### 30.2.37 Salt 2018.3.5 Release Notes

Version 2018.3.5 is a CVE-fix release for 2018.3.0.

Security Fix

CVE-2019-17361

With the Salt NetAPI enabled in addition to having a SSH roster defined, unauthenticated access is possible when specifying the client as SSH. Additionally, when the raw_shell option is specified any arbitrary command may be run on the Salt master when specifying SSH options.

### 30.2.38 Salt 2017.7.0 Release Notes - Codename Nitrogen

### 30.2.39 Python 3

The 2017.7 Salt Release adds initial Python 3 support.

The default Python version of Salt will remain Python 2, although Python 3 packages will be supplied for users who want to help test this new feature.
30.2.40 Python 2.6 Deprecation

Salt will no longer support Python 2.6. We will provide python2.7 packages on our repo for RedHat and CentOS 6 to ensure users can still run Salt on these platforms.

As this will impact the installation of additional dependencies for salt modules please use pip packages if there is not a package available in a repository. You will need to install the python27-pip package to get access to the correct pip27 executable: `yum install python27-pip`

30.2.41 Known Issues

The following salt-cloud drivers have known issues running with Python 3. These drivers will not work with Python 3, and Python 2.7 should be used instead:

• Joyent
  • When running under Python 3, users who require Unicode support should ensure that a locale is set on their machines. Users using the C locale are advised to switch to a UTF-aware locale to ensure proper functionality with Salt with Python 3.

Remember to update the Salt Master first

Salt's policy has always been that when upgrading, the minion should never be on a newer version than the master. Specifically with this update, because of changes in the fileclient, the 2017.7 minion requires a 2017.7 master.

Backwards compatibility is still maintained, so older minions can still be used.

More information can be found in the Salt FAQ

States Added for Management of systemd Unit Masking

The service.masked and service.umasked states have been added to allow Salt to manage masking of systemd units.

Additionally, the following functions in the systemd execution module have changed to accommodate the fact that indefinite and runtime masks can co-exist for the same unit:

• service.masked - The return from this function has changed from previous releases. Before, False would be returned if the unit was not masked, and the output of systemctl is-enabled <unit name> would be returned if the unit was masked. However, since indefinite and runtime masks can exist for the same unit at the same time, this function has been altered to accept a runtime argument. If True, the minion will be checked for a runtime mask assigned to the named unit. If False, then the minion will be checked for an indefinite mask. If one is found, True will be returned. If not, then False will be returned.

• service.masked - This function used to just run systemctl is-enabled <unit name> and based on the return from this function the corresponding mask type would be removed. However, if both runtime and indefinite masks are set for the same unit, then systemctl is-enabled <unit name> would show just the indefinite mask. The indefinite mask would be removed, but the runtime mask would remain. The function has been modified to accept a runtime argument, and will attempt to remove a runtime mask if that argument is set to True. If set to False, it will attempt to remove an indefinite mask.

These new runtime arguments default to False.
Pillar Encryption

Beginning in 2016.3.0 the CLI pillar data passed to several functions could conditionally be passed through a renderer to be decrypted. This functionality has now been extended to pillar SLS files as well. See here for detailed documentation on this feature.

Grains Changes

- The osmajorrelease grain has been changed from a string to an integer. State files, especially those using a templating language like Jinja, may need to be adjusted to account for this change.
- Add ability to specify disk backing mode in the VMWare salt cloud profile.

State Module Changes

- The service.running and service.dead states now support a no_block argument which, when set to True on systemd minions, will start/stop the service using the --no-block flag in the systemctl command. On non-systemd minions, a warning will be issued.
- The module.run state has dropped its previous syntax with m_prefix for reserved keywords. Additionally, it allows running several functions in a batch.

Note: It is necessary to explicitly turn on the new behavior (see below)

```yaml
# Before
run_something:
    module.run:
        - name: mymodule.something
        - m_name: 'some name'
        - kwargs: {
                  first_arg: 'one',
                  second_arg: 'two',
                  do_stuff: 'True'
                }

# After
run_something:
    module.run:
        - mymodule.something:
          - name: some name
          - first_arg: one
          - second_arg: two
          - do_stuff: True
```

Since a lot of users are already using module.run states, this new behavior must currently be explicitly turned on, to allow users to take their time updating their SLS files. However, please keep in mind that the new syntax will take effect in the next feature release of Salt (Oxygen) and the old usage will no longer be supported at that time.

Another feature of the new module.run is that it allows calling many functions in a single batch, such as:

```yaml
run_something:
    module.run:
        - mymodule.function_without_parameters:
```

(continues on next page)
In a rare case that you have a function that needs to be called several times but with the different parameters, an additional feature of “tagging” is to the rescue. In order to tag a function, use a colon delimiter. For example:

```
run_something:
  module.run:
    - mymodule.same_function:1:
    - mymodule.same_function:2:
      - myparam
      - my_other_param
    - mymodule.same_function:3:
      - foo: bar
```

The example above will run `mymodule.same_function` three times with the different parameters.

To enable the new behavior for `module.run`, add the following to the minion config file:

```
use_superseded:
  - module.run
```

- The default for the `fingerprint_hash_type` option used in the `present` function in the `ssh` state changed from `md5` to `sha256`.

### Execution Module Changes

- Several functions in the `systemd` execution module have gained a `no_block` argument, which when set to `True` will use `--no-block` in the `systemctl` command.
- In the `solarisips pkg` module, the default value for the `refresh` argument to the `list_upgrades` function has been changed from `False` to `True`. This makes the function more consistent with all of the other `pkg` modules (The other `pkg.list_upgrades` functions all defaulted to `True`).
- The functions which handle masking in the `systemd` module have changed. These changes are described above alongside the information on the new states which have been added to manage masking of systemd units.
- The `pkg.list_repo_pkgs` function for yum/dnf-based distros has had its default output format changed. In prior releases, results would be organized by repository. Now, the default for each package will be a simple list of versions. To get the old behavior, pass `byrepo=True` to the function.
- A `pkg.list_repo_pkgs` function has been added for both Debian/Ubuntu and Arch Linux-based distros.
- The `system` module changed its return format from "HH:MM AM/PM" to "HH:MM:SS AM/PM" for `get_system_time`.
- The default for the `fingerprint_hash_type` option used in the `ssh` execution module changed from `md5` to `sha256`.
Proxy Module Changes

The `proxy_merge_grains_in_module` configuration variable introduced in 2016.3, has been changed, defaulting to **True**.

The connection with the remote device is kept alive by default, when the module implements the `alive` function and `proxy_keep_alive` is set to **True**. The polling interval is set using the `proxy_keep_alive_interval` option which defaults to 1 minute.

The developers are also able to use the `proxy_always_alive`, when designing a proxy module flexible enough to open the connection with the remote device only when required.

Wildcard Versions in `pkg.installed` States

- The `pkg.installed` state now supports wildcards in package versions, for the following platforms:
  - SUSE/openSUSE Leap/Thumbleweed
  - Debian/Ubuntu
  - RHEL/CentOS
  - Arch Linux

  This support also extends to any derivatives of these distros, which use the `aptpkg`, `yumpkg`, or `pacman` providers for the `pkg` virtual module.

  Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like `1.2.34-5.el7`. An example of the usage for this would be:

  ```
  mypkg:
  pkg.installed:
    - version: '1.2.34*'
  ```

Master Configuration Additions

- `syndic_forward_all_events` - Option on multi-syndic or single when connected to multiple masters to be able to send events to all connected masters.
- `eauth_acl_module` - In case external auth is enabled master can get authenticate and get the authorization list from different auth modules.
- `keep_acl_in_token` - Option that allows master to build ACL once for each user being authenticated and keep it in the token.

Minion Configuration Additions

- `pillarenv_from_saltenv` - When set to `True` (default is `False`), the `pillarenv` option will take the same value as the effective saltenv when running states. This would allow a user to run `salt '*' state.apply mysls saltenv=dev`, and the SLS for both the state and pillar data would be sourced from the dev environment, essentially the equivalent of running `salt '*' state.apply mysls saltenv=dev pillarenv=dev`. Note that if `pillarenv` is set in the minion config file, or if `pillarenv` is provided on the CLI, it will override this option.
salt-api Changes

The `rest_cherrypy` netapi module has received a few minor improvements:

- A CORS bugfix.
- A new `/token` convenience endpoint to generate Salt eauth tokens.
- A proof-of-concept JavaScript single-page application intended to demonstrate how to use the Server-Sent Events stream in an application. It is available in a default install by visiting the `/app` URL in a browser.

Python API Changes

`expr_form` Deprecation

The `LocalClient`'s `expr_form` argument has been deprecated and renamed to `tgt_type`. This change was made due to numerous reports of confusion among community members, since the targeting method is published to minions as `tgt_type`, and appears as `tgt_type` in the job cache as well.

While `expr_form` will continue to be supported until the `2019.2.0` release cycle (two major releases after this one), those who are using the `LocalClient` (either directly, or implicitly via a `netapi module`) are encouraged to update their code to use `tgt_type`.

`full_return` Argument in `LocalClient` and `RunnerClient`

An `full_return` argument has been added to the `cmd` and `cmd_sync` methods in `LocalClient` and `RunnerClient` which causes the return data structure to include job meta data such as `retcode`.

This is useful at the Python API:

```
>>> import salt.client
>>> client = salt.client.LocalClient()
>>> client.cmd('x', 'cmd.run', ['return 1'], full_return=True)
{'jerry': {'jid': '20170520151213898053', 'ret': '', 'retcode': 1}}
```

As well as from salt-api:

```
% curl -b /tmp/cookies.txt -sS http://localhost:8000 \
   -H 'Content-type: application/json' \n   -d '[[
       "client": "local",
       "tgt": "x",
       "fun": "cmd.run",
       "arg": ["return 1"],
       "full_return": true
   ]]
{"return": [["jerry": {"jid": "20170520151213898053", "retcode": 1, "ret": ""}]]}
```

Logs

Another new feature - although not limited to Jinja only - is being able to log debug messages directly from the template:

```{%- do salt.log.error('logging from jinja') -%}
```

See the logs paragraph.

Network Automation

NAPALM

Introduced in 2016.11, the modules for cross-vendor network automation have been improved, enhanced and widened in scope:
Manage network devices like servers: the NAPALM modules have been transformed so they can run in both proxy and regular minions. That means, if the operating system allows, the salt-minion package can be installed directly on the network gear. Examples of such devices (also covered by NAPALM) include: Arista, Cumulus, Cisco IOS-XR or Cisco Nexus.

Not always alive: in certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In those particular cases, the user can select to initialize the connection only when needed, by specifying the field `always_alive: false` in the proxy configuration or using the `proxy_always_alive` option.

Proxy keepalive: due to external factors, the connection with the remote device can be dropped, e.g.: packet loss, idle time (no commands issued within a couple of minutes or seconds), or simply the device decides to kill the process. In 2017.7.0 we have introduced the functionality to re-establish the connection. One can disable this feature through the `proxy_keep_alive` option and adjust the polling frequency specifying a custom value for `proxy_keep_alive_interval`, in minutes.

New modules:

- **Netconfig state module** - Manage the configuration of network devices using arbitrary templates and the Salt-specific advanced templating methodologies.
- **Network ACL execution module** - Generate and load ACL (firewall) configuration on network devices.
- **Network ACL state** - Manage the firewall configuration. It only requires writing the pillar structure correctly!
- **NAPALM YANG execution module** - Parse, generate and load native device configuration in a standard way, using the OpenConfig/IETF models. This module contains also helpers for the states.
- **NAPALM YANG state module** - Manage the network device configuration according to the YANG models (OpenConfig or IETF).
- **NET finder** - Runner to find details easily and fast. It’s smart enough to know what you are looking for. It will search in the details of the network interfaces, IP addresses, MAC address tables, ARP tables and LLDP neighbors.
- **BGP finder** - Runner to search BGP neighbors details.
- **NAPALM syslog** - Engine to import events from the napalm-logs library into the Salt event bus. The events are based on the syslog messages from the network devices and structured following the OpenConfig/IETF YANG models.
- **NAPALM Helpers** - Generic helpers for NAPALM-related operations. For example, the Compliance report function can be used inside the state modules to compare the expected and the existing configuration.

New functions:

- **Configuration getter** - Return the whole configuration of the network device.
- **Optics getter** - Fetches the power usage on the various transceivers installed on the network device (in dBm).

New grains: Host, Host DNS, Username and Optional args.
Custom Refspecs in GitFS / git_pillar / winrepo

It is now possible to specify the refspecs to use when fetching from remote repositories for GitFS, git_pillar, and winrepo. More information on how this feature works can be found here in the GitFS Walkthrough. The git_pillar and winrepo versions of this feature work the same as their GitFS counterpart.

**git_pillar "mountpoints" Feature Added**

See here for detailed documentation.

**Big Improvements to Docker Support**

The old docker state and execution modules have been moved to salt-contrib. The dockerng execution module has been renamed to docker and now serves as Salt's official Docker execution module.

The old dockerng state module has been split into 4 state modules:

- docker_container - States to manage Docker containers
- docker_image - States to manage Docker images
- docker_volume - States to manage Docker volumes
- docker_network - States to manage Docker networks

The reason for this change was to make states and requisites more clear. For example, imagine this SLS:

```yaml
myuser/appimage:
  docker.image_present:
    - sls: docker.images.appimage

myapp:
  docker.running:
    - image: myuser/appimage
    - require:
      - docker: myuser/appimage
```

The new syntax would be:

```yaml
myuser/appimage:
  docker_image.present:
    - sls: docker.images.appimage

myapp:
  docker_container.running:
    - image: myuser/appimage
    - require:
      - docker_image: myuser/appimage
```

This is similar to how Salt handles MySQL, MongoDB, Zabbix, and other cases where the same execution module is used to manage several different kinds of objects (users, databases, roles, etc.).

**Note:** With the Moby announcement coming at this year's DockerCon, Salt's docker execution module (as well as the state modules) work interchangeably when docker is replaced with moby (e.g. moby_container.running, moby_image.present, moby.inspect_container, etc.)
The old syntax will continue to work until the 2019.2.0 release of Salt. The old docker naming will also continue to work until that release, so no immediate changes need to be made to your SLS files (unless you were still using the old docker states that have been moved to salt-contrib).

The docker_container.running state has undergone a significant change in how it determines whether or not a container needs to be replaced. Rather than comparing individual arguments to their corresponding values in the named container, a temporary container is created (but not started) using the passed arguments. The two containers are then compared to each other to determine whether or not there are changes, and if so, the old container is stopped and destroyed, and the temporary container is renamed and started.

Salt still needs to translate arguments into the format which docker-py expects, but if it does not properly do so, the skip_translate argument can be used to skip input translation on an argument-by-argument basis, and you can then format your SLS file to pass the data in the format that the docker-py expects. This allows you to work around any changes in Docker's API or issues with the input translation, and continue to manage your Docker containers using Salt. Read the documentation for skip_translate for more information.

Note: When running the docker_container.running state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is None. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.

New SSH Cache Roster

The SSH cache Roster has been rewritten from scratch to increase its usefulness. The new roster supports all minion matchers, so it is now possible to target minions identically through salt and salt-ssh.

Using the new roster_order configuration syntax it’s now possible to compose a roster out of any combination of grains, pillar and mine data and even Salt SDB URLs. The new release is also fully IPv4 and IPv6 enabled and even has support for CIDR ranges.

Salt-SSH Default Options

Defaults for rosters can now be set, so that they don’t have to be set on every entry in a roster or specified from the commandline.

The new option is roster_defaults and is specified in the master config file:

```
roster_defaults:
    user: daniel
    sudo: True
    priv: /root/.ssh/id_rsa
    tty: True
```
Blacklist or Whitelist Extmod Sync

The modules that are synced to minions can now be limited.

The following configuration options have been added for the master:

- `extmod_whitelist`
- `extmod_blacklist`

and for the minion:

- `extmod_whitelist`
- `extmod_blacklist`

Additional Features

- The `mine.update` function has a new optional argument `mine_functions` that can be used to refresh mine functions at a more specific interval than scheduled using the `mine_interval` option. However, this argument can be used by explicit schedule. For example, if we need the mines for `net.lldp` to be refreshed every 12 hours:

```python
schedule:
  lldp_mine_update:
    function: mine.update
    kwargs:
      mine_functions:
        net.lldp: []
      hours: 12
```

- The `salt` runner has a new function: `salt.execute`. It is mainly a shortcut to facilitate the execution of various functions from other runners, e.g.:

```python
ret1 = __salt__['salt.execute']('*', 'mod.fun')
```

Deprecations

General Deprecations

- Removed support for aliasing `cmd.run` to `cmd.shell`.
- Removed support for Dulwich from `GitFS`.
- Beacon configurations should be lists instead of dictionaries.
- The `PidfileMixin` has been removed. Please use `DaemonMixIn` instead.
- The `use_pending` argument was removed from the `salt.utils.event.get_event` function.
- The `pending_tags` argument was removed from the `salt.utils.event.get_event` function.

Configuration Option Deprecations

- The `client_acl` configuration option has been removed. Please use `publisher_acl` instead.
- The `client_acl_blacklist` configuration option has been removed. Please use `publisher_acl_blacklist` instead.
- The `win_gitrepos` configuration option has been removed. Please use the `winrepo_remotes` option instead.
- The `win_repo` configuration option has been removed. Please use `winrepo_dir` instead.
- The `win_repo_mastercache_file` configuration option has been removed. Please use the `winrepo_cache_file` option instead.

Module Deprecations

The `git` execution module had the following changes:

- The `fmt` argument was removed from the `archive` function. Please use `format` instead.
- The `repository` argument was removed from the `clone` function. Please use `url` instead.
- The `is_global` argument was removed from the `config_set` function. Please use `global` instead.
- The `branch` argument was removed from the `merge` function. Please use `rev` instead.
- The `branch` argument was removed from the `push` function. Please use `rev` instead.

The `glusterfs` execution module had the following functions removed:

- `create`: Please use `create_volume` instead.
- `delete`: Please use `delete_volume` instead.
- `list_peers`: Please use `peer_status` instead.

The `htpasswd` execution module had the following function removed:

- `useradd_all`: Please use `useradd` instead.

The `img` execution module has been removed. All of its associated functions were marked for removal in the 2017.7.0 release. The functions removed in this module are mapped as follows:

- `mount_image/mnt_image`: Please use `mount.mount` instead.
- `umount_image`: Please use `mount.umount` instead.
• **bootstrap**: Please use `genesis.bootstrap` instead.

The `smartos_virt` execution module had the following functions removed:

• **create**: Please use `start` instead.
• **destroy**: Please use `stop` instead.
• **list_vms**: Please use `list_domains` instead.

The `virt` execution module had the following functions removed:

• **create**: Please use `start` instead.
• **destroy**: Please use `stop` instead.
• **list_vms**: Please use `list_domains` instead.

The `virtualenv_mod` execution module had the following changes:

• The `package_or_requirement` argument was removed from both the `get_resource_path` and the `get_resource_content` functions. Please use `package` instead.
• The `resource_name` argument was removed from both the `get_resource_path` and `get_resource_content` functions. Please use `resource` instead.

The `win_repo` execution module had the following changes:

• The `win_repo_source_dir` option was removed from the `win_repo` module. Please use `winrepo_source_dir` instead.

The `xapi` execution module had the following functions removed:

• **create**: Please use `start` instead.
• **destroy**: Please use `stop` instead.
• **list_vms**: Please use `list_domains` instead.

The `zypper` execution module had the following function removed:

• **info**: Please use `info_available` instead.

---

**Pillar Deprecations**

• Support for the `raw_data` argument for the `file_tree` ext_pillar has been removed. Please use `keep_newline` instead.
• SQLite3 database connection configuration previously had keys under pillar. This legacy compatibility has been removed.

**Proxy Minion Deprecations**

• The `proxy_merge_grains_in_module` default has been switched from `False` to `True`. 
Salt Documentation, Release 3002.5

Salt-API Deprecations

- The `SaltAPI.run()` function has been removed. Please use the `SaltAPI.start()` function instead.

Salt-Cloud Deprecations

- Support for using the keyword `provider` in salt-cloud provider config files has been removed. Please use `driver` instead. The `provider` keyword should now only be used in cloud profile config files.

Salt-SSH Deprecations

- The `wipe_ssh` option for `salt-ssh` has been removed. Please use the `ssh_wipe` option instead.

State Deprecations

The `apache_conf` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_module` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_site` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `chocolatey` state had the following functions removed:
- `install`: Please use `installed` instead.
- `uninstall`: Please use `uninstalled` instead.

The `git` state had the following changes:
- The `config` function was removed. Please use `config_set` instead.
- The `is_global` option was removed from the `config_set` function. Please use `global` instead.
- The `always_fetch` option was removed from the `latest` function, as it no longer has any effect. Please see the `2015.8.0` release notes for more information.
- The `force` option was removed from the `latest` function. Please use `force_clone` instead.
- The `remote_name` option was removed from the `latest` function. Please use `remote` instead.

The `glusterfs` state had the following function removed:
- `created`: Please use `volume_present` instead.

The `openvswitch_port` state had the following change:
- The `type` option was removed from the `present` function. Please use `tunnel_type` instead.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

Correct a flaw in minion id validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

Windows Changes

**pkg Execution Module**

Significant changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

- **pkg.list_available** no longer defaults to refreshing the winrepo meta database.
- **pkg.install** without a version parameter no longer upgrades software if the software is already installed. Use **pkg.install version=latest** (or simply use a **pkg.latest** state to get the old behavior.
- **pkg.list_pkgs** now returns multiple versions if software installed more than once.
- **pkg.list_pkgs** now returns *Not Found* when the version is not found instead of *(value not set)* which matches the contents of the sls definitions.
- **pkg.remove** will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- **pkg.remove** can remove *latest* software, if *latest* is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behave more like their Unix/Linux versions.
**cmd Execution Module**

Due to a difference in how Python's `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows' `CreateProcess` requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into as string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

  - 494835c3f2 I backported develop and applied a long list of fixes to 2016.11 this brings these fixes into 2017.7 - Software was not always being removed, general if & was in the string or msi was downloaded to uninstall the software - pkg.list_upgrades failed. Added support for 'latest' and 'Not Found' for version_cmp() to fix this. - output fixes - pkg.list_available no longer forces a pkg.refresh_db this is no longer required, as by default it will update if older than 6 hours - cmd /s /c is prefixed for all commands i.e. installs and removes. - cmd are now strings, instead of a list when using cmd.run. As windows only supports strings. And the ” were being broken

Changes to file.blockreplace State

The append_newline argument was added to this state. Additionally, to improve idempotence, if the string represented by marker_end is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove append_newline: False from the SLS and have the block properly replaced if the end of the content block is immediately followed by the marker_end (i.e. no newline before the marker).

Note: This will require changes to your SLS if your marker_end does not include the very beginning of the content you want to keep.
Salt Documentation, Release 3002.5

See the file.blockreplace state documentation for further information.

Tornado 5.0 Support for Python 2 Only

Tornado 5.0 moves to using asyncio for all python3 versions. Because of this and changes in asyncio between python 3.4 and 3.5 to only be able to use one ioloop, which requires some rearchitecting, support for tornado 5.0 and python3 versions of salt has been delayed to a later release.

For now, to use tornado 5.0, the python 2 version of salt must be used.

Option to Return to Previous Pillar Include Behavior

Prior to version 2017.7.3, keys from pillar includes would be merged on top of the pillar SLS. Since 2017.7.3, the includes are merged together and then the pillar SLS is merged on top of that.

The pillar_includes_override_sls option has been added allow users to switch back to the pre-2017.7.3 behavior.

  - 152c43e843 Accounting for a case when multiple onfails are used along with requires. Previously if you have multiple states using 'onfail' and two of those states using a 'require' against the first one state, the last two will run even if the 'onfail' isn't met because the 'require' is met because the first state returns true even though it didn't execute. This change adds an additional hidden variable that is used when checking requisities to determine if the state actually ran.

### 30.2.48 Salt 2017.7.7 Release Notes

Version 2017.7.7 is a bugfix release for 2017.7.0.

The 2017.7.7 release contains only a small number of fixes, which are detailed below.

This release fixes two critical issues.

The first is Issue #48038, which is a critical bug that occurs in a multi-syndic setup where the same job is run multiple times on a minion.

The second issue is #48130. This bug appears in certain setups where the Master reports a Minion time-out, even though the job is still running on the Minion.

Both of these issues have been fixed with this release.

30.2.49 Salt 2017.7.8 Release Notes

Version 2017.7.8 is a security and bugfix release for 2017.7.0.

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

New win_snmp behavior

- win_snmp.get_community_names now returns the SNMP settings actually in effect on the box. If settings are managed via GroupPolicy, those settings will be returned. Otherwise, normal settings are returned.
- win_snmp.set_community_names now raises an error when SNMP settings are being managed by GroupPolicy.

Option Added to Disable Docker Mine Updates

When a docker container is added, removed, started, stopped, etc., the results of a docker.ps verbose=True all=True host=True are sent to the mine, to be used by mine.get_docker.

A new config option (docker.update_mine) has been added. When set to False, Salt will not send this information to the mine. This is useful in cases where sensitive information is stored in the container’s environment.

• PR #48426: (garethgreenaway) [2017.7] fixes to states/pkg.py @ 2018-07-31 20:18:05 UTC

2390 Chapter 30. Release Notes
- 8a1285239a Merge pull request #48426 from garethgreenaway/46689_fixing_pkg_held_when_package_is_installed
- 9b0f5dd212 Fixing indentation, removing some unnecessary conditionals.
- 727964ab55 One last cleanup.
- 11c8b6e6eb General cleanup in pkg state, reducing duplicate code. Fixing the requires_salt_modules decorator, sys.doc was returning too much information for the event to handle. This change specifically calls sys.doc with the module name.
- 16fb6ae635 Make sure pkg.hold and pkg.unhold are available before running the test.
- 998651102d Fixing a situation when a package is already installed via salt or manually and a state attempts to set that package to be held. Previously the holding/unholding logic was only being run against packages that were being installed. This change moves the holding logic outside and runs it against all desired packages. Adding a new test to test holding logic.

30.2.50 In Progress: Salt 2017.7.9 Release Notes

Version 2017.7.9 is an unreleased bugfix release for 2017.7.0. This release is still in progress and has not been released yet.

Salt Cloud Features

GCE Driver

The GCE salt cloud driver can now be used with GCE instance credentials by setting the configuration paramaters service_account_private_key and service_account_private_email to an empty string.

30.2.51 Salt 2016.11.0 Release Notes - Codename Carbon

New Features

Docker Introspection and Configuration

Major additions have been made to the Docker support in 2016.11.0. The new addition allows Salt to be executed within a Docker container without a minion running or installed in the container. This allows states to be run inside a container, but also all of Salt's remote execution commands to be run inside docker containers as well. This makes container introspection simple and powerful. See the tutorial on using this new feature here:

See Salt in Docker Containers.

Advanced Ceph Control

Our friends over at SUSE have delivered a powerful new tool to make the deployment of Ceph storage systems using Salt very easy. These new Ceph tools allow for a storage system to be easily defined using the new ceph.quorum state.
Thorium Additions and Improvements

The Thorium advanced reactor has undergone extensive testing and updates. These updates include many more Thorium states, a system for automating key management, the ability to use Thorium to easily replace old reactors and a great deal of stability and bug fixes.

State Rollback Using Snapper

Rollback has been one of the most prevalent requests for Salt. We have researched it extensively and concluded that the only way to accomplish truly reliable rollback would be to execute it at the filesystem layer. To accomplish this we have introduced Snapper integration into Salt States.

Snapper is a tool which allows for simple and reliable snapshots of the filesystem to be made. With the new `snapper_states` option set to `True` in the minion config a snapshot will be made before and after every Salt State run.

These snapshots can be viewed, managed and rolled back to via the `snapper` execution module.

Preserve File Perms in File States

This feature has been requested for years, the ability to set a flag and use the same file permissions for files deployed to a minion as the permissions set to the file on the master. Just set the `keep_mode` option on any file management state to `True`.

Ponies!

We all agreed that cowsay was just not good enough, install the `ponysay` command and the new `pony` outputter will work. Fun for the whole family!

Additional Features

- Minions can run in stand-alone mode to use beacons and engines without having to connect to a master. (Thanks @adelcast!)
- Added a `salt` runner to allow running salt modules via `salt-run`.

```
salt-run salt.cmd test.ping
  # call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 a=1
```

- Added SSL support to Cassandra CQL returner. SSL can be enabled by setting `ssl_options` for the returner. Also added support for specifying `protocol_version` when establishing cluster connection.
- The `mode` parameter in the `file.managed` state, and the `file_mode` parameter in the `file.recurse` state, can both now be set to `keep` and the minion will keep the mode of the file from the Salt fileserver. This works only with files coming from sources prefixed with `salt://`, or files local to the minion (i.e. those which are absolute paths, or are prefixed with `file://`). For example:

```
/etc/myapp/myapp.conf:
  file.managed:
    - source: salt://conf/myapp/myapp.conf
    - mode: keep
```

(continues on next page)
The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.

The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.

The minion data cache is a pluggable data store now. It's configurable with `cache` option. Default is `localfs`.

User names in `client_acl` support glob matching now.

### New Top File Merging Strategy for States

A new strategy called `merge_all` has been added to provide a new way of merging top file matches when executing a `highstate`. See the `top_file_merging_strategy` documentation for further information.

In addition, the `same` merging strategy was not functioning as documented. This has now been corrected. While this is technically a bugfix, we decided to hold a change in top file merging until a feature release to minimize user impact.

### Improved Archive Extraction Support

The `archive.extracted` state has been overhauled. Notable changes include the following:

- When enforcing ownership (with the `user` and/or `group` arguments), the `if_missing` argument no longer has any connection to which path(s) have ownership enforced. Instead, the paths are determined using the either the newly-added `archive.list` function, or the newly-added `enforce_ownership_on` argument.

- `if_missing` also is no longer required to skip extraction, as Salt is now able to tell which paths would be present if the archive were extracted. It should, in most cases, only be necessary in cases where a semaphore file is used to conditionally skip extraction of the archive.

- Password-protected ZIP archives are now detected before extraction, and the state fails without attempting to extract the archive if no password was specified.

- By default, a single top-level directory is enforced, to guard against 'tar-bombs'. This enforcement can be disabled by setting `enforce_toplevel` to `False`.

- The `tar_options` and `zip_options` arguments have been deprecated in favor of a single `options` argument.

- The `archive_format` argument is now optional. The ending of the `source` argument is used to guess whether it is a tar, zip or rar file. If the `archive_format` cannot be guessed, then it will need to be specified, but in many cases it can now be omitted.

- Ownership enforcement is now performed irrespective of whether or not the archive needed to be extracted. This means that the state can be re-run after the archive has been fully extracted to repair changes to ownership.

A number of new arguments were also added. See the docs `docs for the archive.extracted state <salt.states.archive.extracted>` for more information.
Additionally, the following changes have been made to the archive execution module:

- A new function (archive.list) has been added. This function lists the files/directories in an archive file, and supports a verbose argument that gives a more detailed breakdown of which paths are files, which are directories, and which paths are at the top level of the archive.

- A new function (archive.is_encrypted) has been added. This function will return True if the archive is a password-protected ZIP file, False if not. If the archive is not a ZIP file, an error will be raised.

-archive.cmd unzip now supports passing a password, bringing it to feature parity with archive.unzip. Note that this is still not considered to be secure, and archive.unzip is recommended for dealing with password-protected ZIP archives.

- The default value for the extract_perms argument to archive.unzip has been changed to True.

**Improved Checksum Handling in file.managed, archive.extracted States**

When the source_hash argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (source_hash_name) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the source_hash file.

A more detailed explanation of this functionality can be found in the file.managed documentation, in the section for the new source_hash_name argument.

Note: This improved functionality is also available in the 2016.3 (Boron) release cycle, starting with the 2016.3.5 release.

**Config Changes**

The following default config values were changed:

- gitfs_ssl_verify: Changed from False to True
- git_pillar_ssl_verify: Changed from False to True
- winrepo_ssl_verify: Changed from False to True

**Grains Changes**

- All core grains containing VMWare have been changed to VMware, which is the official capitalization. Additionally, all references to VMWare in the documentation have been changed to VMware issue #30807. Environments using versions of Salt before and after Salt 2016.11.0 should employ case-insensitive grain matching on these grains.

```python
{% set on_vmware = grains['virtual'].lower() == 'vmware' %}
```

- On Windows the cpu_model grain has been changed to provide the actual cpu model name and not the cpu family.

Old behavior:
root@master:~# salt 'testwin200' grains.item cpu_model
testwin200:
    -----------
    cpu_model:
      Intel64 Family 6 Model 58 Stepping 9, GenuineIntel

New behavior:

root@master:~# salt 'testwin200' grains.item cpu_model
testwin200:
    -----------
    cpu_model:
      Intel(R) Core(TM) i7-3520M CPU @ 2.90GHz

Beacons Changes

- The `loadavg` beacon now outputs averages as integers instead of strings. (Via issue #31124.)

Runner Changes

- Runners can now call out to `utility modules` via `__utils__`.
- ref:`Utility modules <writing-utility-modules>` (placed in `salt://_utils/`) are now able to be synced to the master, making it easier to use them in custom runners. A `saltutil.sync_utils` function has been added to the `saltutil` runner to facilitate the syncing of utility modules to the master.

Pillar Changes

- Thanks to the new `saltutil.sync_utils` runner, it is now easier to get `ref:utility modules <writing-utility-modules>` synced to the correct location on the Master so that they are available in execution modules called from Pillar SLS files.

Junos Module Changes

- The following new functionalities were added to the junos module
  - `facts` - Displays the facts gathered during the connection.
  - `shutdown` - Shut down or reboot a device running Junos OS.
  - `install_config` - Modify the configuration of a Junos device.
  - `install_os` - Install Junos OS software package.
  - `zeroize` - Remove all configuration information on the Routing Engines and reset all key values on a device.
  - `file_copy` - Copy file from proxy to the Junos device.
Network Automation: NAPALM

Beginning with 2016.11.0, network automation is included by default in the core of Salt. It is based on the NAPALM library and provides facilities to manage the configuration and retrieve data from network devices running widely used operating systems such as JunOS, IOS-XR, eOS, IOS, NX-OS etc.

- see the complete list of supported devices.

The connection is established via the NAPALM proxy.

In the current release, the following modules were included:

- NAPALM grains - Select network devices based on their characteristics
- NET execution module - Networking basic features
- NTP execution module
- BGP execution module
- Routes execution module
- SNMP execution module
- Users execution module
- Probes execution module
- NTP peers management state
- SNMP configuration management state
- Users management state

Cisco NXOS Proxy Minion

Beginning with 2016.11.0, there is a proxy minion that can be used to configure nxos cisco devices over ssh.

- Proxy Minion
- Execution Module
- State Module

Cisco Network Services Orchestrator Proxy Minion

Beginning with 2016.11.0, there is a proxy minion to use the Cisco Network Services Orchestrator as a proxy minion.

- Proxy Minion
- Execution Module
- State Module
Junos Module Changes

- The following new functionalities were added to the junos module
  - facts - Displays the facts gathered during the connection.
  - shutdown - Shut down or reboot a device running Junos OS.
  - install_config - Modify the configuration of a Junos device.
  - install_os - Install Junos OS software package.
  - zeroize - Remove all configuration information on the Routing Engines and reset all key values on a device.
  - file_copy - Copy file from proxy to the Junos device.

Returner Changes

- Any returner which implements a save_load function is now required to accept a minions keyword argument.
  All returners which ship with Salt have been modified to do so.

Renderer Changes

Added the ability to restrict allowed renderers. Two new config parameters, renderer_whitelist and renderer_blacklist are introduced for this purpose.

eAuth Changes

- External auth modules’ auth method can return an ACL list for the given username instead of True. This list should be in the same format as described in the eAuth documentation. It will be used for the user instead of one set in master config.

  Example of the auth method return that allows a user to execute functions in the test and network modules on the minions that match the web* target and allow access to wheel and runner modules:

  ```
  [{"web*": ["test.*", "network.*"]}, "@wheel", "@runner"]
  ```

- External auth is supported by salt-run and salt-key now. Note that master must be started to use them with eAuth.

External Module Packaging

Modules may now be packaged via entry-points in setuptools. See external module packaging tutorial for more information.
Functionality Changes

- The `onfail` requisite now uses OR logic instead of AND logic. issue #22370
- The consul external pillar now strips leading and trailing whitespace. issue #31165
- The `win_system.py` state is now case sensitive for computer names. Previously computer names set with a state were converted to all caps. If you have a state setting computer names with lower case letters in the name that has been applied, the computer name will be changed again to apply the case sensitive name.
- The `mac_user.list_groups` function in the `mac_user` execution module now lists all groups for the specified user, including groups beginning with an underscore. In previous releases, groups beginning with an underscore were excluded from the list of groups.
- The `junos.call_rpc` function in the `junos` execution module can now be used to call any valid rpc. Earlier it used to call only "get_software_information".
- A new option for minions called `master_tries` has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.
- The default `hash_type` is now sha256 instead of md5. You will need to make sure both your master and minion share the same `hash_type`.
- Nodegroups consisting of a simple list of minion IDs can now also be declared as a yaml list. The below two examples are equivalent:

```
# Traditional way
nodegroups:
  - group1: L@host1,host2,host3

# New way (optional)
nodegroups:
  - group1:
    - host1
    - host2
    - host3
```

New Azure ARM Cloud Driver

A new cloud driver has been added for Azure ARM, aka, the Azure Resource Manager. The older Azure driver is still required to work with the older Azure API. This new driver works with the newer ARM API, which is managed via the newer Azure Portal website.

Deprecations

General Deprecations

- `env` to `saltenv`

  All occurrences of `env` and some occurrences of `__env__` marked for deprecation in Salt 2016.11.0 have been removed. The new way to use the salt environment setting is with a variable called `saltenv`:

  ```python
  def fcn(msg="", env="base", refresh=True, saltenv="base", **kwargs):
    ...
  ```

  has been changed to

  ```python
  def fcn(msg="", refresh=True, saltenv="base", **kwargs):
    ...
  ```

  - If `env` (or `__env__`) is supplied as a keyword argument to a function that also accepts arbitrary keyword arguments, then a new warning informs the user that `env` is no longer used if it is found. This new warning will be removed in Salt 2017.7.0.

    ```python
    def fcn(msg="", refresh=True, saltenv="base", **kwargs):
      ...
    # will result in a warning log message
    fcn(msg="add more salt", env="prod", refresh=False)
    ```

  - If `env` (or `__env__`) is supplied as a keyword argument to a function that does not accept arbitrary keyword arguments, then python will issue an error.

    ```python
    def fcn(msg="", refresh=True, saltenv="base"):
      ...
    # will result in a python TypeError
    fcn(msg="add more salt", env="prod", refresh=False)
    ```

  - If `env` (or `__env__`) is supplied as a positional argument to a function, then undefined behavior will occur, as the removal of `env` and `__env__` from the function's argument list changes the function's signature.

    ```python
    def fcn(msg="", refresh=True, saltenv="base"):
      ...
    ```
# will result in refresh evaluating to True and saltenv likely not being a string at all
fcn("add more salt", "prod", False)

- Deprecations in minion.py:
  - The salt.minion.parse_args_and_kwArgs function has been removed. Please use the salt.minion.load_args_and_kwArgs function instead.

Cloud Deprecations

- The vsphere cloud driver has been removed. Please use the vmware cloud driver instead.
- The private_ip option in the linode cloud driver is deprecated and has been removed. Use the assign_private_ip option instead.
- The create_dns_record and delete_dns_record functions are deprecated and have been removed from the digital_ocean driver. Use the post_dns_record function instead.

Execution Module Deprecations

- The blockdev execution module had four functions removed:
  - dump
  - tune
  - resize2fs
  - wipe
  The disk module should be used instead with the same function names.
- The boto_vpc execution module had two functions removed, boto_vpc.associate_new_dhcp_options_to_vpc and boto_vpc.associate_new_network_acl_to_subnet in favor of more concise function names, boto_vpc.create_dhcp_options and boto_vpc.create_network_acl, respectively.
- The data execution module had getval and getvals functions removed in favor of one function, get, which combines the functionality of the removed functions.
- File module deprecations:
  - The contains_regex multiline function was removed. Use file.search instead.
  - Additional command line options for file.grep should be passed one at a time. Please do not pass more than one in a single argument.
- The lxc execution module has the following changes:
  - The run_cmd function was removed. Use lxc.run instead.
  - The nic argument was removed from the lxc.init function. Use network_profile instead.
  - The clone argument was removed from the lxc.init function. Use clone_from instead.
  - passwords passed to the lxc.init function will be assumed to be hashed, unless password_encrypted=False.
  - The restart argument for lxc.start was removed. Use lxc.restart instead.
The old style of defining lxc containers has been removed. Please use keys under which LXC profiles should be configured such as `lxc.container_profile.profile_name`.

- The `env` and `activate` keyword arguments have been removed from the `install` function in the `pip` execution module. The use of `bin_env` replaces both of these options.

- **reg** execution module

  Functions in the `reg` execution module had misleading and confusing names for dealing with the Windows registry. They failed to clearly differentiate between hives, keys, and name/value pairs. Keys were treated like value names. There was no way to delete a key.

  New functions were added in 2015.5 to properly work with the registry. They also made it possible to edit key default values as well as delete an entire key tree recursively. With the new functions in place, the following functions have been deprecated:

  - `read_key`
  - `set_key`
  - `create_key`
  - `delete_key`

  Use the following functions instead:

  - for `read_key` use `read_value`
  - for `set_key` use `set_value`
  - for `create_key` use `set_value` with no `vname` and no `vdata`
  - for `delete_key` use `delete_key_recursive`. To delete a value, use `delete_value`.

- The `hash_hostname` option was removed from the `salt.modules.ssh` execution module. The `hash_known_hosts` option should be used instead.

- The `human_readable` option was removed from the `uptime` function in the `status` execution module. The function was also updated in 2015.8.9 to return a more complete offering of uptime information, formatted as an easy-to-read dictionary. This updated function replaces the need for the `human_readable` option.

- The `persist` kwarg was removed from the `win_useradd` execution module. This option is no longer supported for Windows. `persist` is only supported as part of user management in UNIX/Linux.

- The `zpool_list` function in the `zpool` execution module was removed. Use `list` instead.

**Outputter Module Deprecations**

- The `compact` outputter has been removed. Set `state_verbose` to `False` instead.

**Runner Module Deprecations**

- The `grains.cache` runner no longer accepts `outputter` or `minion` as keyword arguments. Users will need to specify an outputter using the `--out` option. `tgt` is replacing the `minion` kwarg.

- The `fileserver` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.

- The `jobs` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.

- `virt` runner module:
The hyper kwarg was removed from the init, list, and query functions. Use the host option instead.

The next_hyper function was removed. Use the next_host function instead.

The hyper_info function was removed. Use the host_info function instead.

**State Module Deprecations**

- The env and activate keyword arguments were removed from the installed function in the pip state module. The use of bin_env replaces both of these options.

- reg state module

The reg state module was modified to work with the new functions in the execution module. Some logic was left in the reg.present and the reg.absent functions to handle existing state files that used the final key in the name as the value name. That logic has been removed so you now must specify value name (vname) and, if needed, value data (vdata).

For example, a state file that adds the version value/data pair to the Software\Salt key in the HKEY_LOCAL_MACHINE hive used to look like this:

```
HKEY_LOCAL_MACHINE\Software\Salt\version:
  reg.present:
    - value: 2016.3.1
```

Now it should look like this:

```
HKEY_LOCAL_MACHINE\Software\Salt
  reg.present:
    - vname: version
    - vdata: 2016.3.1
```

A state file for removing the same value added above would have looked like this:

```
HKEY_LOCAL_MACHINE\Software\Salt\version:
  reg.absent:
```

Now it should look like this:

```
HKEY_LOCAL_MACHINE\Software\Salt
  reg.absent:
    - vname: version
```

This new structure is important as it allows salt to deal with key default values which was not possible before. If vname is not passed, salt will work with the default value for that hivekey.

Additionally, since you could only delete a value from a the state module, a new function (key_absent) has been added to allow you to delete a registry key and all subkeys and name/value pairs recursively. It uses the new delete_key_recursive function.

For additional information see the documentation for the reg execution and state modules.

- lxc state module: The following functions were removed from the \lxc state module:
  - created: replaced by the present state.
  - started: replaced by the running state.
- cloned: replaced by the present state. Use the clone_from argument to set the name of the clone source.

  - The hash_hostname option was removed from the salt.states.ssh_known_hosts state. The hash_known_hosts option should be used instead.
  - The always kwarg used in the built function of the pkgbuild state module was removed. Use force instead.

**Utils Module Deprecations**

  - The use of jid_dir and jid_load were removed from the salt.utils.jid.jid_dir functionality for job_cache management was moved to the local_cache returner. jid_load data is now retrieved from the master_job_cache.
  - ip_in_subnet function in salt.utils.network.py has been removed. Use the in_subnet function instead.
  - The iam utils module had two functions removed: salt.utils.iam.get_iam_region and salt.utils.iam.get_iam_metadata in favor of the aws utils functions salt.utils.aws.get_region_from_metadata and salt.utils.aws.creds, respectively.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The LocalClient.cmd_batch() method client does not accept external_auth credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the root user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt's ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone upgrade to 2016.11.2 as soon as possible.

• PR #39153: (nicholasmhughes) Fix selinux.mode state config file handling @ 2017-02-06 18:37:34 UTC
  - 30455079fe Merge pull request #39153 from nicholasmhughes/fix-selinux.mode-config-predictability
  - 8d8ba9c7d2 added the new getconfig function to the test
  - a6a24e1a1b Addressed edge case when attempting to set the config file to 'Disabled'. The state should only check the file, since the in-memory setting won't disappear until after reboot.
  - 6858658ccc2 The selinux.mode state only checked the current status of SELinux in memory (getenforce) when determining if changes needed to be made. The /etc/selinux/config file could have a different value, and it would not be changed. This commit enhances idempotency of the state in regards to both the in-memory and configuration file enforcement of SELinux.

AIX Support Expanded

AIX support has been added for the following execution modules:

- user
- group
- network
- status
- timezone

Additionally, AIX is now supported in the `disk.iostat` remote-execution function, and the `status` beacon is now supported.

Minion Data Cache Enhancement

Memcache is now supported as a data store for the minion data cache.

Memcache is an additional cache layer that keeps a limited amount of data fetched from the minion data cache for a limited period of time in memory that makes cache operations faster. It doesn't make much sense for the localfs cache driver but helps for more complex drivers like consul.

For more details see `memcache_expire_seconds` and other `memcache_*` options in the master config reference.

Docker Fixes

- Docker authentication has been re-organized. Instead of attempting a login for each push/pull (which was unnecessary), a new function called `dockerng.login` has been added, which authenticates to the registry and adds the credential token to the `~/.docker/config.json`. After upgrading, if you have not already performed a `docker login` on the minion using the docker CLI, you will need to run `dockerng.login` to login. This only needs to be done once.

- A bug in resolving the tag name for images in a custom registry (where a colon can appear in the image name, e.g. `myregistry.com:5000/image:tagname`) has been fixed. In previous releases, Salt would use the colon to separate the tag name from the image name, and if there was no colon, the default tag name of `latest` would be assumed. However, this caused custom registry images to be misidentified when no explicit tag name was passed (e.g. `myregistry.com:5000/image`). To work around this in earlier releases, simply specify the tag name.

Salt-Cloud Fixes

2016.11.0 added support for templating userdata files for the `ec2` driver, using the `renderer` option from the master config file. However, as the default renderer first evaluates jinja templating, followed by loading the data as a YAML dictionary, this results in unpredictable results when userdata files are comprised of non-YAML data (which they generally are).

2016.11.4 fixes this by only templating the userdata_file when it is explicitly configured to do so. This is done by adding a new optional parameter to the cloud profile called `userdata_template`. This option is used in the same way as the `template` argument in `file.managed` states, it is simply set to the desired templating renderer:
my-ec2-config:

```
# Pass userdata to the instance to be created
userdata_file: /etc/salt/my-userdata-file
userdata_template: jinja
```

If no `userdata_template` option is set in the cloud profile, then salt-cloud will check for the presence of the master configuration parameter `userdata_renderer`. If this is also not set, then no templating will be performed on the `userdata_file`.

In addition, the other cloud drivers which support setting a `userdata_file` (azurearm, nova, and openstack) have had templating support added to bring them to feature parity with the ec2 driver's implementation of the `userdata_file` option.

Patched Packages

Due to the critical nature of issue issue #41230 we have decided to patch the 2016.11.5 packages with PR #41244. This issue affects all calls to a salt-minion if there is an ipv6 nameserver set on the minion's host. The patched packages on repo.saltstack.com will divert from the v2016.11.5 tag and pypi packages due to the patches applied to the packages.

• ISSUE #41540: (UtahDave) archive.extracted fails on second run (refs: #41599)

• PR #41599: (garethgreenaway) Fixes to modules/archive.py @ 2017-06-06 18:02:14 UTC
  - d9546c6283 Merge pull request #41599 from garethgreenaway/41540_fixes_to_archive_module
  - 66a1366ed8 Fixing issues raised in #41540 when a zip file is created on a Windows system. The issue has two parts, first directories that end up in the archive end up in the results of archive.list twice as they show up as both files and directories because of the logic to handle the fact that Windows doesn't mark them as directories. This issue shows up when an extraction is run a second time since the module verified the file types and the subdirectory is not a file. The second issue is related to permissions, if Salt is told to extract permissions (which is the default) then the directory and files end up being unreadable since the permissions are not available. This change sets the permissions to what the default umask for the user running Salt is.

30.2.59 Salt 2016.11.7 Release Notes

Version 2016.11.7 is a bugfix release for 2016.11.0.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

This release corrects a flaw in minion ID validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

30.2.60 Salt 2016.11.8 Release Notes

Version 2016.11.8 is a bugfix release for 2016.11.0.

Security Fix

CVE-2017-14695 Directory traversal vulnerability in minion id validation in SaltStack. Allows remote minions with incorrect credentials to authenticate to a master via a crafted minion ID. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

CVE-2017-14696 Remote Denial of Service with a specially crafted authentication request. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)
Anonymous Binds and LDAP/Active Directory

When `auth.ldap.anonymous` is set to `False`, the bind password can no longer be empty.

Windows Changes

pkg Execution Module

Significant changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

- pkg.list_available no longer defaults to refreshing the winrepo meta database.
- pkg.install without a version parameter no longer upgrades software if the software is already installed. Use pkg.install version=latest (or simply use a pkg.latest state to get the old behavior.
- pkg.list_pkgs now returns multiple versions if software installed more than once.
- pkg.list_pkgs now returns Not Found when the version is not found instead of (value not set) which matches the contents of the sls definitions.
- pkg.remove will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- pkg.remove can remove latest software, if latest is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behave more like their Unix/Linux versions.
Salt Documentation, Release 3002.5

**cmd Execution Module**

Due to a difference in how Python's `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows' `CreateProcess` requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into a string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

Warning: Some Salt Masters may need to apply a patch for Default Job Cache to prevent a possible crash

An issue exists that prevents the Salt master from cleaning the default job cache. This issue can cause an over-consumption of resources resulting in a crash. 2016.3.0 Salt masters should apply the patch in PR #33555. This issue will be addressed in 2016.3.1.

- issue #33516: When upgrading from 2015.8.10 to 2016.3.0 on centos7/redhat7 salt-minion must be restarted twice.
- issue #33517: SPM does not work on amazon linux 2015 in 2016.3.0.

Backwards-incompatible Changes

- The default path for the extension_modules master config option has been changed. Prior to this release, the location was a directory named extmods in the Salt cachedir. On most platforms, this would put the extension_modules directory in /var/cache/salt/extmods. It has been moved one directory down, into the master cachedir. On most platforms, this is /var/cache/salt/master/extmods. Most users won’t have to worry about this, but those who have been manually placing custom runners into /var/cache/salt/extmods/runners, or outputters into /var/cache/salt/extmods/output, etc. will be affected by this. To transition, it is recommended not to simply move the extmods directory into /var/cache/salt/master, but to copy the custom modules into the salt fileserver under salt://_runners, salt://_output, etc. and sync them using the functions in the new saltutil runner.
- The pkg.check_db function has been removed for yum/dnf.

Core Changes

- The onchanges requisite now fires if any watched state changes. issue #19592.
- The ext_pillar functions must now accept a minion ID as the first argument. This stops the deprecation path started in Salt 0.17.x. Before this minion ID first argument was introduced, the minion ID could be retrieved accessing __opts__['id'] losing the reference to the master ID initially set in opts. This is no longer the case, __opts__['id'] will be kept as the master ID.
- Custom types can now be synced to the master using the new saltutil runner. Before, these needed to manually be placed under the extension_modules directory. This allows custom modules to easily be synced to the master to make them available when compiling Pillar data. Just place custom runners into salt://_runners, custom outputters into salt://_output, etc. and use the functions from the saltutil runner to sync them.
- The client_acl configuration options were renamed to publisher_acl.
- Added a new --config-dump option (issue #26639).
- TCP Transport presence events were updated to work with a NAT (PR #30629).
• A `minion_pillar_cache` setting was added to save rendered pillar data to cachedir for later use when `file_client` is set to local (PR #30428).

• Added the ability for binary data (such as a license key) to be distributed via pillar using the `file.managed` (issue #9569).

• Scheduled jobs now include `success` and `retcode` (issue #24237).

• The `saltversioninfo` grain was changed from a string to a list to enable reading values by index. (PR #30082).

• A `pillar_merge_lists` option was added to enable recursively merging pillar lists by aggregating them instead of replacing them (PR #30062).

• Grain values reported by Debian 8 (jessie) when `lsb-release` is installed were updated for consistency (PR #28649).

• A new option for minions called `master_tries` has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.

• The default directory for deploying the salt-thin tarball has changed for salt-ssh. It is now `/var/tmp` instead of `/tmp`. Users may also wish to delete any directories in `/tmp` ending with `_salt/` (issue #32771)

### External Module Packaging

Modules may now be packaged via entry-points in setuptools. See external module packaging tutorial for more information.

### Cloud Changes

• Refactored the OpenNebula driver and added numerous `--function` and `--action` commands to enhance Salt support for image, template, security group, virtual network and virtual machine management in OpenNebula.

• Added execution/state modules to support the deployment of AWS cognito identity pools (PR #31094).

• Added ability to set tags and listener policies on a AWS ELB (PR #27552).

### Platform Changes

• Renamed modules related to macOS. The following module filenames were changed. The virtual name remained unchanged.
  - PR ##30558: renamed osxdesktop.py to mac_desktop.py
  - PR ##30557: renamed macports.py to mac_ports.py
  - PR ##30556: renamed darwin_sysctl.py to mac_sysctl.py
  - PR ##30555: renamed brew.py to mac_brew.py
  - PR ##30552: renamed darwin_pkgutil.py to mac_pkgutil.py
Package Support

- Ubuntu Xenial: Packages for Ubuntu Xenial (16.04) are available for 2016.3.0 and onwards. See repo.saltstack.com for more information. Note that Xenial comes with Debian’s packaged version of Salt 2015.8.8 and official repo.saltstack.com packages are available for 2015.8 releases beginning with Salt 2015.8.11.

Proxy Minion Changes

The deprecated config option `enumerate_proxy_minions` has been removed.

As mentioned in earlier documentation, the `add_proxymodule_to_opts` configuration variable defaults to `False` in this release. This means if you have proxymodules or other code looking in `__opts__['proxymodule']` you will need to set this variable in your `/etc/salt/proxy` file, or modify your code to use the `__proxy__` injected variable.

The `__proxyenabled__` directive now only applies to grains and proxy modules themselves. Standard execution modules and state modules are not prevented from loading for proxy minions.

Support has been added to Salt's loader allowing custom proxymodules to be placed in `salt://_proxy`. Proxy minions that need these modules will need to be restarted to pick up any changes. A corresponding utility function, `saltutil.sync_proxymodules`, has been added to sync these modules to minions.

Enhancements in grains processing have made the `__proxyenabled__` directive somewhat redundant in dynamic grains code. It is still required, but best practices for the `__virtual__` function in grains files have changed. It is now recommended that the `__virtual__` functions check to make sure they are being loaded for the correct proxymodule, example below:

```python
def __virtual__():
    
    """
    Only work on proxy
    """
    try:
        if salt.utils.is_proxy() and __opts__['proxy']['proxytype'] == 'ssh_sample':
            return __virtualname__
    except KeyError:
        pass

    return False
```

Note: `salt.utils.is_proxy()` has been renamed to `salt.utils.platform.is_proxy` as of the Oxygen release.

The try/except block above exists because grains are processed very early in the proxy minion startup process, sometimes earlier than the proxy key in the `__opts__` dictionary is populated.

Grains are loaded so early in startup that no dunder dictionaries are present, so `__proxy__`, `__salt__`, etc. are not available. Custom grains located in `/srv/salt/_grains` and in the salt install grains directory can now take a single argument, `proxy`, that is identical to `__proxy__`. This enables patterns like

```python
def get_ip(proxy):
    
    """
    Ask the remote device what IP it has
    """
    return {'ip': proxy['proxymodulename.get_ip']()}
```
Then the grain ip will contain the result of calling the `get_ip()` function in the proxymodule called proxymodulename.

Proxy modules now benefit from including a function called `initialized()`. This function should return `True` if the proxy's `init()` function has been successfully called. This is needed to make grains processing easier.

Finally, if there is a function called `grains` in the proxymodule, it will be executed on proxy-minion startup and its contents will be merged with the rest of the proxy's grains. Since older proxy-minions might have used other methods to call such a function and add its results to grains, this is config-gated by a new proxy configuration option called `proxy_merge_grains_in_module`. This defaults to `False` in this release. It will default to `True` in the release after next. The next release is codenamed Carbon, the following is Nitrogen.

The example proxy minions `rest_sample` and `ssh_sample` have been updated to reflect these changes.

**Syndic Updates**

A major performance and management issue was found and fixed in the syndic. This makes the Salt Syndic substantially more reliable and performant. Please make sure that the syndic and the master of masters which syndics attach to are updated, otherwise the syndic fixes alone can cause minor performance issues with older master of masters. Please update masters first, then syndics. Minions do not need to be updated for this fix to work.

**Module Changes**

- **file execution module**: `show_diff` is deprecated in favor of `show_changes`. (PR #30988)
- **reg execution module**:
  - Removed the following deprecated functions from the reg module (PR #30956):
    - read_key
    - set_key
    - create_key
    - delete_key
  - Removed force parameter from reg state module
  - Fixed virtual function in state
  - Improved error information for reg.delete_value function
- **jboss7 execution module**: deployed function was decoupled from Artifactory by removing Artifactory-specific functionality. Note that the changes in some of the function arguments break existing state files, see issue #30515 and PR #3080 for details.
- **pkg state module**: The wait function was removed, the functionality was replaced with the onchanges requisite (PR #30297).
- **firewalld state module**: A permanent argument was added add_port. Note that permanent defaults to `True`, which changes previous behavior (PR #30275). A bind function was also added that allows binding zones to interfaces and sources (PR #29497).
- **journald beacon module**: The event string was updated to include a tag. Note this might impact existing reactors based on this beacon. (PR #30116).
- **postgres_privileges state module**: The default value of the prepend argument was changed from None to public.
- **zenoss execution module**: The add_device function was updated with a default value of 1000 for prod_state to match the documentation (PR #28924).
The etcd execution module, state module, returner module, and util module were refactor (PR #28599). This refactor changes error returns for several functions (primarily edge cases):

- get: Used to return " on key-not-found. Now returns None.
- set: Used to return " on issues setting keys. Now returns None.
- ls: Used to return [path: {}] on key-not-found. Now returns None.
- Tree: Used to return {} on key-not-found. Now returns None.

smartos_virt execution module: Updated to use most of the new smartos_vmadm (PR #28284).

apache_conf state module, apache_module state module, and apache_site state module: the enable and disable functions were renamed to enabled and disabled, respectively. In PR #33562, these functions were readded and properly deprecated and will be removed in Salt 2017.7.0. This fix will be available in 2016.3.1. As a workaround, try

```python
apache_module.enable({ 'd' if grains.saltversioninfo == [2016, 3, 0] else '' })
```

New Features

Thorium - Provisional New Reactor

The 2016.3 release introduces the new Thorium Reactor. This reactor is an experimental new feature that implements a flow programming interface using the salt state system as the engine. This means that the Thorium reactor uses a classic state tree approach to create a reactor that can aggregate event data from multiple sources and make aggregate decisions about executing reactions.

This feature is both experimental and provisional, it may be removed and APIs may be changed. This system should be considered as ambitious as the Salt State System in that the scope of adding a programmable logic engine of this scale into the event systems is non trivial.

See Thorium Complex Reactor.

Improved Mac OS Support

Improved Solaris Support

A lot of work was done to improve support for SmartOS. This work also resulted in improvements for Solaris and illumos as SmartOS.

- rewrite of vmadm module (SmartOS)
- rewrite of imgadm module (SmartOS)
- depreciation of virt module in favor of vmadm (SmartOS)
- implemented smartos state (SmartOS)
- improved zpool module add SmartOS, illumos and Solaris support
- improved zfs module add SmartOS, illumos and Solaris support
- implemented zpool state
- implemented zfs state implemented solaris_system system module to provide better Solaris support (PR #30519)
- other minor fixes to grains, localmod, ...
**Tornado Transport**

**Important:** The Tornado Transport wire protocol was changed in 2016.3, making it incompatible with 2015.8 (PR #29339).

---

**Windows DSC Integration (Experimental)**

**Dimension Data Cloud Support**

A SaltStack Cloud driver for Dimension Data Public Cloud, provides the driver functionality to service automation for any of the Dimension Data Public Cloud locations:

- Deploy new virtual machines
- List and query virtual machine images
- Destroy and query virtual machines

Documentation of the Dimension Data SaltStack integration is found on developer.dimensiondata.com

**Minion Blackout**

During a blackout, minions will not execute any remote execution commands, except for saltutil.refresh_pillar. Blackouts are enabled using a special pillar key, minion_blackout set to True.

See Minion Blackout.

**Splunk Returner**

A Splunk Returner that uses HTTP Event Collector is now available (PR #30718).

**SQLCipher Pillar Module**

Support was added for retrieving pillar data via queries to SQLCipher databases (PR #29782).

Final Release of Debian 7 Packages

Regular security support for Debian 7 ended on April 25th, 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

- Total PR References: 115
- Contributors: 36 (The-Loeki, abednarik, cachedout, cro, deniszh, dkruger, dmurphy18, eliasp, farcaller, galet, gtmanfred, hu-dabao, isbm, jacobhammons, jacobweinstock, jfindlay, justinta, kstreee, lubyou, markuskramerlgitt, meaksh, mihael, nzupan, nishigori, rallytime, s0undt3ch, skizunov, tankywoo, termimalmage, thatch45, theredcat, ticosax, tonybaloney, twangboy, vutny, whiteinge)

Known Issues

issue #36055: Salt Cloud events (salt/cloud) are not generated on the master event bus when provisioning cloud systems.

Bootstrap Issue #973: python-futures is not installed when installing from a git tag on RedHat-based distributions. Python futures is needed when running Salt with the TCP transport. This is fixed on the develop branch of the salt-bootstrap repo and the fix will be included in the upcoming release of salt-bootstrap, but is a bug in the bootstrap release that ships with this version of Salt. Please see the salt-bootstrap repo for more information on how to update your bootstrap version.

Known Issues

The Salt Minion does not clean up files in /tmp when rendering templates. This potentially results in either running out of disk space or running out of inodes. Please see issue #37541 for more information. This bug was fixed with PR #37540, which will be available in the 2016.3.5 release of Salt.

The release of the bootstrap-salt.sh script that is included with 2016.3.4 release has a bug in it that fails to install salt correctly for git installs using tags in the 2015.5 branch. This bug has not been fixed in the salt-bootstrap repository yet, but the previous bootstrap release (v2016.08.16) does not contain this bug.

Changes

- The disk.wipe execution module function has been modified so that it correctly wipes a disk.
- Add ability to clone from a snapshot to the VMWare salt-cloud driver.
- Add ability to specify disk backing mode in the VMWare salt cloud profile.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The LocalClient.cmd_batch() method client does not accept external_auth credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the root user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt's ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone on the 2016.3 branch upgrade to a patched release as soon as possible.

Improved Checksum Handling in file.managed, archive.extracted States

When the source_hash argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (source_hash_name) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the source_hash file.

A more detailed explanation of this functionality can be found in the file.managed documentation, in the section for the new source_hash_name argument.

30.2.69 Salt 2016.3.7 Release Notes

Version 2016.3.7 is a bugfix release for 2016.3.0.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

This release corrects a flaw in minion ID validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

30.2.70 Salt 2016.3.8 Release Notes

Version 2016.3.8 is a bugfix release for 2016.3.0.

Security Fix

CVE-2017-14695 Directory traversal vulnerability in minion id validation in SaltStack. Allows remote minions with incorrect credentials to authenticate to a master via a crafted minion ID. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

CVE-2017-14696 Remote Denial of Service with a specially crafted authentication request. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

30.2.71 Salt 2016.3.9 Release Notes

Version 2016.3.9 is a bugfix release for 2016.3.0.

Master Changes

The following options have been added to the master config file:

- allow_minion_key_revoke - This option controls whether a minion can request that the master revoke its key. When True, a minion can request a key revocation and the master will comply. If it is False, the key will not be revoked by the master.

- require_minion_sign_messages - This requires that minions cryptographically sign the messages they publish to the master. If minions are not signing, then log this information at loglevel INFO and drop the message without acting on it.

- drop_messages_signature_fail - Drop messages from minions when their signatures do not validate. Note that when this option is False but require_minion_sign_messages is True, minions MUST sign their messages, but the validity of their signatures is ignored.

- minion_sign_messages - Causes the minion to cryptographically sign the payload of messages it places on the event bus for the master. The payloads are signed with the minion's private key so the master can verify the signature with its public key.

30.2. Previous Releases 2731
The 2015.8.0 feature release of Salt contains several major new features. As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.

New SaltStack Installation Repositories

SaltStack now provides installation repositories for several platforms, with more to come. See the following links for instructions:

- Red Hat / CentOS 5, 6, 7
- Debian 8
- Windows
Send Event on State Completion

A `fire_event` global state keyword argument was added that allows any state to send an event upon completion. Useful for custom progress bars and checking in on long state runs. See `fire_event`.

ZeroMQ socket monitoring

If `zmq_monitor` is enabled, log all ZMQ events for socket monitoring purposes. Verbose, but useful.

SPM (Salt Package Manager)

Allows Salt formulas to be packaged for ease of deployment. See `spm`.

---

Note: The `spm` executable was not included in the Debian or Ubuntu packages for the 2015.8.0 or the 2015.8.1 releases. This executable will be included in an upcoming release. As a workaround, copy the SPM script from the salt library installation into `/usr/local/bin` or your local equivalent.

---

Specify a Single Environment for Top Files

A new `default_top` option was added to load the state top file from a single, specific environment, rather than merging top data across all environments. Additionally, new `top_file_merge_strategy` and `env_order` options were added for more control over top file merging. See The Top File.

Tornado TCP Transport

Implemented a pure-TCP transport, in addition to ZeroMQ and RAET. The new transport uses Tornado, which allows Salt to use a standardized set of libraries for asynchronous behavior, which should greatly improve reliability and performance.

Note: Tornado is considered expiermental in this release. The following known issues were being investigated at the time of release:

- TCP tests show performance degradation over time (issue #26051)
- TCP transport stacktrace on windows minion: Future exception was never retrieved (issue #25718)
- [freebsd] TCP transport not working in 2015.8.0rc3 (issue #26364)

Proxy Minion Enhancements

Proxy Minions have undergone a significant overhaul in 2015.8, see Proxy Minion Enhancements.
Engines

Salt engines are long-running, external processes that leverage Salt. See Salt Engines.

Core Changes

- Add system version info to versions_report, which appears in both salt --versions-report and salt '*' test.versions_report. Also added is an alias test.versions to test.versions_report. (issue #21906)

- Add colorized console logging support. This is activated by using %\(\text{colorlevel}\)s, %\(\text{colorname}\)s, %\(\text{colorprocess}\)s, %\(\text{colormsg}\)s in log_fmt_console in the config file for any of salt-master, salt-minion, and salt-cloud.

Git Pillar

The git external pillar has been rewritten to bring it up to feature parity with gitfs. Support for pygit2 has been added, bringing with it the ability to access authenticated repositories.

Using the new features will require updates to the git ext_pillar configuration, further details can be found in the pillar.git_pillar docs.

Salt Cloud Improvements

- Pricing data from several cloud providers (GCE, DigitalOcean, SoftLayer_HW, EC2)
- All cloud providers now use standardized bootstrapping code.
- Modified the Linode Salt Cloud driver to use Linode's native API instead of depending on apache-libcloud or linode-python.

Salt Cloud Changes

- Changed the default behavior of rename_on_destroy to be set to True in the EC2 and AWS drivers.
- Changed the default behavior of the EC2 and AWS drivers to always check for duplicate names of VMs before trying to create a new VM. Will now throw an error similarly to other salt-cloud drivers when trying to create a VM of the same name, even if the VM is in the terminated state.
- When querying for VMs in digital_ocean.py, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.Ocean.

State and Execution Module Improvements

- New and improved Docker state and execution modules (state and execution module).
Git State and Execution Modules Rewritten

The git state and execution modules have gone through an extensive overhaul.

Changes in the `git.latest` State

- The `branch` argument has been added, allowing for a custom branch name to be used in the local checkout maintained by the `git.latest` state. This can be helpful in avoiding ambiguous refs in the local checkout when a tag is used as the `rev` argument. If no `branch` is specified, then the state uses the value of `rev` as the branch name.

- The `always_fetch` argument no longer has any effect, and will be removed in a future release. The state now detects whether or not a fetch is needed based on comparisons made between the local and remote repositories.

- The `force_fetch` argument has been added to force a fetch if the fetch is not a fast-forward (for instance, if someone has done a reset and force-pushed to the remote repository).

- The `remote_name` argument has been deprecated and renamed to `remote`.

- The `force` argument has been deprecated and renamed to `force_clone` to reduce ambiguity with the other "force" arguments.

- Using SHA1 hashes (full or shortened) in the `rev` argument is now properly supported.

- Non-fast-forward merges are now detected before the repository is updated, and the state will not update the repository if the change is not a fast-forward. Non-fast-forward updates must be overridden with the `force_reset` argument. If `force_reset` is set to `True`, the state will only reset the repository if it cannot be fast-forwarded. This is in contrast to the earlier behavior, in which a hard-reset would be performed every time the state was run if `force_reset` was set to `True`.

- A `git pull` is no longer performed by this state, dropped in favor of a fetch-and-merge (or fetch-and-reset) workflow.

`git.config_unset` state added

This state allows for configuration values (or entire keys) to be unset. See here for more information and example SLS.

`git.config` State Renamed to `git.config_set`

To reduce confusion after the addition of `git.config_unset`, the `git.config` state has been renamed to `git.config_set`. The old `config.get` name will still work for a couple releases, allowing time for SLS files to be updated. In addition, this state now supports managing multivar git configuration values. See here for more information and example SLS.
Initial Support for Git Worktrees in Execution Module

Several functions have been added to the execution module to manage worktrees (a feature new to Git 2.5.0). State support does not exist yet, but will follow soon.

New Functions in Git Execution Module

- `git.config_get_regexp`
- `git.config_unset`
- `git.is_worktree`
- `git.list_branches`
- `git.list_tags`
- `git.list_worktrees`
- `git.merge_base`
- `git.merge_tree`
- `git.rev_parse`
- `git.version`
- `git.worktree_rm`
- `git.worktree_add`
- `git.worktree_prune`

Changes to Functions in Git Execution Module

**git.add**

- `--verbose` is now implied when running the `git add` command, to provide a list of the files added in the return data.

**git.archive**

- Now returns `True` when the `git archive` command was successful, and otherwise raises an error.
- The `overwrite` argument has been added to prevent an existing archive from being overwritten by this function.
- The `fmt` argument has been deprecated and renamed to `format`.
- Trailing slash no longer implied in `prefix` argument, must be included if this argument is passed.
The rev argument is now optional when using -b or -B in opts, allowing for a branch to be created (or reset) using HEAD as the starting point.

The name argument has been added to specify the name of the directory in which to clone the repository. If this option is specified, then the clone will be made within the directory specified by the cwd, instead of at that location.

The repository argument has been deprecated and renamed to url.

The setting_name argument has been deprecated and renamed to key.

The global argument has been added, to query the global git configuration.

The all argument has been added to return a list of all values for the specified key, allowing for all values in a multivar to be returned.

The cwd argument is now optional if global is set to True.

The value(s) of the key being set are now returned.

The setting_name argument has been deprecated and renamed to key.

The setting_value argument has been deprecated and renamed to value.

The is_global argument has been deprecated and renamed to global.

The multivar argument has been added to specify a list of values to set for the specified key. The value argument is not compatible with multivar.

The add argument has been added to add a value to a key (this essentially just adds an --add to the git config command that is run to set the value).

The force argument has been added to force the fetch when it is not a fast-forward. This could have been achieved in previous Salt versions by including --force in the opts argument, this argument is just for convenience and to match the usage of other functions with force arguments.

The refspects argument has been added to allow for one or more refspects to be provided which override the one(s) specified by the remote.remote_name.fetch git configuration option.
**git.ls_remote**

- The repository argument has been deprecated and renamed to remote.
- The branch argument has been deprecated and renamed to ref.
- The opts argument has been added to allow for additional CLI options to be passed to the `git ls-remote` command.

**git.merge**

- The branch argument has been deprecated and renamed to rev.

**git.status**

- Return data has been changed from a list of lists to a dictionary containing lists of files in the modified, added, deleted, and untracked states.

**git.submodule**

- Added the command argument to allow for operations other than update to be run on submodules, and deprecated the init argument. To do a submodule update with init=True moving forward, use command=update opts='--init'.
- OpenStack Glance API V2 execution module
- Amazon VPC state module
- RallyDev execution module
- BambooHR execution module
- Stormpath execution, state modules
- Remove unused argument timeout in jboss7.status.
- Deprecate enabled argument in pkgrepo.managed in favor of disabled.
- Archive module changes: In the archive.tar and archive.cmd_unzip module functions, remove the arbitrary prefixing of the options string with -. An options string beginning with a --long-option, would have uncharacteristically needed its first - removed under the former scheme. Also, tar will parse its options differently if short options are used with or without a preceding -, so it is better to not confuse the user into thinking they're using the non- - format, when really they are using the with- - format.
- Added __states__ to state modules, for cross-calling states. This enables using existing states when writing custom states. See cross calling states.
Windows Improvements

- Enhanced the windows minion silent installation with command line parameters to configure the salt master and minion name. See Silent Installer Options.
- Improved user management with additional capabilities in the user module for Windows.
- Improved patch management with a new module for managing windows updates (win_wua).
- Turned on multi-processing by default for windows in minion configuration.

Windows Software Repo Changes

A next-generation (ng) windows software repo is available for 2015.8.0 and later minions. When using this new repository, the repo cache is compiled on the Salt Minion, which enables pillar, grains and other things to be available during compilation time.

See the Windows Software Repository documentation for more information.

Changes to legacy Windows repository

If you have pre 2015.8 Windows minions connecting to your 2015.8 Salt master, you can continue to use the legacy Windows repository for these Salt minions.

If you were previously using this repository and have customized settings, be aware that several config options have been renamed to make their naming more consistent.

See the Windows Software Repository documentation for more information.

Win System Module

The unit of the timeout parameter in the system.halt, system.poweroff, system.reboot, and system.shutdown functions has been changed from seconds to minutes in order to be consistent with the linux timeout setting. (issue #24411) Optionally, the unit can be reverted to seconds by specifying in_seconds=True.

Other Improvements

- Sanitize sensitive fields in http.query
- Allow authorization to be read from Django and eauth
- Add templating to SMTP returner
- New REST module for SDB
- Added rest_timeout config option and timeout argument to jobs api call
- Provide config options for Raet lane and road buffer count. (Useful for BSD kernels)
- Implemented ZeroMQ socket monitor for master and minion
- Add end time to master job cache for jobs (optional, off by default)
- Tornado is now the default backend for http.request
- Support pillarenv selection as it’s done for saltenv
- salt was updated to use python-crypto version 2.6.1, which removes the dependency on python-m2crypto.
Deprecations

- The `digital_ocean.py` Salt Cloud driver was removed in favor of the `digital_ocean_v2.py` driver as DigitalOcean has removed support for APIv1. The `digital_ocean_v2.py` was renamed to `digital_ocean.py` and supports DigitalOcean's APIv2.
- The `vsphere.py` Salt Cloud driver has been deprecated in favor of the `vmware.py` driver.
- The `openstack.py` Salt Cloud driver has been deprecated in favor of the `nova.py` driver.
- The use of `provider` in Salt Cloud provider files to define cloud drivers has been deprecated in favor of using `driver`. Both terms will work until the 2017.7.0 release of Salt. Example provider file:

```
my-ec2-cloud-config:
id: 'HJGRYCILJLKJYG'
key: 'kdjgfsgm;woormgl/aserigksjhasdfgn'
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key
securitygroup: default
driver: ec2
```

- The use of `lock` has been deprecated and from `salt.utils.fopen`, `salt.utils.flopen` should be used instead.
- The following args have been deprecated from the `rabbitmq_vhost.present` state: `user`, `owner`, `conf`, `write`, `read`, and `runas`.
- The use of `runas` has been deprecated from the `rabbitmq_vhost.absent` state.
- Support for output in `mine.get` was removed. `--out` should be used instead.
- The use of `delim` was removed from the following functions in the `match` execution module: `pillar_pcre`, `pillar`, `grain_pcre`,

Security Fixes

CVE-2015-6918 - Git modules leaking HTTPS auth credentials to debug log

Updated the Git state and execution modules to no longer display HTTPS basic authentication credentials in log level debug output on the Salt master. These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <asteiger@suse.com> for bringing this to our attention.

Major Bug Fixes

- Fixed minion failover to next master on DNS errors (issue #21082)
- Fixed memory consumption in SaltEvents (issue #25557)
- Don't lookup outside system path in which() util (issue #24085)
- Fixed broken jobs rest api call (issue #23408)
- Fixed stale grains data using in modules (issue #24073)
- Added `ssh_identities_only` config flag for ssh-agent configured environments (issue #24096)
- Fixed "object has no attribute" errors for Raet transport (issue #21640)
- Flush event returners before master exit (issue #22814)
- Fix `CommandExecutionError` in grains generation with `lspci` missing (issue #23342)
- Fix salt-ssh against CentOS 7 when python-zmq not installed (issue #23503)
- Fix salt-ssh issues related to out-of-date six module (issue #20949)
- Fix salt-ssh thin generation after previous run was interrupted (issue #24376)
- Use proper line endings on Windows with "file.managed" w/contents (issue #25675)
- Fixed broken comment/uncomment functions in file.py (issue #24620)
- Fixed problem with unicode when changing computer description (issue #12255)
- Fixed problem with chocolatey module not loading (issue #25717)

Security Fixes

CVE-2015-6941 The Windows user module and salt-cloud display passwords in log when log level is set to debug or more verbose.

For the Windows user module, the password is now replaced with the string XXX-REDACTED-XXX.

For salt-cloud, debug logging no longer displays win_password and sudo_password authentication credentials.

CVE-2015-6918 Git state/execution modules log HTTPS auth credentials when log level is set to debug or more verbose.

These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <asteiger@suse.com> for bringing this to our attention.

Major Bug Fixes

- Add support for spm.d/*.conf configuration of SPM (issue #27010)
- Fix proxy grains breakage for non-proxy minions (issue #27039)
- Fix global key management for git state
- Fix passing http auth to util.http from state.file (issue #21917)
- Fix multiprocessing: True in windows (on by default)
- Add pkg.info to pkg modules
- Fix name of serial grain (this was accidentally renamed in 2015.8.0)
- Merge config values from master.d/minion.d conf files (rather than flat update)
- Clean grains cache on grains sync (issue #19853)
- Remove streamed response for fileclient to avoid HTTP redirection problems (issue #27093)
- Fixed incorrect warning about osrelease grain (issue #27065)
- Fix authentication via Salt-API with tokens (issue #27270)
- Fix winrepo downloads from https locations (issue #27081)
- Fix potential error with salt-call as non-root user (issue #26889)
- Fix global minion provider overrides (issue #27209)
- Fix backward compatibility issues for pecl modules
- Fix Windows uninstaller to only remove ./bin, salt*, nssm.exe, uninst.exe (issue #27383)
- Fix misc issues with mongo returner.
- Add sudo option to cloud config files (issue #27398)
- Fix regression in RunnerClient argument handling (issue #25107)
- Fix dockerng.running replacing creation hostconfig with runtime hostconfig (issue #27265)
- Fix dockerng.running replacing creation hostconfig with runtime hostconfig (issue #27265)
- Increased performance on boto asg/elb states due to __states__ integration
- Windows minion no longer requires powershell to restart (issue #26629)
- Fix x509 module to support recent versions of OpenSSL (issue #27326)
• Some issues with proxy minions were corrected.

Known Issues

• Proxy minions currently cannot execute a highstate because of the way the proxymodule is being loaded internally. This will be fixed in a future release.

30.2.74 Salt 2015.8.10 Release Notes

Version 2015.8.10 is a bugfix release for 2015.8.0.

This release includes fixes for two issues discovered in 2015.8.9:

- Pip state broken in 2015.8.9 with pip <6.0 (issue #33376)
- Fix traceback in logging for config validation (PR #33386)

Final Release of Debian 7 Packages

Regular security support for Debian 7 ended on April 25th 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

Important Post-Upgrade Instructions for Linux Mint

As a result of some upstream changes, the os grain on Mint Linux is now being detected as LinuxMint (issue #33295). Run the following command after you upgrade to 2015.8.10 to reset the os grain to Mint and the os_family grain to Debian:

```
salt -G 'os:LinuxMint' grains.setvals "{'os': 'Mint', 'os_family': 'Debian'}"
```

Ubuntu 16.04 Packages

SaltStack is now providing official Salt 2015.8 packages for Ubuntu 16.04.

Returner Changes

- Any returner which implements a `save_load` function is now required to accept a `minions` keyword argument. All returners which ship with Salt have been modified to do so.

New Master Configuration Parameter

- `rotate_aes_key` - if `True`, causes Salt to generate a new AES key whenever a minion key is deleted. This eliminates the chance that a deleted minion could continue to eavesdrop on communications with the master if it continues to run after its key is deleted.

30.2.77 Salt 2015.8.13 Release Notes

Version 2015.8.13 is a bugfix release for 2015.8.0.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The `LocalClient.cmd_batch()` method client does not accept `external_auth` credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the `root` user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt's ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone on the 2015.8 branch upgrade to a patched release as soon as possible.

30.2.78 Salt 2015.8.2 Release Notes

Version 2015.8.2 is a bugfix release for 2015.8.0.

Security Fix

CVE-2015-8034 Saving state.sls cache data to disk with insecure permissions

This affects users of the state.sls function. The state run cache on the minion was being created with incorrect permissions. This file could potentially contain sensitive data that was inserted via jinja into the state SLS files. The permissions for this file are now being set correctly. Thanks to zmalone for bringing this issue to our attention.

Known Issues

• *_in requisites (issue #30820)

  This issue affects all users targeting an explicit - name: <name> with a _in requisite (such as watch_in or require_in). If you are not using explicit - name: <name> arguments, are targeting with the state ID instead of the name, or are not using _in requisites, then you should be safe to upgrade to 2015.8.4.

  This issue is resolved in the 2015.8.5 release.

Security Fix

CVE-2016-1866 Improper handling of clear messages on the minion, which could result in executing commands not sent by the master.

This issue affects only the 2015.8.x releases of Salt. In order for an attacker to use this attack vector, they would have to execute a successful attack on an existing TCP connection between minion and master on the pub port. It does not allow an external attacker to obtain the shared secret or decrypt any encrypted traffic between minion and master. Thank you to Sebastian Krahmer <krahmer@suse.com> for bringing this issue to our attention.

We recommend everyone upgrade to 2015.8.4 as soon as possible.
Core Changes

• Support for IAM roles added to S3 module
• Added option mock=True for state.sls and state.highstate. This allows the state compiler to process sls data in a state run without actually calling the state functions, thus providing feedback on the validity of the arguments used for the functions beyond the preprocessing validation provided by state.show_sls (issue #30118 and issue #30189).

```
salt '*' state.sls core,edit.vim mock=True
salt '*' state.highstate mock=True
salt '*' state.apply edit.vim mock=True
```

  - e9ade42d10 Merge pull request #30273 from rallytime/bp-30121
  - c8ec0f2105 I fail at linting... Fixed my uppercase/lowercase problem
  - 0877b33026 Fixed some linting issues
  - 8ec36497a1 Added note about systemd and uncleanshutdown. Also fixed line length of comments to max 80 characters as per PEP0008
  - a50428d02c On an unclean shutdown, if oncleanshutdown is given a path, an key:value of shutdown:unclean is added to the returned data. The documentation states that the key should be 'uncleanshutdown' and that the value should either be True or False. This is fixed in the code
  - 51b57f1820 Fixed issue number #30117 - When no parameters are given to a service, the service object is of type None and thus isn't iterable. This is contrary to the documentation which states that there are default values. Default values added as False

## 30.2.81 Salt 2015.8.5 Release Notes

Version 2015.8.5 is a bugfix release for 2015.8.0.

**Important**: About this Release Salt 2015.8.5 is identical to the 2015.8.4 release with the addition of a fix for issue #30820, fixed by PR #30833. See [here](#) for the 2015.8.4 release notes.

### Known Issue in boto_* execution modules

This release contains an issue that causes the boto_* execution modules to display a __salt__ not defined error (issue #30300). This issue will be fixed in an upcoming release, but can be manually resolved by completing the following:

1. Download the boto_* execution modules that you would like to update from the 2015.8 branch of Salt. A complete list of affected modules with the specific changes is available in :pull`30867`. A simple way to get the updated modules is to [download](#) a zip file of the 2015.8 branch from GitHub. The updated modules are in the salt\modules directory.

2. Place the boto_* modules into salt://_modules.

3. Run the following command to sync these modules to all Salt minions:

   ```
   salt '*' saltutil.sync_modules
   ```

30.2.82 Salt 2015.8.7 Release Notes

Version 2015.8.7 is a bugfix release for 2015.8.0.

Note: Salt 2015.8.4, 2015.8.5, and 2015.8.7 were all released within a short period due to regressions found soon after the releases of 2015.8.4 and 2015.8.5. See here for the 2015.8.4 release notes, and here for the 2015.8.5 release notes.

Change to Epoch Support for YUM/DNF

For pkg.installed states, on Linux distributions which use yum/dnf, packages which have a non-zero epoch in the version number now require this epoch to be included when specifying an exact version for a package. For example:

```
vim-enhanced:
pkg.installed:
   - version: 2:7.4.160-1.el7
```

The pkg.latest_version and pkg.list_repo_pkgs functions can be used to get the correct version string to use, as they will now contain the epoch when it is non-zero.

### 30.2.83 Salt 2015.8.8 Release Notes

Version 2015.8.8 is a bugfix release for 2015.8.0.

**Important:** Version 2015.8.8.2 was released shortly after 2015.8.8 to fix several known issues. If you installed 2015.8.8 before 03/30/2016, you likely have installed 2015.8.8 and can optionally upgrade (find out which version you have installed using `salt --version`).

Security Fix

CVE-2016-3176 Insecure configuration of PAM external authentication service

This issue affects all Salt versions prior to 2015.8.8/2015.5.10 when PAM external authentication is enabled. This issue involves passing an alternative PAM authentication service with a command that is sent to LocalClient, enabling the attacker to bypass the configured authentication service. Thank you to Dylan Frese <dmfrese@gmail.com> for bringing this issue to our attention.

This update defines the PAM eAuth service that users authenticate against in the Salt Master configuration.

Read Before Upgrading Debian 7 (Wheezy) from 2015.8.7 to 2015.8.8

Before you upgrade from 2015.8.7 on Debian 7, you must run the following commands to remove previous packages:

```
sudo apt-get remove python-pycrypto
sudo apt-get remove python-apache-libcloud
```

Note that python-pycrypto will likely remove python-apache-libcloud, so the second command might not be necessary. These have been replaced by python-crypto and python-libcloud with ~bpo70+1 moniker.

Read Before Upgrading Debian 8 (Jessie) from Salt Versions Earlier than 2015.8.4

Salt systemd service files are missing the following statement in these versions:

```
[Service]
KillMode=process
```

This statement must be added to successfully upgrade on these earlier versions of Salt.

  - de215bd0cd Merge pull request #30978 from garethgreenaway/30472_state_functions_no_default_retcode
  - e33b5140f6 removing extra spaces.
  - f668c017f7 removing duplicate code, just set the default in the _set_retcode function
  - 5f2f8f60c The functions in the state module that return a retcode when something goes wrong, eg. a 1 or a 2, do not return a 0 when things go the way they’re supposed to go. With the recent changes to the scheduler to ensure that the retcode is returned this is problematic and results in exceptions when a state function is run from the schedule. This simple fix ensures a default retcode of 0 exists, it is then override in the _set_retcode function if there is an issue with the run

30.2.84 Salt 2015.8.8.2 Release Notes

Version 2015.8.2 is a bugfix release for 2015.8.0.

Fixes to 2015.8.8

Salt 2015.8.8.2 includes fixes for the following known issues in 2015.8.8:

- Key master with value [...] has an invalid type of list Error (issue #32044)
- Failed to import module win_dacl Error (issue #32004)
- Wrong validation type for file_ignore_glob key (issue #32114)
- Fix file.managed for windows (issue #31969)

Important: issue #32183 prevents Salt Cloud from installing the Salt minion on new systems. To workaround this issue, call `salt-cloud -u` to update the bootstrap script to the latest version.

Important Post-Upgrade Instructions for Linux Mint

As a result of some upstream changes, the os grain on Mint Linux is now being detected as LinuxMint (issue #33295). Run the following command after you upgrade to 2015.8.9 to reset the os grain to Mint and the os_family grain to Debian:

```bash
salt -G 'os:LinuxMint' grains.setvals "{'os': 'Mint', 'os_family': 'Debian'}"
```

30.2.86 Salt 2015.5.0 Release Notes - Codename Lithium

The 2015.5.0 feature release of Salt is focused on hardening Salt and mostly on improving existing systems. A few major additions are present, primarily the new Beacon system. Most enhancements have been focused around improving existing features and interfaces.

As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.
Warning: In order to fix potential shell injection vulnerabilities in salt modules, a change has been made to the various cmd module functions. These functions now default to `python_shell=False`, which means that the commands will not be sent to an actual shell.

The largest side effect of this change is that "shellisms", such as pipes, will not work by default. The modules shipped with salt have been audited to fix any issues that might have arisen from this change. Additionally, the cmd state module has been unaffected, and use of `cmd.run` in jinja is also unaffected. `cmd.run` calls on the CLI will also allow shellisms.

However, custom execution modules which use shellisms in cmd calls will break, unless you pass `python_shell=True` to these calls.

As a temporary workaround, you can set `cmd_safe: False` in your minion and master configs. This will revert the default, but is also less secure, as it will allow shell injection vulnerabilities to be written in custom code. We recommend you only set this setting for as long as it takes to resolve these issues in your custom code, then remove the override.

Note: Starting in this version of salt, `pillar_opts` defaults to False instead of True. This means that master opts will not be present in minion pillar, and as a result, `config.get` calls will not include master opts.

We recommend pillar is used for configuration options which need to make it to the minion.

Beacons

The beacon system allows the minion to hook into system processes and continually translate external events into the salt event bus. The primary example of this is the `inotify` beacon. This beacon uses inotify to watch configured files or directories on the minion for changes, creation, deletion etc.

This allows for the changes to be sent up to the master where the reactor can respond to changes.

Sudo Minion Settings

It is now possible to run the minion as a non-root user and for the minion to execute commands via sudo. Simply add `sudo_user: root` to the minion config, run the minion as a non-root user and grant that user sudo rights to execute `salt-call`.

Lazy Loader

The Lazy Loader is a significant overhaul of Salt's module loader system. The Lazy Loader will lazily load modules on access instead of all on start. In addition to a major performance improvement, this "sandboxes" modules so a bad/broken import of a single module will only affect jobs that require accessing the broken module. (issue: 20274)
Enhanced Active Directory Support

The eauth system for LDAP has been extended to support Microsoft Active Directory out of the box. This includes Active Directory and LDAP group support for eauth.

Salt LXC Enhancements

The LXC systems have been overhauled to be more consistent and to fix many bugs.
This overhaul makes using LXC with Salt much easier and substantially improves the underlying capabilities of Salt’s LXC integration.

Salt SSH

- Additional configuration options and command line flags have been added to configure the scan roster on the fly
- Added support for state.single in salt-ssh
- Added support for publish.publish, publish.full_data, and publish.runner in salt-ssh
- Added support for mine.get in salt-ssh

New Windows Installer

The new Windows installer changes how Salt is installed on Windows. The old installer used bbfreeze to create an isolated python environment to execute in. This made adding modules and python libraries difficult. The new installer sets up a more flexible python environment making it easy to manage the python install and add python modules.

Instead of frozen packages, a full python implementation resides in the bin directory (C:\salt\bin). By executing pip or easy_install from within the Scripts directory (C:\salt\bin\Scripts) you can install any additional python modules you may need for your custom environment.

The .exe's that once resided at the root of the salt directory (C:\salt) have been replaced by .bat files and should function the same way as the .exe's in previous versions.

The new Windows Installer will not replace the minion config file and key if they already exist on the target system. Only the salt program files will be replaced. C:\salt\conf and C:\salt\var will remain unchanged.

Removed Requests Dependency

The hard dependency on the requests library has been removed. Requests is still required by a number of cloud modules but is no longer required for normal Salt operations.

This removal fixes issues that were introduced with requests and salt-ssh, as well as issues users experienced from the many different packaging methods used by requests package maintainers.
Python 3 Updates

While Salt does not YET run on Python 3 it has been updated to INSTALL on Python 3, taking us one step closer. What remains is getting the test suite to the point where it can run on Python 3 so that we can verify compatibility.

RAET Additions

The RAET support continues to improve. RAET now supports multi-master and many bugs and performance issues have been fixed. RAET is much closer to being a first class citizen.

Modified File Detection

A number of functions have been added to the RPM-based package managers to detect and diff files that are modified from the original package installs. This can be found in the new pkg.modified functions.

Reactor Update

Fix an infinite recursion problem for runner/wheel reactor jobs by passing a "user" (Reactor) to all jobs that the reactor starts. The reactor skips all events created by that username -- thereby only reacting to events not caused by itself. Because of this, runner and wheel executions from the runner will have user "Reactor" in the job cache.

Misc Fixes/Additions

- SDB driver for etcd. (:issue: 22043)
- Add only_upgrade argument to apt-based pkg.install to only install a package version if the package is already installed. (Great for security updates!)
- Joyent now requires a keyname to be specified in the provider configuration. This change was necessitated upstream by the 7.0+ API.
- Add args argument to cmd.script_retcode to match cmd.script in the cmd module. (:issue: 21122)
- Fixed bug where TCP keepalive was not being sent on the defined interval on the return port (4506) from minion to master. (issue: 21465)
- LocalClient may now optionally raise SaltClientError exceptions. If using this class directly, checking for and handling this exception is recommended. (issue: 21501)
- The SAuth object is now a singleton, meaning authentication state is global (per master) on each minion. This reduces sign-ins of minions from 3->1 per startup.
- Nested outputter has been optimized, it is now much faster.
- Extensive filesystem backend updates.
Deprecations

- Removed parameter keyword argument from `eselect.exec_action` execution module.
- Removed `runas` parameter from the following `pip` execution module functions: `install`, `uninstall`, `freeze`, `list_`, `list_upgrades`, `upgrade_available`, `upgrade`. Please migrate to `user`.
- Removed `runas` parameter from the following `pip` state module functions: `installed`, `removed`, `uptodate`. Please migrate to `user`.
- Removed `quiet` option from all functions in `cmdmod` execution module. Please use `output_loglevel=quiet` instead.
- Removed parameter argument from `eselect.set_state`. Please migrate to `module_parameter` or `action_parameter`.
- The `salt_events` table schema has changed to include an additional field called `master_id` to distinguish between events flowing into a database from multiple masters. If `event_return` is enabled in the master config, the database schema must first be updated to add the `master_id` field. This alteration can be accomplished as follows:

  ```sql
  ALTER TABLE salt_events ADD master_id VARCHAR(255) NOT NULL;
  ```

Known Issues

- In multi-master mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting 'auth_timeout' and 'auth_tries' down to shorter periods.

30.2.88 Salt 2015.5.10 Release Notes

release 2015-03-22

Version 2015.5.10 is a bugfix release for 2015.5.0.
Security Fix

CVE-2016-3176 Insecure configuration of PAM external authentication service

This issue affects all Salt versions prior to 2015.8.8/2015.5.10 when PAM external authentication is enabled. This issue involves passing an alternative PAM authentication service with a command that is sent to LocalClient, enabling the attacker to bypass the configured authentication service. Thank you to Dylan Frese <dmfrese@gmail.com> for bringing this issue to our attention.

This update defines the PAM eAuth service that users authenticate against in the Salt Master configuration. No additional fixes are included in this release.

Read Before Upgrading Debian 8 (Jessie) from Salt Versions Earlier than 2015.5.9

Salt systemd service files are missing the following statement in these versions:

```
[Service]
KillMode=process
```

This statement must be added to successfully upgrade on these earlier versions of Salt.

Changelog for v2015.5.9..v2015.5.10

- 69ba1de71d Remove ability of authenticating user to specify pam service

30.2.89 Salt 2015.5.11 Release Notes

**Bug Fixes**

- The cron.present state now correctly defaults to state ID as identifier.

**Salt-Cloud Changes**

- When querying for VMs in the digital_ocean_v2 cloud driver, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.
- The vmware salt-cloud driver was back-ported from the develop branch in order for installations of Salt that are older than 2015.8.0 to be able to use the vmware driver without stack-tracing on various deprecation paths that were implemented in the 2015.8.0 release.

### 30.2.94 Salt 2015.5.6 Release Notes

**release** 2015-10-13

Version 2015.5.6 is a bugfix release for 2015.5.0.

**Statistics**

- Total Merges: 145
- Total Issue References: 71
- Total PR References: 178

- **Contributors**: 53 (Arabus, JensRantil, PierreR, SaltyCharles, TheBigBear, abh, aboe76, anluto, arthurlogilab, asyatkin, basepi, benhosmer, bersace, cachedout, carlpett, damonzheng, derphilipp, dmyerscough, dsumsky, efficks, eguven, garethgreenaway, hexedpackets, jacksontj, jacobhammons, jfindlay, jocjulian, johank, julianbrost, kev009, lorengordon, madprog, marccardinal, netroby, nmadhok, plastikos, rallytime, serge-p, spud-fkc, stanislavb, styro, systembell, tankywoo, techhat, terminalmage, thatch45, tjstansell, twangboy, vakulich, vtek21, whiteinge, zmalone, zyio)

**Security Fixes**

CVE-2015-6941 The Windows user module and salt-cloud display passwords in log when log level is set to debug or more verbose.

For the Windows user module, the password is now replaced with the string XXX-REDACTED-XXX.

For salt-cloud, debug logging no longer displays win_password and sudo_password authentication credentials.

CVE-2015-6918 Git state/execution modules log HTTPS auth credentials when log level is set to debug or more verbose.

These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <asteiger@suse.com> for bringing this to our attention.

Security Fix

CVE-2015-8034 Saving state.sls cache data to disk with insecure permissions

This affects users of the state.sls function. The state run cache on the minion was being created with incorrect permissions. This file could potentially contain sensitive data that was inserted via jinja into the state SLS files. The permissions for this file are now being set correctly. Thanks to zmalone for bringing this issue to our attention.

### 30.2.98 Salt 2014.7.0 Release Notes - Codename Helium

This release is the largest Salt release ever, with more features and commits then any previous release of Salt. Everything from the new RAET transport to major updates in Salt Cloud and the merging of Salt API into the main project.

**Important:** The Fedora/RHEL/CentOS salt-master package has been modified for this release. The following components of Salt have been broken out and placed into their own packages:

- salt-syndic
- salt-cloud
- salt-ssh
When the **salt-master** package is upgraded, these components will be removed, and they will need to be manually installed.

---

**Important**: Compound/pillar matching have been temporarily disabled for the **mine** and **publish** modules for this release due to the possibility of inferring pillar data using pillar glob matching. A proper fix is now in the 2014.7 branch and scheduled for the 2014.7.1 release, and compound matching and non-globbing pillar matching will be re-enabled at that point.

Compound and pillar matching for normal salt commands are unaffected.

---

**New Transport!**

**RAET Transport Option**

This has been a HUGE amount of work, but the beta release of Salt with RAET is ready to go. RAET is a reliable queuing transport system that has been developed in partnership with a number of large enterprises to give Salt an alternative to ZeroMQ and a way to get Salt to scale well beyond tens of thousands of servers. Unlike ZeroMQ, RAET is completely asynchronous in every aspect of its operation and has been developed using the flow programming paradigm. This allows for many new capabilities to be added to Salt in the upcoming releases.

Please keep in mind that this is a beta release of RAET and we hope for bugs to be worked out, performance to be better realized and more in the 2015.5.0 release.

Simply stated, users running Salt with RAET should expect some hiccups as we hammer out the update. This is a BETA release of Salt RAET.

**Salt SSH Enhancements**

Salt SSH has just entered a new league, with substantial updates and improvements to make salt-ssh more reliable and easier then ever! From new features like the ansible roster and fileserver backends to the new pypi salt-ssh installer to lowered deps and a swath of bugfixes, salt-ssh is basically reborn!

**Install salt-ssh Using pip**

Salt-ssh is now pip-installable!

https://pypi.org/project/salt-ssh/

Pip will bring in all of the required deps, and while some deps are compiled, they all include pure python implementations, meaning that any compile errors which may be seen can be safely ignored.

```
pip install salt-ssh
```
Fileserver Backends

Salt-ssh can now use the salt fileserver backend system. This allows for the gitfs, hgfs, s3, and many more ways to centrally store states to be easily used with salt-ssh. This also allows for a distributed team to easily use a centralized source.

Saltfile Support

The new saltfile system makes it easy to have a user specific custom extended configuration.

Ext Pillar

Salt-ssh can now use the external pillar system. Making it easier then ever to use salt-ssh with teams.

No More sshpass

Thanks to the enhancements in the salt vt system, salt-ssh no longer requires sshpass to send passwords to ssh. This also makes the manipulation of ssh calls substantially more flexible, allowing for intercepting ssh calls in a much more fluid way.

Pure Python Shim

The salt-ssh call originally used a shell script to discover what version of python to execute with and determine the state of the ssh code deployment. This shell script has been replaced with a pure python version making it easy to increase the capability of the code deployment without causing platform inconsistency issues with different shell interpreters.

Custom Module Delivery

Custom modules are now seamlessly delivered. This makes the deployment of custom grains, states, execution modules and returners a seamless process.

CP Module Support

Salt-ssh now makes simple file transfers easier then ever! The cp module allows for files to be conveniently sent from the salt fileserver system down to systems.

More Thin Directory Options

Salt ssh functions by copying a subset of the salt code, or salt thin down to the target system. In the past this was always transferred to /tmp/salt and cached there for subsequent commands.

Now, salt thin can be sent to a random directory and removed when the call is complete with the -W option. The new -W option still uses a static location but will clean up that location when finished.

The default salt thin location is now user defined, allowing multiple users to cleanly access the same systems.
State System Enhancements

**New Imperative State Keyword "Listen"**

The new `listen` and `listen_in` keywords allow for completely imperative states by calling the `mod_watch()` routine after all states have run instead of re-ordering the states.

**Mod Aggregate Runtime Manipulator**

The new `mod_aggregate` system allows for the state system to rewrite the state data during execution. This allows for state definitions to be aggregated dynamically at runtime.

The best example is found in the `pkg` state. If `mod_aggregate` is turned on, then when the first `pkg` state is reached, the state system will scan all of the other running states for `pkg` states and take all other packages set for install and install them all at once in the first `pkg` state.

These runtime modifications make it easy to run groups of states together. In future versions, we hope to fill out the `mod_aggregate` system to build in more and more optimizations.

For more documentation on `mod_aggregate`, see the documentation.

**New Requisites: onchanges and onfail**

The new `onchanges` and `onchanges_in` requisites make a state apply only if there are changes in the required state. This is useful to execute post hooks after changes occur on a system.

The other new requisites, `onfail`, and `onfail_in`, allow for a state to run in reaction to the failure of another state.

For more information about these new requisites, see the requisites documentation.

**Global onlyif and unless**

The `onlyif` and `unless` options can now be used for any state declaration.

**Use names to expand and override values**

The `names` declaration in Salt’s state system can now override or add values to the expanded data structure. For example:

```yaml
my_users:
  user.present:
    - names:
      - larry
      - curly
      - moe:
        - shell: /bin/zsh
        - groups:
          - wheel
        - shell: /bin/bash
```
Major Features

Scheduler Additions

The Salt scheduler system has received MAJOR enhancements, allowing for cron-like scheduling and much more granular timing routines. See [here](#) for more info.

Red Hat 7 Family Support

All the needed additions have been made to run Salt on RHEL 7 and derived OSes like CentOS and Scientific.

Fileserver Backends in salt-call

Fileserver backends like gitfs can now be used without a salt master! Just add the fileserver backend configuration to the minion config and execute salt-call. This has been a much-requested feature and we are happy to finally bring it to our users.

Amazon Execution Modules

An entire family of execution modules further enhancing Salt’s Amazon Cloud support. They include the following:

- **Autoscale Groups** (includes state support) -- related: *Launch Control* states
- **Cloud Watch** (includes state support)
- **Elastic Cache** (includes state support)
- **Elastic Load Balancer** (includes state support)
- **IAM Identity and Access Management** (includes state support)
- **Route53 DNS** (includes state support)
- **Security Groups** (includes state support)
- **Simple Queue Service** (includes state support)

LXC Runner Enhancements

BETA The Salt LXC management system has received a number of enhancements which make running an LXC cloud entirely from Salt an easy proposition.

Next Gen Docker Management

The Docker support in Salt has been increased at least ten fold. The Docker API is now completely exposed and Salt ships with Docker data tracking systems which make automating Docker deployments very easy.
Peer System Performance Improvements

The peer system communication routines have been refined to make the peer system substantially faster.

SDB

Encryption at rest for configs

GPG Renderer

Encrypted pillar at rest

OpenStack Expansion

Lots of new OpenStack stuff

Queues System

Ran change external queue systems into Salt events

Multi Master Failover Additions

Connecting to multiple masters is more dynamic then ever

Chef Execution Module

Managing Chef with Salt just got even easier!

salt-api Project Merge

The salt-api project has been merged into Salt core and is now available as part of the regular salt-master package install. No API changes were made, the salt-api script and init scripts remain intact.

salt-api has always provided Yet Another Pluggable Interface to Salt (TM) in the form of "netapi" modules. These are modules that bind to a port and start a service. Like many of Salt’s other module types, netapi modules often have library and configuration dependencies. See the documentation for each module for instructions.

See also:

The full list of netapi modules.
Synchronous and Asynchronous Execution of Runner and Wheel Modules

`salt.runner.RunnerClient` and `salt.wheel.WheelClient` have both gained complimentary `cmd_sync` and `cmd_async` methods allowing for synchronous and asynchronous execution of any Runner or Wheel module function, all protected using Salt's `external authentication` system. `salt-api` benefits from this addition as well.

**rest_cherrypy** Additions

The `rest_cherrypy` netapi module provides the main REST API for Salt.

**Web Hooks**

This release of course includes the Web Hook additions from the most recent `salt-api` release, which allows external services to signal actions within a Salt infrastructure. External services such as Amazon SNS, Travis-CI, or GitHub, as well as internal services that cannot or should not run a Salt minion daemon can be used as first-class components in Salt's rich orchestration capabilities.

The raw HTTP request body is now available in the event data. This is sometimes required information for checking an HMAC signature in order to verify a HTTP request. As an example, Amazon or GitHub requests are signed this way.

**Generating and Accepting Minion Keys**

The `/key` convenience URL generates a public and private key for a minion, automatically pre-accepts the public key on the Salt Master, and returns both keys as a tarball for download.

This allows for easily bootstrapping the key on a new minion with a single HTTP call, such as with a Kickstart script, all using regular shell tools.

```
curl -ss http://salt-api.example.com:8000/keys \
   -d mid=jerry \n   -d username=kickstart \n   -d password=kickstart \n   -d eauth=pam \n   -o jerry-salt-keys.tar
```

**Fileserver Backend Enhancements**

All of the fileserver backends have been overhauled to be faster, lighter, and more reliable. The VCS backends (`gitfs`, `hgfs`, and `svnfs`) have also received a lot of new features.

Additionally, most config parameters for the VCS backends can now be configured on a per-remote basis, allowing for global config parameters to be overridden for a specific `gitfs/hgfs/svnfs` remote.
New **gitfs** Features

**Pygit2 and Dulwich**

In addition to supporting GitPython, support for **pygit2** (0.20.3 and newer) and **dulwich** have been added. Provided a compatible version of **pygit2** is installed, it will now be the default provider. The config parameter **gitfs_provider** has been added to allow one to choose a specific provider for gitfs.

**Mountpoints**

Prior to this release, to serve a file from gitfs at a salt fileserver URL of `salt://foo/bar/baz.txt`, it was necessary to ensure that the parent directories existed in the repository. A new config parameter **gitfs_mountpoint** allows gitfs remotes to be exposed starting at a user-defined `salt://` URL.

**Environment Whitelisting/Blacklisting**

By default, gitfs will expose all branches and tags as Salt fileserver environments. Two new config parameters, **gitfs_env_whitelist** and **gitfs_env_blacklist**, allow more control over which branches and tags are exposed. More detailed information on how these two options work can be found in the **Gitfs Walkthrough**.

**Expanded Authentication Support**

As of **pygit2** 0.20.3, both http(s) and SSH key authentication are supported, and Salt now also supports both authentication methods when using **pygit2**. Keep in mind that **pygit2** 0.20.3 is not yet available on many platforms, so those who had been using authenticated git repositories with a passphraseless key should stick to GitPython if a new enough **pygit2** is not yet available for the platform on which the master is running.

A full explanation of how to use authentication can be found in the **Gitfs Walkthrough**.

New **hgfs** Features

**Mountpoints**

This feature works exactly like its **gitfs counterpart**. The new config parameter is called **hgfs_mountpoint**.

**Environment Whitelisting/Blacklisting**

This feature works exactly like its **gitfs counterpart**. The new config parameters are called **hgfs_env_whitelist** and **hgfs_env_blacklist**.
New **svnfs** Features

Mountpoints

This feature works exactly like its **gitfs** counterpart. The new config parameter is called **svnfs_mountpoint**.

Environment Whitelisting/Blacklisting

This feature works exactly like its **gitfs** counterpart. The new config parameters are called **svnfs_env_whitelist** and **svnfs_env_blacklist**.

Configurable Trunk/Branches/Tags Paths

Prior to this release, the paths where trunk, branches, and tags were located could only be in directories named "trunk", "branches", and "tags" directly under the root of the repository. Three new config parameters (**svnfs_trunk**, **svnfs_branches**, and **svnfs_tags**) allow SVN repositories which are laid out differently to be used with svnfs.

New **minionfs** Features

Mountpoint

This feature works exactly like its **gitfs** counterpart. The new config parameter is called **minionfs_mountpoint**. The one major difference is that, as minionfs doesn’t use multiple remotes (it just serves up files pushed to the master using `cp.push`) there is no such thing as a per-remote configuration for **minionfs_mountpoint**.

Changing the Saltenv from Which Files are Served

A new config parameter (**minionfs_env**) allows minionfs files to be served from a Salt fileserver environment other than **base**.

Minion Whitelisting/Blacklisting

By default, minionfs will expose the pushed files from all minions. Two new config parameters, **minionfs_whitelist**, and **minionfs_blacklist**, allow minionfs to be restricted to serve files from only the desired minions.

Pyobjects Renderer

Salt now ships with with the **Pyobjects Renderer** that allows for construction of States using pure Python with an idiomatic object interface.
New Modules

In addition to the Amazon modules mentioned above, there are also several other new execution modules:

- Oracle
- Random
- Redis
- Amazon Simple Queue Service
- Block Device Management
- CoreOS etcd
- Genesis
- InfluxDB
- Server Density
- Twilio Notifications
- Varnish
- ZNC IRC Bouncer
- SMTP

New Runners

- Map/Reduce Style
- Queue

New External Pillars

- CoreOS etcd

New Salt-Cloud Providers

- Aliyun ECS Cloud
- LXC Containers

### 30.2.99 Salt 2014.7.1 Release Notes

**release** 2015-01-12

Version 2014.7.1 is a bugfix release for 2014.7.0.

The changes include:

- Fixed gitfs serving symlinks in `file.recurse` states ([issue #17700](issue #17700))
- Fixed holding of multiple packages (YUM) when combined with version pinning ([issue #18468](issue #18468))
- Fixed use of Jinja templates in masterless mode with non-roots fileserver backend ([issue #17963](issue #17963))
- Re-enabled pillar and compound matching for mine and publish calls. Note that pillar globbing is still disabled for those modes, for security reasons. ([issue #17194](issue #17194))
- Fix for `tty: True` in `salt-ssh` ([issue #16847](issue #16847))
- Fix for supervisor states when supervisor not installed to system python ([issue #18044](issue #18044))
- Fix for logging when `log_level='quiet'` for `cmd.run` ([issue #19479](issue #19479))

### 30.2.100 Salt 2014.7.2 Release Notes

**release** 2015-02-09

Version 2014.7.2 is a bugfix release for 2014.7.0.

The changes include:

- Fix erroneous warnings for systemd service enabled check ([issue #19606](issue #19606))
- Fix FreeBSD kernel module loading, listing, and persistence `kmod` ([issue #197151](issue #197151), [issue #19682](issue #19682))

### 30.2. Previous Releases
• Allow case-sensitive npm package names in the `npm state`. This may break behavior for people expecting the state to lowercase their npm package names for them. The `npm module` was never affected by mandatory lowercasing. ([issue #20329](https://gitlab.com/saltstack/salt/issues/20329))

• Deprecate the `activate` parameter for `pip.install` for both the module and the state. If `bin_env` is given and points to a virtualenv, there is no need to activate that virtualenv in a shell for `pip` to install to the virtualenv.

• Fix a file-locking bug in `gitfs` ([issue #18839](https://gitlab.com/saltstack/salt/issues/18839))

• Deprecated `archive_user` in favor of standardized `user` parameter in `state` and added `group` parameter.

### 30.2.101 Salt 2014.7.3 Release Notes

**release** 2015-03-25

Version 2014.7.3 is a bugfix release for 2014.7.0.

Changes:

• Multi-master minions mode no longer route fileclient operations asymetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.

• Fix bug wherein `network.iface` could produce stack traces.

• `net.arp` will no longer be made available unless `arp` is installed on the system.

• Major performance improvements to Saltnado

• Allow KVM module to operate under KVM itself or VMware Fusion

• Various fixes to the Windows installation scripts

• Fix issue where the syndic would not correctly propagate loads to the master job cache.

• Improve error handling on invalid `/etc/network/interfaces` file in salt networking modules

• Fix bug where a response status was not checked for in `fileclient.get_url`

• Enable eauth when running salt in batch mode

• Increase timeout in Boto Route53 module

• Fix bugs with Salt's 'tar' module option parsing

• Fix parsing of NTP servers on Windows

• Fix issue with blockdev tuning not reporting changes correctly

• Update to the latest Salt bootstrap script

• Update Linode salt-cloud driver to use either linode-python or apache-libcloud

• Fix for `s3.query` function to return correct headers

• Fix for `s3.head` returning `None` for files that exist

• Fix the `disable` function in `win_service` module so that the service is disabled correctly

• Fix race condition between master and minion when making a directory when both daemons are on the same host

• Fix an issue where `file.recurse` would fail at the root of an `svn` repo when the repo has a mountpoint

• Fix an issue where `file.recurse` would fail at the root of an `hgfs` repo when the repo has a mountpoint
• Fix an issue where file.recurse would fail at the root of an gitfs repo when the repo has a mountpoint
• Add status.master capability for Windows.
• Various fixes to ssh_known_hosts
• Various fixes to states.network bonding for Debian
• The debian_ip.get_interfaces module no longer removes nameservers.
• Better integration between grains.virtual and systemd-detect-virt and virt-what
• Fix traceback in sysctl.present state output
• Fix for issue where mount.mounted would fail when superopts were not a part of mount.active (extended=True). Also mount.mounted various fixes for Solaris and FreeBSD.
• Fix error where datetimes were not correctly safeguarded before being passed into msgpack.
• Fix file.replace regressions. If the pattern is not found, and if dry run is False, and if backup is False, and if a pre-existing file exists with extension .bak, then that backup file will be overwritten. This backup behavior is a result of how fileinput works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting file.replace so it doesn’t use fileinput
• VCS filreserver fixes/optimizations
• Catch fileserver configuration errors on master start
• Raise errors on invalid gitfs configurations
• set_locale when locale file does not exist (Redhat family)
• Fix to correctly count active devices when created mdadm array with spares
• Fix to correctly target minions in batch mode
• Support ssh:// urls using the gitfs dulwhich backend
• New fileserver runner
• Fix various bugs with argument parsing to the publish module.
• Fix disk.usage for Synology OS
• Fix issue with tags occurring twice with docker.pulled
• Fix incorrect key error in SMTP returner
• Fix condition which would remount loopback filesystems on every state run
• Remove requisites from listens after they are called in the state system
• Make system implementation of service.running aware of legacy service calls
• Fix issue where publish.publish would not handle duplicate responses gracefully.
• Accept Kali Linux for aptpkg salt execution module
• Fix bug where cmd.which could not handle a dirname as an argument
• Fix issue in ps.pgrep where exceptions were thrown on Windows.

Known issues:

• In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting `auth_timeout` and `auth_tries` down to shorter periods.
30.2.102 Salt 2014.7.4 Release Notes

release 2015-03-30

Version 2014.7.4 is a bugfix release for 2014.7.0.

This is a security release. The security issues fixed have only been present since 2014.7.0, and only users of the two listed modules are vulnerable. The following CVEs have been resolved:

- CVE-2015-1838 SaltStack: insecure /tmp file handling in salt/modules/serverdensity_device.py
- CVE-2015-1839 SaltStack: insecure /tmp file handling in salt/modules/chef.py

Changes:

- Multi-master minions mode no longer route fileclient operations asymmetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.
- Fix bug wherein network.iface could produce stack traces.
- net.arp will no longer be made available unless arp is installed on the system.
- Major performance improvements to SaltNado
- Allow KVM module to operate under KVM itself or VMware Fusion
- Various fixes to the Windows installation scripts
- Fix issue where the syndic would not correctly propagate loads to the master job cache.
- Improve error handling on invalid /etc/network/interfaces file in salt networking modules

This backup behavior is a result of how fileinput works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting file.replace so it doesn’t use fileinput

• VCS filreserver fixes/optimizations

• Catch fileserserver configuration errors on master start

• Raise errors on invalid gitfs configurations

• set_locale when locale file does not exist (Redhat family)

• Fix to correctly count active devices when created mdadm array with spares

• Fix to correctly target minions in batch mode

• Support ssh:// urls using the gitfs dulwich backend

• New fileserserver runner

• Fix various bugs with argument parsing to the publish module.

• Fix disk.usage for Synology OS

• Fix issue with tags occurring twice with docker.pulled

• Fix incorrect key error in SMTP returner

Known issues:

• In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting 'auth_timeout' and 'auth_tries' down to shorter periods.

• There are known issues with batch mode operating on the incorrect number of minions. This bug can be patched with the change in Pull Request #22464.

• The fun, state, and unless keywords are missing from the state internals, which can cause problems running some states. This bug can be patched with the change in Pull Request #22365.
30.2.103 Salt 2014.7.5 Release Notes

release 2015-04-16

Version 2014.7.5 is a bugfix release for 2014.7.0.

Changes:

- Fixed a key error bug in salt-cloud
- Updated man pages to better match documentation
- Fixed bug concerning high CPU usage with salt-ssh
- Fixed bugs with remounting cvfs and fuse filesystems
- Fixed bug with alowing requisite tracking of entire sls files
- Fixed bug with aptpkg.mod_repo returning OK even if apt-add-repository fails
- Increased frequency of ssh terminal output checking
- Fixed malformed locale string in localmod module
- Fixed checking of available version of package when accept_keywords were changed
- Fixed bug to make git.latest work with empty repositories
- Added **kwargs to service.mod_watch which removes warnings about enable and __reqs__ not being supported by the function
- Improved state comments to not grow so quickly on failed requisites
- Added force argument to service to trigger force_reload
- Fixed bug to andle pkgrepo keyids that have been converted to int
- Fixed module.portage_config bug with appending accept_keywords
- Fixed bug to correctly report disk usage on windows minion
- Added the ability to specify key prefix for S3 ext_pillar
- Fixed issues with batch mode operating on the incorrect number of minions
- Fixed a bug with the proxmox cloud provider stacktracing on disk definition
- Fixed a bug with the changes dictionary in the file state
- Fixed the TCP keep alive settings to work better with SREQ caching
- Fixed many bugs within the iptables state and module
- Fixed bug with states by adding fun, state, and unless to the state runtime internal keywords listing
- Added ability to eAuth against Active Directory
- Fixed some salt-ssh issues when running on Fedora 21
- Fixed grains.get_or_set_hash to work with multiple entries under same key
- Added better explanations and more examples of how the Reactor calls functions to docs
- Fixed bug to not pass ex_config_drive to libcloud unless it's explicitly enabled
- Fixed bug with pip.install on windows
- Fixed bug where puppet.run always returns a 0 retcode
- Fixed race condition bug with minion scheduling via pillar
• Made efficiency improvements and bug fixes to the windows installer
• Updated environment variables to fix bug with pygit2 when running salt as non-root user
• Fixed cas behavior on data module -- data.cas was not saving changes
• Fixed GPG rendering error
• Fixed strace error in virt.query
• Fixed stacktrace when running chef-solo command
• Fixed possible bug wherein uncaught exceptions seem to make zmq3 tip over when threading is involved
• Fixed argument passing to the reactor
• Fixed glibc caching to prevent bug where salt-minion getaddrinfo in dns_check() never got updated name-servers

Known issues:
• In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting 'auth_timeout' and 'auth_tries' down to shorter periods.

30.2.104 Salt 2014.7.6 Release Notes

Security Fix

CVE-2015-4017 Certificates are not verified when connecting to server in the Aliyun and Proxmox modules

Only users of the Aliyun or Proxmox cloud modules are at risk. The vulnerability does not exist in the latest 2015.5.0 release of Salt.

  - d7f0db1dd8 updated version number to not reference a specific build from the latest branch

- **ISSUE #29295**: (douardda) systemd's service file should use the 'process' KillMode option on Debian also (refs: #29296)

- **PR #29296**: (douardda) Use process KillMode on Debian systems also @ 2015-12-01 16:00:16 UTC
  - d2fb2109a3 Merge pull request #29296 from douardda/patch-3
  - d2885390f4 Use process KillMode on Debian systems also

### 30.2.108 Salt 2014.1.0 Release Notes - Codename Hydrogen

**Note**: Due to a change in master to minion communication, 2014.1.0 minions are not compatible with older-version masters. Please upgrade masters first. More info on backwards-compatibility policy [here](#), under the "Upgrading Salt" subheading.

**Note**: A change in the grammar in the state compiler makes `module.run` in requisites illegal syntax. Its use is replaced simply with the word `module`. In other words you will need to change requisites like this:

```
require:
  module.run: some_module_name
```

to:

```
require:
  module: some_module_name
```

This is a breaking change. We apologize for the inconvenience, we needed to do this to remove some ambiguity in parsing requisites.

**release** 2014-02-24

The 2014.1.0 release of Salt is a major release which not only increases stability but also brings new capabilities in virtualization, cloud integration, and more. This release brings a great focus on the expansion of testing making roughly double the coverage in the Salt tests, and comes with many new features.

2014.1.0 is the first release to follow the new date-based release naming system. See the version numbers page for more details.
Major Features

Salt Cloud Merged into Salt

Salt Cloud is a tool for provisioning salted minions across various cloud providers. Prior to this release, Salt Cloud was a separate project but this marks its full integration with the Salt distribution. A Getting Started guide and additional documentation for Salt Cloud can be found [here](#).

Google Compute Engine

Alongside Salt Cloud comes new support for the Google Compute Engine. Salt Stack can now deploy and control GCE virtual machines and the application stacks that they run.

For more information on Salt Stack and GCE, please see [this blog post](#).

Documentation for Salt and GCE can be found [here](#).

Salt Virt

Salt Virt is a cloud controller that supports virtual machine deployment, inspection, migration, and integration with many aspects of Salt.

Salt Virt has undergone a major overhaul with this release and now supports many more features and includes a number of critical improvements.

Docker Integration

Salt now ships with states and an execution module to manage Docker containers.

Substantial Testing Expansion

Salt continues to increase its unit/regression test coverage. This release includes over 300 new tests.

BSD Package Management

BSD package management has been entirely rewritten. FreeBSD 9 and older now default to using pkg_add, while FreeBSD 10 and newer will use pkgng. FreeBSD 9 can be forced to use pkgng, however, by specifying the following option in the minion config file:

```
providers:
  pkg: pkgng
```

In addition, support for installing software from the ports tree has been added. See the documentation for the ports state and execution module for more information.
Network Management for Debian/Ubuntu

Initial support for management of network interfaces on Debian-based distros has been added. See the documentation for the `network state` and the `debian_ip` for more information.

IPv6 Support for iptables State/Module

The `iptables state` and `module` now have IPv6 support. A new parameter `family` has been added to the states and execution functions, to distinguish between IPv4 and IPv6. The default value for this parameter is `ipv4`, specifying `ipv6` will use `ip6tables` to manage firewall rules.

GitFS Improvements

Several performance improvements have been made to the `Git fileserver backend`. Additionally, file states can now use any SHA1 commit hash as a fileserver environment:

```
/etc/httpd/httpd.conf:
  file.managed:
    - source: salt://webserver/files/httpd.conf
    - saltenv: 45af879
```

This applies to the functions in the `cp module` as well:

```
salt '*' cp.get_file salt://readme.txt /tmp/readme.txt saltenv=45af879
```

MinionFS

This new fileserver backend allows files which have been pushed from the minion to the master (using `cp.push`) to be served up from the salt fileserver. The path for these files takes the following format:

```
salt://minion-id/path/to/file
```

`minion-id` is the id of the "source" minion, the one from which the files were pushed to the master. `/path/to/file` is the full path of the file.

The `MinionFS Walkthrough` contains a more thorough example of how to use this backend.

`saltenv`

To distinguish between fileserver environments and execution functions which deal with environment variables, fileserver environments are now specified using the `saltenv` parameter. `env` will continue to work, but is deprecated and will be removed in a future release.
Grains Caching

A caching layer has been added to the Grains system, which can help speed up minion startup. Disabled by default, it can be enabled by setting the minion config option `grains_cache`:

```
grains_cache: True
# Seconds before grains cache is considered to be stale.
grains_cache_expiration: 300
```

If set to `True`, the grains loader will read from/write to a msgpack-serialized file containing the grains data.

Additional command-line parameters have been added to salt-call, mainly for testing purposes:

- `--skip-grains` will completely bypass the grains loader when salt-call is invoked.
- `--refresh-grains-cache` will force the grains loader to bypass the grains cache and refresh the grains, writing a new grains cache file.

Improved Command Logging Control

When using the `cmd` module, either on the CLI or when developing Salt execution modules, a new keyword argument `output_loglevel` allows for greater control over how (or even if) the command and its output are logged. For example:

```
salt '*' cmd.run 'tail /var/log/messages' output_loglevel=debug
```

The package management modules (`apt`, `yum` etc.) have been updated to log the copious output generated from these commands at loglevel `debug`.

**Note:** To keep a command from being logged, `output_loglevel=quiet` can be used.

Prior to this release, this could be done using `quiet=True`. This argument is still supported, but will be removed in a future Salt release.

PagerDuty Support

Initial support for firing events via PagerDuty has been added. See the documentation for the `pagerduty` module.

Virtual Terminal

Sometimes the subprocess module is not good enough, and, in fact, not even `askpass` is. This virtual terminal is still in its infant childhood, needs quite some love, and was originally created to replace `askpass`, but, while developing it, it immediately proved that it could do so much more. It's currently used by salt-cloud when bootstrapping salt on clouds which require the use of a password.
Proxy Minions

Initial basic support for Proxy Minions is in this release. Documentation can be found here.

Proxy minions are a developing feature in Salt that enables control of devices that cannot run a minion. Examples include network gear like switches and routers that run a proprietary OS but offer an API, or “dumb” devices that just don’t have the horsepower or ability to handle a Python VM.

Proxy minions can be difficult to write, so a simple REST-based example proxy is included. A Python bottle-based webserver can be found at https://github.com/cro/salt-proxy-rest as an endpoint for this proxy.

This is an ALPHA-quality feature. There are a number of issues with it currently, mostly centering around process control, logging, and inability to work in a masterless configuration.

Additional Bugfixes (Release Candidate Period)

Below are many of the fixes that were implemented in salt during the release candidate phase.

- Fix mount.mounted leaving conflicting entries in fstab (issue #7079)
- Fix mysql returner serialization to use json (issue #9590)
- Fix ZMQError: Operation cannot be accomplished in current state errors (issue #6306)
- Rbenv and ruby improvements
- Fix quoting issues with mysql port (issue #9568)
- Update mount module/state to support multiple swap partitions (issue #9520)
- Fix archive state to work with bsdtar
- Clarify logs for minion ID caching
- Add numeric revision support to git state (issue #9718)
- Update master_uri with master_ip (issue #9694)
- Add comment to Debian mod_repo (issue #9923)
- Fix potential undefined loop variable in rabbitmq state (issue #8703)
- Fix for salt-virt runner to delete key on VM deletion
- Fix for salt-run -d to limit results to specific runner or function (issue #9975)
- Add backtracks to jinja renderer when applicable (issue #10010)
- Fix parsing in monit module (issue #10041)
- Fix highstate output from syndic minions (issue #9732)
- Quiet logging when dealing with passwords/hashes (issue #10000)
- Fix for multiple remotes in git_pillar (issue #9932)
- Fix npm installed command (issue #10109)
- Add safeguards for utf8 errors in zcbuildout module
- Fix compound commands (issue #9746)
- Add systemd notification when master is started
- Many doc improvements
30.2.109 Salt 2014.1.1 Release Notes

release  2014-03-18

Version 2014.1.1 is a bugfix release for 2014.1.0. The changes include:

- Various doc fixes, including up-to-date Salt Cloud installation documentation.
- Renamed state.sls runner to state.orchestrate, to reduce confusion with the state.sls execution function
- Fix various bugs in the dig module (issue #10367)
- Add retry for query on certain EC2 status codes (issue #10154)
- Fix various bugs in mongodb_user state module (issue #10430)
- Fix permissions on ~/.salt_token (issue #10422)
- Add PyObjects support
- Fix launchctl module crash with missing files
- Fix saltutil.find_job for Windows (issue #10581)
- Fix OS detection for OpenSolaris (issue #10601)
- Fix broken salt-ssh key_deploy
- Add support for multiline cron comments (issue #10721)
- Fix timezone module for Arch (issue #10789)
- Fix symlink support for file.recurse (issue #10809)
- Fix multi-master bugs (issue #10732 and issue #10969)
- Fix file.patch to error when source file is unavailable (issue #10380)
- Fix pkg to handle packages set as purge in pkg.installed (issue #10719)
- Add zmqversion grain
- Fix highstate summary for masterless minions (issue #10945)
- Fix saltutil.find_job for 2014.1 masters talking to 0.17 minions (issue #11020)
- Fix file.recurse states with trailing slashes in source (issue #11002)
- Fix pkg states to allow pkgname.x86_64 (issue #7306)
- Make iptables states set a default table for flush (issue #11037)
- Added iptables --reject-with after final iptables call in iptables states (issue:10757)
- Fix improper passing of "family" in iptables states (issue #10774)
- Fix traceback in iptables.insert states (issue #10988)
- Fix zombie processes (issue #10867 and others)
- Fix batch mode to obey --return settings (issue #9146)
- Fix localclient issue that was causing batch mode breakage (issue #11094, issue #10470, and others)
- Multiple salt-ssh fixes
- FreeBSD: look in /usr/local/etc/salt for configuration by default, if installed using pip --editable.
- Add a skip_suggestions parameter to pkg.installed states which allows pre-flight check to be skipped (issue #11106)
• Fixed tag-based gitfs fileserver environments regression (issue #10956)
• Yum: fix cache of available pkgs not cleared when repos are changed (issue #11001)
• Yum: fix for plugin-provided repositories (i.e. RHN/Spacewalk) (issue #11145)
• Fix regression in chocolatey.bootstrap (issue #10541)
• Fix fail on unknown target in jobs runner (issue #11151)
• Don’t log errors for commands which are expected to sometimes exit with non-zero exit status (issue #11154, issue #11090)
• Fix test=True CLI override of config option (issue #10877)
• Log sysctl key listing at loglevel TRACE (issue #10931)

30.2.110 Salt 2014.1.10 Release Notes

release 2014-08-01

Note: Version 2014.1.9 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.9.

Version 2014.1.10 is another bugfix release for 2014.1.0. Changes include:
• Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
• Use the bootstrap script distributed with Salt instead of relying on an external resource
• Remove unused testing code
• Ensure salt states are placed into the .salt directory in salt-ssh
• Use a randomized path for temporary files in a salt-cloud deployment
• Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

Salt 2014.1.10 fixes security issues documented by CVE-2014-3563: "Insecure tmp-file creation in seed.py, salt-ssh, and salt-cloud." Upgrading is recommended.

30.2.111 Salt 2014.1.11 Release Notes

release 2014-08-29

Version 2014.1.11 is another bugfix release for 2014.1.0. Changes include:
• Fix for minion_id with byte-order mark (BOM) (issue #12296)
• Fix runas deprecation in at module
• Fix trailing slash behavior for file.makedirs_ (issue #14019)
• Fix chocolatey path (issue #13870)
• Fix git_pillar infinite loop issues (issue #14671)
• Fix json outputter null case
• Fix for minion error if one of multiple masters are down (issue #14099)
30.2.112 Salt 2014.1.12 Release Notes

release 2014-10-08

Version 2014.1.12 is another bugfix release for 2014.1.0. Changes include:

• Fix scp_file always failing (which broke salt-cloud) (issue #16437)
• Fix regression in pillar in masterless (issue #16210, issue #16416, issue #16428)

30.2.113 Salt 2014.1.13 Release Notes

release 2014-10-14

Version 2014.1.13 is another bugfix release for 2014.1.0. Changes include:

• Fix sftp_file by checking the exit status code of scp (which broke salt-cloud) (issue #16599)

30.2.114 Salt 2014.1.2 Release Notes

release 2014-04-15

Version 2014.1.2 is another bugfix release for 2014.1.0. The changes include:

• Fix username detection when su'ed to root on FreeBSD (issue #11628)
• Fix minionfs backend for file.recurse states
• Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS (issue #11822)
• Fix bug with specifying alternate home dir on user creation (FreeBSD) (issue #11790)
• Don’t reload site module on module refresh for MacOS
• Fix regression with running execution functions in Pillar SLS (issue #11453)
• Fix some modules missing from Windows installer
• Don’t log an error for yum commands that return nonzero exit status on non-failure (issue #11645)
• Fix bug in rabbitmq state (issue #8703)
• Fix missing ssh config options (issue #10604)
• Fix top.sls ordering (issue #10810 and issue #11691)
• Fix salt-key --list all (issue #10982)
• Fix win_servermanager install/remove function (issue #11038)
• Fix interaction with tokens when running commands as root (issue #11223)
• Fix overstate bug with find_job and **kwargs (issue #10503)
• Fix saltenv for aptpkg.mod_repo from pkgrepo state
• Fix environment issue causing file caching problems (issue #11189)
• Fix bug in __parse_key in registry state (issue #11408)
• Add minion auth retry on rejection (issue #10763)
• Fix publish_session updating the encryption key (issue #11493)
• Fix for bad AssertionError raised by GitPython (issue #11473)
• Fix debian_ip to allow disabling and enabling networking on Ubuntu (issue #11164)
• Fix potential memory leak caused by saved (and unused) events (issue #11582)
• Fix exception handling in the MySQL module (issue #11616)
• Fix environment-related error (issue #11534)
• Include psutil on Windows
• Add file.replace and file.search to Windows (issue #11471)
• Add additional file module helpers to Windows (issue #11235)
• Add pid to netstat output on Windows (issue #10782)
• Fix Windows not caching new versions of installers in winrepo (issue #10597)
• Fix hardcoded md5 hashing
• Fix kwargs in salt-ssh (issue #11609)
• Fix file backup timestamps (issue #11745)
• Fix stacktrace on sys.doc with invalid eauth (issue #11293)
• Fix git.latest with test=True (issue #11595)
• Fix file.check_perms hardcoded follow_symlinks (issue #11387)
• Fix certain pkg states for RHEL5/Cent5 machines (issue #11719)

30.2.115 Salt 2014.1.3 Release Notes

release 2014-04-15

Version 2014.1.3 is another bugfix release for 2014.1.0. It was created as a hotfix for a regression found in 2014.1.2, which was not distributed. The only change made was as follows:

• Fix regression that caused saltutil.find_job to fail, causing premature terminations of salt CLI commands.

Changes in the not-distributed 2014.1.2, also included in 2014.1.3:

• Fix username detection when su’ed to root on FreeBSD (issue #11628)
• Fix minionfs backend for file.recurse states
• Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS (issue #11822)
• Fix bug with specifying alternate home dir on user creation (FreeBSD) (issue #11790)
• Don’t reload site module on module refresh for MacOS
• Fix regression with running execution functions in Pillar SLS (issue #11453)
• Fix some modules missing from Windows installer
• Don’t log an error for yum commands that return nonzero exit status on non-failure (issue #11645)
• Fix bug in rabbitmq state (issue #8703)
• Fix missing ssh config options (issue #10604)
• Fix top.sls ordering (issue #10810 and issue #11691)
• Fix salt-key --list all (issue #10982)
• Fix win_servermanager install/remove function (issue #11038)
• Fix interaction with tokens when running commands as root (issue #11223)
• Fix overstate bug with find_job and **kwargs (issue #10503)
• Fix saltenv for aptpkgs.mod_repo from pkgrepo state
• Fix environment issue causing file caching problems (issue #11189)
• Fix bug in __parse_key in registry state (issue #11408)
• Add minion auth retry on rejection (issue #10763)
• Fix publish_session updating the encryption key (issue #11493)
• Fix for bad AssertionError raised by GitPython (issue #11473)
• Fix debian_ip to allow disabling and enabling networking on Ubuntu (issue #11164)
• Fix potential memory leak caused by saved (and unused) events (issue #11582)
• Fix exception handling in the MySQL module (issue #11616)
• Fix environment-related error (issue #11534)
• Include psutil on Windows
• Add file.replace and file.search to Windows (issue #11471)
• Add additional file module helpers to Windows (issue #11235)
• Add pid to netstat output on Windows (issue #10782)
• Fix Windows not caching new versions of installers in winrepo (issue #10597)
• Fix hardcoded md5 hashing
• Fix kwargs in salt-ssh (issue #11609)
• Fix file backup timestamps (issue #11745)
• Fix stacktrace on sys.doc with invalid eauth (issue #11293)
• Fix git.latest with test=True (issue #11595)
• Fix file.check_perms hardcoded follow_symlinks (issue #11387)
• Fix certain pkg states for RHEL5/Cent5 machines (issue #11719)

30.2.116 Salt 2014.1.4 Release Notes

release 2014-05-05

Version 2014.1.4 is another bugfix release for 2014.1.0. Changes include:

• Fix setup.py dependency issue (issue #12031)
• Fix handling for IOErrors under certain circumstances (issue #11783 and issue #11853)
• Fix fatal exception when /proc/1/cgroup is not readable (issue #11619)
• Fix os grains for OpenSolaris (issue #11907)
• Fix lvs.zero module argument pass-through (issue #9001)
• Fix bug in debian_ip interaction with network.system state (issue #11164)
• Remove bad binary package verification code (issue #12177)
• Fix traceback in solaris package installation (issue #12237)
• Fix file.directory state symlink handling (issue #12209)
• Remove external_ip grain
• Fix file.managed mkmkdirs issues (issue #10446)
• Fix hang on non-existent Windows drive letter for file module (issue #9880)
• Fix salt minion caching all users on the server (issue #9743)
• Add strftime formatting for ps.boot_time (issue #12428)

30.2.117 Salt 2014.1.5 Release Notes

release 2014-06-11

Version 2014.1.5 is another bugfix release for 2014.1.0. Changes include:
• Add function for finding cached job on the minion
• Fix iptables save file location for Debian (issue #11730)
• Fix for minion caching jobs when master is down
• Bump default syndic_wait to 5 to fix syndic-related problems (issue #12262)
• Add OpenBSD, FreeBSD, and NetBSD support for network.netstat (issue #12121)
• Fix false positive error in logs for makeconf state (issue #9762)
• Fix for yum fromrepo package installs when repo is disabled by default (issue #12466)
• Fix for extra blank lines in file.blockreplace (issue #12422)
• Fix grain detection for OpenVZ guests (issue #11877)
• Fix get_dns_servers function for Windows win_dns_client
• Use system locale for ports package installations
• Use correct stop/restart procedure for Debian networking in debian_ip (issue #12614)
• Fix for cmd_iter/cmd_iter_no_block blocking issues (issue #12617)
• Fix traceback when syncing custom types (issue #12883)
• Fix cleaning directory symlinks in file.directory
• Add performance optimizations for saltutil.sync_all and state.highstate
• Fix possible error in saltutil.running
• Fix for kmod modules with dashes (issue #13239)
• Fix possible race condition for Windows minions in state module reloading (issue #12370)
• Fix bug with roster for passwd option that is loaded as a non-string object (issue #13249)
• Keep duplicate version numbers from showing up in pkg.list_pks output
• Fixes for Jinja renderer, timezone module/state (issue #12724)
• Fix timedatectl parsing for systemd>=210 (issue #12728)
• Fix saltenv being written to YUM repo config files (issue #12887)
• Removed the deprecated external nodes classifier (originally accessible by setting a value for external_nodes in the master configuration file). Note that this functionality has been marked deprecated for some time and was replaced by the more general master tops system.
- More robust escaping of ldap filter strings.
- Fix trailing slash in `gitfs_root` causing files not to be available (issue #13185)

### 30.2.118 Salt 2014.1.6 Release Notes

**release** 2014-07-08

Version 2014.1.6 is another bugfix release for 2014.1.0. Changes include:

- Fix extra `iptables --help` output (Sorry!) (issue #13648, issue #13507, issue #13527, issue #13607)
- Fix `mount.active` for Solaris
- Fix support for `allow-hotplug` statement in `debian_ip` network module
- Add `sqlite3` to esky builds
- Fix `jobs.active` output (issue #9526)
- Fix the `virtual` grain for Xen (issue #13534)
- Fix `_ext_nodes` unavailable on master (issue #13535)
- Fix eauth for batch mode (issue #9605)
- Fix force-related issues with `tomcat` support (issue #12889)
- Fix `salt-minion` restart loop in Windows (issue #12086)
- Fix detection of `service` virtual module on Fedora minions
- Fix traceback with missing `ipv4` grain (issue #13838)
- Fix issue in roots backend with invalid data in `mtime_map` (issue #13836)
- Fix traceback in `jobs.active` (issue #11151)
- Fix `master_tops` and `_ext_nodes` issue (issue #13535, issue #13673)

### 30.2.119 Salt 2014.1.7 Release Notes

**release** 2014-07-09

Version 2014.1.7 is another bugfix release for 2014.1.0. Changes include:

- Fix batch mode regression (issue #14046)

This release was a hotfix release for the regression listed above which was present in the 2014.1.6 release. The changes included in 2014.1.6 are listed below:

- Fix extra `iptables --help` output (Sorry!) (issue #13648, issue #13507, issue #13527, issue #13607)
- Fix `mount.active` for Solaris
- Fix support for `allow-hotplug` statement in `debian_ip` network module
- Add `sqlite3` to esky builds
- Fix `jobs.active` output (issue #9526)
- Fix the `virtual` grain for Xen (issue #13534)
- Fix eauth for batch mode (issue #9605)
- Fix force-related issues with `tomcat` support ([issue #12889](#12889))
- Fix `KeyError` when cloud mapping
- Fix salt-minion restart loop in Windows ([issue #12086](#12086))
- Fix detection of `service` virtual module on Fedora minions
- Fix traceback with missing ipv4 grain ([issue #13838](#13838))
- Fix issue in roots backend with invalid data in `mtime_map` ([issue #13836](#13836))
- Fix traceback in `jobs.active` ([issue #11151](#11151))
- Fix `master_tops` and `_ext_nodes` issue ([issue #13535](#13535), [issue #13673](#13673))

### 30.2.120 Salt 2014.1.8 Release Notes

**release** 2014-07-30

**Note:** This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

Version 2014.1.8 is another bugfix release for 2014.1.0. Changes include:
- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

### 30.2.121 Salt 2014.1.9 Release Notes

**release** 2014-07-31

**Note:** This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

**Note:** Version 2014.1.8 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.8.

Version 2014.1.9 is another bugfix release for 2014.1.0. Changes include:
- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

**30.2.122  Salt 0.10.0 Release Notes**

**release** 2012-06-16

0.10.0 has arrived! This release comes with MANY bug fixes, and new capabilities which greatly enhance performance and reliability. This release is primarily a bug fix release with many new tests and many repaired bugs. This release also introduces a few new key features which were brought in primarily to repair bugs and some limitations found in some of the components of the original architecture.

**Major Features**

**Event System**

The Salt Master now comes equipped with a new event system. This event system has replaced some of the back end of the Salt client and offers the beginning of a system which will make plugging external applications into Salt. The event system relies on a local ZeroMQ publish socket and other processes can connect to this socket and listen for events. The new events can be easily managed via Salt’s event library.

**Unprivileged User Updates**

Some enhancements have been added to Salt for running as a user other than root. These new additions should make switching the user that the Salt Master is running as very painless, simply change the `user` option in the master configuration and restart the master, Salt will take care of all of the particulars for you.

**Peer Runner Execution**

Salt has long had the peer communication system used to allow minions to send commands via the salt master. 0.10.0 adds a new capability here, now the master can be configured to allow for minions to execute Salt runners via the `peer_runner` option in the salt master configuration.

**YAML Parsing Updates**

In the past the YAML parser for sls files would return the incorrect numbers when the file mode was set with a preceding 0. The YAML parser used in Salt has been modified to no longer convert these number into octal but to keep them as the correct value so that sls files can be a little cleaner to write.

**State Call Data Files**

It was requested that the minion keep a local cache of the most recent executed state run. This has been added and now with state runs the data is stored in a msgpack file in the minion’s cachedir.
Turning Off the Job Cache

A new option has been added to the master configuration file. In previous releases the Salt client would look over the Salt job cache to read in the minion return data. With the addition of the event system the Salt client can now watch for events directly from the master worker processes.

This means that the job cache is no longer a hard requirement. Keep in mind though, that turning off the job cache means that historic job execution data cannot be retrieved.

Test Updates

Minion Swarms Are Faster

To continue our efforts with testing Salt’s ability to scale the minionswarm script has been updated. The minion-swarm can now start up minions much faster than it could before and comes with a new feature allowing modules to be disabled, thus lowering the minion’s footprint when making a swarm. These new updates have allows us to test:

```
# python minionswarm.py -m 20 --master salt-master
```

Many Fixes

Master and Minion Stability Fixes

As Salt deployments grow new ways to break Salt are discovered. 0.10.0 comes with a number of fixes for the minions and master greatly improving Salt stability.

30.2.123 Salt 0.10.1 Release Notes

release 2012-06-19

30.2.124 Salt 0.10.2 Release Notes

release 2012-07-30

0.10.2 is out! This release comes with enhancements to the pillar interface, cleaner ways to access the salt-call capabilities in the API, minion data caching and the event system has been added to salt minions.

There have also been updates to the ZeroMQ functions, many more tests (thanks to sponsors, the code sprint and many contributors) and a swath of bug fixes.
Major Features

Ext Pillar Modules

The ranks of available Salt modules directories sees a new member in 0.10.2. With the popularity of pillar a higher demand has arisen for `ext_pillar` interfaces to be more like regular Salt module additions. Now `ext_pillar` interfaces can be added in the same way as other modules, just drop it into the pillar directory in the salt source.

Minion Events

In 0.10.0 an event system was added to the Salt master. 0.10.2 adds the event system to the minions as well. Now event can be published on a local minion as well.

The minions can also send events back up to the master. This means that Salt is able to communicate individual events from the minions back up to the Master which are not associated with command.

Minion Data Caching

When pillar was introduced the landscape for available data was greatly enhanced. The minion's began sending grain data back to the master on a regular basis.

The new config option on the master called `minion_data_cache` instructs the Salt master to maintain a cache of the minion's grains and pillar data in the cachedir. This option is turned off by default to avoid hitting the disk more, but when enabled the cache is used to make grain matching from the salt command more powerful, since the minions that will match can be predetermined.

Backup Files

By default all files replaced by the file.managed and file.recurse states we simply deleted. 0.10.2 adds a new option. By setting the backup option to `minion` the files are backed up before they are replaced.

The backed up files are located in the cachedir under the file_backup directory. On a default system this will be at: `/var/cache/salt/file_backup`

Configuration files

`salt-master` and `salt-minion` automatically load additional configuration files from `master.d/*\.conf` respective `minion.d/*\.conf` where `master.d/minion.d` is a directory in the same directory as the main configuration file.

Salt Key Verification

A number of users complained that they had inadvertently deleted the wrong salt authentication keys. 0.10.2 now displays what keys are going to be deleted and verifies that they are the keys that are intended for deletion.
Key auto-signing

If `autosign_file` is specified in the configuration file incoming keys will be compared to the list of keynames in `autosign_file`. Regular expressions as well as globbing is supported.

The file must only be writable by the user otherwise the file will be ignored. To relax the permission and allow group write access set the `permissive_pki_access` option.

Module changes

Improved OpenBSD support

New modules for managing services and packages were provided by Joshua Elsasser to further improve the support for OpenBSD.

Existing modules like the `disk` module were also improved to support OpenBSD.

SQL Modules

The MySQL and PostgreSQL modules have both received a number of additions thanks to the work of Avi Marcus and Roman Imankulov.

ZFS Support on FreeBSD

A new ZFS module has been added by Kurtis Velarde for FreeBSD supporting various ZFS operations like creating, extending or removing zpools.

Augeas

A new Augeas module by Ulrich Dangel for editing and verifying config files.

Native Debian Service module

The support for the Debian was further improved with an new service module for Debian by Ahmad Khayyat supporting `disable` and `enable`.

Cassandra

Cassandra support has been added by Adam Garside. Currently only status and diagnostic information are supported.
Networking

The networking support for RHEL has been improved and supports bonding support as well as zeroconf configuration.

Monit

Basic monit support by Kurtis Velarde to control services via monit.

nzbget

Basic support for controlling nzbget by Joseph Hall

Bluetooth

Basic bluez support for managing and controlling Bluetooth devices. Supports scanning as well as pairing/unpairing by Joseph Hall.

Test Updates

Consistency Testing

Another testing script has been added. A bug was found in pillar when many minions generated pillar data at the same time. The new consist.py script is the tests directory was created to reproduce bugs where data should always be consistent.

30.2.125 Salt 0.10.3 Release Notes

release 2012-09-30

The latest taste of Salt has come, this release has many fixes and feature additions. Modifications have been made to make ZeroMQ connections more reliable, the beginning of the ACL system is in place, a new command line parsing system has been added, dynamic module distribution has become more environment aware, the new master_finger option and many more!
Major Features

ACL System

The new ACL system has been introduced. The ACL system allows for system users other than root to execute salt commands. Users can be allowed to execute specific commands in the same way that minions are opened up to the peer system.

The configuration value to open up the ACL system is called `client_acl` and is configured like so:

```
client_acl:
    fred:
      - test..*
      - pkg.list_pkgs
```

Where `fred` is allowed access to functions in the test module and to the `pkg.list_pkgs` function.

Master Finger Option

The `master_finger` option has been added to improve the security of minion provisioning. The `master_finger` option allows for the fingerprint of the master public key to be set in the configuration file to double verify that the master is valid. This option was added in response to a motivation to pre-authenticate the master when provisioning new minions to help prevent man in the middle attacks in some situations.

Salt Key Fingerprint Generation

The ability to generate fingerprints of keys used by Salt has been added to `salt-key`. The new option `finger` accepts the name of the key to generate and display a fingerprint for.

```
salt-key -F master
```

Will display the fingerprints for the master public and private keys.

Parsing System

Pedro Algavio, aka s0undt3ch, has added a substantial update to the command line parsing system that makes the help message output much cleaner and easier to search through. Salt parsers now have `--versions-report` besides usual `--version` info which you can provide when reporting any issues found.

Key Generation

We have reduced the requirements needed for `salt-key` to generate minion keys. You're no longer required to have salt configured and its common directories created just to generate keys. This might prove useful if you're batch creating keys to pre-load on minions.
Startup States

A few configuration options have been added which allow for states to be run when the minion daemon starts. This can be a great advantage when deploying with Salt because the minion can apply states right when it first runs. To use startup states set the `startup_states` configuration option on the minion to `highstate`.

New Exclude Declaration

Some users have asked about adding the ability to ensure that other sls files or ids are excluded from a state run. The `exclude` statement will delete all of the data loaded from the specified sls file or will delete the specified id:

```yaml
exclude:
- sls: http
- id: /etc/vimrc
```

Max Open Files

While we're currently unable to properly handle ZeroMQ's abort signals when the max open files is reached, due to the way that's handled on ZeroMQ's, we have minimized the chances of this happening without at least warning the user.

More State Output Options

Some major changes have been made to the state output system. In the past state return data was printed in a very verbose fashion and only states that failed or made changes were printed by default. Now two options can be passed to the master and minion configuration files to change the behavior of the state output. State output can be set to verbose (default) or non-verbose with the `state_verbose` option:

```yaml
state_verbose: False
```

It is noteworthy that the `state_verbose` option used to be set to `False` by default but has been changed to `True` by default in 0.10.3 due to many requests for the change.

The next option to be aware of new and called `state_output`. This option allows for the state output to be set to `full` (default) or `terse`.

The `full` output is the standard state output, but the new `terse` output will print only one line per state making the output much easier to follow when executing a large state system.

```yaml
state_output: terse
```

`state.file.append` Improvements

The salt `state.file.append()` tries not to append existing text. Previously the matching check was being made line by line. While this kind of check might be enough for most cases, if the text being appended was multi-line, the check would not work properly. This issue is now properly handled, the match is done as a whole ignoring any white space addition or removal except inside commas. For those thinking that, in order to properly match over multiple lines, salt will load the whole file into memory, that's not true. For most cases this is not important but an erroneous order to read a 4GB file, if not properly handled, like salt does, could make salt chew that amount of memory. Salt has a buffered file reader which will keep in memory a maximum of 256KB and iterates over the file in chunks of 32KB to test for the match, more than enough, if not, explain your usage on a ticket. With this change, also
salt.modules.file.contains(), salt.modules.file.contains_regex(), salt.modules.file.contains_glob() and salt.utils.find now do the searching and/or matching using the buffered chunks approach explained above.

Two new keyword arguments were also added, makedirs, and source. The first, makedirs will create the necessary directories in order to append to the specified file, of course, it only applies if we’re trying to append to a non-existing file on a non-existing directory:

```
/tmp/salttest/file-append-makedirs:
  file.append:
    text: foo
    makedirs: True
```

The second, source, allows one to append the contents of a file instead of specifying the text.

```
/tmp/salttest/file-append-source:
  file.append:
    - source: salt://testfile
```

Security Fix

A timing vulnerability was uncovered in the code which decrypts the AES messages sent over the network. This has been fixed and upgrading is strongly recommended.

30.2.126 Salt 0.10.4 Release Notes

release 2012-10-23

Salt 0.10.4 is a monumental release for the Salt team, with two new module systems, many additions to allow granular access to Salt, improved platform support and much more.

This release is also exciting because we have been able to shorten the release cycle back to under a month. We are working hard to keep up the aggressive pace and look forward to having releases happen more frequently!

This release also includes a serious security fix and all users are very strongly recommended to upgrade. As usual, upgrade the master first, and then the minion to ensure that the process is smooth.

Major Features

External Authentication System

The new external authentication system allows for Salt to pass through authentication to any authentication system to determine if a user has permission to execute a Salt command. The Unix PAM system is the first supported system with more to come!

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file, and uses the new access control system:

```
external_auth:
  pam:
    thatch:
      - 'web*':
      - test.*
      - network.*
```
The configuration above allows the user *thatch* to execute functions in the test and network modules on minions that match the `web*` target.

**Access Control System**

All Salt systems can now be configured to grant access to non-administrative users in a granular way. The old configuration continues to work. Specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

Access controls are configured like this:

```yaml
client_acl:
  fred:
    - web\*:
      - pkg.list_pkgs
      - test.*
      - apache.*
```

**Target by Network**

A new matcher has been added to the system which allows for minions to be targeted by network. This new matcher can be called with the `-S` flag on the command line and is available in all places that the matcher system is available. Using it is simple:

```
$ salt -S '192.168.1.0/24' test.ping
$ salt -S '192.168.1.100' test.ping
```

**Nodegroup Nesting**

Previously a nodegroup was limited by not being able to include another nodegroup, this restraint has been lifted and now nodegroups will be expanded within other nodegroups with the `N@` classifier.

**Salt Key Delete by Glob**

The ability to delete minion keys by glob has been added to `salt-key`. To delete all minion keys whose minion name starts with `web`:

```
$ salt-key -d 'web*'
```

**Master Tops System**

The `external_nodes` system has been upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run.

The `external_nodes` option still works but will be deprecated in the future in favor of the new `master_tops` option.

Example of using `master_tops`:

```yaml
master_tops:
  ext_nodes: cobbler-external-nodes
```
Next Level Solaris Support

A lot of work has been put into improved Solaris support by Romeo Theriault. Packaging modules (pkgadd/pkgrm and pkgutil) and states, cron support and user and group management have all been added and improved upon. These additions along with SMF (Service Management Facility) service support and improved Solaris grain detection in 0.10.3 add up to Salt becoming a great tool to manage Solaris servers with.

Security

A vulnerability in the security handshake was found and has been repaired, old minions should be able to connect to a new master, so as usual, the master should be updated first and then the minions.

Pillar Updates

The pillar communication has been updated to add some extra levels of verification so that the intended minion is the only one allowed to gather the data. Once all minions and the master are updated to salt 0.10.4 please activate pillar 2 by changing the pillar_version in the master config to 2. This will be set to 2 by default in a future release.

30.2.127 Salt 0.10.5 Release Notes

release 2012-11-15

Salt 0.10.5 is ready, and comes with some great new features. A few more interfaces have been modularized, like the outputter system. The job cache system has been made more powerful and can now store and retrieve jobs archived in external databases. The returner system has been extended to allow minions to easily retrieve data from a returner interface.

As usual, this is an exciting release, with many noteworthy additions!

Major Features

External Job Cache

The external job cache is a system which allows for a returner interface to also act as a job cache. This system is intended to allow users to store job information in a central location for longer periods of time and to make the act of looking up information from jobs executed on other minions easier.

Currently the external job cache is supported via the mongo and redis returners:

```
ext_job_cache: redis
redis.host: salt
```

Once the external job cache is turned on the new ret module can be used on the minions to retrieve return information from the job cache. This can be a great way for minions to respond and react to other minions.
OpenStack Additions

OpenStack integration with Salt has been moving forward at a blistering pace. The new nova, glance, and keystone modules represent the beginning of ongoing OpenStack integration.

The Salt team has had many conversations with core OpenStack developers and is working on linking to OpenStack in powerful new ways.

Wheel System

A new API was added to the Salt Master which allows the master to be managed via an external API. This new system allows Salt API to easily hook into the Salt Master and manage configs, modify the state tree, manage the pillar and more. The main motivation for the wheel system is to enable features needed in the upcoming web UI so users can manage the master just as easily as they manage minions.

The wheel system has also been hooked into the external auth system. This allows specific users to have granular access to manage components of the Salt Master.

Render Pipes

Jack Kuan has added a substantial new feature. The render pipes system allows Salt to treat the render system like unix pipes. This new system enables sls files to be passed through specific render engines. While the default renderer is still recommended, different engines can now be more easily merged. So to pipe the output of Mako used in YAML use this shebang line:

```
#!/mako|yaml
```

Salt Key Overhaul

The Salt Key system was originally developed as only a CLI interface, but as time went on it was pressed into becoming a clumsy API. This release marks a complete overhaul of Salt Key. Salt Key has been rewritten to function purely from an API and to use the outputter system. The benefit here is that the outputter system works much more cleanly with Salt Key now, and the internals of Salt Key can be used much more cleanly.

Modular Outputters

The outputter system is now loaded in a modular way. This means that output systems can be more easily added by dropping a python file down on the master that contains the function output.

Gzip from Fileserver

Gzip compression has been added as an option to the cp.get_file and cp.get_dir commands. This will make file transfers more efficient and faster, especially over slower network links.
Unified Module Configuration

In past releases of Salt, the minions needed to be configured for certain modules to function. This was difficult because it required pre-configuring the minions. 0.10.5 changes this by making all module configs on minions search the master config file for values.

Now if a single database server is needed, then it can be defined in the master config and all minions will become aware of the configuration value.

Salt Call Enhancements

The salt-call command has been updated in a few ways. Now, salt-call can take the --return option to send the data to a returner. Also, salt-call now reports executions in the minion proc system, this allows the master to be aware of the operation salt-call is running.

Death to pub_refresh and sub_timeout

The old configuration values pub_refresh and sub_timeout have been removed. These options were in place to alleviate problems found in earlier versions of ZeroMQ which have since been fixed. The continued use of these options has proven to cause problems with message passing and have been completely removed.

Git Revision Versions

When running Salt directly from git (for testing or development, of course) it has been difficult to know exactly what code is being executed. The new versioning system will detect the git revision when building and how many commits have been made since the last release. A release from git will look like this:

0.10.4-736-gec74d69

Svn Module Addition

Anthony Cornehl (twinshadow) contributed a module that adds Subversion support to Salt. This great addition helps round out Salt’s VCS support.

Noteworthy Changes

Arch Linux Defaults to Systemd

Arch Linux recently changed to use systemd by default and discontinued support for init scripts. Salt has followed suit and defaults to systemd now for managing services in Arch.
Salt, Salt Cloud and Openstack

With the releases of Salt 0.10.5 and Salt Cloud 0.8.2, OpenStack becomes the first (non-OS) piece of software to include support both on the user level (with Salt Cloud) and the admin level (with Salt). We are excited to continue to extend support of other platforms at this level.

## 30.2.128 Salt 0.11.0 Release Notes

**release** 2012-12-14

Salt 0.11.0 is here, with some highly sought after and exciting features. These features include the new overstate system, the reactor system, a new state run scope component called __context__, the beginning of the search system (still needs a great deal of work), multiple package states, the MySQL returner and a better system to arbitrarily reference outputters.

It is also noteworthy that we are changing how we mark release numbers. For the life of the project we have been pushing every release with features and fixes as point releases. We will now be releasing point releases for only bug fixes on a more regular basis and major feature releases on a slightly less regular basis. This means that the next release will be a bugfix only release with a version number of 0.11.1. The next feature release will be named 0.12.0 and will mark the end of life for the 0.11 series.

### Major Features

**OverState**

The overstate system is a simple way to manage rolling state executions across many minions. The overstate allows for a state to depend on the successful completion of another state.

**Reactor System**

The new reactor system allows for a reactive logic engine to be created which can respond to events within a salted environment. The reactor system uses sls files to match events fired on the master with actions, enabling Salt to react to problems in an infrastructure.

Your load-balanced group of webservers is under extra load? Spin up a new VM and add it to the group. Your fileserver is filling up? Send a notification to your sysadmin on call. The possibilities are endless!

**Module Context**

A new component has been added to the module loader system. The module context is a data structure that can hold objects for a given scope within the module.

This allows for components that are initialized to be stored in a persistent context which can greatly speed up ongoing connections. Right now the best example can be found in the cp execution module.
Multiple Package Management

A long desired feature has been added to package management. By definition Salt States have always installed packages one at a time. On most platforms this is not the fastest way to install packages. Erik Johnson, aka terminalmage, has modified the package modules for many providers and added new capabilities to install groups of packages. These package groups can be defined as a list of packages available in repository servers:

```
python_pkgs:
  pkg.installed:
    - pkgs:
      - python-mako
      - whoosh
      - python-git
```

or specify based on the location of specific packages:

```
python_pkgs:
  pkg.installed:
    - sources:
      - python-mako: http://some-rpms.org/python-mako.rpm
      - whoosh: salt://whoosh/whoosh.rpm
      - python-git: ftp://companyserver.net/python-git.rpm
```

Search System

The bones to the search system have been added. This is a very basic interface that allows for search backends to be added as search modules. The first supported search module is the whoosh search backend. Right now only the basic paths for the search system are in place, making this very experimental. Further development will involve improving the search routines and index routines for whoosh and other search backends.

The search system has been made to allow for searching through all of the state and pillar files, configuration files and all return data from minion executions.

Notable Changes

All previous versions of Salt have shared many directories between the master and minion. The default locations for keys, cached data and sockets has been shared by master and minion. This has created serious problems with running a master and a minion on the same systems. 0.11.0 changes the defaults to be separate directories. Salt will also attempt to migrate all of the old key data into the correct new directories, but if it is not successful it may need to be done manually. If your keys exhibit issues after updating make sure that they have been moved from `/etc/salt/pki` to `/etc/salt/pki/{master,minion}`.

The old setup will look like this:

```
/etc/salt/pki
|-- master.pem
|-- master.pub
|-- minions
|   |-- ragnarok.saltstack.net
|   |-- minions_pre
|   |-- minion.pem
|   |-- minion.pub
|   |-- minion_master.pub
|   |-- minions_pre
|   |-- minions_rejected
```
With the accepted minion keys in /etc/salt/pki/minions, the new setup places the accepted minion keys in /etc/salt/pki/master/minions.

```
/etc/salt/pki
|-- master
| `-- master.pem
| `-- master.pub
|-- minions
| `-- ragnarok.saltstack.net
|    `-- minions_pre
|    `-- minions_rejected
|-- minion
|    `-- minion.pem
|    `-- minion.pub
|    `-- minion_master.pub
```

30.2.129 Salt 0.11.1 Release Notes

**release** 2012-12-19

30.2.130 Salt 0.12.0 Release Notes

**release** 2013-01-15

Another feature release of Salt is here! Some exciting additions are included with more ways to make salt modular and even easier management of the salt file server.

**Major Features**

**Modular Fileserver Backend**

The new modular fileserver backend allows for any external system to be used as a salt file server. The main benefit here is that it is now possible to tell the master to directly use a git remote location, or many git remote locations, automatically mapping git branches and tags to salt environments.

**Windows is First Class!**

A new Salt Windows installer is now available! Much work has been put in to improve Windows support. With this much easier method of getting Salt on your Windows machines, we hope even more development and progress will occur. Please file bug reports on the Salt GitHub repo issue tracker so we can continue improving.

One thing that is missing on Windows that Salt uses extensively is a software package manager and a software package repository. The Salt pkg state allows sys admins to install software across their infrastructure and across operating systems. Software on Windows can now be managed in the same way. The SaltStack team built a package manager that interfaces with the standard Salt pkg module to allow for installing and removing software on Windows. In addition, a software package repository has been built on top of the Salt fileserver. A small YAML file provides the information necessary for the package manager to install and remove software.

An interesting feature of the new Salt Windows software package repository is that one or more remote git repositories can supplement the master’s local repository. The repository can point to software on the master’s fileserver or on an HTTP, HTTPS, or ftp server.
New Default Outputter

Salt displays data to the terminal via the outputter system. For a long time the default outputter for Salt has been the python pretty print library. While this has been a generally reasonable outputter, it did have many failings. The new default outputter is called "nested", it recursively scans return data structures and prints them out cleanly.

If the result of the new nested outputter is not desired any other outputter can be used via the --out option, or the output option can be set in the master and minion configs to change the default outputter.

Internal Scheduler

The internal Salt scheduler is a new capability which allows for functions to be executed at given intervals on the minion, and for runners to be executed at given intervals on the master. The scheduler allows for sequences such as executing state runs (locally on the minion or remotely via an overstate) or continually gathering system data to be run at given intervals.

The configuration is simple, add the schedule option to the master or minion config and specify jobs to run, this in the master config will execute the state.over runner every 60 minutes:

```yaml
schedule:
  overstate:
    function: state.over
    minutes: 60
```

This example for the minion configuration will execute a highstate every 30 minutes:

```yaml
schedule:
  highstate:
    function: state.highstate
    minutes: 30
```

Optional DSL for SLS Formulas

Jack Kuan, our renderer expert, has created something that is astonishing. Salt, now comes with an optional Python based DSL, this is a very powerful interface that makes writing SLS files in pure python easier than it was with the raw py renderer. As usual this can be used with the renderer shebang line, so a single sls can be written with the DSL if pure python power is needed while keeping other sls files simple with YAML.

Set Grains Remotely

A new execution function and state module have been added that allows for grains to be set on the minion. Now grains can be set via a remote execution or via states. Use the `grains.present` state or the `grains.setval` execution functions.
Gentoo Additions

Major additions to Gentoo specific components have been made. The encompasses executions modules and states ranging from supporting the make.conf file to tools like layman.

30.2.131 Salt 0.12.1 Release Notes

release 2013-01-21

30.2.132 Salt 0.13.0 Release Notes

release 2013-02-12

The lucky number 13 has turned the corner! From CLI notifications when quitting a salt command, to substantial improvements on Windows, Salt 0.13.0 has arrived!

Major Features

Improved file.recurse Performance

The file.recurse system has been deployed and used in a vast array of situations. Fixes to the file state and module have led towards opening up new ways of running file.recurse to make it faster. Now the file.recurse state will download fewer files and will run substantially faster.

Windows Improvements

Minion stability on Windows has improved. Many file operations, including file.recurse, have been fixed and improved. The network module works better, to include network.interfaces. Both 32bit and 64bit installers are now available.

Nodegroup Targeting in Peer System

In the past, nodegroups were not available for targeting via the peer system. This has been fixed, allowing the new nodegroup expr_form argument for the publish.publish function:

    salt-call publish.publish group1 test.ping expr_form=nodegroup

Blacklist Additions

Additions allowing more granular blacklisting are available in 0.13.0. The ability to blacklist users and functions in client_acl have been added, as well as the ability to exclude state formulas from the command line.
Salt Documentation, Release 3002.5

Command Line Pillar Embedding
Pillar data can now be embedded on the command line when calling state.sls and state.highstate. This
allows for on the fly changes or settings to pillar and makes parameterizing state formulas even easier. This is done
via the keyword argument:
salt '*' state.highstate pillar='{"cheese": "spam"}'

The above example will extend the existing pillar to hold the cheese key with a value of spam. If the cheese key
is already specified in the minion's pillar then it will be overwritten.
CLI Notifications
In the past hitting ctrl-C and quitting from the salt command would just drop to a shell prompt, this caused
confusion with users who expected the remote executions to also quit. Now a message is displayed showing what
command can be used to track the execution and what the job id is for the execution.
Version Specification in Multiple-Package States
Versions can now be specified within multiple-package pkg.installed states. An example can be found below:
mypkgs:
pkg.installed:
- pkgs:
- foo
- bar: 1.2.3-4
- baz

Noteworthy Changes
The configuration subsystem in Salt has been overhauled to make the opts dict used by Salt applications more
portable, the problem is that this is an incompatible change with salt-cloud, and salt-cloud will need to be updated
to the latest git to work with Salt 0.13.0. Salt Cloud 0.8.5 will also require Salt 0.13.0 or later to function.
The SaltStack team is sorry for the inconvenience here, we work hard to make sure these sorts of things do not
happen, but sometimes hard changes get in.

30.2.133 Salt 0.13.1 Release Notes
release 2013-02-15

30.2. Previous Releases

3197


Salt 0.14.0 is here! This release was held up primarily by PyCon, Scale, and illness, but has arrived! 0.14.0 comes with many new features and is breaking ground for Salt in the area of cloud management with the introduction of Salt providing basic cloud controller functionality.

Major Features

Salt - As a Cloud Controller

This is the first primitive inroad to using Salt as a cloud controller is available in 0.14.0. Be advised that this is alpha, only tested in a few very small environments.

The cloud controller is built using kvm and libvirt for the hypervisors. Hypervisors are autodetected as minions and only need to have libvirt running and kvm installed to function. The features of the Salt cloud controller are as follows:

- Basic vm discovery and reporting
- Creation of new virtual machines
- Seeding virtual machines with Salt via qemu-nbd or libguestfs
- Live migration (shared and non shared storage)
- Delete existing VMs

It is noteworthy that this feature is still Alpha, meaning that all rights are reserved to change the interface if needs be in future releases!

Libvirt State

One of the problems with libvirt is management of certificates needed for live migration and cross communication between hypervisors. The new libvirt state makes the Salt Master hold a CA and manage the signing and distribution of keys onto hypervisors, just add a call to the libvirt state in the sls formulas used to set up a hypervisor:

```
libvirt_keys:
  libvirt.keys
```
New get Functions

An easier way to manage data has been introduced. The pillar, grains, and config execution modules have been extended with the new get function. This function works much in the same way as the get method in a python dict, but with an enhancement, nested dict components can be extracted using a : delimiter.

If a structure like this is in pillar:

```python
foo:
    bar:
        baz: quo
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```python
{{ pillar['foo']['bar']['baz'] }}
```

Now with the new get function the data can be safely gathered and a default can be set allowing the template to fall back if the value is not available:

```python
{{ salt['pillar.get']['foo:bar:baz', 'qux'] }}
```

This makes handling nested structures much easier, and defaults can be cleanly set. This new function is being used extensively in the new formulae repository of salt sls formulas.

30.2.137 Salt 0.14.1 Release Notes

release 2013-04-13

30.2.138 Salt 0.15.0 Release Notes

release 2013-05-03

The many new features of Salt 0.15.0 have arrived! Salt 0.15.0 comes with many smaller features and a few larger ones.

These features range from better debugging tools to the new Salt Mine system.

Major Features

The Salt Mine

First there was the peer system, allowing for commands to be executed from a minion to other minions to gather data live. Then there was the external job cache for storing and accessing long term data. Now the middle ground is being filled in with the Salt Mine. The Salt Mine is a system used to execute functions on a regular basis on minions and then store only the most recent data from the functions on the master, then the data is looked up via targets.

The mine caches data that is public to all minions, so when a minion posts data to the mine all other minions can see it.
IPV6 Support

0.13.0 saw the addition of initial IPV6 support but errors were encountered and it needed to be stripped out. This time the code covers more cases and must be explicitly enabled. But the support is much more extensive than before.

Copy Files From Minions to the Master

Minions have long been able to copy files down from the master file server, but until now files could not be easily copied from the minion up to the master.

A new function called `cp.push` can push files from the minions up to the master server. The uploaded files are then cached on the master in the master cachedir for each minion.

Better Template Debugging

Template errors have long been a burden when writing states and pillar. 0.15.0 will now send the compiled template data to the debug log, this makes tracking down the intermittent stage templates much easier. So running `state.sls` or `state.highstate` with `-l debug` will now print out the rendered templates in the debug information.

State Event Firing

The state system is now more closely tied to the master's event bus. Now when a state fails the failure will be fired on the master event bus so that the reactor can respond to it.

Major Syndic Updates

The Syndic system has been basically re-written. Now it runs in a completely asynchronous way and functions primarily as an event broker. This means that the events fired on the syndic are now pushed up to the higher level master instead of the old method used which waited for the client libraries to return.

This makes the syndic much more accurate and powerful, it also means that all events fired on the syndic master make it up the pipe as well making a reactor on the higher level master able to react to minions further downstream.

Peer System Updates

The Peer System has been updated to run using the client libraries instead of firing directly over the publish bus. This makes the peer system much more consistent and reliable.

Minion Key Revocation

In the past when a minion was decommissioned the key needed to be manually deleted on the master, but now a function on the minion can be used to revoke the calling minion's key:

```bash
$ salt-call saltutil.revoke_auth
```
Function Return Codes

Functions can now be assigned numeric return codes to determine if the function executed successfully. While not all functions have been given return codes, many have and it is an ongoing effort to fill out all functions that might return a non-zero return code.

Functions in Overstate

The overstate system was originally created to just manage the execution of states, but with the addition of return codes to functions, requisite logic can now be used with respect to the overstate. This means that an overstate stage can now run single functions instead of just state executions.

Pillar Error Reporting

Previously if errors surfaced in pillar, then the pillar would consist of only an empty dict. Now all data that was successfully rendered stays in pillar and the render error is also made available. If errors are found in the pillar, states will refuse to run.

Using Cached State Data

Sometimes states are executed purely to maintain a specific state rather than to update states with new configs. This is grounds for the new cached state system. By adding `cache=True` to a state call the state will not be generated fresh from the master but the last state data to be generated will be used. If no previous state data is available then fresh data will be generated.

Monitoring States

The new monitoring states system has been started. This is very young but allows for states to be used to configure monitoring routines. So far only one monitoring state is available, the `disk.status` state. As more capabilities are added to Salt UI the monitoring capabilities of Salt will continue to be expanded.

30.2.139 Salt 0.15.1 Release Notes

release 2013-05-08

The 0.15.1 release has been posted, this release includes fixes to a number of bugs in 0.15.1 and a three security patches.

Security Updates

A number of security issues have been resolved via the 0.15.1 release.
Path Injection in Minion IDs

Salt masters did not properly validate the id of a connecting minion. This can lead to an attacker uploading files to the master in arbitrary locations. In particular this can be used to bypass the manual validation of new unknown minions. Exploiting this vulnerability does not require authentication.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

Patch

The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:
https://github.com/saltstack/salt/commit/5427b9438e452a5a8910d9128c6aaaf45d8fd5d3
https://github.com/saltstack/salt/commit/7560908ee62351769c3cd43b03d74c1ca772cc52
https://github.com/saltstack/salt/commit/e200b8a7ff53780124e08d2bdefde7587e52bfca

RSA Key Generation Fault

RSA key generation was done incorrectly, leading to very insecure keys. It is recommended to regenerate all RSA keys.

This issue can be used to impersonate Salt masters or minions, or decrypt any transferred data.

This issue can only be exploited by attackers who are able to observe or modify traffic between Salt minions and the legitimate Salt master.

A tool was included in 0.15.1 to assist in mass key regeneration, the manage.regen_keys runner.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

Patch

The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:
https://github.com/saltstack/salt/commit/5dd304276ba5745ec21fc1e6686a0b28da29e6fc

Command Injection Via ext_pillar

Arbitrary shell commands could be executed on the master by an authenticated minion through options passed when requesting a pillar.

Ext pillar options have been restricted to only allow safe external pillars to be called when prompted by the minion.

This issue affects Salt versions from 0.14.0 to 0.15.0.

This issue was reported by Ronald Volgers.

30.2.142 Salt 0.16.0 Release Notes

release 2013-07-01

The 0.16.0 release is an exciting one, with new features in master redundancy, and a new, powerful requisite.

Major Features

Multi-Master

This new capability allows for a minion to be actively connected to multiple salt masters at the same time. This allows for multiple masters to send out commands to minions and for minions to automatically reconnect to masters that have gone down. A tutorial is available to help get started here:

Multi Master Tutorial

Prereq, the New Requisite

The new prereq requisite is very powerful! It allows for states to execute based on a state that is expected to make changes in the future. This allows for a change on the system to be preempted by another execution. A good example is needing to shut down a service before modifying files associated with it, allowing, for instance, a webserver to be shut down allowing a load balancer to stop sending requests while server side code is updated. In this case, the prereq will only run if changes are expected to happen in the prerequired state, and the prerequired state will always run after the prereq state and only if the prereq state succeeds.
Peer System Improvements

The peer system has been revamped to make it more reliable, faster, and like the rest of Salt, async. The peer calls when an updated minion and master are used together will be much faster!

Relative Includes

The ability to include an sls relative to the defined sls has been added, the new syntax id documented here:

Includes

More State Output Options

The state_output option in the past only supported full and terse, 0.16.0 add the mixed and changes modes further refining how states are sent to users' eyes.

Improved Windows Support

Support for Salt on Windows continues to improve. Software management on Windows has become more seamless with Linux/UNIX/BSD software management. Installed software is now recognized by the short names defined in the repository SLS. This makes it possible to run salt '*' pkg.version firefox and get back results from Windows and non-Windows minions alike.

When templating files on Windows, Salt will now correctly use Windows appropriate line endings. This makes it much easier to edit and consume files on Windows.

When using the cmd state the shell option now allows for specifying Windows Powershell as an alternate shell to execute cmd.run and cmd.script. This opens up Salt to all the power of Windows Powershell and its advanced Windows management capabilities.

Several fixes and optimizations were added for the Windows networking modules, especially when working with IPv6.

A system module was added that makes it easy to restart and shutdown Windows minions.

The Salt Minion will now look for its config file in c:\salt\conf by default. This means that it's no longer necessary to specify the -c option to specify the location of the config file when starting the Salt Minion on Windows in a terminal.

Multiple Targets for pkg.removed, pkg.purged States

Both pkg.removed and pkg.purged now support the pkgs argument, which allow for multiple packages to be targeted in a single state. This, as in pkg.installed, helps speed up these states by reducing the number of times that the package management tools (apt, yum, etc.) need to be run.
Random Times in Cron States

The temporal parameters in `cron.present` states (minute, hour, etc.) can now be randomized by using `random` instead of a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
cron.present:
    - user: root
    - minute: random
    - hour: 2
```

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

Confirmation Prompt on Key Acceptance

When accepting new keys with `salt-key -a minion-id` or `salt-key -A`, there is now a prompt that will show the affected keys and ask for confirmation before proceeding. This prompt can be bypassed using the `-y` or `--yes` command line argument, as with other `salt-key` commands.

Support for Setting Password Hashes on BSD Minions

FreeBSD, NetBSD, and OpenBSD all now support setting passwords in `user.present` states.

30.2.143 Salt 0.16.1 Release Notes

```
release 2013-07-29
```

30.2.144 Salt 0.16.2 Release Notes

```
release 2013-08-01
```

Version 0.16.2 is a bugfix release for 0.16.0, and contains a number of fixes.

Windows

- Only allow Administrator's group and SYSTEM user access to C:salt. This eliminates a race condition where a non-admin user could modify a template or managed file before it is executed by the minion (which is running as an elevated user), thus avoiding a potential escalation of privileges. (issue #6361)
Grains

- Fixed detection of virtual grain on OpenVZ hardware nodes
- Gracefully handle lsb_release data when it is enclosed in quotes
- LSB grains are now prefixed with lsb_distrib_ instead of simply lsb_. The old naming is not preserved, so SLS may be affected.
- Improved grains detection on MacOS

Pillar

- Don't try to load git_pillar if not enabled in master config (issue #6052)
- Functions pillar.item and pillar.items added for parity with grains.item/grains.items. The old function pillar.data is preserved for backwards compatibility.
- Fixed minion traceback when Pillar SLS is malformed (issue #5910)

Peer Publishing

- More gracefully handle improperly quoted publish commands (issue #5958)
- Fixed traceback when timeout specified via the CLI for publish.publish, publish.full_data (issue #5959)
- Fixed unintended change in output of publish.publish (issue #5928)

Minion

- Fixed salt-key usage in minionswarm script
- Quieted warning about SALT_MINION_CONFIG environment variable on minion startup and for CLI commands run via salt-call (issue #5956)
- Added minion config parameter random_reauth_delay to stagger re-auth attempts when the minion is waiting for the master to approve its public key. This helps prevent SYN flooding in larger environments.

User/Group Management

- Implement previously-ignored unique option for user.present states in FreeBSD
- Report in state output when a group.present state attempts to use a gid in use by another group
- Fixed regression that prevents a user.present state to set the password hash to the system default (i.e. an unset password)
- Fixed multiple group.present states with the same group (issue #6439)
### File Management

- Fixed file.mkdir setting incorrect permissions ([issue #6033](#))
- Fixed cleanup of source files for templates when `/tmp` is in file_roots ([issue #6118](#))
- Fixed caching of zero-byte files when a non-empty file was previously cached at the same path
- Added HTTP authentication support to the cp module ([issue #5641](#))
- Diffs are now suppressed when binary files are changed

### Package/Repository Management

- Fixed traceback when there is only one target for `pkg.latest` states
- Fixed regression in detection of virtual packages (apt)
- Limit number of pkg database refreshes to once per `state.sls`/`state.highstate`
- YUM: Allow 32-bit packages with arches other than i686 to be managed on 64-bit systems ([issue #6299](#))
- Fixed incorrect reporting in pkgrepo.managed states ([issue #5517](#))
- Fixed 32-bit binary package installs on 64-bit RHEL-based distros, and added proper support for 32-bit packages on 64-bit Debian-based distros ([issue #6303](#))
- Fixed issue where requisites were inadvertently being put into YUM repo files ([issue #6471](#))

### Service Management

- Fixed inaccurate reporting of results in `service.running` states when the service fails to start ([issue #5894](#))
- Fixed handling of custom initscripts in RHEL-based distros so that they are immediately available, negating the need for a second state run to manage the service that the initscript controls

### Networking

- Function `network.hwaddr` renamed to `network.hw_addr` to match `network.ip_addrs` and `network.ip_addrs6`. All three functions also now work without the underscore in the name, as well.
- Fixed traceback in `bridge.show` when interface is not present ([issue #6326](#))

### SSH

- Fixed incorrect result reporting for some `ssh_known_hosts.present` states
- Fixed inaccurate reporting when `ssh_auth.present` states are run with `test=True`, when rsa/dss is used for the `enc` param instead of `ssh-rsa/ssh-dss` ([issue #5374](#))
pip

- Properly handle -f lines in pip freeze output
- Fixed regression in pip.installed states with specifying a requirements file (issue #6003)
- Fixed use of editable argument in pip.installed states (issue #6025)
- Deprecated runas parameter in execution function calls, in favor of user

MySQL

- Allow specification of MySQL connection arguments via the CLI, overriding/bypassing minion config params
- Allow mysql_user.present states to set a passwordless login (issue #5550)
- Fixed endless loop when mysql.processlist is run (issue #6297)

PostgreSQL

- Fixed traceback in postgres.user_list (issue #6352)

Miscellaneous

- Don't allow npm states to be used if npm module is not available
- Fixed alternatives.install states for which the target is a symlink (issue #6162)
- Fixed traceback in sysbench module (issue #6175)
- Fixed traceback in job cache
- Fixed tempfile cleanup for windows
- Fixed issue where SLS files using the pydsl renderer were not being run
- Fixed issue where returners were being passed incorrect information (issue #5518)
- Fixed traceback when numeric args are passed to cmd.script states
- Fixed bug causing cp.get_dir to return more directories than expected (issue #6048)
- Fixed traceback when supervisord.running states are run with test=True (issue #6053)
- Fixed tracebacks when Salt encounters problems running rbenv (issue #5888)
- Only make the monit module available if monit binary is present (issue #5871)
- Fixed incorrect behavior of img.mount_image
- Fixed traceback in tomcat.deploy_war in Windows
- Don't re-write /etc/fstab if mount fails
- Fixed tracebacks when Salt encounters problems running gem (issue #5886)
- Fixed incorrect behavior of selinux.boolean states (issue #5912)
- RabbitMQ: Quote passwords to avoid symbols being interpolated by the shell (issue #6338)
- Fixed tracebacks in extfs.mkfs and extfs.tune (issue #6462)
- Fixed a regression with the module.run state where the m_name and m_fun arguments were being ignored (issue #6464)
30.2.145 Salt 0.16.3 Release Notes

release 2013-08-09

Version 0.16.3 is another bugfix release for 0.16.0. The changes include:

- Various documentation fixes
- Fix proc directory regression (issue #6502)
- Properly detect Linaro Linux (issue #6496)
- Fix regressions in mount.mounted (issue #6522, issue #6545)
- Skip malformed state requisites (issue #6521)
- Fix regression in gitfs from bad import
- Fix for watching prereq states (including recursive requisite error) (issue #6057)
- Fix mod_watch not overriding prereq (issue #6520)
- Don't allow functions which compile states to be called within states (issue #5623)
- Return error for malformed top.sls (issue #6544)
- Fix traceback in mysql.query
- Fix regression in binary package installation for 64-bit packages on Debian-based Linux distros (issue #6563)
- Fix traceback caused by running cp.push without having set file_recv in the master config file
- Fix scheduler configuration in pillar (issue #6201)

30.2.146 Salt 0.16.4 Release Notes

release 2013-09-07

Version 0.16.4 is another bugfix release for 0.16.0, likely to be the last before 0.17.0 is released. The changes include:

- Multiple documentation improvements/additions
- Added the osfinger and osarch grains
- Properly handle 32-bit packages for debian32 on x86_64 (issue #6607)
- Fix regression in yum package installation in CentOS 5 (issue #6677)
- Fix bug in hg.latest state that would erroneously delete directories (issue #6661)
- Fix bug related to pid not existing for ps.top (issue #6679)
- Fix regression in MySQL returner (issue #6695)
- Fix IP addresses grains (ipv4 and ipv6) to include all addresses (issue #6656)
- Fix regression preventing authenticated FTP (issue #6733)
- Fix setting password for windows users (issue #6824)
- Fix file.contains on values YAML parses as non-string (issue #6817)
- Fix file.get_gid, file.get_uid, and file.chown for broken symlinks (issue #6826)
- Fix comment for service reloads in service state (issue #6851)
The 0.17.0 release is a very exciting release of Salt, this brings to Salt some very powerful new features and advances. The advances range from the state system to the test suite, covering new transport capabilities and making states easier and more powerful, to extending Salt Virt and much more!

The 0.17.0 release will also be the last release of Salt to follow the old 0.XX.X numbering system, the next release of Salt will change the numbering to be date based following this format:

<Year>.<Month>.<Minor>

So if the release happens in November of 2013 the number will be 13.11.0, the first bugfix release will be 13.11.1 and so forth.

Major Features

Halite

The new Halite web GUI is now available on PyPI. A great deal of work has been put into Halite to make it fully event driven and amazingly fast. The Halite UI can be started from within the Salt Master (after being installed from PyPI), or standalone, and does not require an external database to run. It is very lightweight!

This initial release of Halite is primarily the framework for the UI and the communication systems, making it easy to extend and build the UI up. It presently supports watching the event bus and firing commands over Salt.

At this time, Halite is not available as a package, but installation documentation is available at: http://docs.saltstack.com/topics/tutorials/halite.html

Halite is, like the rest of Salt, Open Source!

Much more will be coming in the future of Halite!

Salt SSH

The new salt-ssh command has been added to Salt. This system allows for remote execution and states to be run over ssh. The benefit here being, that salt can run relying only on the ssh agent, rather than requiring a minion to be deployed.

The salt-ssh system runs states in a compatible way as Salt and states created and run with salt-ssh can be moved over to a standard salt deployment without modification.

Since this is the initial release of salt-ssh, there is plenty of room for improvement, but it is fully operational, not just a bootstrap tool.

Rosters

Salt is designed to have the minions be aware of the master and the master does not need to be aware of the location of the minions. The new salt roster system was created and designed to facilitate listing the targets for salt-ssh.

The roster system, like most of Salt, is a plugin system, allowing for the list of systems to target to be derived from any pluggable backend. The rosters shipping with 0.17.0 are flat and scan. Flat is a file which is read in via the salt render system and the scan roster does simple network scanning to discover ssh servers.
State Auto Order

This is a major change in how states are evaluated in Salt. State Auto Order is a new feature that makes states get evaluated and executed in the order in which they are defined in the sls file. This feature makes it very easy to see the finite order in which things will be executed, making Salt now, fully imperative AND fully declarative.

The requisite system still takes precedence over the order in which states are defined, so no existing states should break with this change. But this new feature can be turned off by setting `state_auto_order: False` in the master config, thus reverting to the old lexicographical order.

state.sls Runner

The `state.sls` runner has been created to allow for a more powerful system for orchestrating state runs and function calls across the salt minions. This new system uses the state system for organizing executions.

This allows for states to be defined that are executed on the master to call states on minions via `salt-run state.sls`.

Salt Thin

Salt Thin is an exciting new component of Salt, this is the ability to execute Salt routines without any transport mechanisms installed, it is a pure python subset of Salt.

Salt Thin does not have any networking capability, but can be dropped into any system with Python installed and then `salt-call` can be called directly. The Salt Thin system, is used by the `salt-ssh` command, but can still be used to just drop salt somewhere for easy use.

Event Namespacing

Events have been updated to be much more flexible. The tags in events have all been namespaced allowing easier tracking of event names.

Mercurial Fileserver Backend

The popular git fileserver backend has been joined by the mercurial fileserver backend, allowing the state tree to be managed entirely via mercurial.

External Logging Handlers

The external logging handler system allows for Salt to directly hook into any external logging system. Currently supported are sentry and logstash.
Jenkins Testing

The testing systems in Salt have been greatly enhanced, tests for salt are now executed, via jenkins.saltstack.com, across many supported platforms. Jenkins calls out to salt-cloud to create virtual machines on Rackspace, then the minion on the virtual machine checks into the master running on Jenkins where a state run is executed that sets up the minion to run tests and executes the test suite.

This now automates the sequence of running platform tests and allows for continuous destructive tests to be run.

Salt Testing Project

The testing libraries for salt have been moved out of the main salt code base and into a standalone codebase. This has been done to ease the use of the testing systems being used in salt based projects other than Salt itself.

StormPath External Authentication

The external auth system now supports the fantastic Stormpath cloud based authentication system.

LXC Support

Extensive additions have been added to Salt for LXC support. This included the backend libs for managing LXC containers. Addition into the salt-virt system is still in the works.

macOS User/Group Support

Salt is now able to manage users and groups on Minions running macOS. However, at this time user passwords cannot be managed.

Django ORM External Pillar

Pillar data can now be derived from Django managed databases.

Fixes from RC to release

- Multiple documentation fixes
- Add multiple source files + templating for file.append (issue #6905)
- Support syconfig configuration files in systemd>=207 (issue #7351)
- Add file.search and file.replace
- Fix cross-calling execution functions in provider overrides
- Fix locale override for postgres (issue #4543)
- Fix Raspbian identification for service/pkg support (issue #7371)
- Fix cp.push file corruption (issue #6495)
- Fix ALT Linux password hash specification (issue #3474)
- Multiple salt-ssh-related fixes and improvements
30.2.148 Salt 0.17.1 Release Notes

release 2013-10-17

Note: THIS RELEASE IS NOT COMPATIBLE WITH PREVIOUS VERSIONS. If you update your master to 0.17.1, you must update your minions as well. Sorry for the inconvenience -- this is a result of one of the security fixes listed below.

The 0.17.1 release comes with a number of improvements to salt-ssh, many bugfixes, and a number of security updates.

Salt SSH has been improved to be faster, more featureful and more secure. Since the original release of Salt SSH was primarily a proof of concept, it has been very exciting to see its rapid adoption. We appreciate the willingness of security experts to review Salt SSH and help discover oversights and ensure that security issues only exist for such a tiny window of time.

SSH Enhancements

Shell Improvements

Improvements to Salt SSH's communication have been added that improve routine execution regardless of the target system's login shell.

Performance

Deployment of routines is now faster and takes fewer commands to execute.

Security Updates

Be advised that these security issues all apply to a small subset of Salt users and mostly apply to Salt SSH.

Insufficient Argument Validation

This issue allowed for a user with limited privileges to embed executions inside of routines to execute routines that should be restricted. This applies to users using external auth or client ACL and opening up specific routines.

Be advised that these patches address the direct issue. Additional commits have been applied to help mitigate this issue from resurfacing.

MITM SSH attack in salt-ssh

SSH host keys were being accepted by default and not enforced on future SSH connections. These patches set SSH host key checking by default and can be overridden by passing the -i flag to salt-ssh.

Insecure Usage of /tmp in salt-ssh

The initial release of salt-ssh used the /tmp directory in an insecure way. These patches not only secure usage of files under /tmp in salt-ssh, but also add checksum validation for all packages sent into the now secure locations on target systems.

YAML Calling Unsafe Loading Routine

It has been argued that this is not a valid security issue, as the YAML loading that was happening was only being called after an initial gateway filter in Salt has already safely loaded the YAML and would fail if non-safe routines were embedded. Nonetheless, the CVE was filed and patches applied.

Fix Reference

Version 0.17.1 is the first bugfix release for 0.17.0. The changes include:

- Fix symbolic links in thin.tgz (issue #7482)
- Pass env through to file.patch state (issue #7452)
- Service provider fixes and reporting improvements (issue #7361)
- Add --priv option for specifying salt-ssh private key
- Fix salt-thin's salt-call on setuptools installations (issue #7516)
- Fix salt-ssh to support passwords with spaces (issue #7480)
- Fix regression in wildcard includes (issue #7455)
- Fix salt-call outputter regression (issue #7456)
- Fix custom returner support for startup states (issue #7540)
- Fix value handling in augeas (issue #7605)
- Fix regression in apt (issue #7624)
- Fix minion ID guessing to use socket.getfqdn() first (issue #7558)
- Add minion ID caching (issue #7558)
- Fix salt-key race condition (issue #7304)
- Add --include-all flag to salt-key (issue #7399)
- Fix custom grains in pillar (part of issue #5716, issue #6083)
- Fix race condition in salt-key (issue #7304)
- Fix regression in minion ID guessing, prioritize socket.getfqdn() (issue #7558)
- Cache minion ID on first guess (issue #7558)
- Allow trailing slash in file.directory state
- Fix reporting of file_roots in pillar return (issue #5449 and issue #5951)
- Remove pillar matching for mine.get (issue #7197)
- Sanitize args for multiple execution modules
- Fix yumpkg mod_repo functions to filter hidden args (issue #7656)
- Fix conflicting IDs in state includes (issue #7526)
- Fix mysql_grants.absent string formatting issue (issue #7827)
- Fix postgres.version so it won't return None (issue #7695)
- Fix for trailing slashes in mount.mounted state
- Fix rogue AttributeError in the outputter system (issue #7845)
- Fix for incorrect ssh key encodings resulting in incorrect key added (issue #7718)
• Fix for pillar/grains naming regression in python renderer (issue #7693)
• Fix args/kwarg handling in the scheduler (issue #7422)
• Fix logfile handling for file://, tcp://, and udp:// (issue #7754)
• Fix error handling in config file parsing (issue #6714)
• Fix RVM using sudo when running as non-root user (issue #2193)
• Fix client ACL and underlying logging bugs (issue #7706)
• Fix scheduler bug with returner (issue #7367)
• Fix user management bug related to default groups (issue #7690)
• Fix various salt-ssh bugs (issue #7528)
• Many various documentation fixes

### 30.2.149 Salt 0.17.2 Release Notes

release 2013-11-14

Version 0.17.2 is another bugfix release for 0.17.0. The changes include:

• Add ability to delete key with grains.delval (issue #7872)
• Fix possible state compiler stack trace (issue #5767)
• Fix architecture regression in yumpkg (issue #7813)
• Use correct ps on Debian to prevent truncating (issue #5646)
• Fix grains targeting for new grains (issue #5737)
• Fix bug with merging in git_pillar (issue #6992)
• Fix print_jobs duplicate results
• Fix apt version specification for pkg.install
• Fix possible KeyError from ext_job_cache missing option
• Fix auto_order for - names states (issue #7649)
• Fix regression in new gitfs installs (directory not found error)
• Fix escape pipe issue on Windows for file.recurse (issue #7967)
• Fix fileclient in case of master restart (issue #7987)
• Try to output warning if CLI command malformed (issue #6538)
• Fix --out=quiet to actually be quiet (issue #8000)
• Fix for state.sls in salt-ssh (issue #7991)
• Fix for MySQL grants ordering issue (issue #5817)
• Fix traceback for certain missing CLI args (issue #8016)
• Add ability to disable lspci queries on master (issue #4906)
• Fail if sls defined in topfile does not exist (issue #5998)
• Add ability to downgrade MySQL grants (issue #6606)
• Fix ssh_auth.absent traceback (issue #8043)
• Add upstart detection for Debian/Raspbian (issue #8039)
• Fix ID-related issues (issue #8052, issue #8050, and others)
• Fix for jinja rendering issues (issue #8066 and issue #8079)
• Fix argument parsing in salt-ssh (issue #7928)
• Fix some GPU detection instances (issue #6945)
• Fix bug preventing includes from other environments in SLS files
• Fix for kwargs with dashes (issue #8102)
• Fix salt.utils.which for windows '.exe' (issue #7904)
• Fix apache.adduser without apachectl (issue #8123)
• Fix issue with evaluating test kwarg in states (issue #7788)
• Fix regression in salt.client.Caller() (issue #8078)
• Fix apt-key silent failure
• Fix bug where cmd.script would try to run even if caching failed (issue #7601)
• Fix apt pkg.latest regression (issue #8067)
• Fix for mine data not being updated (issue #8144)
• Fix for noarch packages in yum
• Fix a Xen detection edge case (issue #7839)
• Fix windows __opts__ dictionary persistence (issue #7714)
• Fix version generation for when it's part of another git repo (issue #8090)
• Fix handle_iorder stacktrace so that the real syntax error is shown (issue #8114 and issue #7905)
• Fix git.latest state when a commit SHA is used (issue #8163)
• Fix various small bugs in yumpkg.py (issue #8201)
• Fix for specifying identify file in git.latest (issue #8094)
• Fix for --output-file CLI arg (issue #8205)
• Add ability to specify shutdown time for system.shutdown (issue #7833)
• Fix for salt version using non-salt git repo info (issue #8266)
• Add additional hints at impact of pkgrepo states when test=True (issue #8247)
• Fix for salt-ssh files not being owned by root (issue #8216)
• Fix retry logic and error handling in fileserver (related to issue #7755)
• Fix file.replace with test=True (issue #8279)
• Add flag for limiting file traversal in fileserver (issue #6928)
• Fix for extra mine processes (issue #5729)
• Fix for unloading custom modules (issue #7691)
• Fix for salt-ssh opts (issue #8005 and issue #8271)
• Fix compound matcher for grains (issue #7944)
• Improve error reporting in ebuild module (related to issue #5393)
• Add `dir_mode` to `file.managed` (issue #7860)
• Improve traceroute support for FreeBSD and macOS (issue #4927)
• Fix for matching minions under syndics (issue #7671)
• Improve exception handling for missing ID (issue #8259)
• Fix grain mismatch for ScientificLinux (issue #8338)
• Add configuration option for `minion_id_caching`
• Fix open mode auth errors (issue #8402)

30.2.150 Salt 0.17.3 Release Notes

release 2013-12-08

Note: 0.17.3 had some regressions which were promptly fixed in the 0.17.4 release. Please use 0.17.4 instead.

Version 0.17.3 is another bugfix release for 0.17.0. The changes include:

• Fix some jinja render errors (issue #8418)
• Fix `file.replace` state changing file ownership (issue #8399)
• Fix state ordering with the PyDSL renderer (issue #8446)
• Fix for new npm version (issue #8517)
• Fix for pip state requiring `name` even with requirements file (issue #8519)
• Fix yum logging to open terminals (issue #3855)
• Add sane maxrunning defaults for scheduler (issue #8563)
• Fix states duplicate key detection (issue #8053)
• Fix SUSE patch level reporting (issue #8428)
• Fix managed file creation umask (issue #8590)
• Fix logstash exception (issue #8635)
• Improve argument exception handling for salt command (issue #8016)
• Fix pecl success reporting (issue #8750)
• Fix launchctl module exceptions (issue #8759)
• Fix argument order in `pw_user` module
• Add warnings for failing grains (issue #8690)
• Fix hgfs problems caused by connections left open (issue #8811 and issue #8810)
• Add Debian iptables default for iptables-persistent package (issue #8889)
• Fix installation of packages with dots in pkg name (issue #8614)
• Fix noarch package installation on CentOS 6 (issue #8945)
• Fix `portage_config.enforce_nice_config` (issue #8252)
• Fix `salt.util.copyfile` umask usage (issue #8590)
• Fix rescheduling of failed jobs (issue #8941)
• Fix pkg on Amazon Linux (uses yumpkg5 now) (issue #8226)
• Fix conflicting options in postgres module (issue #8717)
• Fix ps modules for psutil >= 0.3.0 (issue #7432)
• Fix postgres module to return False on failure (issue #8778)
• Fix argument passing for args with pound signs (issue #8585)
• Fix pid of salt CLI command showing in status.pid output (issue #8720)
• Fix rvm to run gem as the correct user (issue #8951)
• Fix namespace issue in win_file module (issue #9060)
• Fix masterless state paths on windows (issue #9021)
• Fix timeout option in master config (issue #9040)

30.2.151 Salt 0.17.4 Release Notes

release 2013-12-10

Version 0.17.4 is another bugfix release for 0.17.0. The changes include:
• Fix file.replace bug when replacement str is numeric (issue #9101)
• Fix regression in file.managed (issue #9131)
• Prevent traceback when job is None. (issue #9145)

30.2.152 Salt 0.17.5 Release Notes

release 2014-01-27

Version 0.17.5 is another bugfix release for 0.17.0. The changes include:
• Fix user.present states with non-string fullname (issue #9085)
• Fix virt.init return value on failure (issue #6870)
• Fix reporting of file.blockreplace state when test=True
• Fix network.interfaces when used in cron (issue #7990)
• Fix bug in pkgrepo when switching to/from mirrorlist-based repo def (issue #9121)
• Fix infinite recursion when cache file is corrupted
• Add checking for rev and mirror/bare args in git.latest (issue #9107)
• Add cmd.watch alias (points to cmd.wait) (issue #8612)
• Fix stacktrace when prereq is not formed as a list (issue #8235)
• Fix stdin issue with lvdisplay command (issue #9128)
• Add pre-check function for range matcher (issue #9236)
• Add exception handling for psutil for processes that go missing (issue #9274)
• Allow _in requisites to match both on ID and name (issue #9061)
• Fix multiple client timeout issues (issue #7157 and issue #9302, probably others)
Salt Documentation, Release 3002.5

- Fix ZMQError: Operation cannot be accomplished in current state errors (issue #6306)
- Multiple optimization in minion auth routines
- Clarify logs for minion ID caching

30.2.153 Salt 0.6.0 release notes

The Salt remote execution manager has reached initial functionality! Salt is a management application which can be used to execute commands on remote sets of servers.

The whole idea behind Salt is to create a system where a group of servers can be remotely controlled from a single master, not only can commands be executed on remote systems, but salt can also be used to gather information about your server environment.

Unlike similar systems, like Func and MCollective, Salt is extremely simple to setup and use, the entire application is contained in a single package, and the master and minion daemons require no running dependencies in the way that Func requires Certmaster and MCollective requires activeMQ.

Salt also manages authentication and encryption. Rather than using SSL for encryption, salt manages encryption on a payload level, so the data sent across the network is encrypted with fast AES encryption, and authentication uses RSA keys. This means that Salt is fast, secure, and very efficient.

Messaging in Salt is executed with ZeroMQ, so the message passing interface is built into salt and does not require an external ZeroMQ server. This also adds speed to Salt since there is no additional bloat on the networking layer, and ZeroMQ has already proven itself as a very fast networking system.

The remote execution in Salt is "Lazy Execution", in that once the command is sent the requesting network connection is closed. This makes it easier to detach the execution from the calling process on the master, it also means that replies are cached, so that information gathered from historic commands can be queried in the future.

Salt also allows users to make execution modules in Python. Writers of these modules should also be pleased to know that they have access to the impressive information gathered from PuppetLabs' Facter application, making Salt module more flexible. In the future I hope to also allow Salt to group servers based on Facter information as well.

All in all Salt is fast, efficient, and clean, can be used from a simple command line client or through an API, uses message queue technology to make network execution extremely fast, and encryption is handled in a very fast and efficient manner. Salt is also VERY easy to use and VERY easy to extend.

You can find the source code for Salt on my GitHub page, I have also set up a few wiki pages explaining how to use and set up Salt. If you are using Arch Linux there is a package available in the Arch Linux AUR.

GitHub page: https://github.com/saltstack/salt
Wiki: https://github.com/saltstack/salt/wiki
Arch Linux Package: https://aur.archlinux.org/packages/salt-git/

I am very open to contributions, for instance I need packages for more Linux distributions as well as BSD packages and testers.

Give Salt a try, this is the initial release and is not a 1.0 quality release, but it has been working well for me! I am eager to get your feedback!
30.2.154 Salt 0.7.0 release notes

I am pleased to announce the release of Salt 0.7.0!

This release marks what is the first stable release of salt, 0.7.0 should be suitable for general use.

0.7.0 Brings the following new features to Salt:

• Integration with Facter data from puppet labs
• Allow for matching minions from the salt client via Facter information
• Minion job threading, many jobs can be executed from the master at once
• Preview of master clustering support - Still experimental
• Introduce new minion modules for stats, virtualization, service management and more
• Add extensive logging to the master and minion daemons
• Add sys.reload_functions for dynamic function reloading
• Greatly improve authentication
• Introduce the saltkey command for managing public keys
• Begin backend development preparatory to introducing butter
• Addition of man pages for the core commands
• Extended and cleaned configuration

0.7.0 Fixes the following major bugs:

• Fix crash in minions when matching failed
• Fix configuration file lookups for the local client
• Repair communication bugs in encryption
• Numerous fixes in the minion modules

The next release of Salt should see the following features:

• Stabilize the cluster support
• Introduce a remote client for salt command tiers
• salt-ftp system for distributed file copies
• Initial support for “butter”

Coming up next is a higher level management framework for salt called Butter. I want salt to stay as a simple and effective communication framework, and allow for more complicated executions to be managed via Butter.

Right now Butter is being developed to act as a cloud controller using salt as the communication layer, but features like system monitoring and advanced configuration control (a puppet manager) are also in the pipe.

Special thanks to Joseph Hall for the status and network modules, and thanks to Matthias Teege for tracking down some configuration bugs!

Salt can be downloaded from the following locations;

Arch Linux Package:
https://aur.archlinux.org/packages/salt-git/

Please enjoy the latest Salt release!
30.2.155 Salt 0.8.0 release notes

Salt 0.8.0 is ready for general consumption! The source tarball is available on GitHub for download:

A lot of work has gone into salt since the last release just 2 weeks ago, and salt has improved a great deal. A swath of new features are here along with performance and threading improvements!

The main new features of salt 0.8.0 are:

Salt-cp
Cython minion modules
Dynamic returners
Faster return handling
Lowered required Python version to 2.6
Advanced minion threading
Configurable minion modules

Salt-cp

The salt-cp command introduces the ability to copy simple files via salt to targeted servers. Using salt-cp is very simple, just call salt-cp with a target specification, the source file(s) and where to copy the files on the minions. For instance:

```
# salt-cp '*' /etc/hosts /etc/hosts
```

Will copy the local /etc/hosts file to all of the minions.

Salt-cp is very young, in the future more advanced features will be added, and the functionality will much more closely resemble the cp command.

Cython minion modules

Cython is an amazing tool used to compile Python modules down to c. This is arguably the fastest way to run Python code, and since pyzmq requires cython, adding support to salt for cython adds no new dependencies.

Cython minion modules allow minion modules to be written in cython and therefore executed in compiled c. Simply write the salt module in cython and use the file extension ".pyx" and the minion module will be compiled when the minion is started. An example cython module is included in the main distribution called cytest.pyx:

```
https://github.com/saltstack/salt/blob/master/salt/modules/cytest.pyx
```

Dynamic Returners

By default salt returns command data back to the salt master, but now salt can return command data to any system. This is enabled via the new returners modules feature for salt. The returners modules take the return data and sends it to a specific module. The returner modules work like minion modules, so any returner can be added to the minions.

This means that a custom data returner can be added to communicate the return data so anything from MySQL, Redis, MongoDB, and more!

There are 2 simple stock returners in the returners directory:

```
https://github.com/saltstack/salt/blob/master/salt/returners
```
The documentation on writing returners will be added to the wiki shortly, and returners can be written in pure
Python, or in cython.

**Configurable Minion Modules**

Minion modules may need to be configured, now the options passed to the minion configuration file can be accessed
inside of the minion modules via the `__opt__` dict.
Information on how to use this simple addition has been added to the wiki: [Writing modules]

The test module has an example of using the `__opts__` dict, and how to set default options:

https://github.com/saltstack/salt/blob/master/salt/modules/test.py

**Advanced Minion Threading**

In 0.7.0 the minion would block after receiving a command from the master, now the minion will spawn a thread
or multiprocess. By default Python threads are used because for general use they have proved to be faster, but the
minion can now be configured to use the Python multiprocessing module instead. Using multiprocessing will cause
executions that are CPU bound or would otherwise exploit the negative aspects of the Python GIL to run faster and
more reliably, but simple calls will still be faster with Python threading. The configuration option can be found in
the minion configuration file:

https://github.com/saltstack/salt/blob/master/conf/minion

**Lowered Supported Python to 2.6**

The requirement for Python 2.7 has been removed to support Python 2.6. I have received requests to take the
minimum Python version back to 2.4, but unfortunately this will not be possible, since the ZeroMQ Python bindings
do not support Python 2.4.

Salt 0.8.0 is a very major update, it also changes the network protocol slightly which makes communication with
older salt daemons impossible, your master and minions need to be upgraded together!

I could use some help bringing salt to the people! Right now I only have packages for Arch Linux, Fedora 14 and
Gentoo. We need packages for Debian and people willing to help test on more platforms. We also need help writing
more minion modules and returner modules. If you want to contribute to salt please hop on the mailing list and send
in patches, make a fork on GitHub and send in pull requests! If you want to help but are not sure where you can,
please email me directly or post to the mailing list!

I hope you enjoy salt, while it is not yet 1.0 salt is completely viable and usable!

**30.2.156 Salt 0.8.7 release notes**

It has been a month since salt 0.8.0, and it has been a long month! But Salt is still coming along strong. 0.8.7 has
a lot of changes and a lot of updates. This update makes Salt’s ZeroMQ back end better, strips Facter from the
dependencies, and introduces interfaces to handle more capabilities.

Many of the major updates are in the background, but the changes should shine through to the surface. A number
of the new features are still a little thin, but the back end to support expansion is in place.

I also recently gave a presentation to the Utah Python users group in Salt Lake City, the slides from this presentation
are available here:
The video from this presentation will be available shortly.

The major new features and changes in Salt 0.8.7 are:

- Revamp ZeroMQ topology on the master for better scalability
- State enforcement
- Dynamic state enforcement managers
- Extract the module loader into salt.loader
- Make Job ids more granular
- Replace Facter functionality with the new salt grains interface
- Support for “virtual” salt modules
- Introduce the salt-call command
- Better debugging for minion modules

The new ZeroMQ topology allows for better scalability, this will be required by the need to execute massive file transfers to multiple machines in parallel and state management. The new ZeroMQ topology is available in the aforementioned presentation.

0.8.7 introduces the capability to declare states, this is similar to the capabilities of Puppet. States in salt are declared via state data structures. This system is very young, but the core feature set is available. Salt states work around rendering files which represent Salt high data. More on the Salt state system will be documented in the near future.

The system for loading salt modules has been pulled out of the minion class to be a standalone module, this has enabled more dynamic loading of Salt modules and enables many of the updates in 0.8.7 –

https://github.com/saltstack/salt/blob/master/salt/loader.py

Salt Job ids are now microsecond precise, this was needed to repair a race condition unveiled by the speed improvements in the new ZeroMQ topology.

The new grains interface replaces the functionality of Facter, the idea behind grains differs from Facter in that the grains are only used for static system data, dynamic data needs to be derived from a call to a salt module. This makes grains much faster to use, since the grains data is generated when the minion starts.

Virtual salt modules allows for a salt module to be presented as something other than its module name. The idea here is that based on information from the minion decisions about which module should be presented can be made. The best example is the pacman module. The pacman module will only load on Arch Linux minions, and will be called pkg. Similarly the yum module will be presented as pkg when the minion starts on a Fedora/RedHat system.

The new salt-call command allows for minion modules to be executed from the minion. This means that on the minion a salt module can be executed, this is a great tool for testing Salt modules. The salt-call command can also be used to view the grains data.

In previous releases when a minion module threw an exception very little data was returned to the master. Now the stack trace from the failure is returned making debugging of minion modules MUCH easier.

Salt is nearing the goal of 1.0, where the core feature set and capability is complete!

30.2.157 Salt 0.8.8 release notes

Salt 0.8.8 is here! This release adds a great deal of code and some serious new features.

Improved Documentation has been set up for salt using sphinx thanks to the efforts of Seth House. This new documentation system will act as the back end to the salt website which is still under heavy development. The new sphinx documentation system has also been used to greatly clean up the salt manpages. The salt 7 manpage in particular now contains extensive information which was previously only in the wiki. The new documentation can be found at: http://docs.saltstack.com/ We still have a lot to add, and when the domain is set up I will post another announcement.

More additions have been made to the ZeroMQ setup, particularly in the realm of file transfers. Salt 0.8.8 introduces a built in, stateless, encrypted file server which allows salt minions to download files from the salt master using the same encryption system used for all other salt communications. The main motivation for the salt file server has been to facilitate the new salt state system.

Much of the salt code has been cleaned up and a new cleaner logging system has been introduced thanks to the efforts of Pedro Algarvio. These additions will allow for much more flexible logging to be executed by salt, and fixed a great deal of my poor spelling in the salt docstrings! Pedro Algarvio has also cleaned up the API, making it easier to embed salt into another application.

The biggest addition to salt found in 0.8.8 is the new state system. The salt module system has received a new front end which allows salt to be used as a configuration management system. The configuration management system allows for system configuration to be defined in data structures. The configuration management system, or as it is called in salt, the “salt state system” supports many of the features found in other configuration managers, but allows for system states to be written in a far simpler format, executes at blazing speeds, and operates via the salt minion matching system. The state system also operates within the normal scope of salt, and requires no additional configuration to use.

The salt state system can enforce the following states with many more to come: Packages Files Services Executing commands Hosts

The system used to define the salt states is based on a data structure, the data structure used to define the salt states has been made to be as easy to use as possible. The data structure is defined by default using a YAML file rendered via a Jinja template. This means that the state definition language supports all of the data structures that YAML supports, and all of the programming constructs and logic that Jinja supports. If the user does not like YAML or Jinja the states can be defined in yaml-mako, json-jinja, or json-mako. The system used to render the states is completely dynamic, and any rendering system can be added to the capabilities of Salt, this means that a rendering system that renders XML data in a cheetah template, or whatever you can imagine, can be easily added to the capabilities of salt.

The salt state system also supports isolated environments, as well as matching code from several environments to a single salt minion.

The feature base for Salt has grown quite a bit since my last serious documentation push. As we approach 0.9.0 the goals are becoming very clear, and the documentation needs a lot of work. The main goals for 0.9.0 are to further refine the state system, fix any bugs we find, get Salt running on as many platforms as we can, and get the documentation filled out. There is a lot more to come as Salt moves forward to encapsulate a much larger scope, while maintaining supreme usability and simplicity.

If you would like a more complete overview of Salt please watch the Salt presentation: Slides:

30.2.158 Salt 0.8.9 Release Notes

Salt 0.8.9 has finally arrived! Unfortunately this is much later than I had hoped to release 0.8.9, life has been very crazy over the last month. But despite challenges, Salt has moved forward!

This release, as expected, adds few new features and many refinements. One of the most exciting aspect of this release is that the development community for salt has grown a great deal and much of the code is from contributors.

Also, I have filled out the documentation a great deal. So information on States is properly documented, and much of the documentation that was out of date has been filled in.

Download!

The Salt source can be downloaded from PyPI:
https://pypi.python.org/packages/source/s/salt/salt-0.8.9.tar.gz

For instructions on how to set up Salt please see the Installation instructions.

New Features

Salt Run

A big feature is the addition of Salt run, the `salt-run` command allows for master side execution modules to be made that gather specific information or execute custom routines from the master.

Documentation for salt-run can be found here

Refined Outputters

One problem often complained about in salt was the fact that the output was so messy. Thanks to help from Jeff Schroeder a cleaner interface for the command output for the Salt CLI has been made. This new interface makes adding new printout formats easy and additions to the capabilities of minion modules makes it possible to set the printout mode or outputter for functions in minion modules.

Cross Calling Salt Modules

Salt modules can now call each other, the `__salt__` dict has been added to the predefined references in minion modules. This new feature is documented in the modules documentation.
Watch Option Added to Salt State System

Now in Salt states you can set the watch option, this will allow watch enabled states to change based on a change in the other defined states. This is similar to subscribe and notify statements in puppet.

Root Dir Option

Travis Cline has added the ability to define the option `root_dir` which allows the salt minion to operate in a subdir. This is a strong move in supporting the minion running as an unprivileged user.

Config Files Defined in Variables

Thanks again to Travis Cline, the master and minion configuration file locations can be defined in environment variables now.

New Modules

Quite a few new modules, states, returners, and runners have been made.

New Minion Modules

apt

Support for apt-get has been added, this adds greatly improved Debian and Ubuntu support to Salt!

useradd and groupadd

Support for manipulating users and groups on Unix-like systems.

moosefs

Initial support for reporting on aspects of the distributed file system, MooseFS. For more information on MooseFS please see: [http://www.moosefs.org](http://www.moosefs.org)

Thanks to Joseph Hall for his work on MooseFS support.

mount

Manage mounts and the fstab.
puppet

Execute puppet on remote systems.

shadow

Manipulate and manage the user password file.

ssh

Interact with ssh keys.

New States

user and group

Support for managing users and groups in Salt States.

mount

Enforce mounts and the fstab.

New Returners

mongo_return

Send the return information to a MongoDB server.

New Runners

manage

Display minions that are up or down.

30.2.159 Salt 0.9.0 Release Notes

release 2011-08-27

Salt 0.9.0 is here. This is an exciting release, 0.9.0 includes the new network topology features allowing peer salt commands and masters of masters via the syndic interface.

0.9.0 also introduces many more modules, improvements to the API and improvements to the ZeroMQ systems.
Download!

The Salt source can be downloaded from PyPI:
https://pypi.python.org/packages/source/s/salt/salt-0.9.0.tar.gz

Here is the md5sum:
9a925da04981e65a0f237f2e77ddab37

For instructions on how to set up Salt please see the *Installation* instructions.

New Features

Salt Syndic

The new *Syndic interface* allows a master to be commanded via another higher level salt master. This is a powerful solution allowing a master control structure to exist, allowing salt to scale to much larger levels then before.

Peer Communication

0.9.0 introduces the capability for a minion to call a publication on the master and receive the return from another set of minions. This allows salt to act as a communication channel between minions and as a general infrastructure message bus.

Peer communication is turned off by default but can be enabled via the `peer` option in the master configuration file. Documentation on the new *Peer interface*.

Easily Extensible API

The minion and master classes have been redesigned to allow for specialized minion and master servers to be easily created. An example on how this is done for the master can be found in the `master.py` salt module:

https://github.com/saltstack/salt/blob/master/salt/master.py

The `Master` class extends the `SMaster` class and set up the main master server.

The minion functions can now also be easily added to another application via the `SMinion` class, this class can be found in the `minion.py` module:

https://github.com/saltstack/salt/blob/master/salt/minion.py

Cleaner Key Management

This release changes some of the key naming to allow for multiple master keys to be held based on the type of minion gathering the master key.

The `-d` option has also been added to the salt-key command allowing for easy removal of accepted public keys.

The `--gen-keys` option is now available as well for salt-key, this allows for a salt specific RSA key pair to be easily generated from the command line.
**Improved 0MQ Master Workers**

The 0MQ worker system has been further refined to be faster and more robust. This new system has been able to handle a much larger load than the previous setup. The new system uses the IPC protocol in 0MQ instead of TCP.

**New Modules**

Quite a few new modules have been made.

**New Minion Modules**

**apache**

Work directly with apache servers, great for managing balanced web servers

**cron**

Read out the contents of a systems crontabs

**mdadm**

Module to manage raid devices in Linux, appears as the `raid` module

**mysql**

Gather simple data from MySQL databases

**ps**

Extensive utilities for managing processes

**publish**

Used by the peer interface to allow minions to make publications

**30.2.160  Salt 0.9.1 Release Notes**

    release  2011-08-29
Salt 0.9.2 has arrived! 0.9.2 is primarily a bugfix release, the exciting component in 0.9.2 is greatly improved support for salt states. All of the salt states interfaces have been more thoroughly tested and the new salt-states git repo is growing with example of how to use states.

This release introduces salt states for early developers and testers to start helping us clean up the states interface and make it ready for the world!

0.9.2 also fixes a number of bugs found on Python 2.6.

Download!

The Salt source can be downloaded from PyPI:
https://pypi.python.org/packages/source/s/salt/salt-0.9.2.tar.gz

For instructions on how to set up Salt please see the Installation instructions.

New Features

Salt-Call Additions

The salt-call command has received an overhaul, it now hooks into the outputter system so command output looks clean, and the logging system has been hooked into salt-call, so the -l option allows the logging output from salt minion functions to be displayed.

The end result is that the salt-call command can execute the state system and return clean output:

```
# salt-call state.highstate
```

State System Fixes

The state system has been tested and better refined. As of this release the state system is ready for early testers to start playing with. If you are interested in working with the state system please check out the (still very small) salt-states GitHub repo:

https://github.com/SS-archive/salt-states

This git repo is the active development branch for determining how a clean salt-state database should look and act. Since the salt state system is still very young a lot of help is still needed here. Please fork the salt-states repo and help us develop a truly large and scalable system for configuration management!
Notable Bug Fixes

Python 2.6 String Formatting

Python 2.6 does not support format strings without an index identifier, all of them have been repaired.

Cython Loading Disabled by Default

Cython loading requires a development tool chain to be installed on the minion, requiring this by default can cause problems for most Salt deployments. If Cython auto loading is desired it will need to be turned on in the minion config.

30.2.162 Salt 0.9.3 Release Notes

release 2011-11-05

Salt 0.9.3 is finally arrived. This is another big step forward for Salt, new features range from proper FreeBSD support to fixing issues seen when attaching a minion to a master over the Internet.

The biggest improvements in 0.9.3 though can be found in the state system, it has progressed from something ready for early testers to a system ready to compete with platforms such as Puppet and Chef. The backbone of the state system has been greatly refined and many new features are available.

Download!

The Salt source can be downloaded from PyPI:

https://pypi.python.org/packages/source/s/salt/salt-0.9.3.tar.gz

For instructions on how to set up Salt please see the Installation instructions.

New Features

WAN Support

Recently more people have been testing Salt minions connecting to Salt Masters over the Internet. It was found that Minions would commonly lose their connection to the master when working over the internet. The minions can now detect if the connection has been lost and reconnect to the master, making WAN connections much more reliable.

State System Fixes

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been found and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.
Extend Declaration

The Salt States have also gained the extend declaration. This declaration allows for states to be cleanly modified in a post environment. Simply said, if there is an apache.sls file that declares the apache service, then another sls can include apache and then extend it:

```python
include:
  - apache

extend:
  apache:
    service:
      - require:
      - pkg: mod_python

mod_python:
  pkg:
    - installed
```

The notable behavior with the extend functionality is that it literally extends or overwrites a declaration set up in another sls module. This means that Salt will behave as though the modifications were made directly to the apache sls. This ensures that the apache service in this example is directly tied to all requirements.

Highstate Structure Specification

This release comes with a clear specification of the Highstate data structure that is used to declare Salt States. This specification explains everything that can be declared in the Salt SLS modules.

The specification is extremely simple, and illustrates how Salt has been able to fulfill the requirements of a central configuration manager within a simple and easy to understand format and specification.

SheBang Renderer Switch

It came to our attention that having many renderers means that there may be a situation where more than one State Renderer should be available within a single State Tree.

The method chosen to accomplish this was something already familiar to developers and systems administrators, a SheBang. The Python State Renderer displays this new capability.

Python State Renderer

Until now Salt States could only be declared in yaml or json using Jinja or Mako. A new, very powerful, renderer has been added, making it possible to write Salt States in pure Python:

```python
#!py

def run():
    
        """
    Install the python-mako package
        """
    return {"include": ["python"], "python-mako": {"pkg": ["installed"]}}
```
This renderer is used by making a run function that returns the Highstate data structure. Any capabilities of Python can be used in pure Python sls modules.

This example of a pure Python sls module is the same as this example in yaml:

```python
include:
  - python

python-mako:
  pkg:
    - installed
```

**FreeBSD Support**

Additional support has been added for FreeBSD, this is Salt's first branch out of the Linux world and proves the viability of Salt on non-Linux platforms.

Salt remote execution already worked on FreeBSD, and should work without issue on any Unix-like platform. But this support comes in the form of package management and user support, so Salt States also work on FreeBSD now.

The new freebsdpkg module provides package management support for FreeBSD and the new pw_user and pw_group provide user and group management.

**Module and State Additions**

**Cron Support**

Support for managing the system crontab has been added, declaring a cron state can be done easily:

```bash
date > /tmp/datesetamp:
  cron:
    - present
    - user: fred
    - minute: 5
    - hour: 3
```

**File State Additions**

The file state has been given a number of new features, primarily the directory, recurse, symlink, and absent functions.

`file.directory` Make sure that a directory exists and has the right permissions.

```
/srv/foo:
  file:
    - directory
    - user: root
    - group: root
    - mode: 1755
```

`file.symlink` Make a symlink.

```
/var/lib/www:
  file:
    - symlink
```
file.recurse  The recurse state function will recursively download a directory on the master file server and place it on the minion. Any change in the files on the master will be pushed to the minion. The recurse function is very powerful and has been tested by pushing out the full Linux kernel source.

```
file:
  - recurse
  - source: salt://linux
```

file.absent  Make sure that the file is not on the system, recursively deletes directories, files, and symlinks.

```
file:
  - absent
```

Sysctl Module and State

The sysctl module and state allows for sysctl components in the kernel to be managed easily. The sysctl module contains the following functions:

- `sysctl.show`  Return a list of sysctl parameters for this minion
- `sysctl.get`  Return a single sysctl parameter for this minion
- `sysctl.assign`  Assign a single sysctl parameter for this minion
- `sysctl.persist`  Assign and persist a simple sysctl parameter for this minion

The sysctl state allows for sysctl parameters to be assigned:

```
vm.swappiness:
  sysctl:
    - present
    - value: 20
```

Kernel Module Management

A module for managing Linux kernel modules has been added. The new functions are as follows:

- `kmod.available`  Return a list of all available kernel modules
- `kmod.check_available`  Check to see if the specified kernel module is available
- `kmod.lsmod`  Return a dict containing information about currently loaded modules
- `kmod.load`  Load the specified kernel module
- `kmod.remove`  Unload the specified kernel module

The kmod state can enforce modules be either present or absent:

```
kvm_intel:
  kmod:
    - present
```
Ssh Authorized Keys

The ssh_auth state can distribute ssh authorized keys out to minions. Ssh authorized keys can be present or absent.

```

30.2.163 Salt 0.9.4 Release Notes

release 2011-11-27

Salt 0.9.4 has arrived. This is a critical update that repairs a number of key bugs found in 0.9.3. But this update is not without feature additions as well! 0.9.4 adds support for Gentoo portage to the pkg module and state system. Also there are 2 major new state additions, the failhard option and the ability to set up finite state ordering with the order option.

This release also sees our largest increase in community contributions. These contributors have and continue to be the life blood of the Salt project, and the team continues to grow. I want to put out a big thanks to our new and existing contributors.

Download!

The Salt source can be downloaded from PyPI:

https://pypi.python.org/packages/source/s/salt/salt-0.9.4.tar.gz

For instructions on how to set up Salt please see the Installation instructions.

New Features

Failhard State Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called failing hard.
State Level Failhard

A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```
/etc/yum.repos.d/company.repo:
  file:
    - managed
    - source: salt://company/yumrepo.conf
    - user: root
    - group: root
    - mode: 644
    - order: 1
    - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

Global Failhard

It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration

Finite Ordering of State Execution

When creating salt sls files, it is often important to ensure that they run in a specific order. While states will always execute in the same order, that order is not necessarily defined the way you want it.

A few tools exist in Salt to set up the correct state ordering, these tools consist of requisite declarations and order options.

The Order Option

Before using the order option, remember that the majority of state ordering should be done with requisite statements, and that a requisite statement will override an order option.

The order option is used by adding an order number to a state declaration with the option order:

```
  vim:
    pkg:
      - installed
      - order: 1
```
By adding the order option to `1` this ensures that the vim package will be installed in tandem with any other state declaration set to the order `1`.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Sometimes you may want to send a state to the end of the line, to do this set the order to last:

```
vim:
  pkg:
    - installed
    - order: last
```

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been found and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.

**Gentoo Support**

Additional experimental support has been added for Gentoo. This is found in the contribution from Doug Renn, aka nestegg.

**30.2.164 Salt 0.9.5 Release Notes**

*release* 2012-01-15

Salt 0.9.5 is one of the largest steps forward in the development of Salt.

0.9.5 comes with many milestones, this release has seen the community of developers grow out to an international team of 46 code contributors and has many feature additions, feature enhancements, bug fixes and speed improvements.

**Warning:** Be sure to *read the upgrade instructions* about the switch to msgpack before upgrading!

**Community**

Nothing has proven to have more value to the development of Salt that the outstanding community that has been growing at such a great pace around Salt. This has proven not only that Salt has great value, but also the expandability of Salt is as exponential as I originally intended.

0.9.5 has received over 600 additional commits since 0.9.4 with a swath of new committers. The following individuals have contributed to the development of 0.9.5:

- Aaron Bull Schaefer
- Antti Kaihola
- Bas Tichelaar
- Brad Barden
This makes 21 new developers since 0.9.4 was released!

To keep up with the growing community follow Salt on Black Duck Open Hub (https://www.openhub.net/p/salt), to join the Salt development community, fork Salt on GitHub, and get coding (https://github.com/saltstack/salt)!

**Major Features**

**SPEED! Pickle to msgpack**

For a few months now we have been talking about moving away from Python pickles for network serialization, but a preferred serialization format had not yet been found. After an extensive performance testing period involving everything from JSON to protocol buffers, a clear winner emerged. Message Pack (https://msgpack.org/) proved to not only be the fastest and most compact, but also the most "salt like". Message Pack is simple, and the code involved is very small. The msgpack library for Python has been added directly to Salt.
This move introduces a few changes to Salt. First off, Salt is no longer a "noarch" package, since the msgpack lib is written in C. Salt 0.9.5 will also have compatibility issues with 0.9.4 with the default configuration.

We have gone through great lengths to avoid backwards compatibility issues with Salt, but changing the serialization medium was going to create issues regardless. Salt 0.9.5 is somewhat backwards compatible with earlier minions. A 0.9.5 master can command older minions, but only if the `serial` config value in the master is set to `pickle`. This will tell the master to publish messages in pickle format and will allow the master to receive messages in both msgpack and pickle formats.

Therefore the suggested methods for upgrading are either to just upgrade everything at once, or:

1. Upgrade the master to 0.9.5
2. Set `serial` to `pickle` in the master config
3. Upgrade the minions
4. Remove the `serial` option from the master config

Since pickles can be used as a security exploit the ability for a master to accept pickles from minions at all will be removed in a future release.

**C Bindings for YAML**

All of the YAML rendering is now done with the YAML C bindings. This speeds up all of the sls files when running states.

**Experimental Windows Support**

David Boucha has worked tirelessly to bring initial support to Salt for Microsoft Windows operating systems. Right now the Salt Minion can run as a native Windows service and accept commands.

In the weeks and months to come Windows will receive the full treatment and will have support for Salt States and more robust support for managing Windows systems. This is a big step forward for Salt to move entirely outside of the Unix world, and proves Salt is a viable cross platform solution. Big Thanks to Dave for his contribution here!

**Dynamic Module Distribution**

Many Salt users have expressed the desire to have Salt distribute in-house modules, states, renderers, returners, and grains. This support has been added in a number of ways:

**Modules via States**

Now when salt modules are deployed to a minion via the state system as a file, then the modules will be automatically loaded into the active running minion - no restart required - and into the active running state. So custom state modules can be deployed and used in the same state run.
Modules via Module Environment Directories

Under the file_roots each environment can now have directories that are used to deploy large groups of modules. These directories sync modules at the beginning of a state run on the minion, or can be manually synced via the Salt module salt.modules.saltutil.sync_all.

The directories are named:
- _modules
- _states
- _grains
- _renderers
- _returners

The modules are pushed to their respective scopes on the minions.

Module Reloading

Modules can now be reloaded without restarting the minion, this is done by calling the salt.modules.sys.reload_modules function.

But wait, there's more! Now when a salt module of any type is added via states the modules will be automatically reloaded, allowing for modules to be laid down with states and then immediately used.

Finally, all modules are reloaded when modules are dynamically distributed from the salt master.

Enable / Disable Added to Service

A great deal of demand has existed for adding the capability to set services to be started at boot in the service module. This feature also comes with an overhaul of the service modules and initial systemd support.

This means that the service state can now accept - enable: True to make sure a service is enabled at boot, and - enable: False to make sure it is disabled.

Compound Target

A new target type has been added to the lineup, the compound target. In previous versions the desired minions could only be targeted via a single specific target type, but now many target specifications can be declared.

These targets can also be separated by and/or operators, so certain properties can be used to omit a node:

```
salt -C 'webserv* and G@os:Debian or E@db.*' test.ping
```

will match all minions with ids starting with webserv via a glob and minions matching the os:Debian grain. Or minions that match the db.* regular expression.
Node Groups

Often the convenience of having a predefined group of minions to execute targets on is desired. This can be accomplished with the new nodegroups feature. Nodegroups allow for predefined compound targets to be declared in the master configuration file:

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
```

And then used via the `-N` option:

```
salt -N group1 test.ping
```

Minion Side Data Store

The data module introduces the initial approach into storing persistent data on the minions, specific to the minions. This allows for data to be stored on minions that can be accessed from the master or from the minion.

The Minion datastore is young, and will eventually provide an interface similar to a more mature key/value pair server.

Major Grains Improvement

The Salt grains have been overhauled to include a massive amount of extra data. This includes hardware data, os data and salt specific data.

Salt -Q is Useful Now

In the past the salt query system, which would display the data from recent executions would be displayed in pure Python, and it was unreadable.

0.9.5 has added the outputter system to the `-Q` option, thus enabling the salt query system to return readable output.

Packaging Updates

Huge strides have been made in packaging Salt for distributions. These additions are thanks to our wonderful community where the work to set up packages has proceeded tirelessly.

FreeBSD

Salt on FreeBSD? There a port for that:

https://svnweb.freebsd.org/ports/head/sysutils/py-salt/

This port was developed and added by Christer Edwards. This also marks the first time Salt has been included in an upstream packaging system!
Fedora and Red Hat Enterprise

Salt packages have been prepared for inclusion in the Fedora Project and in EPEL for Red Hat Enterprise 5 and 6. These packages are the result of the efforts made by Clint Savage (herlo).

Debian/Ubuntu

A team of many contributors have assisted in developing packages for Debian and Ubuntu. Salt is still actively seeking inclusion in upstream Debian and Ubuntu and the package data that has been prepared is being pushed through the needed channels for inclusion.

These packages have been prepared with the help of:

- Corey
- Aaron Toponce
- and`

More to Come

We are actively seeking inclusion in more distributions. Primarily getting Salt into Gentoo, SUSE, OpenBSD, and preparing Solaris support are all turning into higher priorities.

Refinement

Salt continues to be refined into a faster, more stable and more usable application. 0.9.5 comes with more debug logging, more bug fixes and more complete support.

More Testing, More Bug Fixes

0.9.5 comes with more bug fixes due to more testing than any previous release. The growing community and the introduction a dedicated QA environment have unearthed many issues that were hiding under the covers. This has further refined and cleaned the state interface, taking care of things from minor visual issues to repairing misleading data.

Custom Exceptions

A custom exception module has been added to throw salt specific exceptions. This allows Salt to give much more granular error information.
New Modules

**data**

The new data module manages a persistent datastore on the minion. Big thanks to bastichelaar for his help refining this module.

**freebsdkmod**

FreeBSD kernel modules can now be managed in the same way Salt handles Linux kernel modules. This module was contributed thanks to the efforts of Christer Edwards.

**gentoo_service**

Support has been added for managing services in Gentoo. Now Gentoo services can be started, stopped, restarted, enabled, disabled, and viewed.

**pip**

The pip module introduces management for pip installed applications. Thanks goes to whitinge for the addition of the pip module.

**rh_service**

The rh_service module enables Red Hat and Fedora specific service management. Now Red Hat like systems come with extensive management of the classic init system used by Red Hat.

**saltutil**

The saltutil module has been added as a place to hold functions used in the maintenance and management of salt itself. Saltutil is used to salt the salt minion. The saltutil module is presently used only to sync extension modules from the master server.

**systemd**

Systemd support has been added to Salt, now systems using this next generation init system are supported on systems running systemd.
**virtualenv**

The `virtualenv` module has been added to allow salt to create virtual Python environments. Thanks goes to whitinge for the addition of the `virtualenv` module.

**win_disk**

Support for gathering disk information on Microsoft Windows minions. The windows modules come courtesy of Utah_Dave.

**win_service**

The `win_service` module adds service support to Salt for Microsoft Windows services.

**win_useradd**

Salt can now manage local users on Microsoft Windows Systems.

**yumpkg5**

The `yumpkg` module introduces in 0.9.4 uses the yum API to interact with the yum package manager. Unfortunately, on Red Hat 5 systems salt does not have access to the yum API because the yum API is running under Python 2.4 and Salt needs to run under Python 2.6. The `yumpkg5` module bypasses this issue by shelling out to yum on systems where the yum API is not available.

**New States**

**mysql_database**

The new `mysql_database` state adds the ability to systems running a mysql server to manage the existence of mysql databases.

The mysql states are thanks to syphernl.

**mysql_user**

The `mysql_user` state enables mysql user management.
**virtualenv**

The `virtualenv` state can manage the state of Python virtual environments. Thanks to Whitinge for the `virtualenv` state.

**New Returners**

**cassandra_returner**

A returner allowing Salt to send data to a cassandra server. Thanks to Byron Clark for contributing this returner.

### 30.2.165 Salt 0.9.6 Release Notes

**release** 2012-01-21

Salt 0.9.6 is a release targeting a few bugs and changes. This is primarily targeting an issue found in the names declaration in the state system. But a few other bugs were also repaired, like missing support for grains in extmods. Due to a conflict in distribution packaging msgpack will no longer be bundled with Salt, and is required as a dependency.

**New Features**

**HTTP and ftp support in files.managed**

Now under the source option in the file.managed state a HTTP or ftp address can be used instead of a file located on the salt master.

**Allow Multiple Returners**

Now the returner interface can define multiple returners, and will also return data back to the master, making the process less ambiguous.

**Minion Memory Improvements**

A number of modules have been taken out of the minion if the underlying systems required by said modules are not present on the minion system. A number of other modules need to be stripped out in this same way which should continue to make the minion more efficient.

**Minions Can Locally Cache Return Data**

A new option, cache_jobs, has been added to the minion to allow for all of the historically run jobs to cache on the minion, allowing for looking up historic returns. By default cache_jobs is set to False.
Pure Python Template Support For file.managed

Templates in the file.managed state can now be defined in a Python script. This script needs to have a run function that returns the string that needs to be in the named file.

30.2.166 Salt 0.9.7 Release Notes

release 2012-02-15

Salt 0.9.7 is here! The latest iteration of Salt brings more features and many fixes. This release is a great refinement over 0.9.6, adding many conveniences under the hood, as well as some features that make working with Salt much better.

A few highlights include the new Job system, refinements to the requisite system in states, the mod_init interface for states, external node classification, search path to managed files in the file state, and refinements and additions to dynamic module loading.

0.9.7 also introduces the long developed (and oft changed) unit test framework and the initial unit tests.

Major Features

Salt Jobs Interface

The new jobs interface makes the management of running executions much cleaner and more transparent. Building on the existing execution framework the jobs system allows clear introspection into the active running state of the running Salt interface.

The Jobs interface is centered in the new minion side proc system. The minions now store msgpack serialized files under /var/cache/salt/proc. These files keep track of the active state of processes on the minion.

Functions in the saltutil Module

A number of functions have been added to the saltutil module to manage and view the jobs:

- running - Returns the data of all running jobs that are found in the proc directory.
- find_job - Returns specific data about a certain job based on job id.
- signal_job - Allows for a given jid to be sent a signal.
- term_job - Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.
- kill_job Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...
active

The active function runs `saltutil.running` on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

lookup_jid

When jobs are executed the return data is sent back to the master and cached. By default is cached for 24 hours, but this can be configured via the `keep_jobs` option in the master configuration.

Using the `lookup_jid` runner will display the same return data that the initial job invocation with the salt command would display.

list_jobs

Before finding a historic job, it may be required to find the job id. `list_jobs` will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

External Node Classification

Salt can now use external node classifiers like Cobbler’s `cobbler-ext-nodes`.

Salt uses specific data from the external node classifier. In particular the classes value denotes which sls modules to run, and the environment value sets to another environment.

An external node classification can be set in the master configuration file via the `external_nodes` option: https://salt.readthedocs.io/en/latest/ref/configuration/master.html#external-nodes

External nodes are loaded in addition to the top files. If it is intended to only use external nodes, do not deploy any top files.

State Mod Init System

An issue arose with the pkg state. Every time a package was run Salt would need to refresh the package database. This made systems with slower package metadata refresh speeds much slower to work with. To alleviate this issue the `mod_init` interface has been added to salt states.

The `mod_init` interface is a function that can be added to a state file. This function is called with the first state called. In the case of the pkg state, the `mod_init` function sets up a tag which makes the package database only refresh on the first attempt to install a package.

In a nutshell, the `mod_init` interface allows a state to run any command that only needs to be run once, or can be used to set up an environment for working with the state.
Source File Search Path

The file state continues to be refined, adding speed and capabilities. This release adds the ability to pass a list to the source option. This list is then iterated over until the source file is found, and the first found file is used.

The new syntax looks like this:

```
/etc/httpd/conf/httpd.conf:
  file:
    - managed
    - source:
      - salt://httpd/httpd.conf
      - http://myserver/httpd.conf: md5=8c1fe119e6f1fd96bc06614473509bf1
```

The source option can take sources in the list from the salt file server as well as an arbitrary web source. If using an arbitrary web source the checksum needs to be passed as well for file verification.

Refinements to the Requisite System

A few discrepancies were still lingering in the requisite system, in particular, it was not possible to have a require and a watch requisite declared in the same state declaration.

This issue has been alleviated, as well as making the requisite system run more quickly.

Initial Unit Testing Framework

Because of the module system, and the need to test real scenarios, the development of a viable unit testing system has been difficult, but unit testing has finally arrived. Only a small amount of unit testing coverage has been developed, much more coverage will be in place soon.

A huge thanks goes out to those who have helped with unit testing, and the contributions that have been made to get us where we are. Without these contributions unit tests would still be in the dark.

Compound Targets Expanded

Originally only support for and and or were available in the compound target. 0.9.7 adds the capability to negate compound targets with not.

Nodegroups in the Top File

Previously the nodegroups defined in the master configuration file could not be used to match nodes for states. The nodegroups support has been expanded and the nodegroups defined in the master configuration can now be used to match minions in the top file.
30.2.167 Salt 0.9.8 Release Notes

release 2012-03-21

Salt 0.9.8 is a big step forward, with many additions and enhancements, as well as a number of precursors to advanced future developments.

This version of Salt adds much more power to the command line, making the old hard timeout issues a thing of the past and adds keyword argument support. These additions are also available in the salt client API, making the available API tools much more powerful.

The new pillar system allows for data to be stored on the master and assigned to minions in a granular way similar to the state system. It also allows flexibility for users who want to keep data out of their state tree similar to ‘external lookup’ functionality in other tools.

A new way to extend requisites was added, the "requisite in" statement. This makes adding requires or watch statements to external state decs much easier.

Additions to requisites making them much more powerful have been added as well as improved error checking for sls files in the state system. A new provider system has been added to allow for redirecting what modules run in the background for individual states.

Support for openSUSE has been added and support for Solaris has begun serious development. Windows support has been significantly enhanced as well.

The matcher and target systems have received a great deal of attention. The default behavior of grain matching has changed slightly to reflect the rest of salt and the compound matcher system has been refined.

A number of impressive features with keyword arguments have been added to both the CLI and to the state system. This makes states much more powerful and flexible while maintaining the simple configuration everyone loves.

The new batch size capability allows for executions to be rolled through a group of targeted minions a percentage or specific number at a time. This was added to prevent the “thundering herd” problem when targeting large numbers of minions for things like service restarts or file downloads.

Upgrade Considerations

Upgrade Issues

There was a previously missed oversight which could cause a newer minion to crash an older master. That oversight has been resolved so the version incompatibility issue will no longer occur. When upgrading to 0.9.8 make sure to upgrade the master first, followed by the minions.

Debian/Ubuntu Packages

The original Debian/Ubuntu packages were called salt and included all salt applications. New packages in the ppa are split by function. If an old salt package is installed then it should be manually removed and the new split packages need to be freshly installed.

On the master:

```
# apt-get purge salt
# apt-get install salt-{master,minion}
```

On the minions:
# apt-get purge salt
# apt-get install salt-minion

And on any Syndics:

# apt-get install salt-syndic

The official Salt PPA for Ubuntu is located at: https://launchpad.net/~saltstack/+archive/ubuntu/salt

Major Features

Pillar

Pillar offers an interface to declare variable data on the master that is then assigned to the minions. The pillar data is made available to all modules, states, sls files etc. It is compiled on the master and is declared using the existing renderer system. This means that learning pillar should be fairly trivial to those already familiar with salt states.

CLI Additions

The salt command has received a serious overhaul and is more powerful than ever. Data is returned to the terminal as it is received, and the salt command will now wait for all running minions to return data before stopping. This makes adding very large --timeout arguments completely unnecessary and gets rid of long running operations returning empty {} when the timeout is exceeded.

When calling salt via sudo, the user originally running salt is saved to the log for auditing purposes. This makes it easy to see who ran what by just looking through the minion logs.

The salt-key command gained the -D and --delete-all arguments for removing all keys. Be careful with this one!

Running States Without a Master

The addition of running states without a salt-master has been added to 0.9.8. This feature allows for the unmodified salt state tree to be read locally from a minion. The result is that the UNMODIFIED state tree has just become portable, allowing minions to have a local copy of states or to manage states without a master entirely.

This is accomplished via the new file client interface in Salt that allows for the salt:// URI to be redirected to custom interfaces. This means that there are now two interfaces for the salt file server, calling the master or looking in a local, minion defined file_roots.

This new feature can be used by modifying the minion config to point to a local file_roots and setting the file_client option to local.

Keyword Arguments and States

State modules now accept the **kwargs argument. This results in all data in a sls file assigned to a state being made available to the state function.

This passes data in a transparent way back to the modules executing the logic. In particular, this allows adding arguments to the pkg.install module that enable more advanced and granular controls with respect to what the state is capable of.

An example of this along with the new debconf module for installing ldap client packages on Debian:
ldap-client-packages:
  pkg:
    - debconf: salt://debconf/ldap-client.ans
    - installed
  names:
    - nslcd
    - libpam-ldapd
    - libnss-ldapd

Keyword Arguments and the CLI

In the past it was required that all arguments be passed in the proper order to the `salt` and `salt-call` commands. As of 0.9.8, keyword arguments can be passed in the form of `kwarg=argument`.

```bash
# salt -G 'type:dev' git.clone 
  repository=https://github.com/saltstack/salt.git cwd=/tmp/salt user=jeff
```

Matcher Refinements and Changes

A number of fixes and changes have been applied to the Matcher system. The most noteworthy is the change in the grain matcher. The grain matcher used to use a regular expression to match the passed data to a grain, but now defaults to a shell glob like the majority of match interfaces in Salt. A new option is available that still uses the old style regex matching to grain data called `grain-pcre`. To use regex matching in compound matches use the letter `P`.

For example, this would match any ArchLinux or Fedora minions:

```bash
# salt --grain-pcre 'os:(Arch:Fed).*' test.ping
```

And the associated compound matcher suitable for `top.sls` is `P`:

```bash
P@os:(Arch|Fed).*
```

**NOTE:** Changing the grains matcher from pcre to glob is backwards incompatible.

Support has been added for matching minions with Yahoo’s range library. This is handled by passing range syntax with `-R` or `--range` arguments to salt.

More information at: https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec

Requisite "in"

A new means to updating requisite statements has been added to make adding watchers and requires to external states easier. Before 0.9.8 the only way to extend the states that were watched by a state outside of the sls was to use an extend statement:

```yaml
include:
  - http
extend:
  apache:
    service:
      - watch:
```

(continues on next page)
But the new `Requisite in` statement allows for easier extends for requisites:

```
include:
  - http
tomcat:
    pkg:
      - installed
    watch_in:
      - service: apache
```

Requisite in is part of the extend system, so still remember to always include the sls that is being extended!

Providers

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management. The `apt` module maps to `pkg` on Debian and the `yum` module maps to `pkg` on Fedora for instance.

Sometimes in states, it may be necessary for a non-default module to be used for the desired functionality. For instance, an Arch Linux system may have been set up with systemd support. Instead of using the default service module detected for Arch Linux, the `systemd` module can be used:

```
http:
  service:
    - running
    - enable: True
    - provider: systemd
```

Default providers can also be defined in the minion config file:

```
providers:
  service: systemd
```

When default providers are passed in the minion config, then those providers will be applied to all functionality in Salt, this means that the functions called by the minion will use these modules, as well as states.

Requisite Glob Matching

Requisites can now be defined with glob expansion. This means that if there are many requisites, they can be defined on a single line.

To watch all files in a directory:

```
http:
  service:
    - running
    - enable: True
```

(continues on next page)
This example will watch all defined files that match the glob `/etc/http/conf.d/*`

**Batch Size**

The new batch size option allows commands to be executed while maintaining that only so many hosts are executing the command at one time. This option can take a percentage or a finite number:

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run test.ping on 10 of the targeted minions at a time and then restart apache on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using carp much easier with Salt.

**Module Updates**

This is a list of notable, but non-exhaustive updates with new and existing modules.

- Windows support has seen a flurry of support this release cycle. We've gained all new `file`, `network`, and `shadow` modules. Please note that these are still a work in progress.
- For our ruby users, new `rvm` and `gem` modules have been added along with the `associated states`.
- The `virt` module gained basic Xen support.
- The `yum` module gained Scientific Linux support.
- The `pkg` module on Debian, Ubuntu, and derivatives force apt to run in a non-interactive mode. This prevents issues when package installation waits for confirmation.
- A `pkg` module for OpenSUSE's `zypper` was added.
- The `service` module on Ubuntu natively supports upstart.
- A new `debconf` module was contributed by our community for more advanced control over deb package deployments on Debian based distributions.
- The `mysql.user` state and `mysql` module gained a `password_hash` argument.
- The `cmd` module and state gained a `shell` keyword argument for specifying a shell other than `/bin/sh` on Linux / Unix systems.
- New `git` and `mercurial` modules have been added for fans of distributed version control.
In Progress Development

Master Side State Compiling

While we feel strongly that the advantages gained with minion side state compiling are very critical, it does prevent certain features that may be desired. 0.9.8 has support for initial master side state compiling, but many more components still need to be developed, it is hoped that these can be finished for 0.9.9.

The goal is that states can be compiled on both the master and the minion allowing for compilation to be split between master and minion. Why will this be great? It will allow storing sensitive data on the master and sending it to some minions without all minions having access to it. This will be good for handling ssl certificates on front-end web servers for instance.

Solaris Support

Salt 0.9.8 sees the introduction of basic Solaris support. The daemon runs well, but grains and more of the modules need updating and testing.

Windows Support

Salt states on windows are now much more viable thanks to contributions from our community! States for file, service, local user, and local group management are more fully fleshed out along with network and disk modules. Windows users can also now manage registry entries using the new "reg" module.

30.2.168 Salt 0.9.9 Release Notes

release 2012-04-27

0.9.9 is out and comes with some serious bug fixes and even more serious features. This release is the last major feature release before 1.0.0 and could be considered the 1.0.0 release candidate.

A few updates include more advanced kwargs support, the ability for salt states to more safely configure a running salt minion, better job directory management and the new state test interface.

Many new tests have been added as well, including the new minion swarm test that allows for easier testing of Salt working with large groups of minions. This means that if you have experienced stability issues with Salt before, particularly in larger deployments, that these bugs have been tested for, found, and killed.

Major Features

State Test Interface

Until 0.9.9 the only option when running states to see what was going to be changed was to print out the highstate with state.show_highstate and manually look it over. But now states can be run to discover what is going to be changed.

Passing the option test=True to many of the state functions will now cause the salt state system to only check for what is going to be changed and report on those changes.

```
salt '*' state.highstate test=True
```

Now states that would have made changes report them back in yellow.

30.2. Previous Releases
State Syntax Update

A shorthand syntax has been added to sls files, and it will be the default syntax in documentation going forward. The old syntax is still fully supported and will not be deprecated, but it is recommended to move to the new syntax in the future. This change moves the state function up into the state name using a dot notation. This is in-line with how state functions are generally referred to as well:

The new way:

```
/etc/sudoers:
    file.present:
        - source: salt://sudo/sudoers
        - user: root
        - mode: 400
```

Use and Use_in Requisites

Two new requisite statements are available in 0.9.9. The use and use_in requisite and requisite-in allow for the transparent duplication of data between states. When a state “uses” another state it copies the other state’s arguments as defaults. This was created in direct response to the new network state, and allows for many network interfaces to be configured in the same way easily. A simple example:

```
root_file:
    file.absent:
        - name: /tmp/nothing
        - user: root
        - mode: 644
        - group: root
        - use_in:
            - file: /etc/vimrc

fred_file:
    file.absent:
        - name: /tmp/nothing
        - user: fred
        - group: marketing
        - mode: 660

/files/marketing/district7.rst:
    file.present:
        - source: salt://marketing/district7.rst
        - template: jinja
        - use:
            - file: fred_file

/etc/vimrc:
    file.present:
        - source: salt://edit/vimrc
```

This makes the 2 lower state decs inherit the options from their respectively "used" state decs.
Network State

The new network state allows for the configuration of network devices via salt states and the ip salt module. This addition has been given to the project by Jeff Hutchins and Bret Palsson from Jive Communications.

Currently the only network configuration backend available is for Red Hat based systems, like Red Hat Enterprise, CentOS, and Fedora.

Exponential Jobs

Originally the jobs executed were stored on the master in the format: `<cachedir>/jobs/jid/{minion ids}

But this format restricted the number of jobs in the cache to the number of subdirectories allowed on the filesystem. Ext3 for instance limits subdirectories to 32000. To combat this the new format for 0.9.9 is: `<cachedir>/jobs/jid_hash[:2]/jid_hash[2:]/{minion ids}

So that now the number of maximum jobs that can be run before the cleanup cycle hits the job directory is substantially higher.

ssh_auth Additions

The original ssh_auth state was limited to accepting only arguments to apply to a public key, and the key itself. This was restrictive due to the way the we learned that many people were using the state, so the key section has been expanded to accept options and arguments to the key that over ride arguments passed in the state. This gives substantial power to using ssh_auth with names:

```
sshkeys:
  ssh_auth:
    - present
    - user: backup
    - enc: ssh-dss
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: backup
    - names:
      - override

LocalClient Additions

To follow up the recent additions in 0.9.8 of additional kwargs support, 0.9.9 also adds the capability to send kwargs into commands via a dict. This addition to the LocalClient api can be used like so:

```python
import salt.client

client = salt.client.LocalClient("/etc/salt/master")
ret = client.cmd("*", "cmd.run", ["ls -l"], kwarg={"cwd": "/etc"})
```

This update has been added to all cmd methods in the LocalClient class.

Better Self Salting

One problem faced with running Salt states, is that it has been difficult to manage the Salt minion via states, this is due to the fact that if the minion is called to restart while a state run is happening then the state run would be killed. 0.9.9 slightly changes the process scope of the state runs, so now when salt is executing states it can safely restart the salt-minion daemon.

In addition to daemonizing the state run, the apt module also daemonizes. This update makes it possible to cleanly update the salt-minion package on Debian/Ubuntu systems without leaving apt in an inconsistent state or killing the active minion process mid-execution.

Wildcards for SLS Modules

Now, when including sls modules in include statements or in the top file, shell globs can be used. This can greatly simplify listing matched sls modules in the top file and include statements:

```yaml
base:
  '*':
    - files*
    - core*

include:
  - users.dev.*
  - apache.ser*
```
External Pillar

Since the pillar data is just, data, it does not need to come expressly from the pillar interface. The external pillar system allows for hooks to be added making it possible to extract pillar data from any arbitrary external interface. The external pillar interface is configured via the `ext_pillar` option. Currently interfaces exist to gather external pillar data via hiera or via a shell command that sends yaml data to the terminal:

```
ext_pillar:
  - cmd_yaml: cat /etc/salt/ext.yaml
  - hiera: /etc/hirea.yaml
```

The initial external pillar interfaces and extra interfaces can be added to the file salt/pillar.py, it is planned to add more external pillar interfaces. If the need arises a new module loader interface will be created in the future to manage external pillar interfaces.

Single State Executions

The new state.single function allows for single states to be cleanly executed. This is a great tool for setting up a small group of states on a system or for testing out the behavior of single states:

```
salt '*' state.single user.present name=wade uid=2000
```

The test interface functions here as well, so changes can also be tested against as:

```
salt '*' state.single user.present name=wade uid=2000 test=True
```

New Tests

A few exciting new test interfaces have been added, the minion swarm allows not only testing of larger loads, but also allows users to see how Salt behaves with large groups of minions without having to create a large deployment.

Minion Swarm

The minion swarm test system allows for large groups of minions to be tested against easily without requiring large numbers of servers or virtual machines. The minion swarm creates as many minions as a system can handle and roots them in the /tmp directory and connects them to a master.

The benefit here is that we were able to replicate issues that happen only when there are large numbers of minions. A number of elusive bugs which were causing stability issues in masters and minions have since been hunted down. Bugs that used to take careful watch by users over several days can now be reliably replicated in minutes, and fixed in minutes.

Using the swarm is easy, make sure a master is up for the swarm to connect to, and then use the minionswarm.py script in the tests directory to spin up as many minions as you want. Remember, this is a fork bomb, don't spin up more than your hardware can handle!

```
python minionswarm.py -m 20 --master salt-master
```
Shell Tests

The new Shell testing system allows us to test the behavior of commands executed from a high level. This allows for the high level testing of salt runners and commands like salt-key.

Client Tests

Tests have been added to test the aspects of the client APIs and ensure that the client calls work, and that they manage passed data, in a desirable way.

30.3 Upcoming Release

30.3.1 Salt 3003 Release Notes - Codename Aluminium

Salt 3003 is an unreleased upcoming feature release.

New Features

SCRAM-SHA-256 support for PostgreSQL passwords

Support for SCRAM-SHA-256 password hashes has been added to the postgres_user.present and postgres_group.present states. This allows migration away from the insecure and deprecated previous storage methods.

Execution Module Changes

Changed

- The pkg module now supports tdnf used by VMWare Photon OS. As part of this change, VMWare Photon OS's os_family grain will now resolve as RedHat. This may require changes to existing uses of grains.filter_by
- The salt-run CLI now accepts --jid which allows scripting against it.

Salt Cloud

Added

- Firewall groups support to Vultr Salt Cloud provider
Fixed

- The Google Cloud Engine salt-cloud provider now requires `apache-libcloud>=2.5.0`. Service account authentication is broken on older versions.

31.1 Introduction

First, you need to configure the master file. This is because all module functions require either a configured api_key (for Cloud) or a ttp_user with a tpp_password and a base_url (for Trust Platform).

For Venafi Cloud:

```yaml
venafi:
  api_key: abcdef01-2345-6789-abcd-ef0123456789
  base_url: "https://cloud.venafi.example.com/" (optional)
```

If you don't have a Venafi Cloud account, you can sign up for one on the enrollment page.

For Venafi Platform:

```yaml
venafi:
  base_url: "https://tpp.example.com/
  tpp_user: admin
  tpp_password: "Str0ngPa$$w0rd"
  trust_bundle: "/opt/venafi/bundle.pem"
```

It is not common for the Venafi Platform's REST API (WebSDK) to be secured using a certificate issued by a publicly trusted CA, therefore establishing trust for that server certificate is a critical part of your configuration. Ideally this is done by obtaining the root CA certificate in the issuing chain in PEM format and copying that file to your Salt Master (e.g. /opt/venafi/bundle.pem). You then reference that file using the 'trust_bundle' parameter as shown above.

For the Venafi module to create keys and certificates it is necessary to enable external pillars. This is done by adding the following to the /etc/salt/master file:

```yaml
ext_pillar:
  - venafi: True
```

31.2 Runner Functions

31.2.1 request

This command is used to enroll a certificate from Venafi Cloud or Venafi Platform.

- **minion_id** ID of the minion for which the certificate is being issued. Required.
- **dns_name** DNS subject name for the certificate. Required if csr_path is not specified.
**csr_path** Full path name of certificate signing request file to enroll. Required if **dns_name** is not specified.

**zone** Venafi Cloud zone ID or Venafi Platform folder that specify key and certificate policy. Defaults to "Default".
- For Venafi Cloud, the Zone ID can be found in the Zone page for your Venafi Cloud project.

**org_unit** Business Unit, Department, etc. Do not specify if it does not apply.

**org** Exact legal name of your organization. Do not abbreviate.

**loc** City/locality where your organization is legally located.

**state** State or province where your organization is legally located. Must not be abbreviated.

**country** Country where your organization is legally located; two-letter ISO code.

**key_password** Password for encrypting the private key.

The syntax for requesting a new certificate with private key generation looks like this:

```
salt-run venafi.request minion.example.com
dns_name=www.example.com
  country=US state=California loc=Sacramento
  org="Company Name" org_unit=DevOps
  zone=Internet
  key_password=SecretSauce
```

And the syntax for requesting a new certificate using a previously generated CSR looks like this:

```
salt-run venafi.request minion.example.com
csr_path=/tmp/minion.req
  zone=Internet
```

**31.2.2 show_cert**

This command is used to show last issued certificate for domain.

**dns_name** DNS subject name of the certificate to look up.

```
salt-run venafi.show_cert www.example.com
```

**31.2.3 list_domain_cache**

This command lists domains that have been cached on this Salt Master.

```
salt-run venafi.list_domain_cache
```

**31.2.4 del_cached_domain**

This command deletes a domain from the Salt Master's cache.

**domains** A domain name, or a comma-separated list of domain names, to delete from this master's cache.

```
salt-run venafi.del_cached_domain www.example.com
```
31.3 Transfer certificate to a minion

To transfer a cached certificate to a minion, you can use Venafi pillar.

Example state (SLS) file:

```yaml
/etc/ssl/cert/www.example.com.crt:
  file.managed:
    - contents_pillar: venafi:www.example.com:cert
    - replace: True

/etc/ssl/cert/www.example.com.key:
  file.managed:
    - contents_pillar: venafi:www.example.com:pkey
    - replace: True

/etc/ssl/cert/www.example.com-chain.pem:
  file.managed:
    - contents_pillar: venafi:www.example.com:chain
    - replace: True
```
Auto-Order  The evaluation of states in the order that they are defined in a SLS file. See also: ordering.

Bootstrap  A stand-alone Salt project which can download and install a Salt master and/or a Salt minion onto a host. See also: salt-bootstrap.

Compound Matcher  A combination of many target definitions that can be combined with boolean operators. See also: targeting.

EAuth  Shorthand for ‘external authentication’. A system for calling to a system outside of Salt in order to authenticate users and determine if they are allowed to issue particular commands to Salt. See also: external auth.

Environment  A directory tree containing state files which can be applied to minions. See also: top file.

Execution Function  A Python function inside an Execution Module that may take arguments and performs specific system-management tasks. See also: the list of execution modules.

External Job Cache  An external data-store that can archive information about jobs that have been run. A default returner. See also: ext_job_cache, the list of returners.

Execution Module  A Python module that contains execution functions which directly perform various system-management tasks on a server. Salt ships with a number of execution modules but users can also write their own execution modules to perform specialized tasks. See also: the list of execution modules.

External Pillar  A module that accepts arbitrary arguments and returns a dictionary. The dictionary is automatically added to a pillar for a minion.

Event  A notice emitted onto an event bus. Events are often driven by requests for actions to occur on a minion or master and the results of those actions. See also: Salt Reactor.

File Server  A local or remote location for storing both Salt-specific files such as top files or SLS files as well as files that can be distributed to minions, such as system configuration files. See also: Salt's file server.

Grain  A key-value pair which contains a fact about a system, such as its hostname, network addresses. See also: targeting with grains.

Highdata  The data structure in a SLS file the represents a set of state declarations. See also: state layers.

Highstate  The collection of states to be applied to a system. See also: state layers.

Idempotent  An action that ensures the system is in a well-known state regardless of the system’s state before the action is applied. A corollary to this is that applying the action multiple times results in no changes to the system. State module functions should be idempotent. Some state module functions, such as cmd.run are not idempotent by default but can be made idempotent with the proper use of requisites such as unless and onlyif. For more information, see wikipedia.

Jinja  A templating language which allows variables and simple logic to be dynamically inserted into static text files when they are rendered. See also: Salt's Jinja documentation.
Job  The complete set of tasks to be performed by the execution of a Salt command are a single job. See also: jobs runner.

Job Cache  A storage location for job results, which may then be queried by a salt runner or an external system. May be local to a salt master or stored externally.

Job ID  A unique identifier to represent a given job. This is often shortened to JID.

Low State  The collection of processed states after requisites and order are evaluated. See also: state layers.

Master  A central Salt daemon from which commands can be issued to listening minions.

Masterless  A minion which does not require a Salt master to operate. All configuration is local. See also: file_client.

Master Tops  A system for the master that allows hooks into external systems to generate top file data.

Mine  A facility to collect arbitrary data from minions and store that data on the master. This data is then available to all other minions. (Sometimes referred to as Salt Mine.) See also: Salt Mine.

Minion  A server running a Salt minion daemon which can listen to commands from a master and perform the requested tasks. Generally, minions are servers which are to be controlled using Salt.

Minion ID  A globally unique identifier for a minion. See also: id.

Multi-Master  The ability for a minion to be actively connected to multiple Salt masters at the same time in high-availability environments.

Node Group  A pre-defined group of minions declared in the master configuration file. See also: targeting.

Outputer  A formatter for defining the characteristics of output data from a Salt command. See also: list of outputters.

Peer Communication  The ability for minions to communicate directly with other minions instead of brokering commands through the Salt master. See also: peer communication.

Pillar  A simple key-value store for user-defined data to be made available to a minion. Often used to store and distribute sensitive data to minions. See also: Pillar, list of Pillar modules.

Proxy Minion  A minion which can control devices that are unable to run a Salt minion locally, such as routers and switches.

PyDSL  A Pythonic domain-specific-language used as a Salt renderer. PyDSL can be used in cases where adding pure Python into SLS files is beneficial. See also: PyDSL.

Reactor  An interface for listening to events and defining actions that Salt should take upon receipt of given events. See also: Reactor.

Render Pipe  Allows SLS files to be rendered by multiple renderers, with each renderer receiving the output of the previous. See also: composing renderers.

Renderer  Responsible for translating a given data serialization format such as YAML or JSON into a Python data structure that can be consumed by Salt. See also: list of renderers.

Returner  Allows for the results of a Salt command to be sent to a given data-store such as a database or log file for archival. See also: list of returners.

Roster  A flat-file list of target hosts. (Currently only used by salt-ssh.)

Runner Module  A module containing a set of runner functions. See also: list of runner modules.

Runner Function  A function which is called by the salt-run command and executes on the master instead of on a minion. See also: Runner Module.

Salt Cloud  A suite of tools used to create and deploy systems on many hosted cloud providers. See also: salt-cloud.
Salt SSH  A configuration management and remote orchestration system that does not require that any software besides SSH be installed on systems to be controlled.

Salt Thin  A subset of the normal Salt distribution that does not include any transport routines. A Salt Thin bundle can be dropped onto a host and used directly without any requirement that the host be connected to a network. Used by Salt SSH. See also: thin runner.

Salt Virt  Used to manage the creation and deployment of virtual machines onto a set of host machines. Often used to create and deploy private clouds. See also: virt runner.

SLS Module  Contains a set of state declarations.

State Compiler  Translates highdata into lowdata.

State Declaration  A data structure which contains a unique ID and describes one or more states of a system such as ensuring that a package is installed or a user is defined. See also: highstate structure.

State Function  A function contained inside a state module which can manages the application of a particular state to a system. State functions frequently call out to one or more execution modules to perform a given task.

State Module  A module which contains a set of state functions. See also: list of state modules.

State Run  The application of a set of states on a set of systems.

Syndic  A forwarder which can relay messages between tiered masters. See also: Syndic.

Target  Minion(s) to which a given salt command will apply. See also: targeting.

Top File  Determines which SLS files should be applied to various systems and organizes those groups of systems into environments. See also: top file, list of master top modules.

__virtual__  A function in a module that is called on module load to determine whether or not the module should be available to a minion. This function commonly contains logic to determine if all requirements for a module are available, such as external libraries.

Worker  A master process which can send notices and receive replies from minions. See also: worker_threads.
