Management of Zabbix Action object over Zabbix API.
New in version 2017.7.0.

codeauthor
Jakub Sliva <jakub.sliva@ultimum.io>
salt.states.zabbix_action.absent(name, **kwargs)
Makes the Zabbix Action to be absent (either does not exist or delete it).
Parameters
• name -- Zabbix Action name
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
zabbix-action-absent:
zabbix_action.absent:
  - name: Action name
```
salt.states.zabbix_action.present(name, params, **kwargs)
Creates Zabbix Action object or if differs update it according defined parameters
Parameters
• name -- Zabbix Action name
• params -- Definition of the Zabbix Action
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

If there is a need to get a value from current zabbix online (e.g. id of a hostgroup you want to put a discovered system into), put a dictionary with two keys "query_object" and "query_name" instead of the value. In this example we want to get object id of hostgroup named "Virtual machines" and "Databases".

```
zabbix-action-present:
zabbix_action.present:
  - name: VMs
    - params:
      eventsource: 2
      status: 0
      filter:
        evaltype: 2
        conditions:
          - conditiontype: 24
            operator: 2
            value: 'virtual'
          - conditiontype: 24
            operator: 2
            value: 'kvm'
      operations:
```
(continues on next page)
- `operationtype`: 2
- `operationtype`: 4

*`opgroup:`*
  - `groupid`:
    - `query_object`: hostgroup
    - `query_name`: Virtual machines
  - `groupid`:
    - `query_object`: hostgroup
    - `query_name`: Databases

---

### 25.20.339 salt.states.zabbix_host

Management of Zabbix hosts.

**codeauthor**

Jiri Kotlin `<jiri.kotlin@ultimum.io>`

**salt.states.zabbix_host.absent** *(name, **kwargs)*

Ensures that the host does not exists, eventually deletes host.

New in version 2016.3.0.

**Param**

- `name`: technical name of the host

**Parameters**

- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

---

**TestHostWithInterfaces:**

```
salt.states.zabbix_host.absent
```

**salt.states.zabbix_host.assign_templates** *(host, templates, **kwargs)*

Ensures that templates are assigned to the host.

New in version 2017.7.0.

**Parameters**

- `host` -- technical name of the host
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

---

**add_zabbix_templates_to_host:**

```
salt.states.zabbix_host.assign_templates:
  - host: TestHost
    templates:
    - "Template OS Linux"
    - "Template App MySQL"
```
salt.states.zabbix_host.present(host, groups, interfaces, **kwargs)

Ensures that the host exists, eventually creates new host. NOTE: please use argument visible_name instead of name to not mess with name from salt sls. This function accepts all standard host properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host

New in version 2016.3.0.

Parameters

- **host** -- technical name of the host
- **groups** -- groupids of host groups to add the host to
- **interfaces** -- interfaces to be created for the host
- **proxy_host** -- Optional proxy name or proxyid to monitor host
- **inventory** -- Optional list or dictionary of inventory names and values
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- **visible_name** -- Optional - string with visible name of the host, use ‘visible_name’ instead of ‘name’ parameter to not mess with value supplied from Salt sls file.
- **inventory_clean** -- Optional - Boolean value that selects if the current inventory will be cleaned and overwritten by the declared inventory list (True); or if the inventory will be kept and only updated with inventory list contents (False). Defaults to True

```python
create_test_host:
zabbix_host.present:
  - host: TestHostWithInterfaces
  - proxy_host: 12345
  - groups:
    - 5
    - 6
    - 7
  - interfaces:
    - test1.example.com:
      - ip: '192.168.1.8'
      - type: 'Agent'
      - port: 92
    - testing2_create:
      - ip: '192.168.1.9'
      - dns: 'test2.example.com'
      - type: 'agent'
      - main: false
    - testovaci1_ipmi:
      - ip: '192.168.100.111'
      - type: 'ipmi'
  - inventory:
    - alias: some alias
    - asset_tag: jlm3937
```
25.20.340  salt.states.zabbix_hostgroup

Management of Zabbix host groups.

codeauthor
    Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_hostgroup.absent(name, **kwargs)

Ensures that the host group does not exist, eventually delete host group.

New in version 2016.3.0.

Parameters

- name -- name of the host group
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
disable_notifications:  
salt.states.zabbix_hostgroup.absent:  
    - name: 'Off
```

call太久没用

salt.states.zabbix_hostgroup.present(name, **kwargs)

Ensures that the host group exists, eventually creates new host group.

New in version 2016.3.0.

Parameters

- name -- name of the host group
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
disable_notifications:  
salt.states.zabbix_hostgroup.present:  
    - name: 'Off
```

25.20.341  salt.states.zabbix_mediatype

Management of Zabbix mediatypes.

codeauthor
    Raymond Kuiper <qix@the-wired.net>

salt.states.zabbix_mediatype.absent(name, **kwargs)

Ensures that the mediatype does not exist, eventually deletes the mediatype.

Parameters

- name -- name of the mediatype
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
salt.states.zabbix_mediatype.delete_mediatype

- name: 'Email'

```
# delete mediatype
salt.states.zabbix_mediatype.absent:
  - name: 'Email'
```

`salt.states.zabbix_mediatype.present(name, mediatype, **kwargs)`

Creates new mediatype. NOTE: This function accepts all standard mediatype properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/3.0/manual/api/reference/host/object#host_inventory

**Parameters**

- name -- name of the mediatype
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
# make new mediatype
salt.states.zabbix_mediatype.present:
  - name: 'Email'
  - mediatype: 0
  - smtp_server: smtp.example.com
  - smtp_hello: zabbix.example.com
  - smtp_email: zabbix@example.com
```

### 25.20.342 salt.states.zabbix_template

New in version 2017.7.0.

Management of Zabbix Template object over Zabbix API.

**codeauthor**

Jakub Sliva <jakub.sliva@ultimum.io>

```
salt.states.zabbix_template.absent(name, **kwargs)
```

Makes the Zabbix Template to be absent (either does not exist or delete it).

**Parameters**

- name -- Zabbix Template name
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
# zabbix-template-absent
salt.states.zabbix_template.absent:
  - name: Ceph OSD
```
salt.states.zabbix_template.is_present(name, **kwargs)
Check if Zabbix Template already exists.

Parameters
- **name** -- Zabbix Template name
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Example:
```
salt.states.zabbix_template.is_present:
  - name: Template OS Linux
```

does_zabbix-template-exist:
  zabbix_template.is_present:
    - name: Template OS Linux

salt.states.zabbix_template.present(name, params, static_host_list=True, **kwargs)
Creates Zabbix Template object or if differs update it according defined parameters. See Zabbix API documentation.

Zabbix API version: >3.0

Parameters
- **name** -- Zabbix Template name
- **params** -- Additional parameters according to Zabbix API documentation
- **static_host_list** -- If hosts assigned to the template are controlled only by this state or can be also assigned externally
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Example:
```
salt.states.zabbix_template.present:
  name: Testing Template
  params:
    name: "Testing Template"
    template_type: "application"
    description: "This is a test template"
    template_language: "en"
    hostgroupids: [1, 2]
    macros: [
      {"name": "Macro1", "value": "Value1"},
      {"name": "Macro2", "value": "Value2"}
    ]
```

Note: If there is a need to get a value from current zabbix online (e.g. ids of host groups you want the template to be associated with), put a dictionary with two keys "query_object" and "query_name" instead of the value. In this example we want to create template named "Testing Template", assign it to hostgroup Templates, link it to two ceph nodes and create a macro.

Note: IMPORTANT NOTE: Objects (except for template name) are identified by name (or by other key in some exceptional cases) so changing name of object means deleting old one and creating new one with new ID !!

Note: NOT SUPPORTED FEATURES:
- linked templates
- trigger dependencies
- groups and group prototypes for host prototypes

SLS Example:
zabbix-template-present:
  zabbix_template.present:
    - name: Testing Template
      # Do not touch existing assigned hosts
      # True will detach all other hosts than defined here
      - static_host_list: False
    - params:
      description: Template for Ceph nodes
      groups:
        # groups must already exist
        # template must be at least in one hostgroup
        - groupid:
            query_object: hostgroup
            query_name: Templates
      macros:
        - macro: "$CEPH_CLUSTER_NAME"
          value: ceph
      hosts:
        # hosts must already exist
        - hostid:
            query_object: host
            query_name: ceph-osd-01
        - hostid:
            query_object: host
            query_name: ceph-osd-02
      # templates:
      # Linked templates - not supported by state module but can be linked manually (will not be touched)
      applications:
        - name: Ceph OSD
      items:
        - name: Ceph OSD avg fill item
          key_: ceph.osd_avg_fill
          type: 2
          value_type: 0
          delay: 60
          units: '%'
          description: 'Average fill of OSD'
          applications:
            - applicationid:
                query_object: application
                query_name: Ceph OSD
      triggers:
        - description: "Ceph OSD filled more that 90%"
          expression: "{{'{}Testing Template:ceph.osd_avg_fill. last(){{'}}}">90"
          priority: 4
      discoveries:
        - name: Mounted filesystem discovery
          key_: vfs.fs.discovery
          type: 0
          delay: 60
itemprototypes:
   - name: Free disk space on {{'#'}}FSNAME
     key_: vfs.fs.size[{{'#'}}FSNAME,free]
     type: 0
     value_type: 3
     delay: 60
   applications:
     - applicationid:
         query_object: application
         query_name: Ceph OSD

triggerprototypes:
   - description: "Free disk space is less than 20% on\n                 volume {{'#'}}FSNAME[{{''}}]
                 expression: "{{'{'}}Testing Template:vfs.fs.size[{{
                 ->{{'#'}}FSNAME,free}.last(){{''}}}<20"

graphs:
   - name: Ceph OSD avg fill graph
   width: 900
   height: 200
   graphtype: 0
   gitems:
     - color: F63100
       itemid:
       query_object: item
       query_name: Ceph OSD avg fill item

screens:
   - name: Ceph
   hsize: 1
   vsize: 1
   screenitems:
     - x: 0
     y: 0
     resourceid: 0
     query_object: graph
     query_name: Ceph OSD avg fill graph

25.20.343 salt.states.zabbix_user

Management of Zabbix users.

codeauthor
   Jiri Kotlin 
   <jiri.kotlin@ultimum.io>

salt.states.zabbix_user.absent(name, **kwargs)

Ensures that the user does not exist, eventually delete user.

New in version 2016.3.0.

Parameters
   • name -- user alias
   • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see
     module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

George:
  zabbix_user.absent

salt.states.zabbix_user.admin_password_present(name, password=None, **kwargs)

Initial change of Zabbix Admin password to password taken from one of the sources (only the most prioritized one):
1. 'password' parameter
2. '_connection_password' parameter
3. pillar 'zabbix.password' setting

1) Tries to log in as Admin with password found in state password parameter or _connection_password or pillar or default zabbix password in this precise order, if any of them is present.
2) If one of above passwords matches, it tries to change the password to the most prioritized one.
3) If not able to connect with any password then it fails.

Parameters
• name -- Just a name of state
• password -- Optional - desired password for Admin to be set
• _connection_user -- Optional - Ignored in this state (always assumed 'Admin')
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

# password taken from pillar or _connection_password
zabbix-admin-password:
  zabbix_user.admin_password_present

# directly set password
zabbix-admin-password:
  zabbix_user.admin_password_present:
    - password: SECRET_PASS

salt.states.zabbix_user.present(alias, passwd, usgrps=None, medias=None, password_reset=False, **kwargs)

Ensures that the user exists, eventually creates new user. NOTE: use argument firstname instead of name to not mess values with name from salt sls.

New in version 2016.3.0.
Parameters
• alias -- user alias
• passwd -- user's password
• usgrps -- user groups to add the user to
• medias -- Optional - user's medias to create
• password_reset -- whether or not to reset password at update
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
• **firstname** -- string with firstname of the user, use 'firstname' instead of 'name' parameter to not mess with value supplied from Salt sls file.

```python
make_user:
    zabbix_user.present:
        - alias: George
        - passwd: donottellanyone@456x
        - password_reset: True
        - usgrps:
            - 13
            - 7
        - medias:
            - me@example.com:
                - mediatype: mail
                - period: '1-7,00:00-24:00'
                - severity: NIWAHD
            - make_jabber:
                - active: true
                - mediatype: jabber
                - period: '1-5,08:00-19:00'
                - sendto: jabbera@example.com
            - text_me_morning_disabled:
                - active: false
                - mediatype: sms
                - period: '1-5,09:30-10:00'
                - severity: D
                - sendto: '+42032132588568'
```

### 25.20.344 salt.states.zabbix_usergroup

Management of Zabbix user groups.

**codeauthor**

Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_usergroup.absent(name, **kwargs)

Ensures that the user group does not exist, eventually delete user group.

New in version 2016.3.0.

Parameters

- **name** -- name of the user group
- **connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
delete_thai_monks_usrgrp:
    zabbix_usergroup.absent:
        - name: 'Thai monks'
```

salt.states.zabbix_usergroup.present(name, **kwargs)

Creates new user group. NOTE: This function accepts all standard user group properties: keyword argument
names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.0/manual/appendix/api/usergroup/definitions#user_group

New in version 2016.3.0.

Parameters

- **name** -- name of the user group
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
make_new_thai_monks_usergroup:
    zabbix_usergroup.present:
    - name: 'Thai monks'
    - gui_access: 1
    - debug_mode: 0
    - users_status: 0
```

25.20.345 salt.states.zabbix_usermacro

Management of Zabbix usermacros. :codeauthor: Raymond Kuiper <qix@the-wired.net>

**salt.states.zabbix_usermacro.absent(name, hostid=None, **kwargs)**

Ensures that the mediatype does not exist, eventually deletes the mediatype.

Parameters

- **name** -- name of the usermacro
- **hostid** -- id's of the hosts to apply the usermacro on, if missing a global usermacro is assumed.
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
delete_usermacro:
    zabbix_usermacro.absent:
    - name: '${SNMP_COMMUNITY}'
```

**salt.states.zabbix_usermacro.present(name, value, hostid=None, **kwargs)**

Creates a new usermacro.

Parameters

- **name** -- name of the usermacro
- **value** -- value of the usermacro
- **hostid** -- id's of the hosts to apply the usermacro on, if missing a global usermacro is assumed.
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
override host usermacro:
zabbix_usermacro.present:
  - name: '{SNMP_COMMUNITY}''
  - value: 'public'
  - hostid: 21

25.20.346 salt.states.zabbix_valuemap

Management of Zabbix Valuemap object over Zabbix API.
New in version 2017.7.0.

codeauthor
Jakub Sliva <jakub.sliva@ultimum.io>
n
salt.states.zabbix_valuemap.absent(name, **kwargs)

Makes the Zabbix Value map to be absent (either does not exist or delete it).

Parameters
• name -- Zabbix Value map name
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

zabbix-valuemap-absent:
zabbix_valuemap.absent:
  - name: Value map name

salt.states.zabbix_valuemap.present(name, params, **kwargs)

Creates Zabbix Value map object or if differs update it according defined parameters

Parameters
• name -- Zabbix Value map name
• params -- Definition of the Zabbix Value map
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

zabbix-valuemap-present:
zabbix_valuemap.present:
  - name: Number mapping
  - params:
    mappings:
    - value: 1
      newvalue: one
    - value: 2
      newvalue: two
25.20.347 salt.states.zcbuildout

Management of zc.buildout

This module is inspired from minitage's buildout maker (https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py)

New in version 2016.3.0.

Note: This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present

Available Functions

- build

```python
salt.states.zcbuildout.installed(name, config='buildout.cfg', quiet=False, parts=None, user=None, env=(), buildout_ver=None, test_release=False, distribute=None, new_st=None, offline=False, newest=False, python='/builds/saltstack/open/docs/builddocs/venv/bin/python3', debug=False, verbose=False, unless=None, onlyif=None, use_vt=False, loglevel='debug', **kwargs)
```

Install buildout in a specific directory

It is a thin wrapper to modules.buildout.buildout

name
directory to execute in
quiet
do not output console & logs

config
buildout config to use (default: buildout.cfg)

parts
specific buildout parts to run

user
user used to run buildout as

New in version 2014.1.4.
env
    environment variables to set when running
buildout_ver
    force a specific buildout version (1 | 2)
test_release
    buildout accept test release
new_st
    Forcing use of setuptools >= 0.7
distribute
    use distribute over setuptools if possible
offline
    does buildout run offline
python
    python to use
debug
    run buildout with -D debug flag
onlyif
    Only execute cmd if statement on the host return 0
unless
    Do not execute cmd if statement on the host return 0
newest
    run buildout in newest mode
verbose
    run buildout in verbose mode (-vvvvv)
use_vt
    Use the new salt VT to stream output [experimental]
loglevel
    loglevel for buildout commands

25.20.348 salt.states.zenoss

State to manage monitoring in Zenoss.

New in version 2016.3.0.

This state module depends on the 'zenoss' Salt execution module.

Allows for setting a state of minions in Zenoss using the Zenoss API. Currently Zenoss 4.x and 5.x are supported.

```yaml
enable_monitoring:
    zenoss.monitored:
        - name: web01.example.com
        - device_class: /Servers/Linux
        - collector: localhost
        - prod_state: 1000
```

salt.states.zenoss.monitored(name, device_class=None, collector='localhost', prod_state=None)

Ensure a device is monitored. The 'name' given will be used for Zenoss device name and should be resolvable.

```yaml
enable_monitoring:
    zenoss.monitored:
        - name: web01.example.com
        - device_class: /Servers/Linux
```

(continues on next page)
- **collector**: localhost
- **prod_state**: 1000

25.20.349 salt.states.zfs

States for managing zfs datasets

**maintainer**
Jorge Schrauwen <sjorge@blackdot.be>

**maturity**
new

**depends**
salt.utils.zfs, salt.modules.zfs

**platform**
smartos, illumos, solaris, freebsd, linux

New in version 2016.3.0.

Changed in version 2018.3.1: Big refactor to remove duplicate code, better type conversions and improved consistency in output.

```yaml
- test/shares/yuki:
  salt.states.zfs.filesystem_present:
    - create_parent: true
    - properties:
      quota: 16G

- test/iscsi/haruhi:
  salt.states.zfs.volume_present:
    - create_parent: true
    - volume_size: 16M
    - sparse: true
    - properties:
      readonly: on

- test/shares/yuki@frozen:
  salt.states.zfs.snapshot_present

- moka_origin:
  salt.states.zfs.hold_present:
    - snapshot: test/shares/yuki@frozen

- test/shares/moka:
  salt.states.zfs.filesystem_present:
    - cloned_from: test/shares/yuki@frozen

- test/shares/moka@tsukune:
  salt.states.zfs.snapshot_absent

- salt.states.zfs.bookmark_absent(name, force=False, recursive=False)
  ensure bookmark is absent on the system
```
name
  [string] name of snapshot
force
  [boolean] try harder to destroy the dataset (zfs destroy -f)
recursive
  [boolean] also destroy all the child datasets (zfs destroy -r)
salt.states.zfs.bookmark_present(name, snapshot)
  ensure bookmark exists
  name
    [string] name of bookmark
  snapshot
    [string] name of snapshot
salt.states.zfs.filesystem_absent(name, force=False, recursive=False)
  ensure filesystem is absent on the system
  name
    [string] name of filesystem
  force
    [boolean] try harder to destroy the dataset (zfs destroy -f)
  recursive
    [boolean] also destroy all the child datasets (zfs destroy -r)

Warning: If a volume with name exists, this state will succeed without destroying the volume specified by name. This module is dataset type sensitive.

salt.states.zfs.filesystem_present(name, create_parent=False, properties=None, cloned_from=None)
  ensure filesystem exists and has properties set
  name
    [string] name of filesystem
  create_parent
    [boolean] creates all the non-existing parent datasets. any property specified on the command line using the -o option is ignored.
  cloned_from
    [string] name of snapshot to clone
  properties
    [dict] additional zfs properties (-o)

Note: cloned_from is only use if the filesystem does not exist yet, when cloned_from is set after the filesystem exists it will be ignored.

Note: Properties do not get cloned, if you specify the properties in the state file they will be applied on a subsequent run.

salt.states.zfs.hold_absent(name, snapshot, recursive=False)
  ensure hold is absent on the system
  name
    [string] name of hold
  snapshot
    [string] name of snapshot
recursive
  [boolean] recursively releases a hold with the given tag on the snapshots of all descendent file systems.
salt.states.zfs.hold_present(name, snapshot, recursive=False)
  ensure hold is present on the system
  name
    [string] name of hold
  snapshot
    [string] name of snapshot
  recursive
    [boolean] recursively add hold with the given tag on the snapshots of all descendent file systems.
salt.states.zfs.promoted(name)
  ensure a dataset is not a clone
  name
    [string] name of fileset or volume

**Warning:** only one dataset can be the origin, if you promote a clone the original will now point to the promoted dataset

salt.states.zfs.scheduled_snapshot(name, prefix, recursive=True, schedule=None)
  maintain a set of snapshots based on a schedule
  name
    [string] name of filesystem or volume
  prefix
    [string] prefix for the snapshots e.g. 'test' will result in snapshots being named 'test-yyyymmdd_hhmm'
  recursive
    [boolean] create snapshots for all children also
  schedule
    [dict] dict holding the schedule, the following keys are available (minute, hour, day, month, and year)
    by default all are set to 0 the value indicated the number of snapshots of that type to keep around.

**Warning:** snapshots will only be created and pruned every time the state runs. a schedule must be setup to automatically run the state. this means that if you run the state daily the hourly snapshot will only be made once per day!

Changed in version 2018.3.0: switched to localtime from gmtime so times now take into account timezones.
salt.states.zfs.snapshot_absent(name, force=False, recursive=False)
  ensure snapshot is absent on the system
  name
    [string] name of snapshot
  force
    [boolean] try harder to destroy the dataset (zfs destroy -f)
  recursive
    [boolean] also destroy all the child datasets (zfs destroy -r)
salt.states.zfs.snapshot_present(name, recursive=False, properties=None)
  ensure snapshot exists and has properties set
  name
    [string] name of snapshot
  recursive
    [boolean] recursively create snapshots of all descendent datasets
properties
  [dict] additional zfs properties (-o)

`salt.states.zfs.volume_absent(name, force=False, recursive=False)`

- ensure volume is absent on the system
- `name` [string] name of volume
- `force` [boolean] try harder to destroy the dataset (zfs destroy -f)
- `recursive` [boolean] also destroy all the child datasets (zfs destroy -r)

**Warning:** If a filesystem with `name` exists, this state will succeed without destroying the filesystem specified by `name`. This module is dataset type sensitive.

`salt.states.zfs.volume_present(name, volume_size, sparse=False, create_parent=False, properties=None, cloned_from=None)`

- ensure volume exists and has properties set
- `name` [string] name of volume
- `volume_size` [string] size of volume
- `sparse` [boolean] create sparse volume
- `create_parent` [boolean] creates all the non-existing parent datasets. any property specified on the command line using the `-o` option is ignored.
- `cloned_from` [string] name of snapshot to clone
- `properties` [dict] additional zfs properties (-o)

**Note:** `cloned_from` is only use if the volume does not exist yet, when `cloned_from` is set after the volume exists it will be ignored.

**Note:** Properties do not get cloned, if you specify the properties in the state file they will be applied on a subsequent run.

`volume_size` is considered a property, so the volume's size will be corrected when the properties get updated if it differs from the original volume.

The sparse parameter is ignored when using `cloned_from`. 
Control concurrency of steps within state execution using zookeeper

depends
kazoo

configuration
See salt.modules.zookeeper for setup instructions.

This module allows you to "wrap" a state's execution with concurrency control. This is useful to protect against all hosts executing highstate simultaneously if your services don't all HUP restart. The common way of protecting against this is to run in batch mode, but that doesn't protect from another person running the same batch command (and thereby having 2x the number of nodes deploying at once).

This module will block while acquiring a slot, meaning that however the command gets called it will coordinate with zookeeper to ensure that no more than max_concurrency steps are executing with a single path.

```yaml
acquire_lock:
  zk_concurrency.lock:
    - name: /trafficeserver
    - zk hosts: 'zookeeper:2181'
    - max_concurrency: 4
    - prereq:
      - service: trafficserver

trafficserver:
  service.running:
    - watch:
      - file: /etc/trafficeserver/records.config

/etc/trafficeserver/records.config:
  file.managed:
    - source: salt://records.config

release_lock:
  zk_concurrency.unlock:
    - name: /trafficserver
    - require:
      - service: trafficserver
```

This example would allow the file state to change, but would limit the concurrency of the trafficserver service restart to 4.

```python
salt.states.zk_concurrency.lock(name=None, zk_hosts=None, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, profile=None, scheme=None, username=None, password=None, default_acl=None)

Block state execution until you are able to get the lock (or hit the timeout)

salt.states.zk_concurrency.min_party(name=None, zk_hosts=None, min_nodes=None, blocking=False, profile=None, scheme=None, username=None, password=None, default_acl=None)

Ensure that there are min_nodes in the party at name, optionally blocking if not available.

salt.states.zk_concurrency.unlock(name=None, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False, profile=None, scheme=None, username=None, password=None, default_acl=None)
```
Remove lease from semaphore.

25.20.351 salt.states.zone

Management of Solaris Zones

maintainer
Jorge Schrauwen <sjorge@blackdot.be>

maturity
new

depends
salt.modules.zoneadm, salt.modules.zonelfg

platform
solaris

New in version 2017.7.0.

Below are some examples of how to use this state. Let's start with creating a zone and installing it.

```yaml
omipkg1_configuration:
  zone.present:
    - name: omipkg1
    - brand: ipkg
    - zonepath: /zones/omipkg1
    - properties:
      - autoboot: true
      - ip-type: exclusive
      - cpu-shares: 50
    - resources:
      - attr:
        - name: owner
        - value: Jorge Schrauwen
        - type: string
      - attr:
        - name: description
        - value: OmniOS ipkg zone for testing
        - type: string
      - capped-memory:
        - physical: 64M

omipkg1_installation:
  zone.installed:
    - name: omipkg1
    - require:
      - zone: omipkg1_configuration

omipkg1_running:
  zone.booted:
    - name: omipkg1
    - require:
      - zone: omipkg1_installation
```

A zone without network access is not very useful. We could update the zone.present state in the example above to add a network interface or we could use a separate state for this.
omipkg1_network:
  zone.resource_present:
    - name: omipkg1
    - resource_type: net
    - resource_selector_property: mac-addr
    - resource_selector_value: "02:08:20:a2:a3:10"
    - physical: znic1
    - require:
      - zone: omipkg1_configuration

Since this is a single tenant system having the owner attribute is pointless. Let's remove that attribute.

Note: The following state run the omipkg1_configuration state will add it again! If the entire configuration is managed it would be better to add resource_prune and optionally the resource_selector_property properties to the resource.

omipkg1_strip_owner:
  zone.resource_present:
    - name: omipkg1
    - resource_type: attr
    - resource_selector_property: name
    - resource_selector_value: owner
    - require:
      - zone: omipkg1_configuration

Let's bump the zone's CPU shares a bit.

Note: The following state run the omipkg1_configuration state will set it to 50 again. Update the entire zone configuration is managed you should update it there instead.

omipkg1_more_cpu:
  zone.property_present:
    - name: omipkg1
    - property: cpu-shares
    - value: 100

Or we can remove the limit altogether!

Note: The following state run the omipkg1_configuration state will set it to 50 again. Update the entire zone configuration is managed you should set the property to None (nothing after the :) instead.

omipkg1_no_cpu:
  zone.property_absent:
    - name: omipkg1
    - property: cpu-shares

salt.states.zone.absent(name, uninstall=False)

Ensure a zone is absent
name  
    [string] name of the zone
uninstall  
    [boolean] when true, uninstall instead of detaching the zone first.
salt.states.zone.attached(name, force=False)  
    Ensure zone is attached
    name  
        [string] name of the zone
    force  
        [boolean] force attach the zone
salt.states.zone.booted(name, single=False)  
    Ensure zone is booted
    name  
        [string] name of the zone
    single  
        [boolean] boot in single usermode
salt.states.zone.detached(name)  
    Ensure zone is detached
    name  
        [string] name of the zone
salt.states.zone.export(name, path, replace=False)  
    Export a zones configuration
    name  
        [string] name of the zone
    path  
        [string] path of file to export too.
    replace  
        [boolean] replace the file if it exists
salt.states.zone.halted(name, graceful=True)  
    Ensure zone is halted
    name  
        [string] name of the zone
    graceful  
        [boolean] use shutdown instead of halt if true
salt.states.zone.import_(name, path, mode='import', nodataset=False, brand_opts=None)  
    Import a zones configuration
    name  
        [string] name of the zone
    path  
        [string] path of the configuration file to import
    mode  
        [string] either import, install, or attach
    nodataset  
        [boolean] do not create a ZFS file system
    brand_opts  
        [boolean] brand specific options to pass

Note: The mode argument can be set to import, install, or attach. import: will only import the configuration install: will import and then try to install the zone attach: will import and then try to
attach of the zone

```yaml
omipkg1:
  zone.import:
    - path: /foo/bar/baz
```

**salt.states.zone.installed**(name, nodataset=False, brand_opts=None)

Ensure zone is installed

- **name**
  - [string] name of the zone
- **nodataset**
  - [boolean] do not create a ZFS file system
- **brand_opts**
  - [boolean] brand specific options to pass

**salt.states.zone.present**(name, brand, zonepath, properties=None, resources=None)

Ensure a zone with certain properties and resources

- **name**
  - [string] name of the zone
- **brand**
  - [string] brand of the zone
- **zonepath**
  - [string] path of the zone
- **properties**
  - [list of key-value pairs] dict of properties
- **resources**
  - [list of key-value pairs] dict of resources

**Note:** If the zone does not exist it will not be installed. You can use the `zone.installed` state for this.

**Note:**
Default resource selectors:

- fs: dir
- net: mac-addr
- device: match
- rctl: name
- attr: name
- dataset: name
- admin: user

**Warning:** Properties and resource will not be removed when they are absent from the state!

For properties, simple set them to `None`.

For resources, add the `resource_prune` property and set it to `True`. Also specify the `resource_selector_property` if the default is not the one you want.

**salt.states.zone.property_absent**(name, property)

Ensure property is absent
name [string] name of the zone
property [string] name of property

Note: This does a zoneacfg clear call. So the property may be reset to a default value! Does has the side effect of always having to be called.

```
salt.states.zone.property_present(name, property, value)
    Ensure property has a certain value
    name [string] name of the zone
    property [string] name of property
    value [string] value of property
```

```
salt.states.zone.resource_absent(name, resource_type, resource_selector_property, resource_selector_value)
    Ensure resource is absent
    name [string] name of the zone
    resource_type [string] type of resource
    resource_selector_property [string] unique resource identifier
    resource_selector_value [string] value for resource selection
```

Warning: Both resource_selector_property and resource_selector_value must be provided, some properties like `name` are already reserved by salt in there states.

Note: You can set both resource_selector_property and resource_selector_value to None for resources that do not require them.

```
salt.states.zone.resource_present(name, resource_type, resource_selector_property, resource_selector_value, **kwargs)
    Ensure resource exists with provided properties
    name [string] name of the zone
    resource_type [string] type of resource
    resource_selector_property [string] unique resource identifier
    resource_selector_value [string] value for resource selection
    kwargs [string|int|...] resource properties
```
Warning: Both resource_selector_property and resource_selector_value must be provided, some properties like name are already reserved by salt in states.

Note: You can set both resource_selector_property and resource_selector_value to None for resources that do not require them.

salt.states.zone.uninstalled(name)

Ensure zone is uninstalled
name
  [string] name of the zone

25.20.352 salt.states.zookeeper

Zookeeper State

depends
  kazoo

collection
  See salt.modules.zookeeper for setup instructions.

ACLS

For more information about acls, please checkout the kazoo documentation.

http://kazoo.readthedocs.io/en/latest/api/security.html#kazoo.security.make_digest_acl

The following options can be included in the acl dictionary:

  param username
    Username to use for the ACL.

  param password
    A plain-text password to hash.

  param write
    Write permission.

    type write
      bool

  param create
    Create permission.

    type create
      bool

  param delete
    Delete permission.

    type delete
      bool

  param admin
    Admin permission.
type admin
  bool

param all
  All permissions.

type all
  bool

salt.states.zookeeper.absent(name, version=-1, recursive=False, profile=None, hosts=None, scheme=None, username=None, password=None, default_acl=None)

  Make sure znode is absent
  name
    path to znode
  version
    Specify the version which should be deleted Default: -1 (always match)
  recursive
    Boolean to indicate if children should be recursively deleted Default: False
  profile
    Configured Zookeeper profile to authenticate with (Default: None)
  hosts
    Lists of Zookeeper Hosts (Default: '127.0.0.1:2181)
  scheme
    Scheme to authenticate with (Default: 'digest')
  username
    Username to authenticate (Default: None)
  password
    Password to authenticate (Default: None)
  default_acl
    Default acls to assign if a node is created in this connection (Default: None)

delete znode:
  zookeeper.absent:
    - name: /test
    - recursive: True

salt.states.zookeeper.acls(name, acls, version=-1, profile=None, hosts=None, scheme=None, username=None, password=None, default_acl=None)

  Update acls on a znode
  name
    path to znode
  acls
    list of acl dictionaries to set on znode
  version
    Specify the version which should be deleted Default: -1 (always match)
  profile
    Configured Zookeeper profile to authenticate with (Default: None)
  hosts
    Lists of Zookeeper Hosts (Default: '127.0.0.1:2181)
  scheme
    Scheme to authenticate with (Default: 'digest')
  username
    Username to authenticate (Default: None)
  password
    Password to authenticate (Default: None)
**default_acl**
Default acls to assign if a node is created in this connection (Default: None)

```
update acls:
  zookeeper.acls:
    - name: /test/name
    - acls:
      - username: daniel
        password: test
        all: True
      - username: gtmanfred
        password: test
        all: True
```

**salt.states.zookeeper.present**(*name*, *value*, *acls=None*, *ephemeral=False*, *sequence=False*, *makepath=False*, *version=-1*, *profile=None*, *hosts=None*, *scheme=None*, *username=None*, *password=None*, *default_acl=None*)

Make sure znode is present in the correct state with the correct acls

- **name**
  path to znode
- **value**
  value znode should be set to
- **acls**
  list of acl dictionaries to set on znode (make sure the ones salt is connected with are included) Default: None
- **ephemeral**
  Boolean to indicate if ephemeral znode should be created Default: False
- **sequence**
  Boolean to indicate if znode path is suffixed with a unique index Default: False
- **makepath**
  Boolean to indicate if the parent paths should be created Default: False
- **version**
  For updating, specify the version which should be updated Default: -1 (always match)
- **profile**
  Configured Zookeeper profile to authenticate with (Default: None)
- **hosts**
  Lists of Zookeeper Hosts (Default: ‘127.0.0.1:2181)
- **scheme**
  Scheme to authenticate with (Default: ‘digest’)
- **username**
  Username to authenticate (Default: None)
- **password**
  Password to authenticate (Default: None)
- **default_acl**
  Default acls to assign if a node is created in this connection (Default: None)

```
add znode:
  zookeeper.present:
    - name: /test/name
    - value: gtmanfred
    - makepath: True
```

**update znode:**
(continues on next page)
**25.20.353 salt.states.zpool**

States for managing zpools

maintainer
   Jorge Schrauwen <sjorge@blackdot.be>

maturity
   new

depends
   salt.utils.zfs, salt.modules.zpool

platform
   smartos, illumos, solaris, freebsd, linux

New in version 2016.3.0.

Changed in version 2018.3.1: Big refactor to remove duplicate code, better type conversions and improved consistency in output.

```yaml
zookeeper.present:
   - name: /test/name
   - value: daniel
   - acls:
     - username: daniel
       password: test
       read: true
     - username: gtmanfred
       password: test
       read: true
       write: true
       create: true
       delete: true
       admin: true
     - makepath: True
```

```
oldpool:
   zpool.absent:
      - export: true

newpool:
   zpool.present:
      - config:
        import: false
        force: true
      - properties:
        comment: salty storage pool
      - layout:
        - mirror:
          - /dev/disk0
          - /dev/disk1
        - mirror:
          - /dev/disk2
```

(continues on next page)
- /dev/disk3

**partitionpool:**

**zpool.present:**
- **config:**
  - import: false
  - force: true
- **properties:**
  - comment: disk partition salty storage pool
  - ashift: '12'
  - feature@lz4_compress: enabled
- **filesystem_properties:**
  - compression: lz4
  - atime: on
  - relatime: on
- **layout:**
  - /dev/disk/by-uuid/3e43ce94-77af-4f52-a91b-6c6db0b0f41b

**simplepool:**

**zpool.present:**
- **config:**
  - import: false
  - force: true
- **properties:**
  - comment: another salty storage pool
- **layout:**
  - /dev/disk0
  - /dev/disk1

**Warning:** The layout will never be updated, it will only be used at time of creation. It's a whole lot of work to figure out if a devices needs to be detached, removed, etc. This is best done by the sysadmin on a case per case basis.

Filesystem properties are also not updated, this should be managed by the zfs state module.

salt.states.zpool.absent(name, export=False, force=False)

ensure storage pool is absent on the system

**name**
  [string] name of storage pool

**export**
  [boolean] export instead of destroy the zpool if present

**force**
  [boolean] force destroy or export

salt.states.zpool.present(name, properties=None, filesystem_properties=None, layout=None, config=None)

ensure storage pool is present on the system

**name**
  [string] name of storage pool

**properties**
  [dict] optional set of properties to set for the storage pool
filesystem_properties
   [dict] optional set of filesystem properties to set for the storage pool (creation only)
layout: dict
   disk layout to use if the pool does not exist (creation only)
config
   [dict] fine grain control over this state

Note:
The following configuration properties can be toggled in the config parameter.
   • import (true) - try to import the pool before creating it if absent
   • import_dirs (None) - specify additional locations to scan for devices on import (comma-separated)
   • device_dir (None, SunOS=/dev/dsk, Linux=/dev) - specify device directory to prepend for none
     absolute device paths
   • force (false) - try to force the import or creation

Note:  It is no longer needed to give a unique name to each top-level vdev, the old layout format is still
supported but no longer recommended.

Warning:  The legacy format is also still supported but not recommended, because ID’s inside the layout
dict must be unique they need to have a suffix.

Warning:  Pay attention to the order of your dict!

The above yaml will always result in the following zpool create:
zpool create mypool mirror /tmp/vdisk3 /tmp/vdisk2 mirror /tmp/vdisk0 /
   → tmp/vdisk1

The above will result in the following zpool create:
zpool create mypool mirror /tmp/vdisk0 /tmp/vdisk1 /tmp/vdisk2
Creating a 3-way mirror! While you probably expect it to be mirror root vdev with 2 devices + a root vdev of 1 device!

### 25.21.1 salt.thorium.calc

Used to manage the thorium register. The thorium register is where compound values are stored and computed, such as averages etc.

New in version 2016.11.0.

```
depends
    statistics PyPi module
```

salt.thorium.calc.add(name, num, minimum=0, maximum=0, ref=None)

Add together the num most recent values. Requires a list.

**USAGE:**

```
foo:
    calc.add:
        - name: myregentry
        - num: 5
```

salt.thorium.calc.calc(name, num, oper, minimum=0, maximum=0, ref=None)

Perform a calculation on the num most recent values. Requires a list. Valid values for oper are:

- `add`: Add last num values together
- `mul`: Multiple last num values together
- `mean`: Calculate mean of last num values
- `median`: Calculate median of last num values
• median_low: Calculate low median of last num values
• median_high: Calculate high median of last num values
• median_grouped: Calculate grouped median of last num values
• mode: Calculate mode of last num values

USAGE:

foo:
  calc.calc:
    - name: myregentry
    - num: 5
    - oper: mean

salt.thorium.calc.mean(name, num, minimum=0, maximum=0, ref=None)
Calculates the mean of the num most recent values. Requires a list.

USAGE:

foo:
  calc.mean:
    - name: myregentry
    - num: 5

salt.thorium.calc.median(name, num, minimum=0, maximum=0, ref=None)
Calculates the median of the num most recent values. Requires a list.

USAGE:

foo:
  calc.median:
    - name: myregentry
    - num: 5

salt.thorium.calc.median_grouped(name, num, minimum=0, maximum=0, ref=None)
Calculates the grouped median of the num most recent values. Requires a list.

USAGE:

foo:
  calc.median_grouped:
    - name: myregentry
    - num: 5

salt.thorium.calc.median_high(name, num, minimum=0, maximum=0, ref=None)
Calculates the high mean of the num most recent values. Requires a list.

USAGE:

foo:
  calc.median_high:
    - name: myregentry
    - num: 5

salt.thorium.calc.median_low(name, num, minimum=0, maximum=0, ref=None)
Calculates the low mean of the num most recent values. Requires a list.

USAGE:
salt.thorium.calc.mode\(\text{name, num, minimum=0, maximum=0, ref=None}\)
Calculates the mode of the num most recent values. Requires a list.

**USAGE:**

```yaml
foo:
  calc.mode:
    - name: myregentry
    - num: 5
```

salt.thorium.calc.mul\(\text{name, num, minimum=0, maximum=0, ref=None}\)
Multiplies together the num most recent values. Requires a list.

**USAGE:**

```yaml
foo:
  calc.mul:
    - name: myregentry
    - num: 5
```

## 25.21.2 salt.thorium.check

The check Thorium state is used to create gateways to commands, the checks make it easy to make states that watch registers for changes and then just succeed or fail based on the state of the register, this creates the pattern of having a command execution get gated by a check state via a requisite.

salt.thorium.check.contains\(\text{name, value, count_lt=None, count_lte=None, count_eq=None, count_gte=None, count_gt=None, count_ne=None}\)
Only succeed if the value in the given register location contains the given value.

**USAGE:**

```yaml
foo:
  check.contains:
    - value: itni
run_remote_ex:
  local.cmd:
    - tgt: '\*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.eq\(\text{name, value}\)
Only succeed if the value in the given register location is equal to the given value.

**USAGE:**

```yaml
```
foo:
  check.eq:
  - value: 42

runtime.ex:
  local.cmd:
  - tgt: '*'
  - func: test.ping
  - require:
    - check: foo

salt.thorium.check.event(name)
Checks for a specific event match and returns result True if the match happens

USAGE:
salt/foo/*/bar:
  check.event

runtime.ex:
  local.cmd:
  - tgt: '*'
  - func: test.ping
  - require:
    - check: salt/foo/*/bar

salt.thorium.check.gt(name, value)
Only succeed if the value in the given register location is greater than the given value

USAGE:
foo:
  check.gt:
  - value: 42

runtime.ex:
  local.cmd:
  - tgt: '*'
  - func: test.ping
  - require:
    - check: foo

salt.thorium.check.gte(name, value)
Only succeed if the value in the given register location is greater or equal than the given value

USAGE:
foo:
  check.gte:
  - value: 42

runtime.ex:
  local.cmd:
  - tgt: '*'

(continues on next page)
- **func**: `test.ping`
  - **require**:
    - **check**: `foo`

**salt.thorium.check.len_eq(name, value)**

Only succeed if the length of the given register location is equal to the given value.

**USAGE:**

```yaml
foo:
  check.len_eq:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

**salt.thorium.check.len_gt(name, value)**

Only succeed if length of the given register location is greater than the given value.

**USAGE:**

```yaml
foo:
  check.len_gt:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

**salt.thorium.check.len_gte(name, value)**

Only succeed if the length of the given register location is greater or equal than the given value

**USAGE:**

```yaml
foo:
  check.len_gte:
    - value: 42

run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

**salt.thorium.check.len_lt(name, value)**

Only succeed if the length of the given register location is less than the given value.
salt.thorium.check.len_lt(name, value)
Only succeed if the length of the given register location is less than or equal the given value

USAGE:

```yaml
foo:
  check.len_lt:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.len_lte(name, value)
Only succeed if the length of the given register location is less than or equal the given value

USAGE:

```yaml
foo:
  check.len_lte:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.len_ne(name, value)
Only succeed if the length of the given register location is not equal to the given value

USAGE:

```yaml
foo:
  check.len_ne:
    - value: 42
run_remote_ex:
  local.cmd:
    - tgt: '*'
    - func: test.ping
    - require:
      - check: foo
```

salt.thorium.check.lt(name, value)
Only succeed if the value in the given register location is less than the given value

USAGE:

```yaml
foo:
  check.lt:
    - value: 42
run_remote_ex:
```

(continues on next page)
**local.cmd**:
- `tgt`: `'*'`
- `func`: `test.ping`
- `require`:
  - `check`: `foo`

**Salt.thorium.check.lte(name, value)**
Only succeed if the value in the given register location is less than or equal the given value

**Usage:**

```
foo:
  check.lte:
    - value: 42
```

**run_remote_ex**:
```
local.cmd:
  - tgt: `'*'`
  - func: `test.ping`
  - require:
    - check: `foo`
```

**Salt.thorium.check.ne(name, value)**
Only succeed if the value in the given register location is not equal to the given value

**Usage:**

```
foo:
  check.ne:
    - value: 42
```

**run_remote_ex**:
```
local.cmd:
  - tgt: `'*'`
  - func: `test.ping`
  - require:
    - check: `foo`
```

### 25.21.3 Salt.thorium.file

Writes matches to disk to verify activity, helpful when testing

Normally this is used by giving the name of the file (without a path) that the data will be saved to. If for instance you use `foo` as the name:

```
foo:
  file.save
```

Then the file will be saved to:

```
<salt cachedir>/thorium/saves/foo
```

You may also provide an absolute path for the file to be saved to:
Files will be saved in JSON format. However, JSON does not support `set()`'s. If you are saving a register entry that contains a `set()`, then it will fail to save to JSON format. However, you may pass data through a filter which makes it JSON compliant:

```
foo:
  file.save:
    filter: True
```

Be warned that if you do this, then the file will be saved, but not in a format that can be re-imported into Python.

```
salt.thorium.file.save(name, filter=False)
```

Save the register to `<salt cachedir>/thorium/saves/<name>`, or to an absolute path.

If an absolute path is specified, then the directory will be created non-terminously if it doesn't exist.

Usage:

```
foo:
  file.save
/tmp/foo:
  file.save
```

### 25.21.4 `salt.thorium.key`

The key Thorium State is used to apply changes to the accepted/rejected/pending keys

New in version 2016.11.0.

```
salt.thorium.key.timeout(name, delete=0, reject=0)
```

If any minion's status is older than the timeout value then apply the given action to the timed out key. This example will remove keys to minions that have not checked in for 300 seconds (5 minutes)

Usage:

```
statreg:
  status.reg

clean_keys:
  key.timeout:
    - require:
      - status: statreg
      - delete: 300
```
25.21.5 salt.thorium.local

Run remote execution commands via the local client

```python
salt.thorium.local.cmd(name, tgt, func, arg=(), tgt_type='glob', ret='', kwarg=None, **kwargs)
```

Execute a remote execution command

Usage:

```bash
run_remote_ex:
  local.cmd:
  - tgt: '*'
  - func: test.ping

run_remote_ex:
  local.cmd:
  - tgt: '*'
  - func: test.sleep
  - arg:
    - 30

run_remote_ex:
  local.cmd:
  - tgt: '*'
  - func: test.sleep
  - kwarg:
    length: 30
```

25.21.6 salt.thorium.reg

Used to manage the thorium register. The thorium register is where compound values are stored and computed, such as averages etc.

```python
salt.thorium.reg.clear(name)
```

Clear the namespace from the register

Usage:

```bash
clearns:
clear:
  - name: myregister
```

```python
salt.thorium.reg.delete(name)
```

Delete the namespace from the register

Usage:

```bash
deletens:
delete:
  - name: myregister
```

```python
salt.thorium.reg.list_(name, add, match, stamp=False, prune=0)
```

Add the specified values to the named list
If `stamp` is True, then the timestamp from the event will also be added if `prune` is set to an integer higher than 0, then only the last `prune` values will be kept in the list.

**USAGE:**

```
foo:
  reg.list:
    - add: bar
    - match: my/custom/event
    - stamp: True
```

`salt.thorium.reg.mean(name, add, match)`

Accept a numeric value from the matched events and store a running average of the values in the given register. If the specified value is not numeric it will be skipped

**USAGE:**

```
foo:
  reg.mean:
    - add: data_field
    - match: my/custom/event
```

`salt.thorium.reg.set_(name, add, match)`

Add a value to the named set

**USAGE:**

```
foo:
  reg.set:
    - add: bar
    - match: my/custom/event
```

### 25.21.7 `salt.thorium.runner`

React by calling asynchronous runners

`salt.thorium.runner.cmd(name, func=func, arg=(), **kwargs)`

Execute a runner asynchronous:

**USAGE:**

```
run_cloud:
  runner.cmd:
    - func: cloud.create
    - arg:
        - my-ec2-config
        - myinstance

run_cloud:
  runner.cmd:
    - func: cloud.create
    - kwargs:
        provider: my-ec2-config
        instances: myinstance
```
25.21.8 salt.thorium.status

This thorium state is used to track the status beacon events and keep track of the active status of minions
New in version 2016.11.0.

salt.thorium.status.reg(name)

Activate this register to turn on a minion status tracking register, this register keeps the current status beacon data and the time that each beacon was last checked in.

25.21.9 salt.thorium.timer

Allow for flow based timers. These timers allow for a sleep to exist across multiple runs of the flow

salt.thorium.timer.hold(name, seconds)

Wait for a given period of time, then fire a result of True, requiring this state allows for an action to be blocked for evaluation based on time

USAGE:

```
hold_on_a_moment:
    timer.hold:
        - seconds: 30
```

25.21.10 salt.thorium.wheel

React by calling asynchronous runners

salt.thorium.wheel.cmd(name, fun=None, arg=(), **kwargs)

Execute a runner asynchronous:

USAGE:

```
run_cloud:
    wheel.cmd:
        - fun: key.delete
        - match: minion_id
```

25.22 token modules

<table>
<thead>
<tr>
<th>localfs</th>
<th>Stores eauth tokens in the filesystem of the master.</th>
</tr>
</thead>
<tbody>
<tr>
<td>rediscluster</td>
<td>Provide token storage in Redis cluster.</td>
</tr>
</tbody>
</table>
25.22.1 salt.tokens.localfs

Stores eauth tokens in the filesystem of the master. Location is configured by the master config option 'token_dir'

`salt.tokens.localfs.get_token(opts, tok)`

Fetch the token data from the store.

Parameters
- `opts` -- Salt master config options
- `tok` -- Token value to get

Returns
Token data if successful. Empty dict if failed.

`salt.tokens.localfs.list_tokens(opts)`

List all tokens in the store.

Parameters
- `opts` -- Salt master config options

Returns
List of dicts (tokens)

`salt.tokens.localfs.mk_token(opts, tdata)`

Mint a new token using the config option hash_type and store tdata with 'token' attribute set to the token. This module uses the hash of random 512 bytes as a token.

Parameters
- `opts` -- Salt master config options
- `tdata` -- Token data to be stored with 'token' attribute of this dict set to the token.

Returns
tdata with token if successful. Empty dict if failed.

`salt.tokens.localfs.rm_token(opts, tok)`

Remove token from the store.

Parameters
- `opts` -- Salt master config options
- `tok` -- Token to remove

Returns
Empty dict if successful. None if failed.

25.22.2 salt.tokens.rediscluster

Provide token storage in Redis cluster.

To get started simply start a redis cluster and assign all hashslots to the connected nodes. Add the redis hostname and port to master configs as eauth_redis_host and eauth_redis_port. Default values for these configs are as follow:

<table>
<thead>
<tr>
<th><strong>eauth_redis_host</strong></th>
<th>localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>eauth_redis_port</strong></td>
<td>6379</td>
</tr>
</tbody>
</table>

depends
- redis-py-cluster Python package

`salt.tokens.rediscluster.get_token(opts, tok)`

Fetch the token data from the store.

Parameters
- `opts` -- Salt master config options
- `tok` -- Token value to get
Returns
Token data if successful. Empty dict if failed.

```
salt.tokens.rediscluster.list_tokens(opts)
```
List all tokens in the store.

**Parameters**
- **opts** -- Salt master config options

**Returns**
List of dicts (token_data)

```
salt.tokens.rediscluster.mk_token(opts, tdata)
```
Mint a new token using the config option hash_type and store tdata with 'token' attribute set to the token.

This module uses the hash of random 512 bytes as a token.

**Parameters**
- **opts** -- Salt master config options
- **tdata** -- Token data to be stored with 'token' attribute of this dict set to the token.

**Returns**
tdata with token if successful. Empty dict if failed.

```
salt.tokens.rediscluster.rm_token(opts, tok)
```
Remove token from the store.

**Parameters**
- **opts** -- Salt master config options
- **tok** -- Token to remove

**Returns**
Empty dict if successful. None if failed.

### 25.23 master tops modules

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>varstack_top</strong></td>
<td>Use Varstack to provide tops data</td>
</tr>
</tbody>
</table>

#### 25.23.1 salt.tops.cobbler

**Cobbler Tops**

Cobbler Tops is a master tops subsystem used to look up mapping information from Cobbler via its API. The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
master_tops:
  cobbler: {}
cobbler.url: https://example.com/cobbler_api #default is http://localhost/
cobbler_api
  cobbler.user: username # default is no username
cobbler.password: password # default is no password
```
Module Documentation

salt.tops.cobbler.top(**kwargs)
Look up top data in Cobbler for a minion.

25.23.2 salt.tops.ext_nodes

External Nodes Classifier

The External Nodes Classifier is a master tops subsystem that retrieves mapping information from major configuration management systems. One of the most common external nodes classifiers system is provided by Cobbler and is called cobbler-ext-nodes.

The cobbler-ext-nodes command can be used with this configuration:

```
master_tops:
  ext_nodes: cobbler-ext-nodes
```

It is noteworthy that the Salt system does not directly ingest the data sent from the cobbler-ext-nodes command, but converts the data into information that is used by a Salt top file.

Any command can replace the call to 'cobbler-ext-nodes' above, but currently the data must be formatted in the same way that the standard 'cobbler-ext-nodes' does.

See (admittedly degenerate and probably not complete) example:

```
classes:
  - basepackages
  - database
```

The above essentially is the same as a top.sls containing the following:

```
base:
  '*':
    - basepackages
    - database

salt.tops.ext_nodes.top(**kwargs)
Run the command configured
```
25.23.3 salt.tops.mongo

Read tops data from a mongodb collection
This module will load tops data from a mongo collection. It uses the node's id for lookups.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- **mongo.db** - The mongo database to connect to. Defaults to 'salt'.
- **mongo.host** - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- **mongo.port** - The port that the mongo database is running on. Defaults to 27017.
- **mongo.user** - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 
- **mongo.password** - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 

Configuring the Mongo Tops Subsystem

```yaml
master_tops:
  mongo:
    collection: tops
    id_field: _id
    re_replace: ''
    re_pattern: \.example\.com
    states_field: states
    environment_field: environment
```

Module Documentation

salt.tops.mongo.top(**kwargs)

Connect to a mongo database and read per-node tops data.

Parameters

- **collection**(*) -- The mongodb collection to read data from. Defaults to 'tops'.
- **id_field**(*) -- The field in the collection that represents an individual minion id. Defaults to '_id'.
- **re_pattern**(*) -- If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If None, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to None.
- **re_replace**(*) -- Use as the replacement value in node ids matched with `re_pattern`. Defaults to ''. Feel free to use backreferences here.
- **states_field**(*) -- The name of the field providing a list of states.
- **environment_field**(*) -- The name of the field providing the environment. Defaults to environment.
25.23.4 salt.tops.reclass_adapter

Read tops data from a reclass database

This master_tops plugin provides access to the reclass database, such that state information (top data) are retrieved from reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the master_top list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```yaml
master_tops:
  reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.
